    Set GTDTCR.TDE to 1 to enable the automatic dead time setting function.
11. Set buffer operation for dead time setting
    Set buffer operation with the TDBUE and TDBDE bits in the GTDTCR register.
12. Set dead time value
    Set the first half dead time value in the GTDVU register and the second half dead time in the GTDVD register. When the GTDVU register is set with the GTDTCR.TDFER bit set to 1, the same value is also set to the GTDVD register, the same dead time value can be set for the first and second halves.
13. Set buffer value for dead time
    For buffer operation, set the first half dead time in one cycle after the current cycle in the GTDBU register and the second half dead time in the GTDBD register.
14. Set count operation
    Set the GTCR.CST bit to 1 to start count operation.
15. Set buffer value by cycle
    For buffer operation of compare match register, set the GTIOCm_nA pin changing point in one cycle after the current cycle (in triangle-wave PWM mode 1) or half cycle after the current cycle (in triangle-wave PWM mode 2) in the GTCCRC register. For double buffered operation of compare match register, set the GTIOCm_nA pin changing point in two cycles after the current cycle (in triangle-wave PWM mode 1) or one cycle after the current cycle (in triangle-wave PWM mode 2) in the GTCCRD register.
    In the same way, set the dead time value in the first half of the cycle after the current cycle in the GTDBU register and the dead time in the second half in the GTDBD register.

Note: (m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3)

20.4.5 Count Direction Changing Function

The count direction of the GTCNT counter can be changed by modifying the GTUDDTYC.UD bit.

In sawtooth-wave mode, if the UD bit is modified during count operation, the count direction is changed at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the UD bit is modified while count operation is stopped and the GTUDDTYC.UDF bit is 0, the UD bit modification is not reflected at the start of counting and the count direction is changed at an overflow or an underflow. If the UDF bit is set to 1 while count operation is stopped, the UD bit value at that time is reflected at the start of counting.

In triangle-wave mode, changing the value of the GTUDDTYC.UD bit during counting does not switch the direction of counting. Likewise, changing the value of the GTUDDTYC.UD bit while the GTUDDTYC.UDF bit is 0 and counting is stopped does not actually update the value of the bit. If 1 is written to the GTUDDTYC.UDF bit while counting is stopped, the value of the GTUDDTYC.UD bit at that time is reflected from the time counting is started.

When counting direction is switched during count operation in sawtooth-wave mode, the value of GTPR register after the start of up-counting is reflected in the count period in up-counting operation, and the value of GTPR register after the start of down-counting is reflected in the count period in down-counting operation.

Figure 20.29 shows an example of the count direction changing function operation.

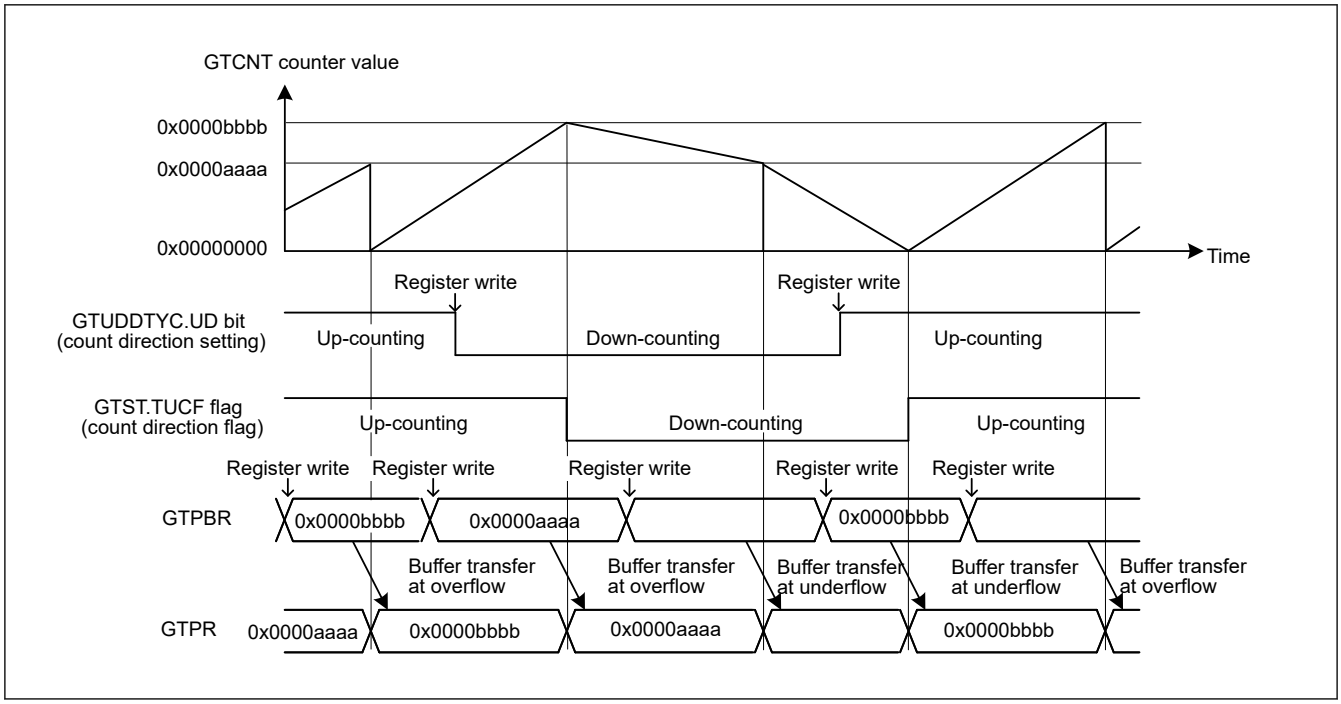

Figure 20.29 Example of count direction changing function operation (during buffer operation)

20.4.6 Function of Output Duty 0% and 100%

Changing the value of the GTUDDTYC.OADTY[1:0] bits and GTUDDTYC.OBDTY[1:0] bits specifies the output duty setting on the GTIOCm_nA and GTIOCm_nB pins to 0% or 100% ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3)).

In sawtooth-wave mode, if the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed during the count operation, the output duty-cycle setting is reflected at an overflow (when changed during up-counting) or an underflow (when changed during down-counting). When the GTUDDTYC.OADTYF bit or GTUDDTYC.OBDTYF bit is 0 while count operation is stopped and the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed, the output duty-cycle setting changed at the start of counting is not reflected, but the output duty-cycle setting changed at an overflow or underflow is reflected. When the OADTYF bit or OBDTYF bit is 1 while count operation is stopped and the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed, the value of the OADTY[1:0] bits or OBDTY[1:0] bits at that time is reflected at the start of counting.

In triangle-wave mode, if the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed during the count operation, the output duty-cycle setting is reflected at trough of triangle-wave.

When the OADTYF bit or OBDTYF bit is 0 while count operation is stopped and the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed, the output duty-cycle setting changed at the start of counting is not reflected, but the output duty-cycle setting changed at trough is reflected. When the OADTYF bit or OBDTYF bit is 1 while count operation is stopped and the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed, the value of the OADTY[1:0] bits or OBDTY[1:0] bits at that time is reflected at the start of counting.

During the operation under the settings of duty cycle for 0% or 100%, compare match operation inside the GPT continues to perform interrupt outputs and buffer operations.

When the output duty setting is changed from 0% or 100% due to a compare match, the GTIOR.GTIOA[3:2] bits and the GTUDDTYC.OADTYR bits determine the level output on the GTIOCm_nA pin and GTIOR.GTIOB[3:2] bits and GTUDDTYC.OBDTYR bits determine the level output on the GTIOCm_nB pin at the end of the cycle. When the GTIOA[3:2] and GTIOB[3:2] bits are set as 01b, output is driven low at the end of the cycle, and when set as 10b, output is driven high at the end of the cycle.

The output is retained at the end of the cycles when the GTIOA[3:2] or GTIOB[3:2] bits are 00b, and toggled at the end of the cycles when the GTIOA[3:2] or GTIOB[3:2] bits are 11b. A value to be output is selectable in the OADTYR or OBDTYR bit when the corresponding GTIOA[3:2] or GTIOB[3:2] bits are either 00b or 11b.

Table 20.11 lists the output values at the end of the cycle when the output setting is changed from duty 0% or 100% to compare match.

Table 20.11 Output value after release of duty 0% or 100%

GTIOR.GTIOm[3:2]	Value at compare match output at the end of the cycle when masking by a duty cycle 0% or 100%	GTUDDTYC.OmDTYR bit at duty 0% setting		GTUDDTYC.OmDTYR bit at duty 100% setting	
		0	1	0	1
00b (output retained at the end of the cycle)	0	0	0	1	0
	1	0	1	1	1
01b (low output at the end of the cycle)	—	0	0	0	0
10b (high output at the end of the cycle)	—	1	1	1	1
11b (toggle output at the end of the cycle)	0	1	1	0	1
	1	1	0	0	0

Note: m = A, B

Figure 20.30 shows an example of operation of the output of the duty cycle 0% or 100%.

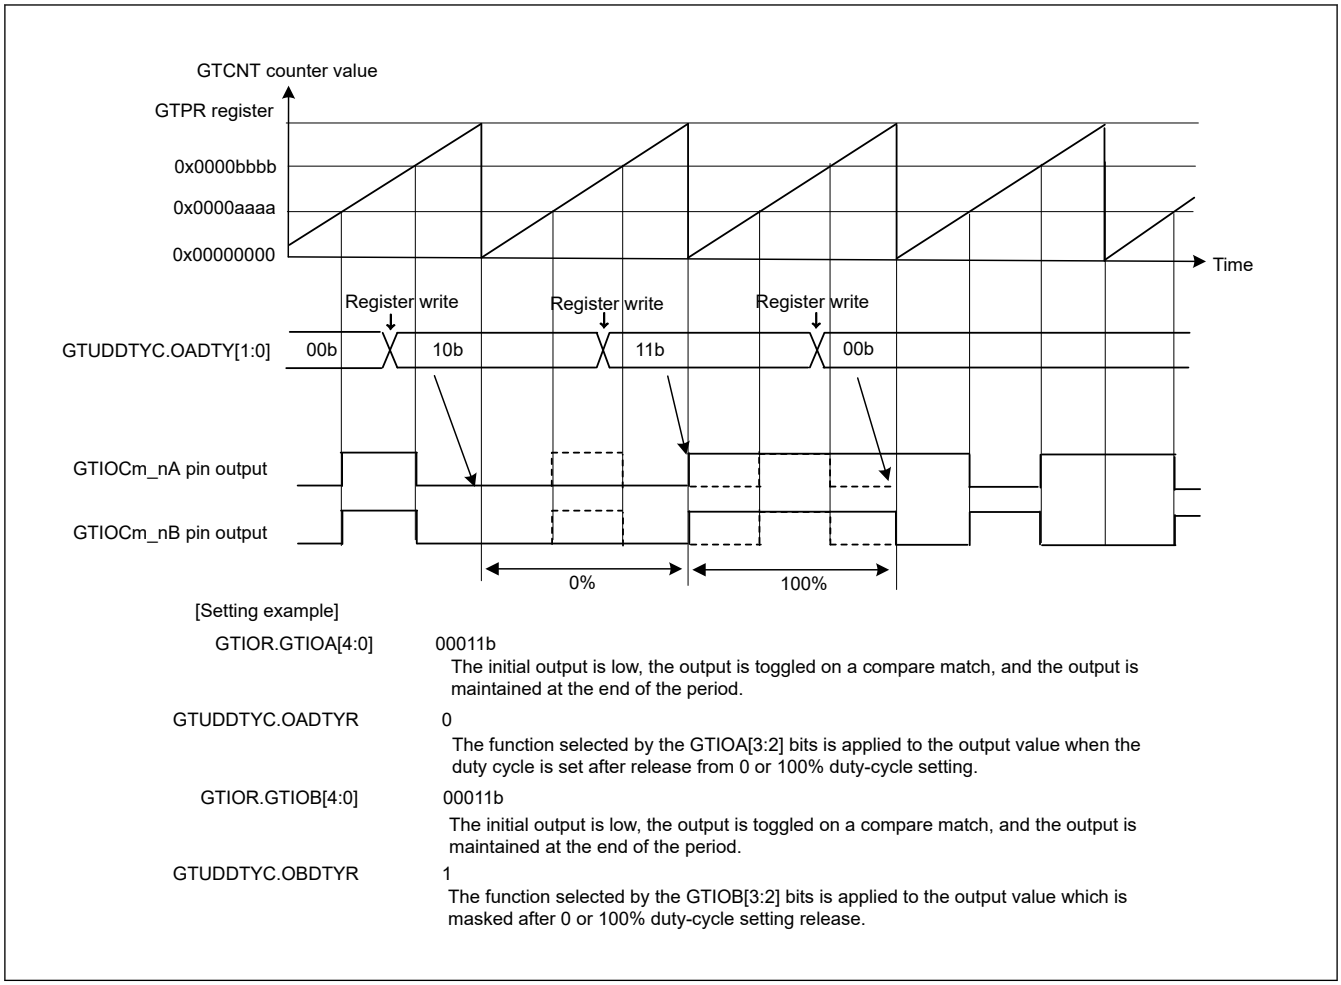

Figure 20.30 Example of operation of output of duty cycle 0% or 100%

20.4.7 Hardware Count Start/Count Stop and Clear Operation

The GTCNT counter can be started, stopped, or cleared by hardware sources. There are 3 types of hardware sources, including external trigger input, ELC event input, and GTIOCm_nA and GTIOCm_nB pin input ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3)).

20.4.7.1 Hardware Start Operation

The GTCNT counter can be started by a hardware source. Select a hardware source to start counting using the GTSSR register, and enable to start counting.

Figure 20.31 shows an example of count start operation by a hardware source.

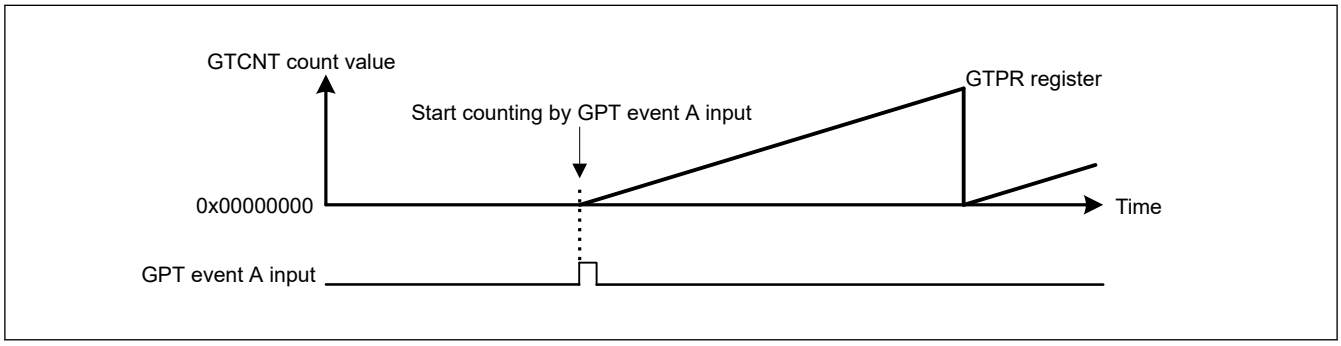

Figure 20.31 Example of count start operation by hardware source (at starting by GPT event A)

The following example shows setting for count start operation by hardware source.

1. Set operating mode
   Set the operating mode with the GTCR.MD[2:0] bits.
   In Figure 20.31, 000b (sawtooth-wave PWM mode 1) is set.
2. Set count direction
   Select the count direction (up or down) with the GTUDDTYC register.
   In Figure 20.31, the lower 2 bits of the GTUDDTYC register is set to 11b and then to 01b for up-counting.
3. Select count clock
   Select the count clock with GTCR.TPCS[3:0] bits.
4. Period setting
   Set a period in the GTPR register.
5. Set initial value for counter
   Set the initial value in the GTCNT counter.
   In Figure 20.31, 0x00000000 is set.
6. Set hardware count start
   Select a hardware source to start count operation with the GTSSR register.
   In Figure 20.31, GTSSR.SSELCA bit = 1.
7. Start hardware source operation
   Set operation of the hardware source selected by the GTSSR register and start counting.
   In Figure 20.31, the GPT event A input operation is set.

20.4.7.2 Hardware Stop Operation

The GTCNT counter can be stopped by a hardware source. Select a hardware source to stop counting with the GTPSR register, and enable to stop counting.

Figure 20.32 shows an example of count stop operation by a hardware source. In this example, the count operation is stopped by the GPT event A input, and is restarted by the GPT event B input.

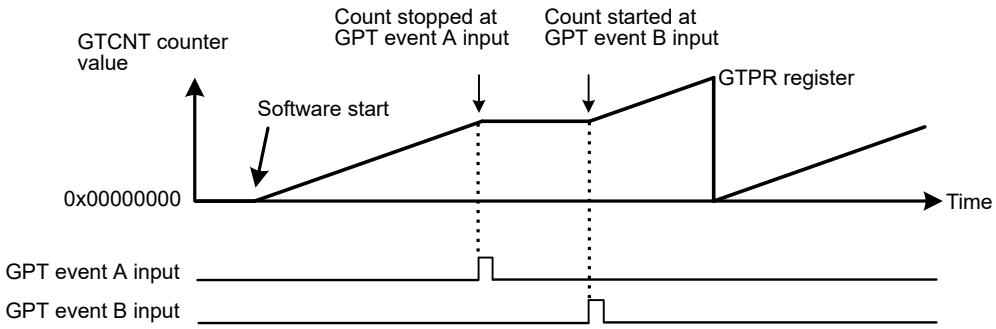

Figure 20.32 Example of count stop operation by hardware source (started by software, stopped at GPT event A input, and restarted at GPT event B input)

The following example shows setting for count stop operation by hardware source.

1. Set operating mode
   Set the operating mode with the GTCR.MD[2:0] bits.
   In Figure 20.32, 000b (sawtooth-wave PWM mode) is set.
2. Set count direction
   Select the count direction (up or down) with the GTUDDTYC register.
   In Figure 20.32, the lower 2 bits of the GTUDDTYC register is set to 11b and then to 01b for up-counting.
3. Select count clock
   Select the count clock with GTCR.TPCS[3:0] bits.
4. Period setting
   Set a period in the GTPR register.

5. Set initial value for counter
   Set the initial value in the GTCNT counter.
   In Figure 20.32, 0x00000000 is set.
6. Set hardware count start
   Select a hardware source for starting count operation with the GTSSR register.
   In Figure 20.32, GTSSR.SSELCB bit = 1.
7. Set hardware count stop
   Select a hardware source for starting count operation with the GTPSR register.
   In Figure 20.32, GTPSR.PSELCA bit = 1.
8. Start hardware source operation
   Set operation of the hardware source selected by the GTSSR or GTPSR register then start and stop counting.
   In Figure 20.32, the GPT event A and GPT event B input operations are set.

Figure 20.33 shows an example of count start/stop operation by a hardware source.

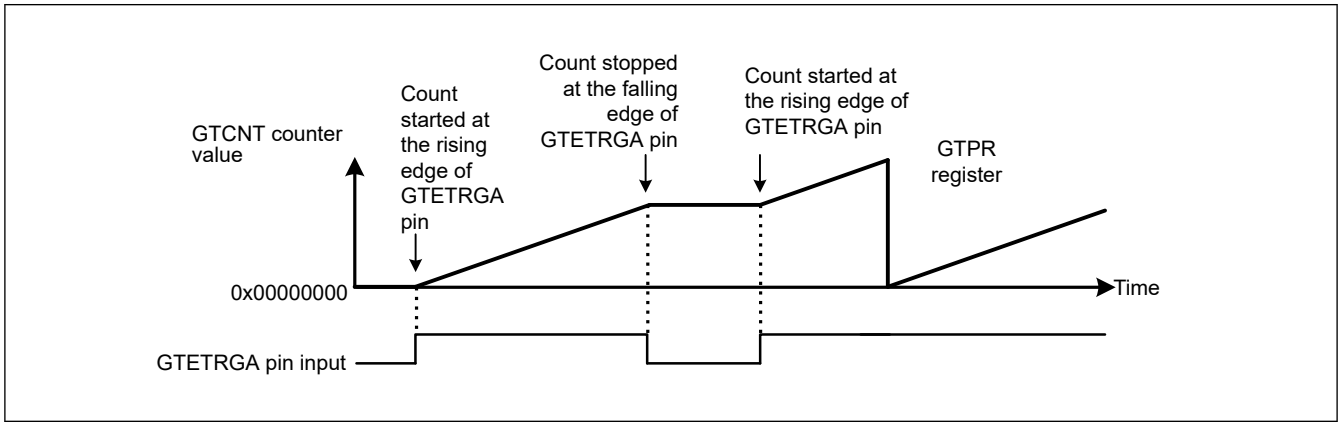

Figure 20.33 Example of count start/stop operation by hardware source (started at rising edge of GTETRGA pin input, stopped at falling edge of GTETRGA pin input)

The following example shows setting for count start/stop operation by hardware source.

1. Set operating mode
   Set the operating mode with the GTCR.MD[2:0] bits.
   In Figure 20.33, 000b (sawtooth-wave PWM mode) is set.
2. Set count direction
   Select the count direction (up or down) with the GTUDDTYC register.
   In Figure 20.33, the lower 2 bits of the GTUDDTYC register is set to 11b and then to 01b for up-counting.
3. Select count clock
   Select the count clock with GTCR.TPCS[3:0] bits.
4. Period setting
   Set a period in the GTPR register.
5. Set initial value for counter
   Set the initial value in the GTCNT counter.
   In Figure 20.33, 0x00000000 is set.
6. Set hardware count start
   Select a hardware source for starting count operation with the GTSSR register.
   In Figure 20.33, GTSSR.SSGTRGAFR[1:0] bits = 01b.
7. Set hardware count stop
   Select a hardware source for stopping count operation with the GTPSR register.
   In Figure 20.33, GTPSR.PSGTRGAFR[1:0] bits = 10b.
8. Start hardware source operation
   Set operation of the hardware source selected by the GTSSR or GTPSR register then start and stop counting.
   In Figure 20.33, the GTETRGA pin operation is set.

20.4.7.3 Hardware Clear Operation

The GTCNT counter can be cleared by a hardware source. Select a hardware source to clear the counter with the GTCSR register, and enable to clear the counter.

Note: The GPTm_n_OVF/GPTm_n_UDF interrupt (overflow/underflow interrupt) is not generated when the GTCNT counter is cleared by a hardware source or by software.

Figure 20.34 and Figure 20.35 show examples of the GTCNT counter clearing operation by a hardware source.

In this example, the GTCNT counter is started at the GPT event A input, and is stopped/cleared at the GPT event B input.

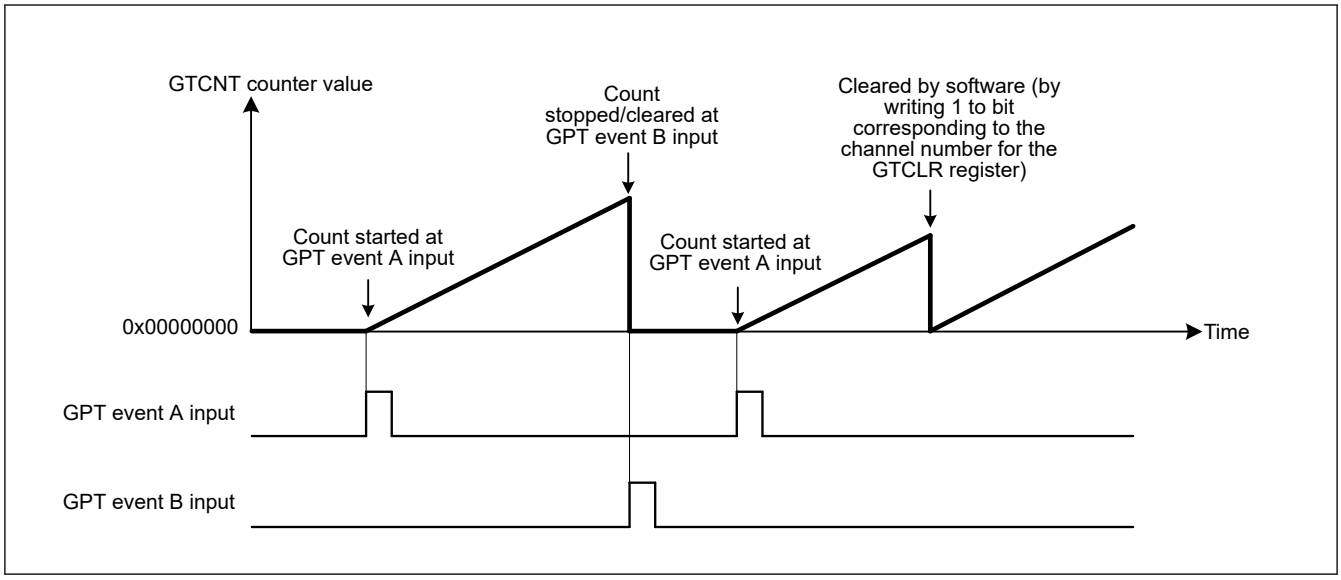

Figure 20.34 Examples of counter clearing operation by hardware source (sawtooth-wave up-counting, started at GPT event A input, and count stopped/counter cleared at GPT event B input)

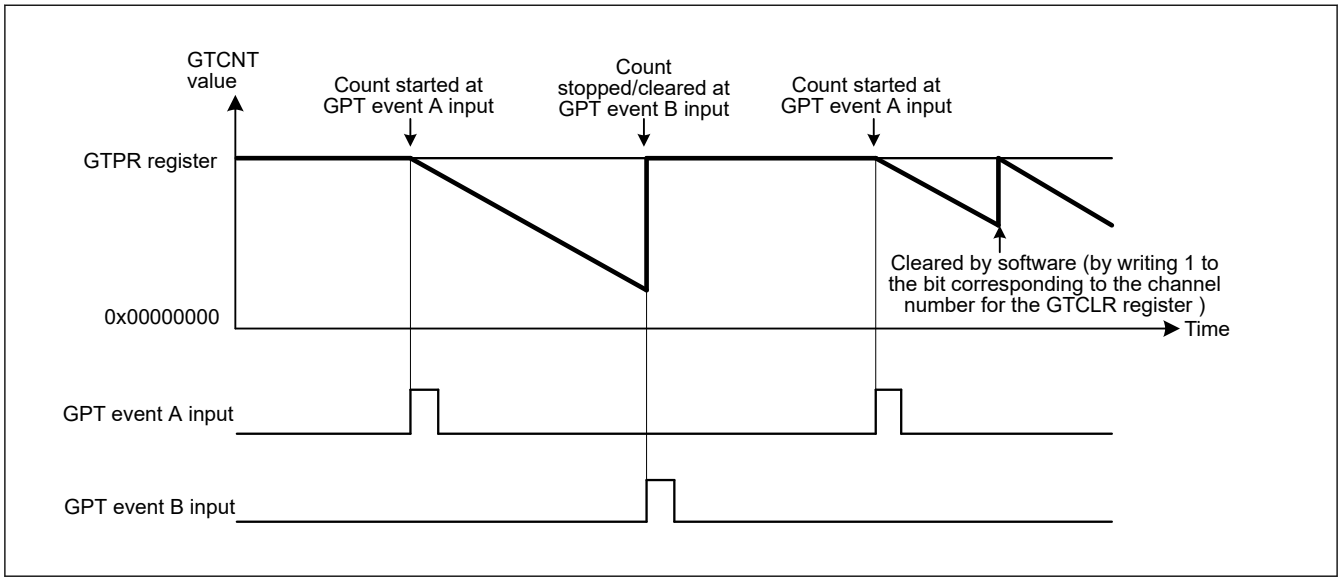

Figure 20.35 Examples of counter clearing operation by hardware source (sawtooth-wave down-counting, started at GPT event A input, and count stopped/counter cleared at GPT event B input)

The following example shows setting for counter clearing operation by hardware source.

1. Set operating mode
   Set the operating mode with the GTCR.MD[2:0] bits.
   In Figure 20.34 and Figure 20.35, 000b (sawtooth-wave PWM mode 1) is set.
2. Set count direction

Select the count direction (up or down) with the GTUDDTYC register.
In Figure 20.34, the lower 2 bits of the GTUDDTYC register is set to 11b and then to 01b for up-counting.
In Figure 20.35, the lower 2 bits of the GTUDDTYC register is set to 10b and then to 00b for down-counting.

3. Select count clock
   Select the count clock with GTCR.TPCS[3:0] bits.
4. Period setting
   Set a period in the GTPR register.
5. Set initial value for counter
   Set the initial value in the GTCNT counter.
   In Figure 20.34, 0x00000000 is set.
   In Figure 20.35, the GTPR register value is set.
6. Set hardware count start
   Select a hardware source for starting count operation with the GTSSR register and wait for count start by the hardware source.
   In Figure 20.34 and Figure 20.35, GTSSR.SSELCA bit = 1.
7. Set hardware count stop
   Select a hardware source for stopping count operation with the GTPSR register and wait for count stop by the hardware source.
   In Figure 20.34 and Figure 20.35, GTPSR.PSELCB bit = 1.
8. Set hardware count clear
   Select a hardware source to clear the counter with the GTCSR register and wait for count clearing by the hardware source.
   In Figure 20.34 and Figure 20.35, GTPSR.CSELCB bit = 1.
9. Start hardware source operation
   Set operation of the hardware source selected by the GTSSR, GTPSR, or GTCSR register then start, stop, or clear counting.
   In Figure 20.34 and Figure 20.35, the GPT event A and B inputs operations are set.

The GPTm_n_OVF/GPTm_n_UDF interrupt (overflow/underflow interrupt) does not occur when the counter is cleared by a hardware source. In the same way, the GPTm_n_OVF/GPTm_n_UDF interrupt does not occur when the counter is cleared by software.

Figure 20.36 shows the relationship between counter clearing by a hardware source and the GPTm_n_OVF interrupt.

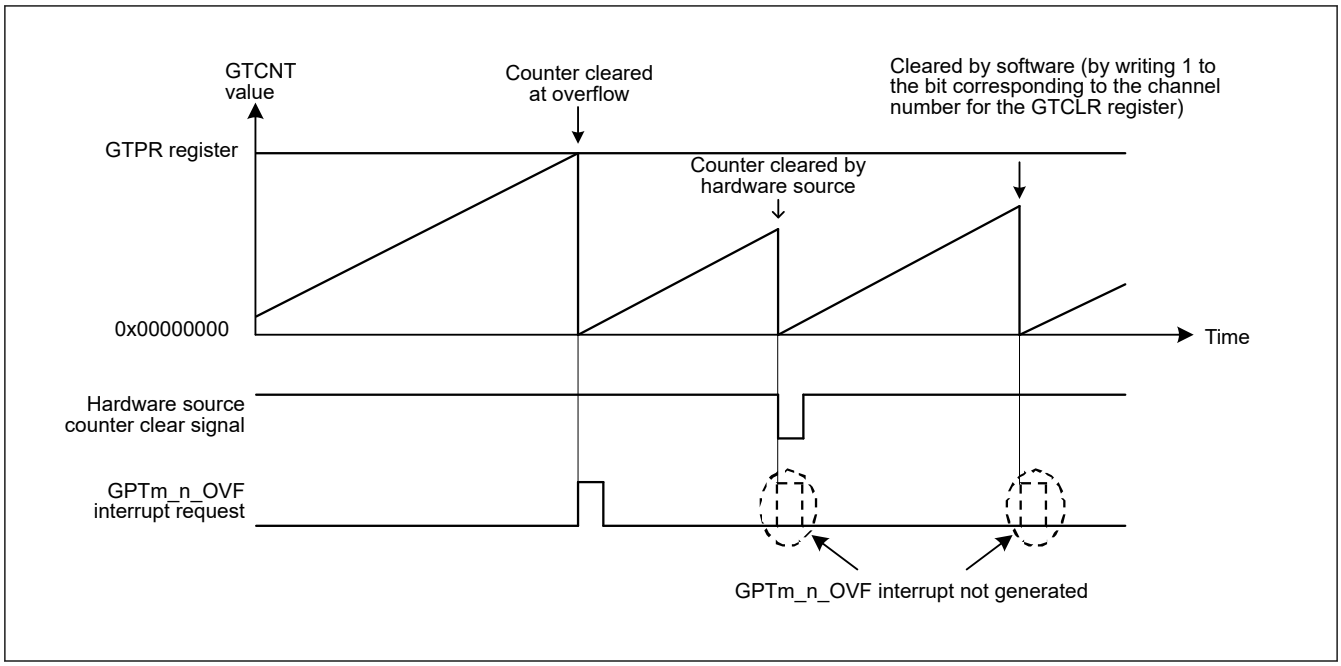

Figure 20.36 Relationship between counter clearing by hardware source and GPTm_n_OVF interrupt

20.4.8 Hardware Count Switch Operation

In the triangle-wave PWM mode, the GTCNT counter can be switched by a hardware source. Select the count switch operation with the GTCR.SWMD[2:0] bits and select a hardware source to switch the counter with the GTSWSR register and enable to switch the counter.

When the offset reload is enabled by the GTCR.SWMD[2:0] bits, the offset value of the GTCNT counter reloaded by count switch is set by the GTSWOS register in the range of 0 to GTPR.

If the count switch and counter clear occur at the same time, the counter clear has priority.

Figure 20.37 to Figure 20.40 show examples of the GTCNT count switch operation by a hardware source.

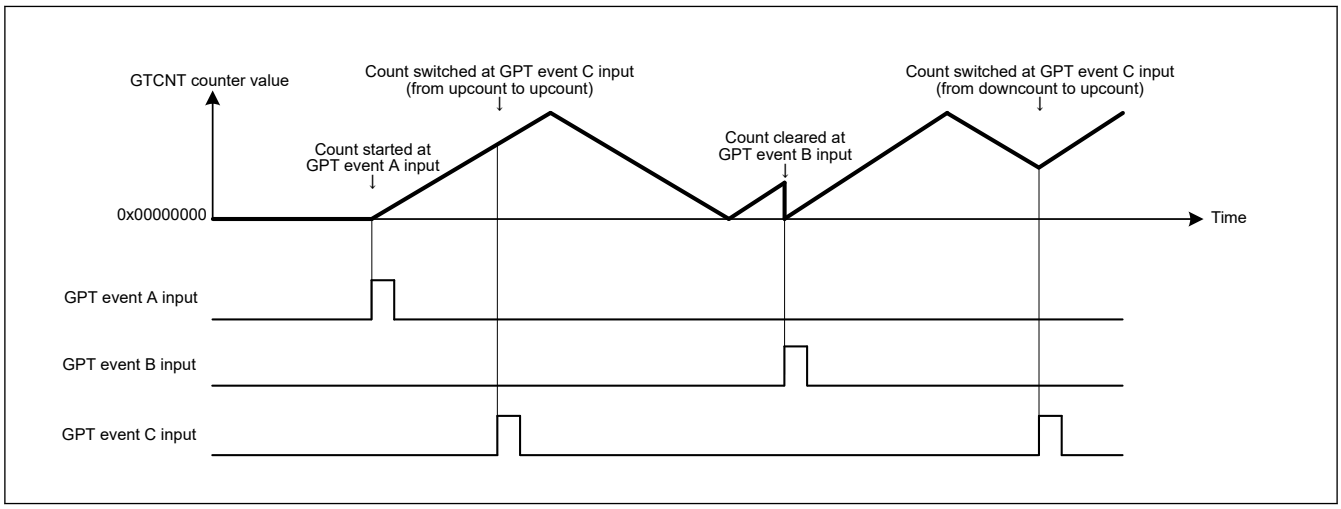

Figure 20.37 Examples of count switch operation by hardware source (switched to upcount without reload at GPT event C input)

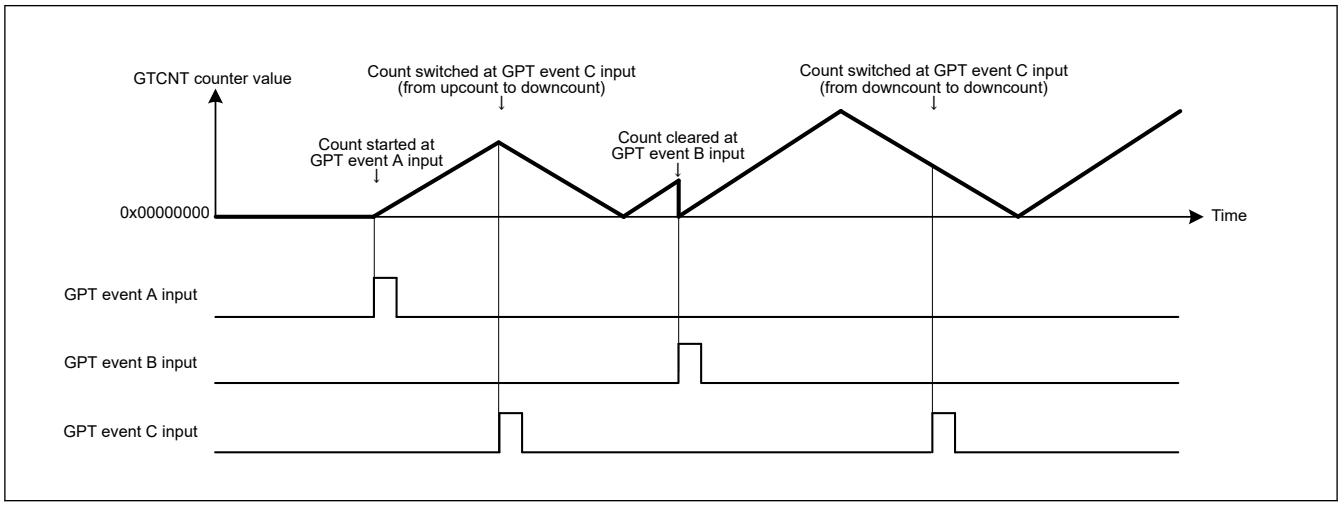

Figure 20.38 Examples of count switch operation by hardware source (switched to downcount without reload at GPT event C input)

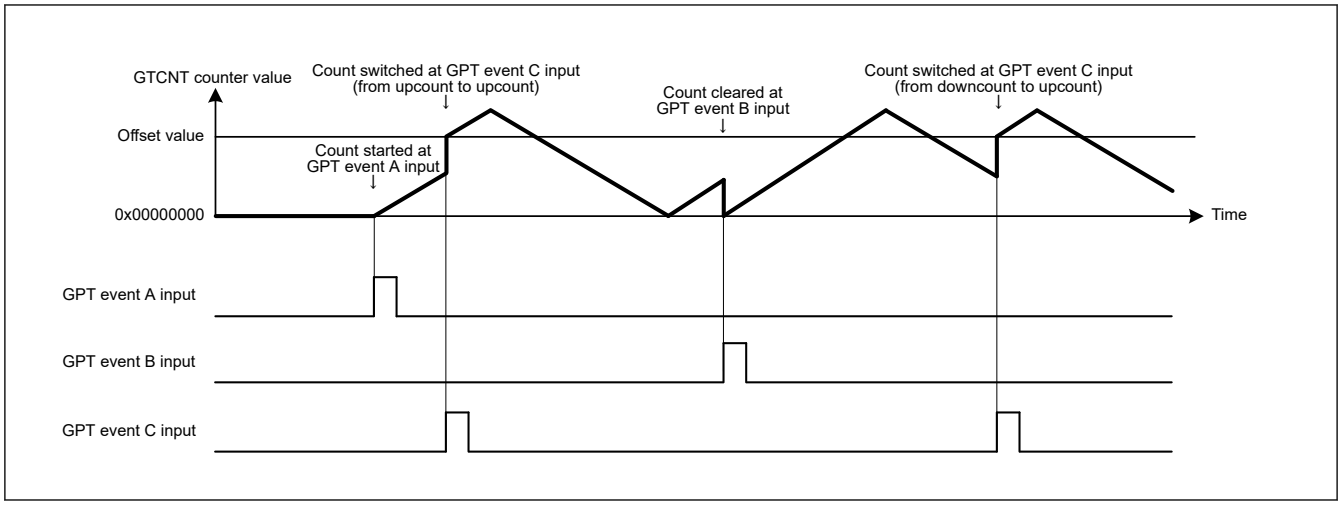

Figure 20.39 Examples of count switch operation by hardware source (switched to upcount with reload at GPT event C input)

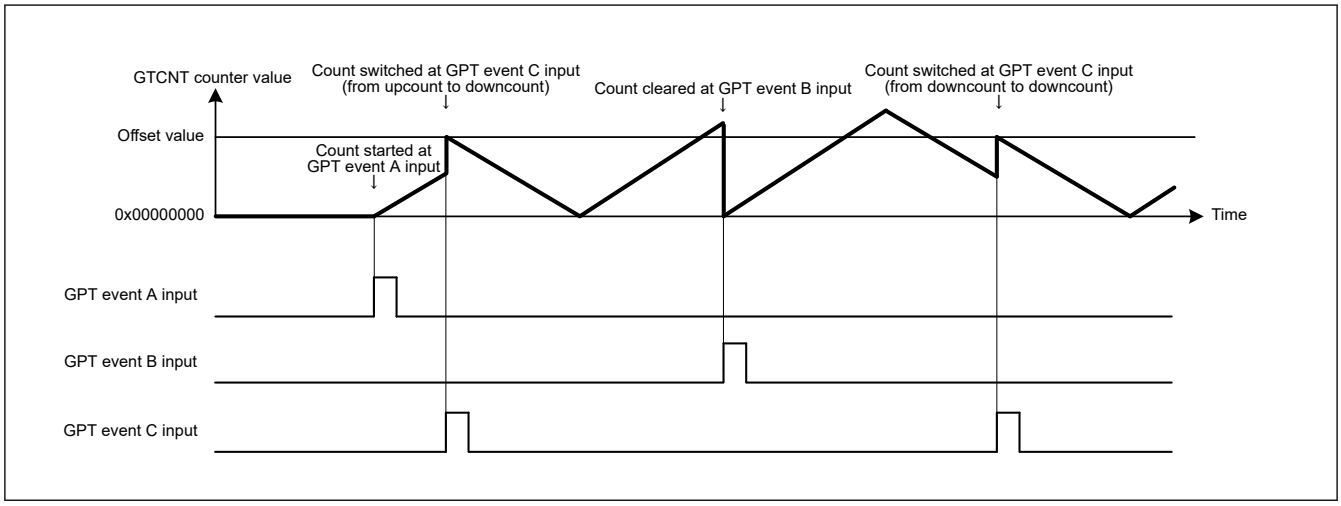

Figure 20.40 Examples of count switch operation by hardware source (switched to downcount with reload at GPT event C input)

The following procedure shows the setting example. In this example, the GTCNT counter started at the GPT event A input, is stopped/cleared at the GPT event B input, and is switched at the GPT event C input.

1. Set operating mode
   Set the operating mode to the triangle-wave PWM mode with the GTCR.MD[2:0] bits.
   In Figure 20.37, Figure 20.38, Figure 20.39, and Figure 20.40, 100b (triangle-wave PWM mode 1) is set.
2. Select count clock
   Select the count clock with GTCR.TPCS[3:0] bits.
3. Period setting
   Set a period in the GTPR register.
4. Set initial value for counter
   Set the initial value in the GTCNT counter.
   In Figure 20.37, Figure 20.38, Figure 20.39, and Figure 20.40, 0x00000000 is set.
5. Set switch mode
   Set the switch mode with the GTCR.SWMD[2:0] bits.
   In Figure 20.37, 101b is set, in Figure 20.38, 110b is set, in Figure 20.39, 001b is set, in Figure 20.40, 010b is set.
6. Set hardware count start
   Select a hardware source for starting count operation with the GTSSR register and wait for count start by the hardware source.
   In Figure 20.37, Figure 20.38, Figure 20.39, and Figure 20.40, GTSSR.SSELCA bit = 1.

7. Set hardware count stop
   Select a hardware source for stopping count operation with the GTPSR register and wait for count stop by the hardware source.
8. Set hardware count clear
   Select a hardware source to clear the counter with the GTCSR register and wait for counter clearing by the hardware source.
   In Figure 20.37, Figure 20.38, Figure 20.39, and Figure 20.40, GTCSR.CSELCB bit = 1.
9. Set hardware count switch
   Select a hardware source to switch the counter with the GTSWSR register and wait for count switch by the hardware source.
   In Figure 20.37, Figure 20.38, Figure 20.39, and Figure 20.40, GTSWSR.WSELCC bit = 1.
10. Set hardware source operation
    Set operation of the hardware source selected with the GTSSR register, GTPSR register, GTCSR register, or GTSWSR register and start, stop, clear, or switch the counter.
    In Figure 20.37, Figure 20.38, Figure 20.39, and Figure 20.40, the GPT event A, GPT event B, and GPT event C input operations are set.

The compare match operation is valid even when the count switch and the compare match occur at the same time. Similarly, even when the count switch occurs at the crest (GTCNT counter matches GTPR register value during upcounting) or trough (GTCNT counter is 0 during downcounting) of triangle-waves, overflow or underflow interrupt is output and the buffer transfer of crest or trough functions normally.

If the count switch is performed at the crest or trough without the offset reload, the crest or trough occurs and then the count direction changes to downcount or upcount regardless of the count switch setting. Also, if the count switch is performed at the count clear state (GTCNT counter value is 0 during upcount) without the offset reload, the count direction continues upcount regardless of the count switch setting.

If the switch mode is set to Switch to upcount with offset reload with the SWMD[2:0] bits and the offset is set to 0 with the GTSWOS register, the count switch functions the same as the counter clear and the GTCNT counter does not operate as the trough. Also, if the switch mode is set to Switch to downcount with offset reload and the offset is set to the GTPR value, the GTCNT counter does not operate as the crest. On the other hand, if the switch mode is set to Switch to upcount with offset reload and the offset is set to the GTPR value, the GTCNT counter operates as the crest, if the switch mode is set to Switch to downcount with offset reload and the offset is set to 0, the GTCNT counter operates as the trough, and in these cases, the interrupt outputs and the buffer transfers of the crest and the trough functions normally.

If the crest or the trough due to the count switch occurs at the timing when the GTCNT counter value is the crest or the trough, the buffer transfer and the interrupt output at the crest or trough will occur twice in a row.

Table 20.12 Triangle-waves condition after the count switch with offset reload

Count direction of switch mode (GTCR.SWMD[2:0])	Offset (GTSWOS)	The triangle-waves condition after the count switch			
		GTCNT	GTST.TUCF	Triangle-waves condition	Buffer transfer/ Interrupt output
Upcount	0	GTSWOS register value	1	Counter clear (start of upcount)	Nothing
	1 to GTPR - 1			Upcount	Nothing
	GTPR			Crest (end of upcount)	Buffer transfer available (only Triangle-Wave PWM Mode 2)/ GPTm_n_OVF Output
Downcount	0		0	Trough (end of downcount)	Buffer transfer available/ GPTm_n_UDF Output
	1 to GTPR - 1			Downcount	Nothing
	GTPR			Start of downcount	Nothing

Figure 20.41 and Figure 20.42 show examples of the buffer operation due to the count switch when the offset is set to 0 and GTPR. Figure 20.43 shows example of the buffer operation due to the count switch when the offset is set other than the crest and trough.

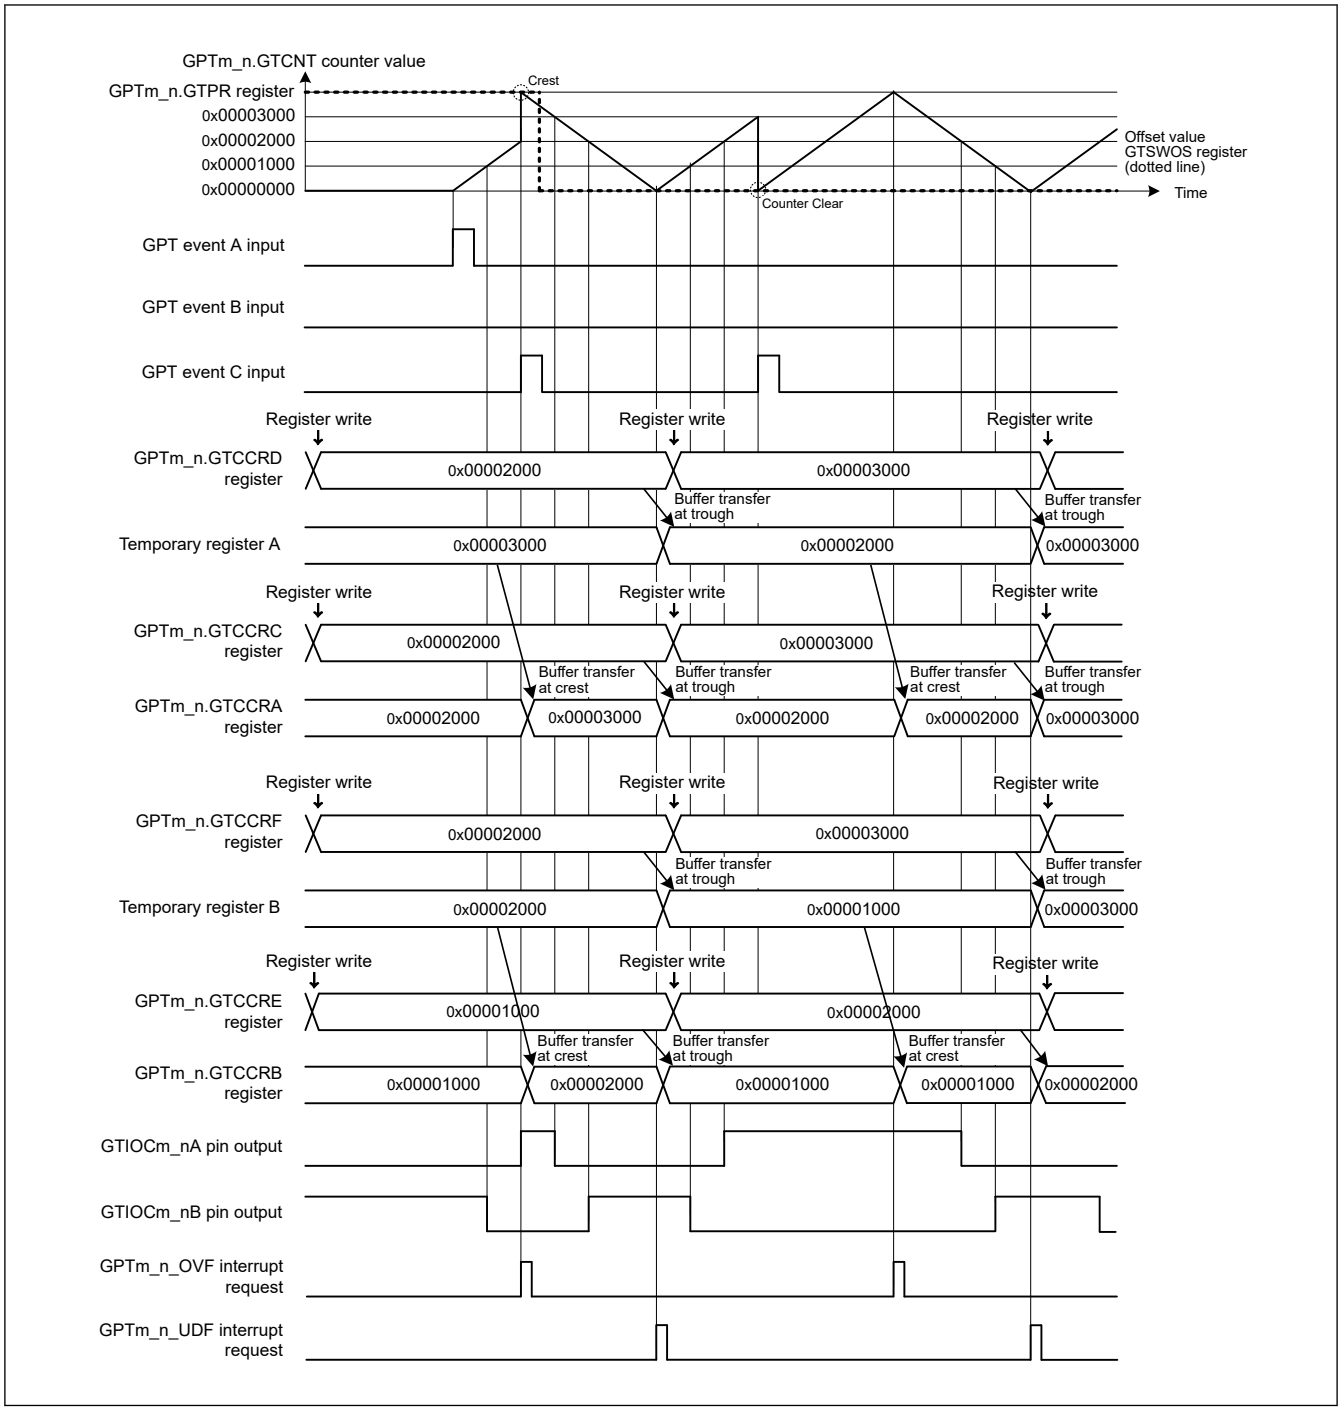

Figure 20.41 Example of the buffer operation due to the count switch (triangle-wave PWM mode 3, offset is set to 0 and GTPR, and switch to upcount)

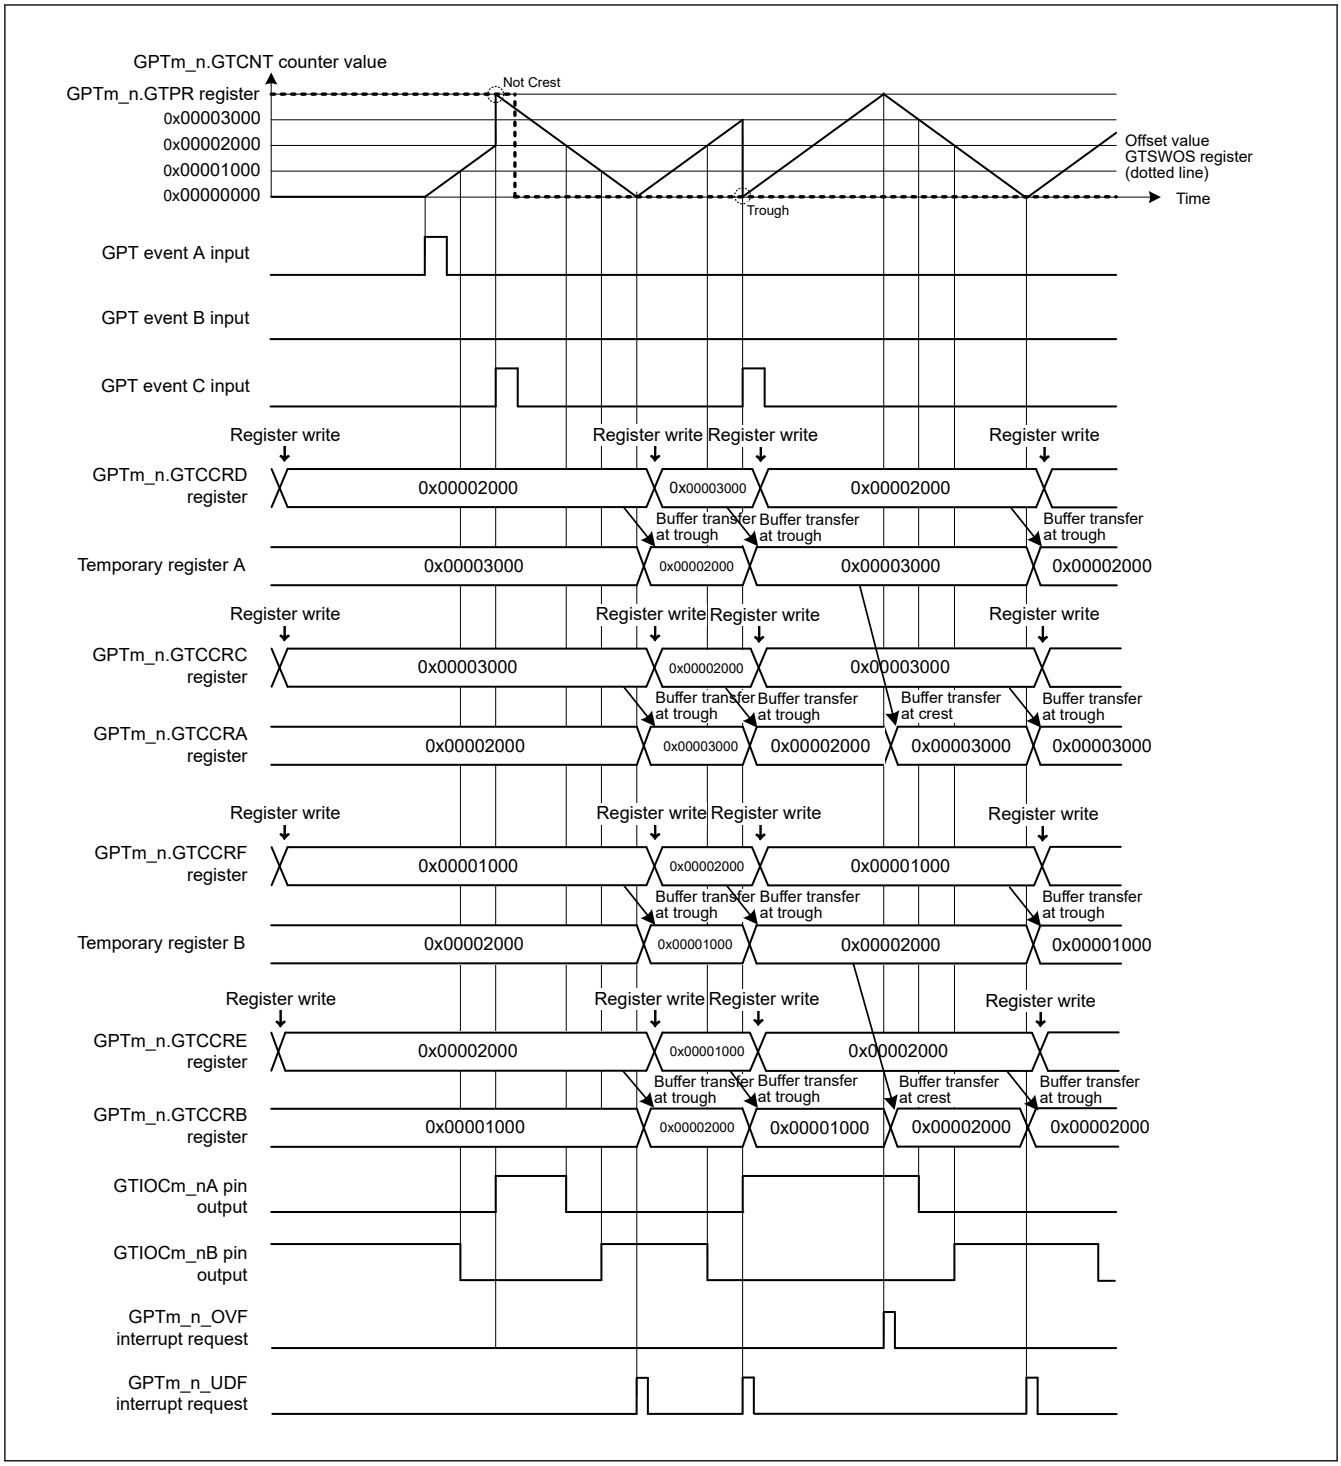

Figure 20.42 Example of the buffer operation due to the count switch (triangle-wave PWM mode 3, offset is set to 0 and GTPR, and switch to downcount)

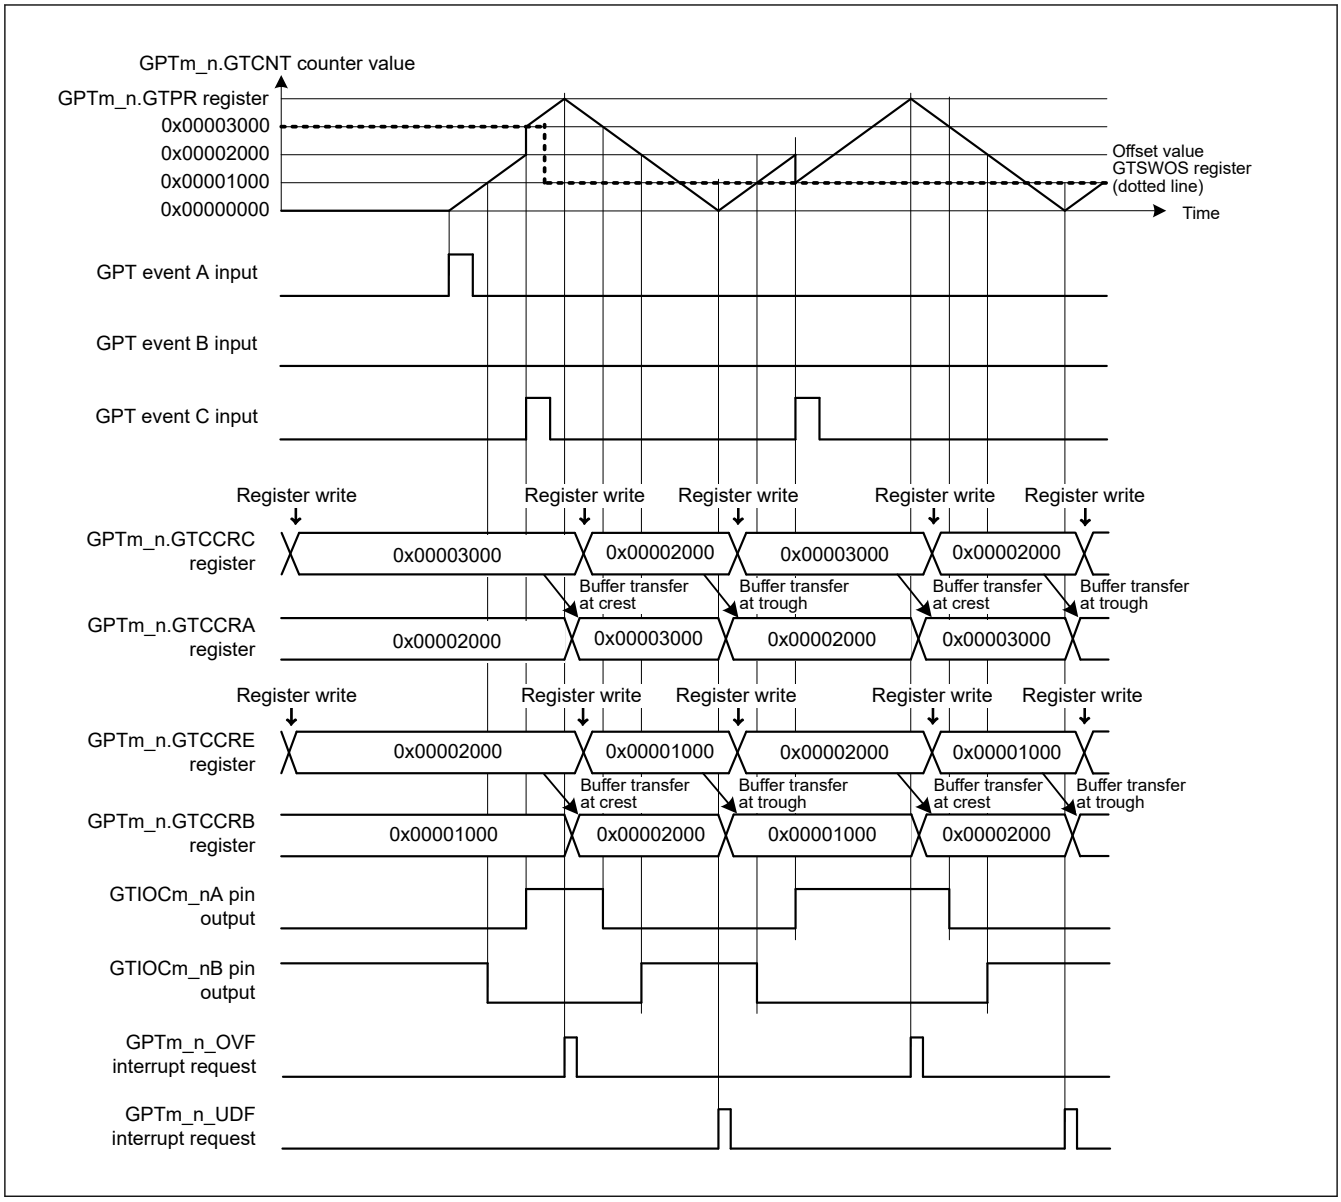

Figure 20.43 Example of the buffer operation due to the count switch (triangle-wave PWM mode 2, no crest and trough occurrence due to the count switch)

When the counter value skips the compare match value by the count switch, no compare match occurs and the GTIOCm_nA and GTIOCm_nB pin output does not change. Figure 20.44 shows example of the operation when the compare match is skipped by switch operation.

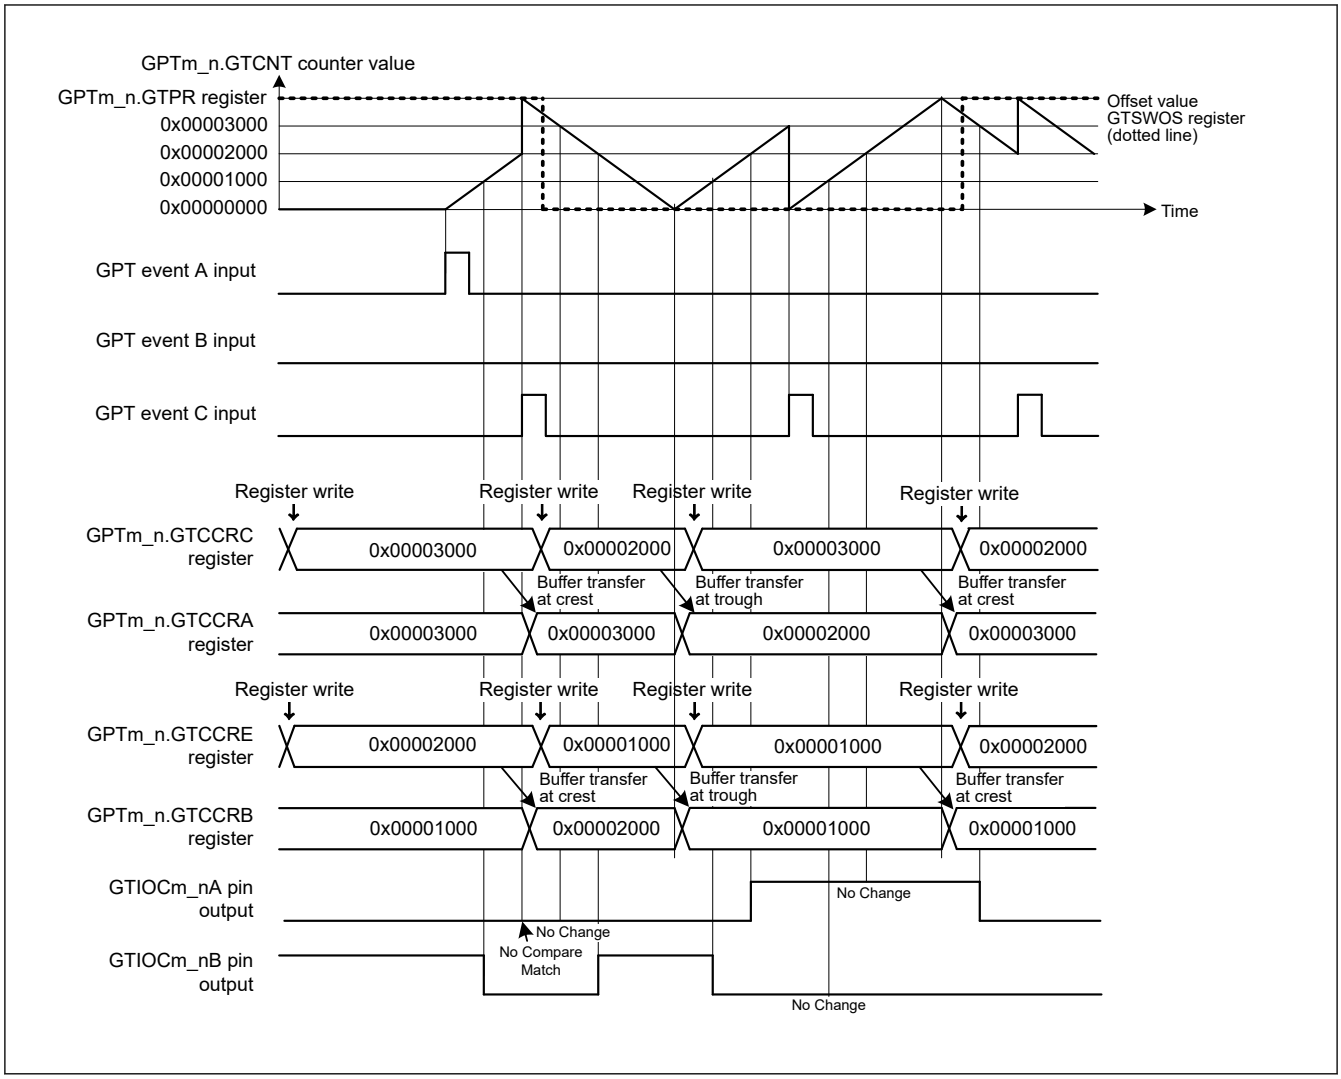

Figure 20.44 Example of the exception operation due to the count switch (switch to upcount with offset reload by GPT event C)

Figure 20.45 and Figure 20.46 show examples of the timing of operations to switch the counter in response to a rising edge of the input on the GTETRGA pin when a clock signal produced by frequency-dividing the Core clock signal is used as the counter clock for the GTCNT counter.

The GTCNT counter is switched when counting is in progress after the GPT has detected the internal switching signal.

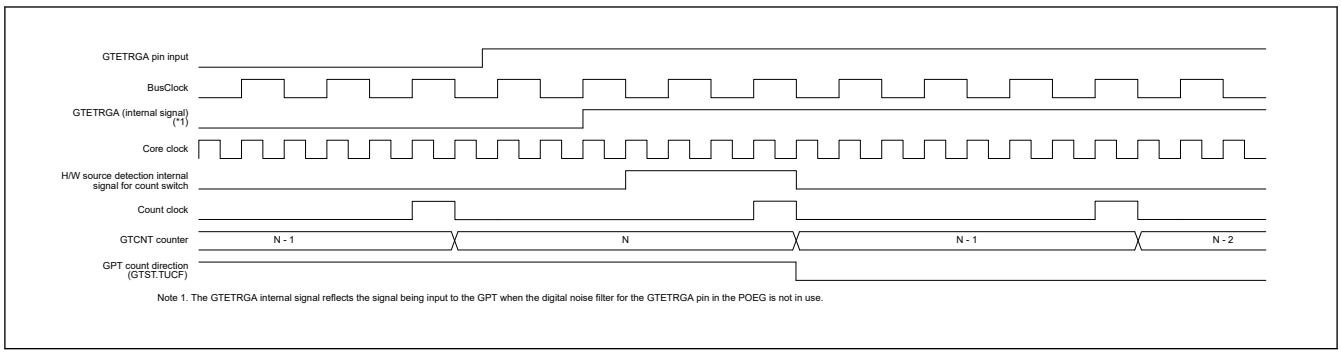

Figure 20.45 Example of the timing of operations for count switch in response to a rising edge of the input on the GTETRGA pin (switch to downcount without offset reload during the counting)

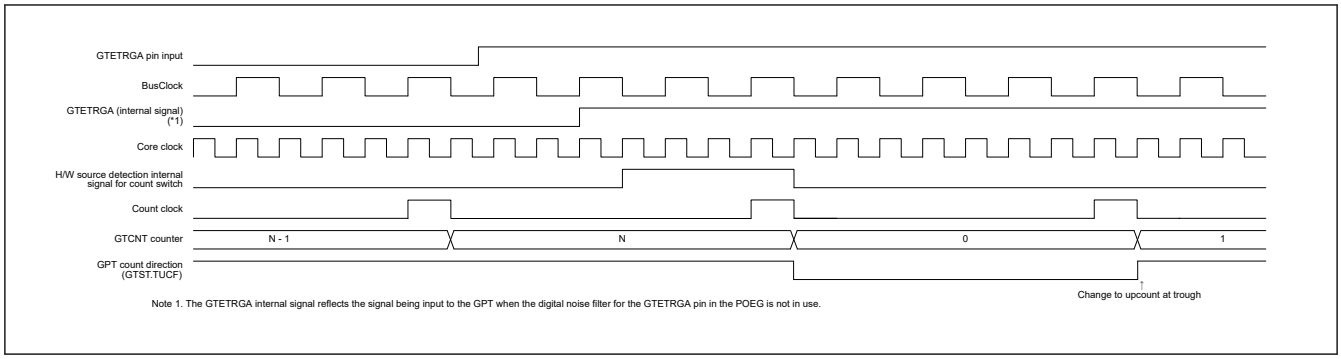

Figure 20.46 Examples of the Timing of Operations for Count Switch in Response to a Rising Edge of the Input on the GTETRGA Pin (switch to downcount with offset reload during the counting and offset value is 0)

Figure 20.47 and Figure 20.48 show examples of the timing of count switch operations in response to the input of an event signal from the GPT event A when counting is triggered by a hardware source.

This is an example of operations to switch the GPT00_1.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPT00_0.GTCCRA register. This is selected as a trigger for output to the GPT by the ELC as event source A.

The GPT00_0 compare match A signal is synchronized with Core clock. The ELC receives the signal in synchronization with BusClock, and outputs the GPT event source A signal after 1 cycle of BusClock has elapsed. The GTCNT counter is switched in synchronization with Core clock after the GPT has detected the internal switching signal.

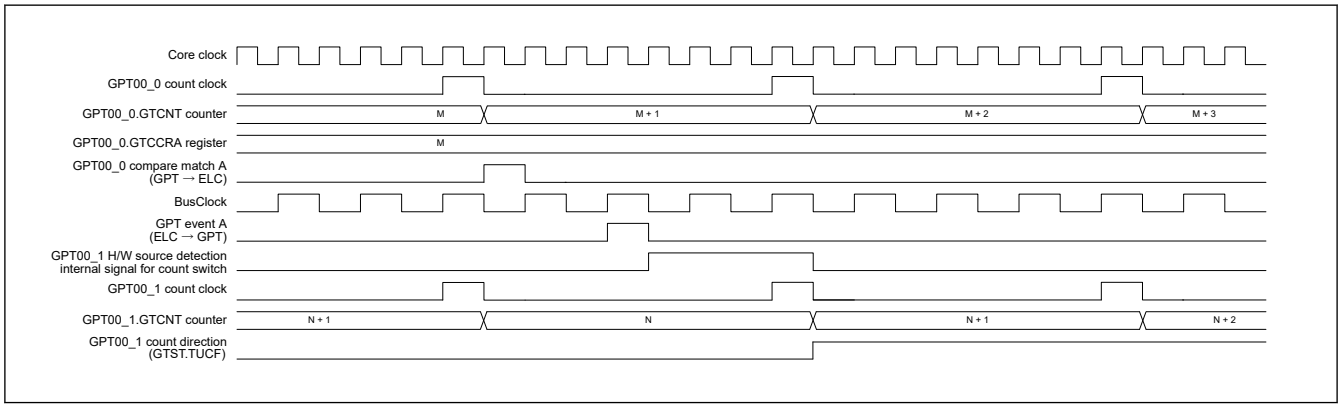

Figure 20.47 Examples of the Timing of Count Switch Operations in Response to Event Input from the GPT event A (switch to upcount without offset reload during the counting)

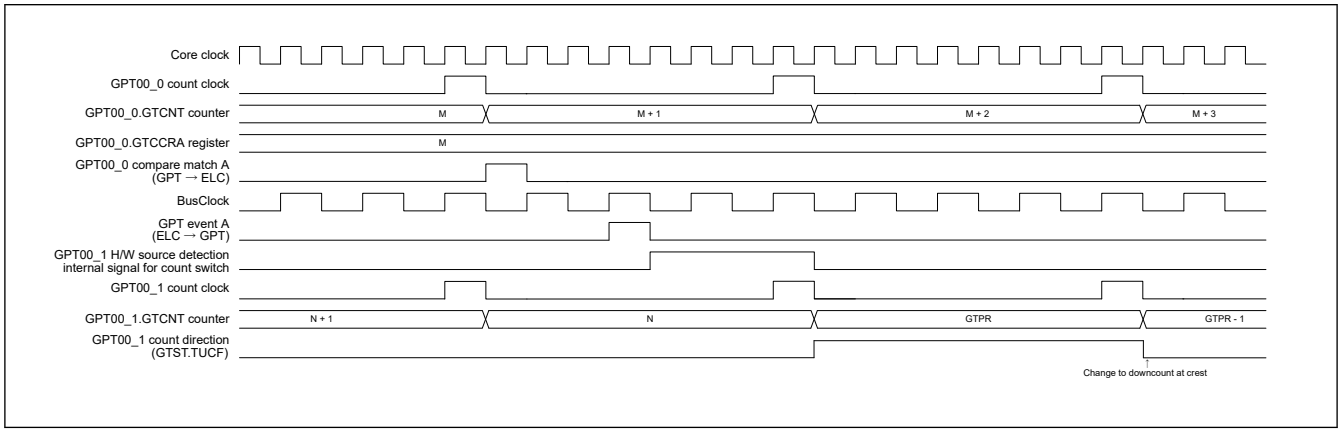

Figure 20.48 Examples of the Timing of Count Switch Operations in Response to Event Input from the GPT event A (switch to upcount with offset reload during the counting and offset value is GTPR)

20.4.9 Synchronous Operation

Synchronous operation on channels such as synchronous start/stop/clear/switch operation can be performed.

20.4.9.1 Synchronous Operation by Software

The count operations for respective channels can be started, stopped and cleared simultaneously by setting multiple bits of the GTSTR, GTSTP, and GTCLR registers to 1 at the same time.

Count start with phase differences among channels is possible by setting the GTCNT counter value before counting starts and then by setting simultaneously multiple bits in the GTSTR register to 1.

The Figure 20.49 shows an example of simultaneous start/stop/clear of four channels by software, and Figure 20.50 shows an example of phase shift start among four channels by software.

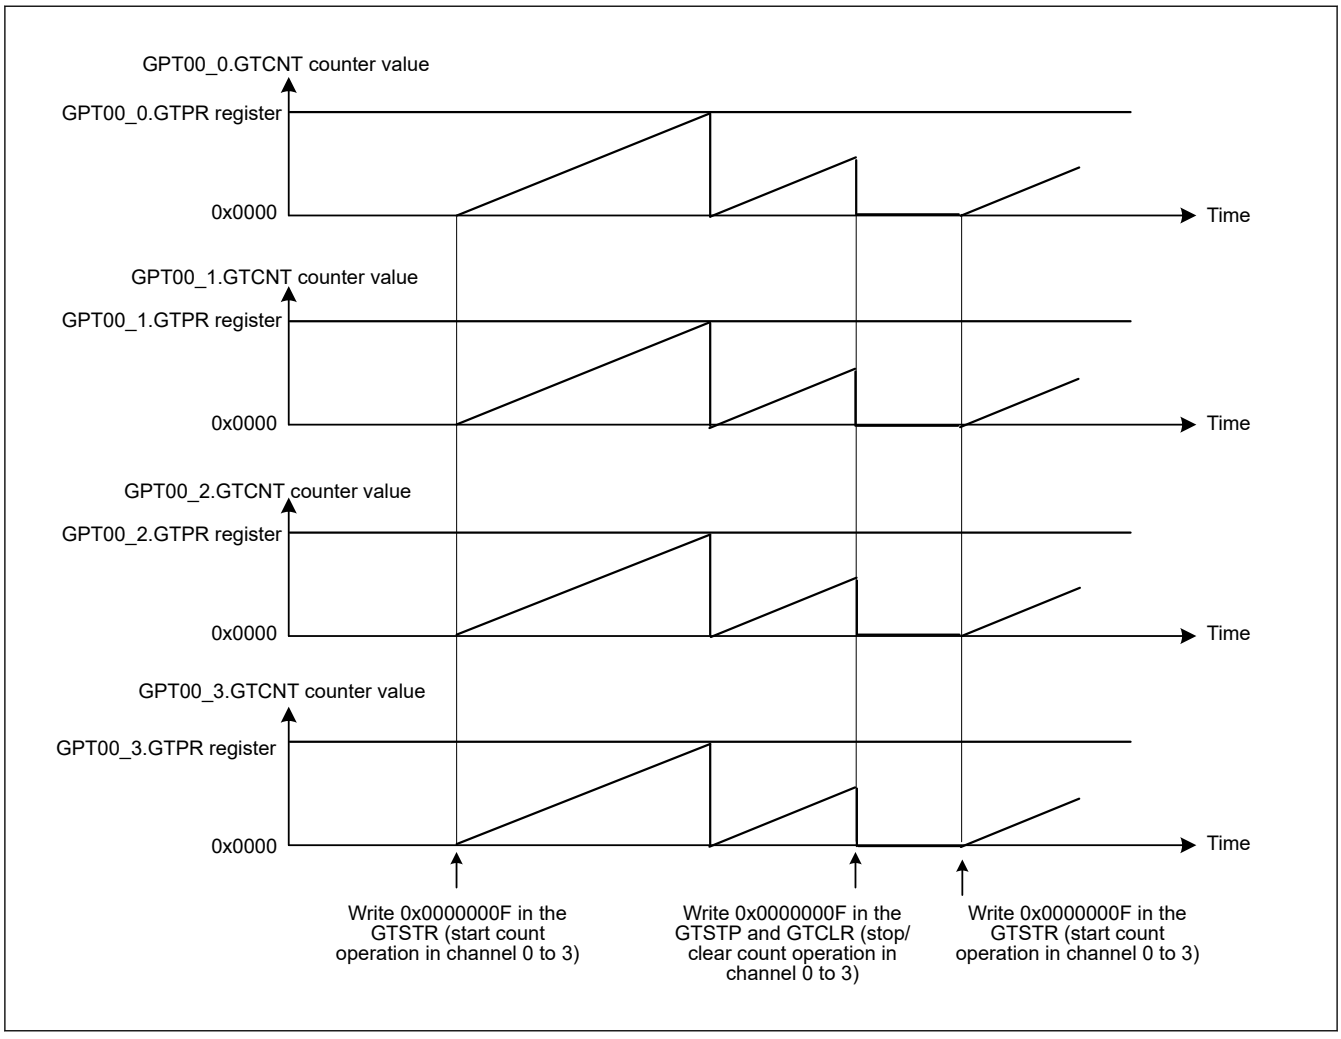

Figure 20.49 Example of simultaneous start/stop/clear operation by software with the same count period (GTPR register value)

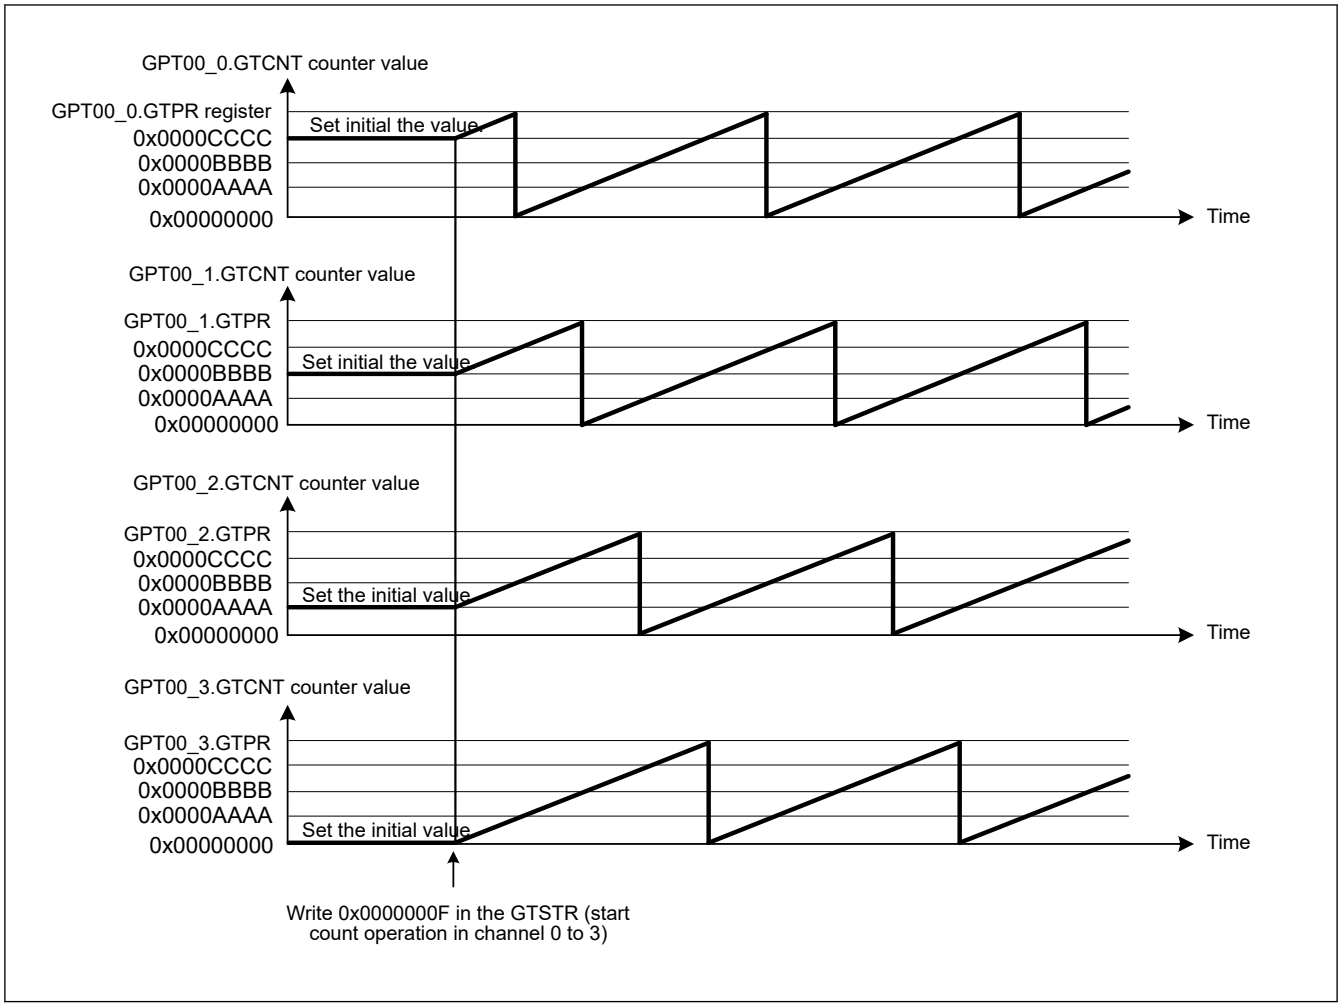

Figure 20.50 Example of software phase shift start with same count period (GTPR register value)

20.4.9.2 Synchronous Operation by Hardware Source

The count operations for respective channels can be started/stopped/cleared/switched simultaneously by hardware sources such as external trigger input and ELC event input.

Synchronous operation by the GTIOCm_nA and GTIOCm_nB pin inputs ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3)) can be performed by setting the ELC event with input capture as a hardware source.

Figure 20.51 shows an example of simultaneous start/stop/clear/switch operation of four channels by hardware source.

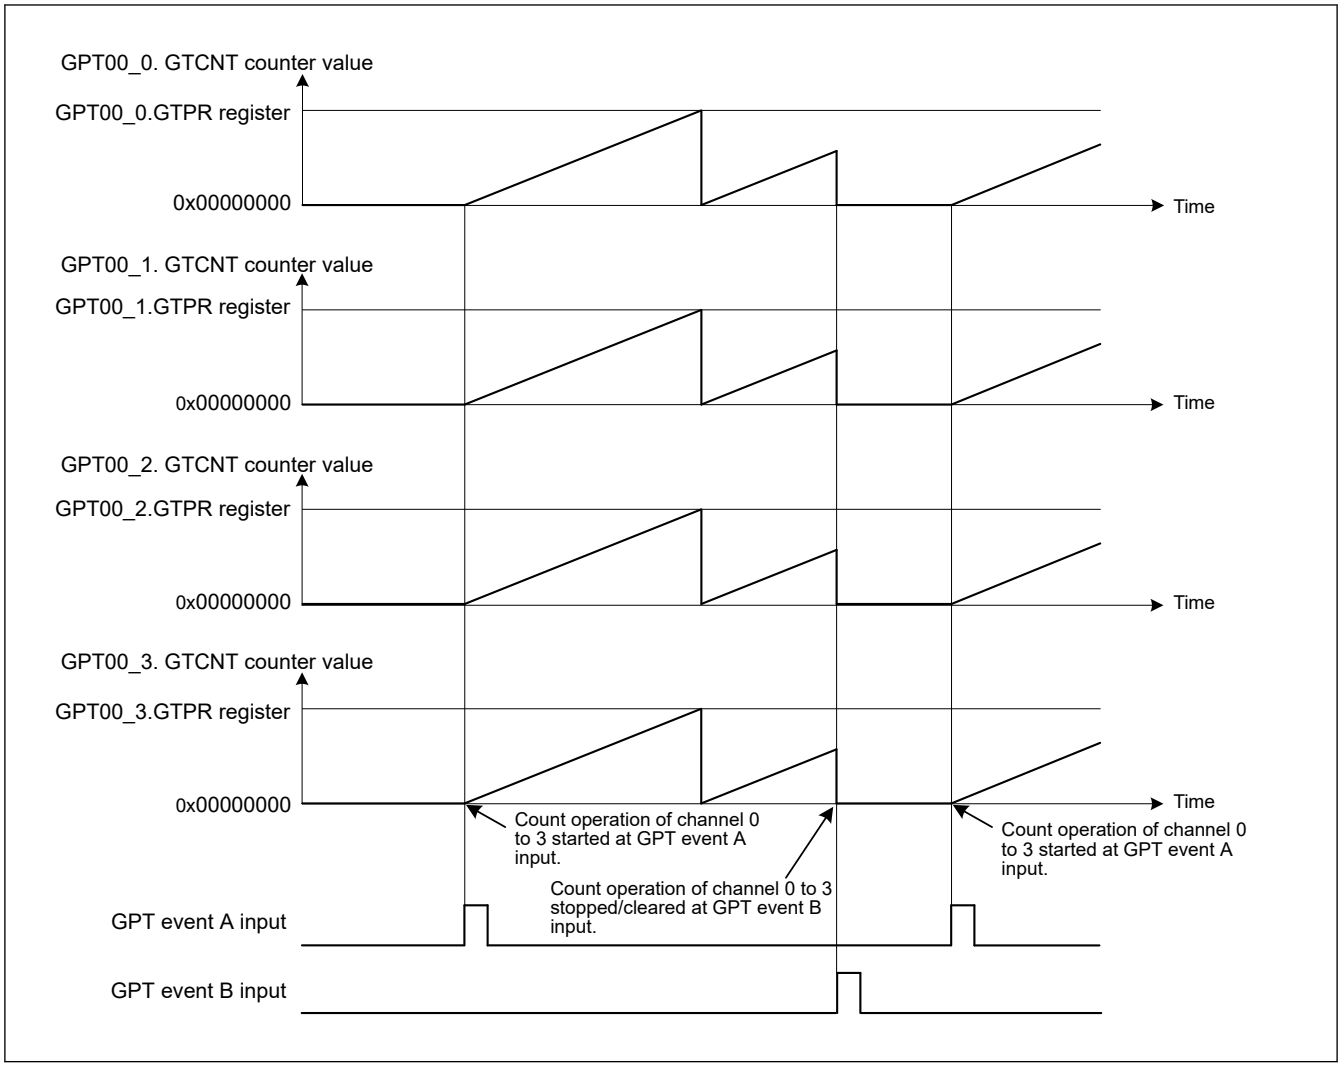

Figure 20.51 Example of simultaneous start/stop/clear operation by hardware source with same count period (GTPR register value)

The following example shows setting for simultaneous start by hardware source.

1. Set operating mode
   Set the operating mode with the GTCR.MD[2:0] bits of the corresponding channel.
   In Figure 20.51, 000b (sawtooth-wave PWM mode) is set.
2. Set count direction
   Select the count direction (up or down) with the GTUDDTYC register.
   In Figure 20.51, the lower 2 bits of the GTUDDTYC register is set to 11b and then to 01b for up-counting.
3. Select count clock
   Select the count clock with GTCR.TPCS[3:0] bits of the corresponding channel.
4. Period setting
   Set a period in the GTPR register of the corresponding channel.
5. Set initial value for counter
   Set the initial value in the GTCNT counter of the corresponding channel.
   In Figure 20.51, 0x00000000 is set.
6. Set hardware count start
   Select a hardware source to start the count operation with the GTSSR register and wait for count start by the hardware source.
   In Figure 20.51, GTSSR.SSELCA bit = 1.
7. Set hardware count stop

Select a hardware source to stop count operation with the GTPSR register and wait for count stop by the hardware source.
In Figure 20.51, GTPSR.PSELCB bit = 1.

8. Set hardware count clearing
Select a hardware source to clear the counter with the GTCSR register and wait for counter clear by the hardware source.
In Figure 20.51, GTCSR.CSELCB bit = 1.

9. Start hardware source operation
Set operation of the hardware source selected by the GTSSR, GTPSR, and GTCSR registers and start counting, stop counting, or clearing the counter.
In Figure 20.51, the GPT event A and B inputs are set.

20.4.10 PWM Output Operation Examples

(1) Synchronous PWM Output

The GPT can output two phases of linked PWM waveforms for one channel or 14 phases of linked PWM waveforms for a maximum of seven channels by one GPT unit or 36 phases of linked PWM waveforms for a maximum of 52 channels by plural GPT units by synchronizing operation of the channels.

Figure 20.52 shows an example in which four channels perform synchronous operation in sawtooth-wave PWM mode and eight phases of PWM waveforms are output. The GTIOC00_nA pin (n = 0 to 3) is set so that it outputs low as the initial output, high at a GTCCRA register compare match, and low at the end of the cycle. The GTIOC00_nB pin is set so that it outputs low as the initial output, high at a GTCCRB register compare match, and low at the end of the cycle.

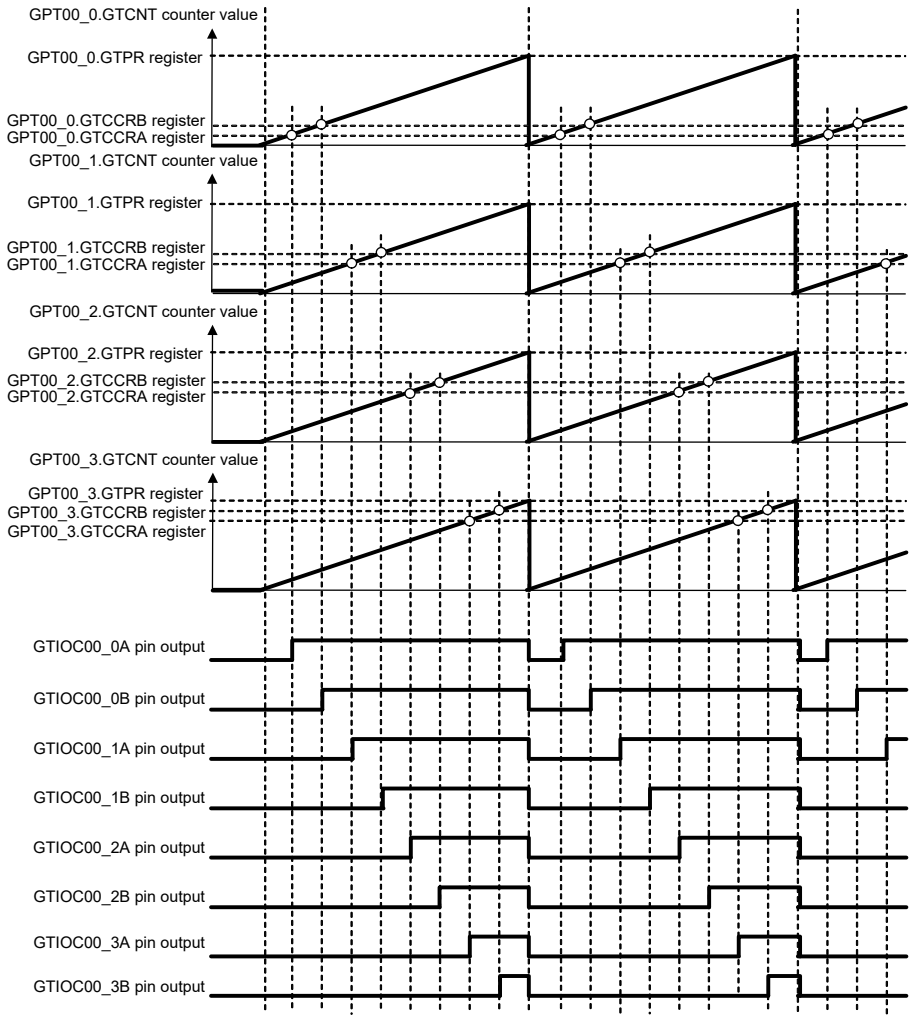

Figure 20.52 Example of synchronous PWM output

(2) 3-Phase Sawtooth-Wave Complementary PWM Output

Figure 20.53 shows an example in which three channels perform synchronous operation in sawtooth-wave PWM mode and 3-phase complementary PWM waveforms are output. The GTIOC00_nA pin (n = 0 to 2) is set so that it outputs low as the initial output, high at a GTCCRA register compare match, and low at the end of the cycle. The GTIOC00_nB pin is set so that it outputs high as the initial output, low at a GTCCRB register compare match, and high at the end of the cycle.

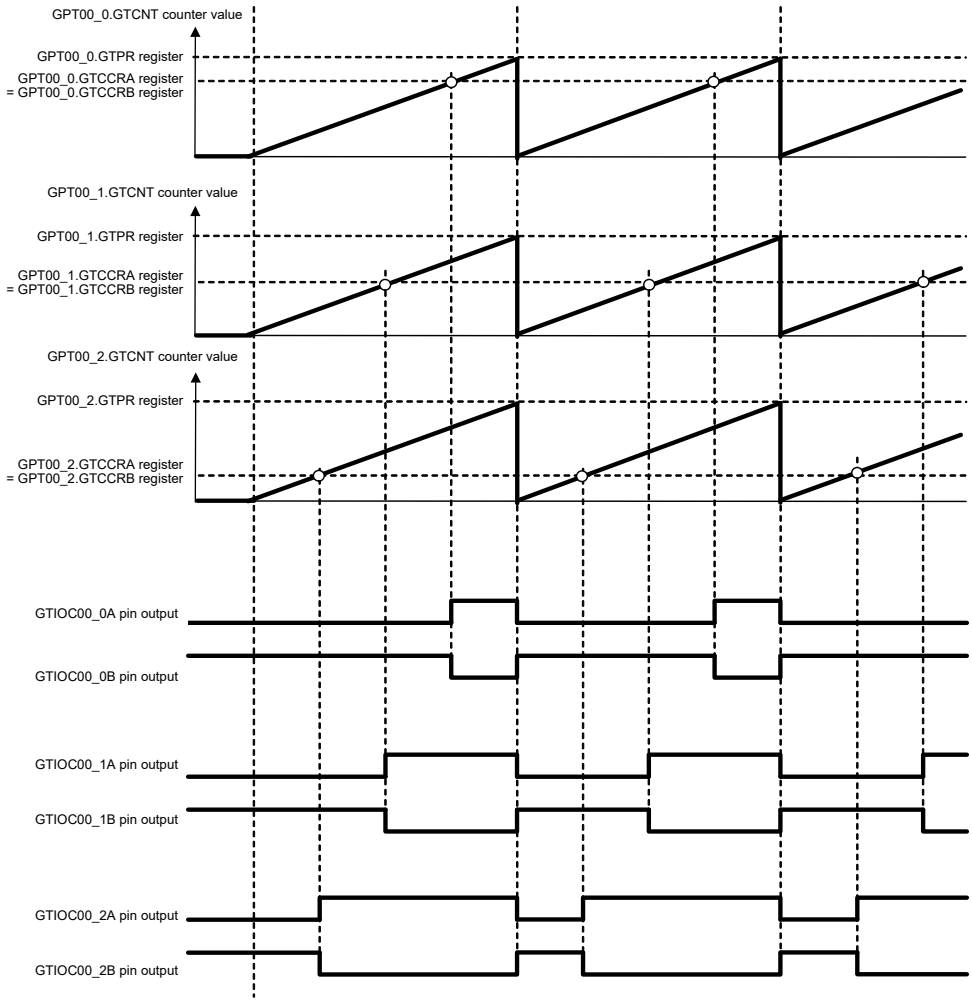

Figure 20.53 Example of 3-phase sawtooth-wave complementary PWM output

(3) 3-Phase Sawtooth-Wave Complementary PWM Output with Automatic Dead Time Setting

Figure 20.54 shows an example in which three channels perform synchronous operation in sawtooth-wave one-shot pulse mode with automatic dead time setting and 3-phase complementary PWM waveforms are output. The GTIOC00_nA pin (n = 0 to 2) is set so that it outputs low as the initial output, toggles the output at a GTCCRA register compare match, and retains the output at the end of the cycle. The GTIOC00_nB pin is set so that it outputs high as the initial output, toggles the output at a GTCCRB register compare match, and retains the output at the end of the cycle.

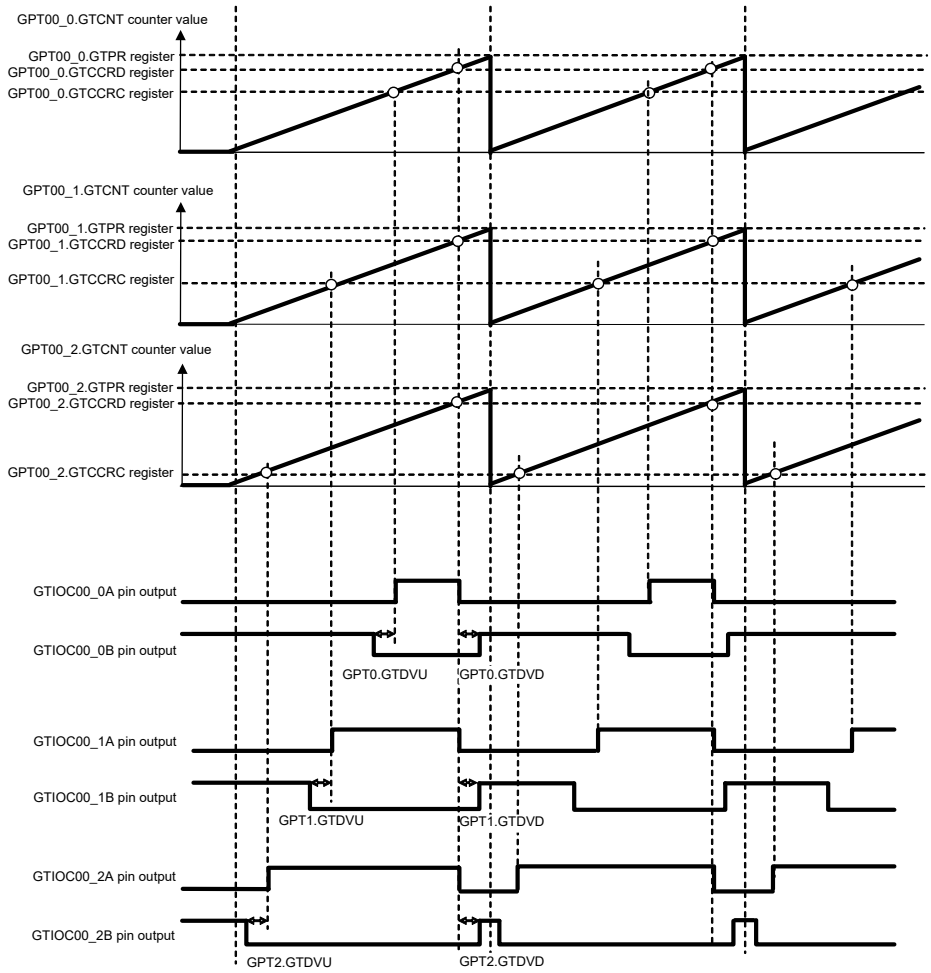

Figure 20.54 Example of 3-phase sawtooth-wave complementary PWM output with automatic dead time setting

(4) 3-Phase Triangle-Wave Complementary PWM Output

Figure 20.55 shows an example in which three channels perform synchronous operation in triangle-wave PWM mode 1 and 3-phase complementary PWM waveforms are output. The GTIOC00_nA pin (n = 0 to 2) is set so that it outputs low as the initial output, toggles the output at a GTCCRA register compare match, and retains the output at the end of the cycle. The GTIOC00_nB pin is set so that it outputs high as the initial output, toggles the output at a GTCCRB register compare match, and retains the output at the end of the cycle.

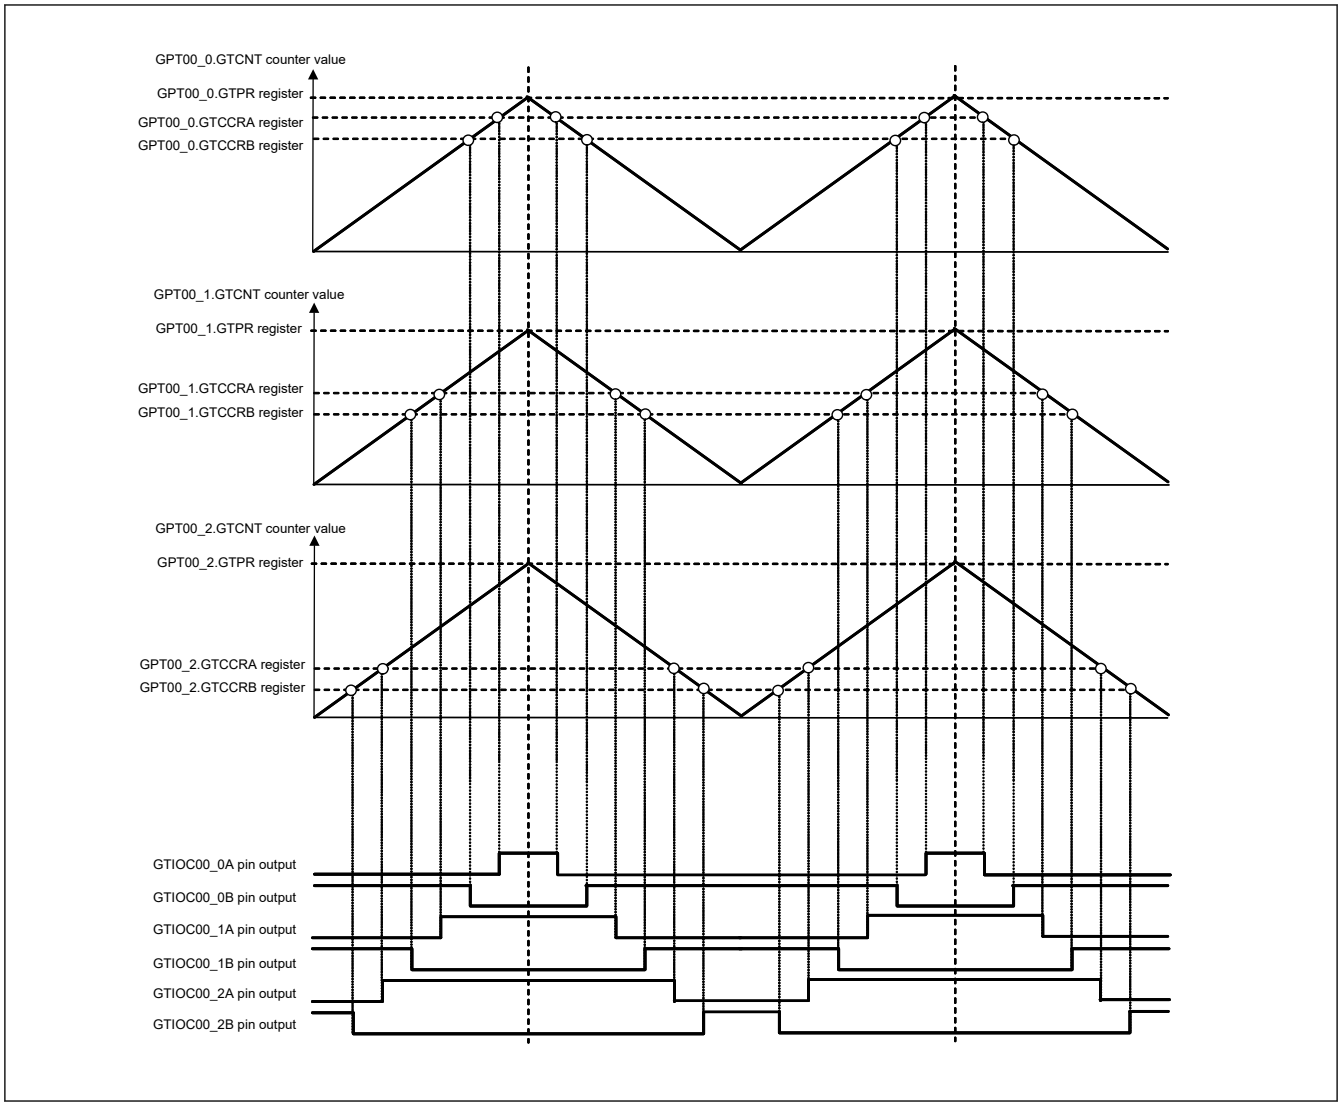

Figure 20.55 Example of 3-phase triangle-wave complementary PWM output

(5) 3-Phase Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

Figure 20.56 shows an example in which three channels perform synchronous operation in triangle-wave PWM mode 1 with automatic dead time setting and 3-phase complementary PWM waveforms are output. The GTIOC00_nA pin (n = 0 to 2) is set so that it outputs low as the initial output, toggles the output at a GTCCRA register compare match, and retains the output at the end of the cycle. The GTIOC00_nB pin is set so that it outputs high as the initial output, toggles the output at a GTCCRB register compare match, and retains the output at the end of the cycle.

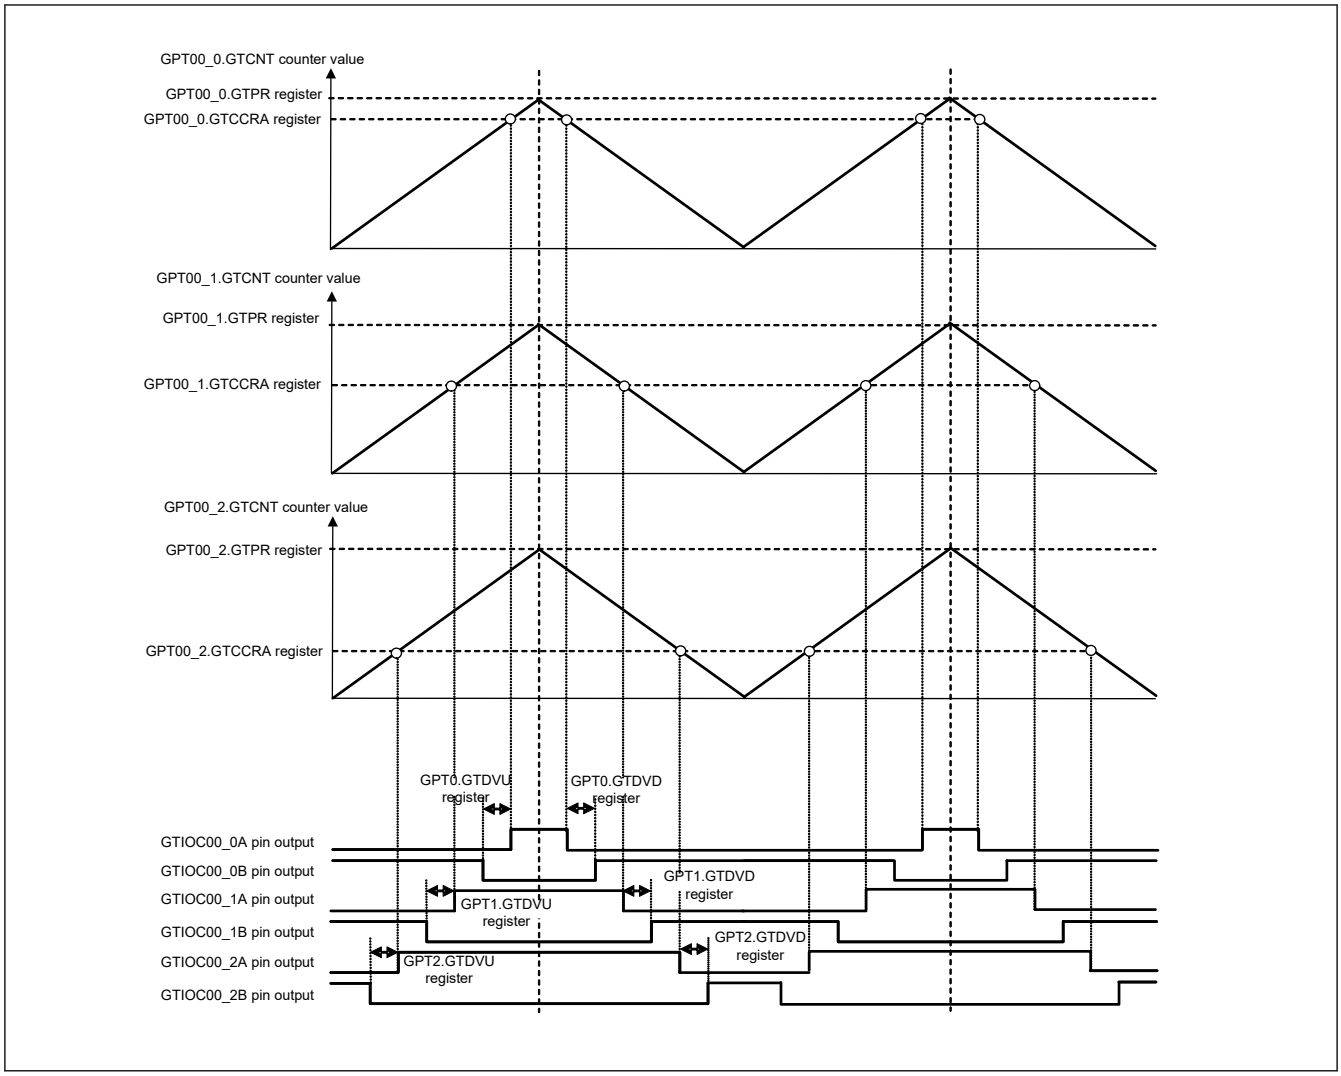

Figure 20.56 Example of 3-phase triangle-wave complementary PWM output with automatic dead time setting

(6) 3-Phase Asymmetric Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

Figure 20.57 shows an example in which three channels perform synchronous operation in triangle-wave PWM mode 3 with automatic dead time setting and 3-phase complementary PWM waveforms are output. The GTIOC00_nA pin (n = 0 to 2) is set so that it outputs low as the initial output, toggles the output at a GTCCRA register compare match, and retains the output at the end of the cycle. The GTIOC00_nB pin is set so that it outputs high as the initial output, toggles the output at a GTCCRB register compare match, and retains the output at the end of the cycle.

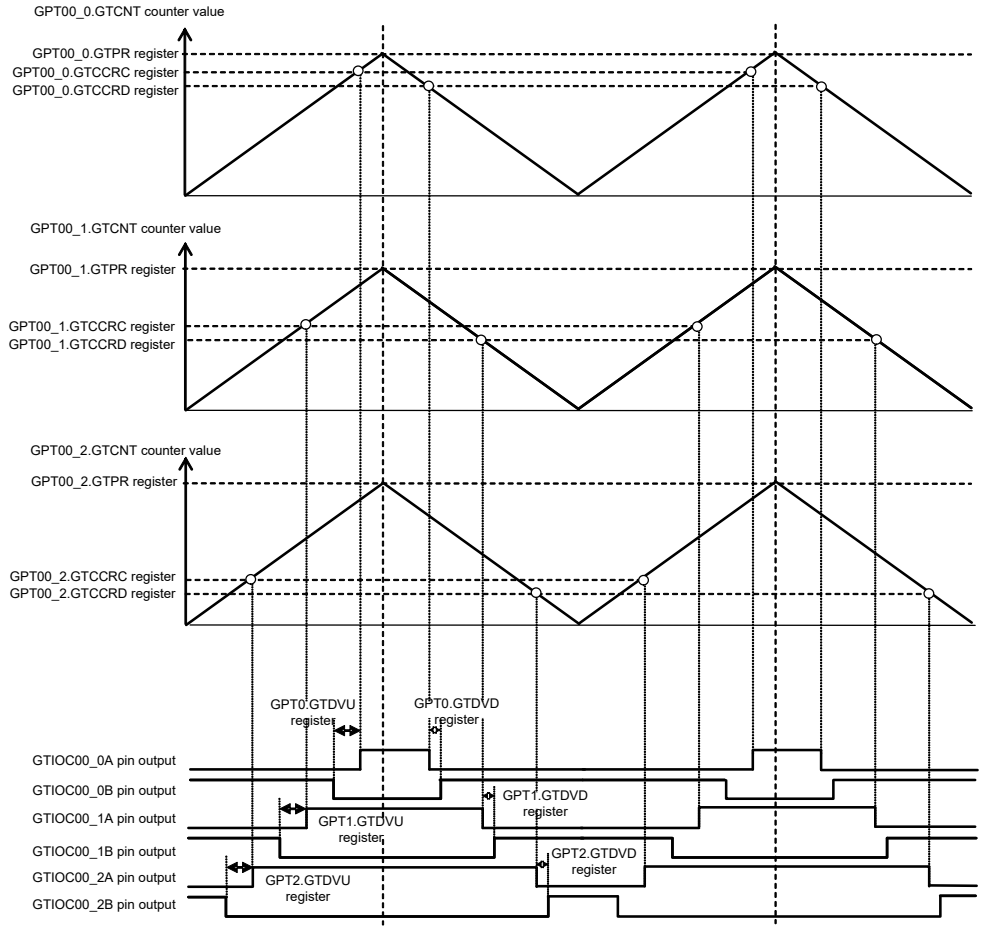

Figure 20.57 Example of 3-Phase Asymmetric Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

20.4.11 Phase Counting Mode

The GTCNT counter can be up-counting or down-counting by detecting the phase difference between the GTIOCm_nA pin input ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3)) and the GTIOCm_nB pin input. Detection of the phase difference can be performed by setting the relationship between the edge and the level of the GTIOCm_nA pin input and the GTIOCm_nB pin input using the GTUPSR and GTDNSR registers for input combination. See section 20.4.1.1. Counter Operation.

Figure 20.58 to Figure 20.67 show the examples of setting procedure for the phase counting mode 1 to 5, and Table 20.13 to Table 20.22 show the setting of the GTUPSR and GTDNSR registers including up-counting and down-counting conditions.

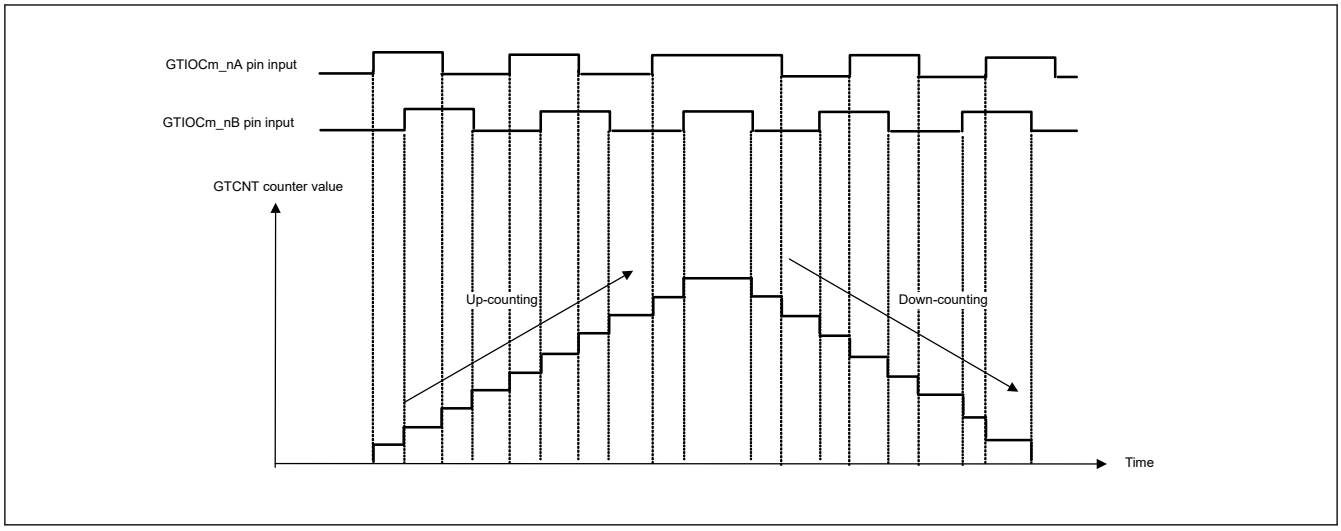

Figure 20.58 Example of setting procedure for the phase counting mode 1 ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

20.5 Interrupt Sources

20.5.1 Interrupt Sources

There are four kinds of interrupt sources:

- GTCCRm register (m = A to F) input capture / compare match
- GTADTR register compare match (only used for ELC)
- GTCNT counter overflow (GTPR register compare match) / underflow
- Dead time error

Each interrupt source has its own status flag and control bit for generating interrupt request signals, where the generation of interrupt request signals can be enabled or disabled individually.

When an interrupt source condition is satisfied, the corresponding status flag in GTST is set to 1 and an interrupt request is generated if the corresponding interrupt request enable or disable bit in the GTINTAD register is 1.

The corresponding status flag in the GTST register is writable to clear. If flag set and flag clear occur at the same time, flag clear has priority over flag set. Both dead time error (DTEF flag) and those flags are automatically updated by internal state.

For details, see section 12, Interrupt Controller (ICU). Table 20.23 shows a list of the GPT interrupt sources.

Table 20.23 Interrupt sources

Channel	Name	Interrupt source	Interrupt flag
GPTm_n	GPTm_n_CCMPA	GPTm_n.GTCCRA register input capture / compare match	—
	GPTm_n_CCMPB	GPTm_n.GTCCRB register input capture / compare match	—
	GPTm_n_CMPC	GPTm_n.GTCCRC register compare match	—
	GPTm_n_CMPD	GPTm_n.GTCCRD register compare match	—
	GPTm_n_CMPE	GPTm_n.GTCCRE register compare match	—
	GPTm_n_CMPF	GPTm_n.GTCCRF register compare match	—
	GPTm_n_DTE*1	GPTm_n dead time error	GPTm_n.GTST.DTEF
	GPTm_n_ADTRGA*1	GPTm_n.GTADTRA register compare match	GPTm_n.GTST.ADTRAUF GPTm_n.GTST.ADTRADF
	GPTm_n_ADTRGB*1	GPTm_n.GTADTRB register compare match	GPTm_n.GTST.ADTRBUF GPTm_n.GTST.ADTRBDF
	GPTm_n_OVF	GPTm_n.GTCNT counter overflow (GPTm_n.GTPR register compare match)	—
	GPTm_n_UDF	GPTm_n.GTCNT counter underflow	—

Note: (m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3)
Note 1. Except m = 10 (Unit 10, SAFETY)

(1) GPTm_n_CCMPA Interrupt ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

When the GTINTAD.GTINTA bit is 1, an interrupt request is generated under the following conditions:

- When the GTCCRA register functions as a compare match register, the GTCNT counter value matches with the GTCCRA register
- When the GTCCRA register functions as an input capture register, the input capture signal causes transfer of the GTCNT counter value to the GTCCRA register

(2) GPTm_n_CCMPB Interrupt ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

When the GTINTAD.GTINTB bit is 1, an interrupt request is generated under the following conditions:

- When the GTCCRB register functions as a compare match register, the GTCNT counter value matches with the GTCCRB register
- When the GTCCRB register functions as an input capture register, the input capture signal causes transfer of the GTCNT counter value to the GTCCRB register

(3) GPTm_n_CMPC Interrupt ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

When the GTINTAD.GTINTC bit is 1, an interrupt request is generated under the following condition:

- When the GTCCRC register functions as a compare match register, the GTCNT counter value matches with the GTCCRC register

A compare match is not performed and thus interrupt is not requested under the following conditions:

- GTCR.MD[2:0] bits = 001b (sawtooth-wave one-shot pulse mode)
- GTCR.MD[2:0] bits = 110b (triangle-wave PWM mode 3)
- GTBER.CCRA[1:0] bits = 01b, 10b, 11b (buffer operation with the GTCCRC register)

(4) GPTm_n_CMPD Interrupt ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

When the GTINTAD.GTINTD bit is 1, an interrupt request is generated under the following condition:

- When the GTCCRD register functions as a compare match register, the GTCNT counter value matches with the GTCCRD register

A compare match is not performed and thus interrupt is not requested under the following conditions:

- GTCR.MD[2:0] bits = 001b (sawtooth-wave one-shot pulse mode)
- GTCR.MD[2:0] bits = 110b (triangle-wave PWM mode 3)
- GTBER.CCRA[1:0] bits = 10b, 11b (buffer operation with the GTCCRD register)

(5) GPTm_n_CMPE Interrupt ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

When the GTINTAD.GTINTE bit is 1, an interrupt request is generated under the following condition:

- When the GTCCRE register functions as a compare match register, the GTCNT counter value matches with the GTCCRE register.

A compare match is not performed and thus interrupt is not requested under the following conditions:

- GTCR.MD[2:0] bits = 001b (sawtooth-wave one-shot pulse mode)
- GTCR.MD[2:0] bits = 110b (triangle-wave PWM mode 3)
- GTBER.CCRB[1:0] bits = 01b, 10b, 11b (buffer operation with the GTCCRE register)

(6) GPTm_n_CMPF Interrupt ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

When the GTINTAD.GTINTF bit is 1, an interrupt request is generated under the following condition:

- When the GTCCRF register functions as a compare match register, the GTCNT counter value matches with the GTCCRF register.

A compare match is not performed and thus interrupt is not requested under the following conditions:

- GTCR.MD[2:0] bits = 001b (sawtooth-wave one-shot pulse mode)
- GTCR.MD[2:0] bits = 110b (triangle-wave PWM mode 3)
- GTBER.CCRB[1:0] bits = 10b, 11b (buffer operation with the GTCCRF register)

(7) GPTm_n_ADTRGA Interrupt ((m = 00 to 08 and n = 0 to 4) or (m = 09 and n = 0 to 6))

When the GTCNT counter value matches with the GTADTRA register, an interrupt request is generated under the following conditions:

- In up-counting, the interrupt enable bit (ADTRAUEN) in the GTINTAD register is 1
- In down-counting, the interrupt enable bit (ADTRADEN) in the GTINTAD register is 1

In event count operation, this interrupt request is not generated.

(8) GPTm_n_ADTRGB Interrupt ((m = 00 to 08 and n = 0 to 4) or (m = 09 and n = 0 to 6))

When the GTCNT counter value matches with the GTADTRB register, an interrupt request is generated under the following conditions:

- In up-counting, the interrupt enable bit (ADTRBUEN) in the GTINTAD register is 1
- In down-counting, the interrupt enable bit (ADTRBDEN) in the GTINTAD register is 1

In event count operation, this interrupt request is not generated.

(9) GPTm_n_OVF Interrupt ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

When the GTINTAD.GTINTPR[0] bit is 1, an interrupt request is generated under the following conditions:

- In sawtooth-wave mode, interrupt requests are enabled at overflows (GTCNT counter value changes from GTPR register value to 0 during up-counting)
- In triangle-wave mode, interrupt requests are enabled at crests (GTCNT counter value changes from GTPR register value to GTPR register value minus 1)
- In count operation by a hardware source, interrupt requests are enabled at overflows (GTCNT counter value changes from GTPR register value to 0 during up-counting)

(10) GPTm_n_UDF Interrupt ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), and (m = 10 and n = 0 to 3))

When the GTINTAD.GTINTPR[1] bit is 1, an interrupt request is generated under the following conditions:

- In sawtooth-wave mode, interrupt requests are enabled at underflows (GTCNT counter value changes from 0 to GTPR register value during down-counting)
- In triangle-wave mode, interrupt requests are enabled at troughs (GTCNT counter value changes from 0 to 1)
- In counting by a hardware source, interrupt requests are enabled at underflows (GTCNT counter value changes from 0 to GTPR register value during down-counting)

(11) GPTm_n_DTE Interrupt ((m = 00 to 08 and n = 0 to 4) or (m = 09 and n = 0 to 6))

When automatic dead time setting is made, the GTST.DTEF flag becomes 1 when the timer output toggle point with dead time added exceeds the count period. If GTINTAD.GRPDTE bit is 1 at this time, a dead time error interrupt request is generated.

In addition, when the timer output toggle point with dead time added is back within the count period, the GTST.DTEF flag changes from 1 to 0.

Table 20.24 Relationship between interrupt signals and interrupt enable bits

Note: (m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3)
Note 1. Except m = 10 (Unit 10, SAFETY)

20.5.2 Interrupt and A/D Conversion Start Request Skipping Function

20.5.2.1 Interrupt Skipping Function by GTITC Register

By setting the GTITC register, the GTCNT counter overflow (GTPR register compare match) interrupt (GPTm_n_OVF) and underflow interrupt (GPTm_n_UDF) can be skipped. Other interrupts and A/D converter start request signals can be skipped in coordination with the GPTm_n_OVF/GPTm_n_UDF skipping function. However, the dead time error interrupts cannot be linked with the GPTm_n_OVF/GPTm_n_UDF skipping function.

The interrupt skipping function is related only to the GTITC register setting, and is not related to setting of the GTINTAD register interrupt enable bit.

When both troughs and crests are counted and skipped in triangle-wave mode, if the number of times of skipping is odd, GPTm_n_OVF/GPTm_n_UDF interrupt requests cannot be generated at troughs only or at crests only depending on the skipping counter start timing. Therefore, to count both troughs and crests and generate the GPTm_n_OVF/GPTm_n_UDF interrupts at troughs only or crests only in triangle-wave mode, the number of times of skipping should be even.

Similarly, in sawtooth-wave mode, when both overflows and underflows are counted and skipped with the count direction changed, GPTm_n_OVF/GPTm_n_UDF interrupt requests cannot be generated at overflows only or at underflows only.

Therefore, to count both overflows and underflows with the count direction changed and generate the GPTm_n_OVF/ GPTm_n_UDF interrupts at overflows only or underflows only in sawtooth-wave mode, the skipping state should be carefully checked before using.

When changing the skipping count, be sure to release the skipping count setting (GTITC.IVTC[1:0] bits = 00b).

Figure 20.68 to Figure 20.73 show examples of skipping function operation.

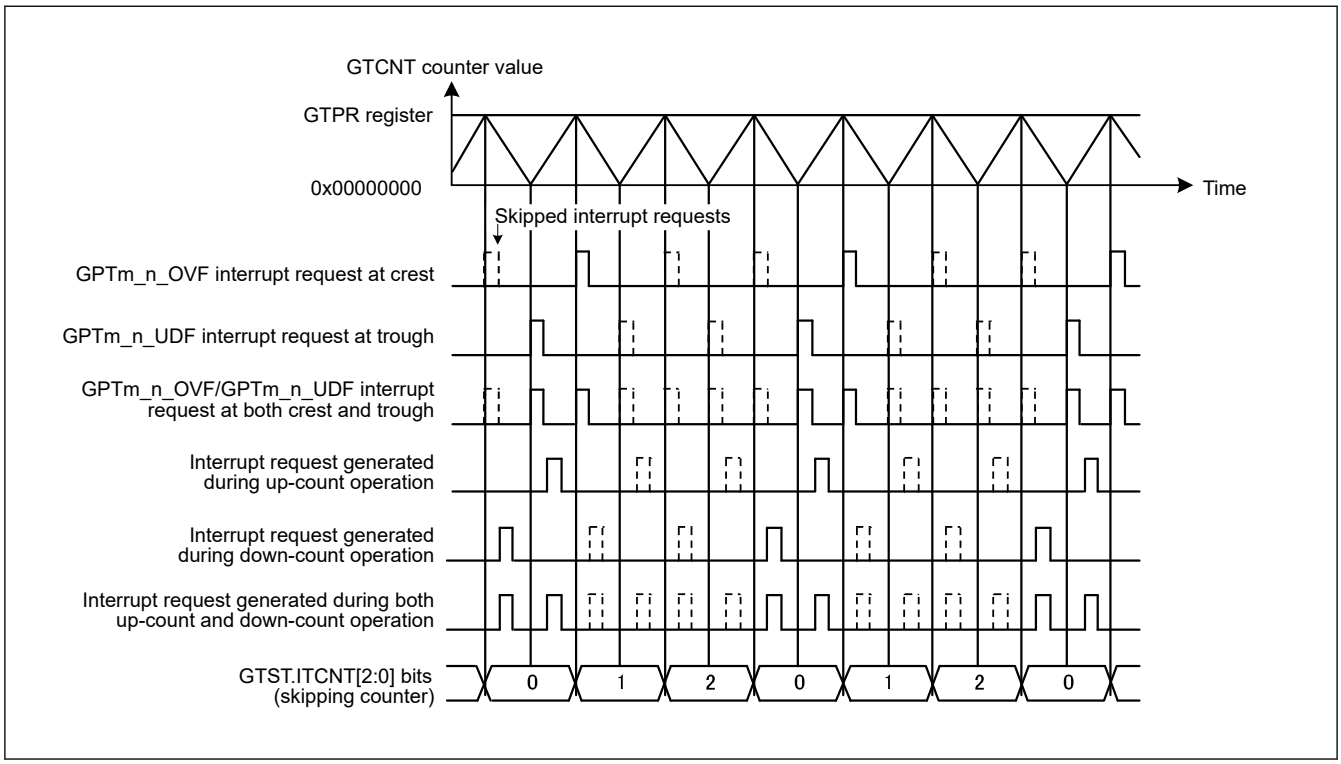

Figure 20.68 Example of interrupt skipping function operation (triangle waves, counting and skipping crests, skipping count = 2)

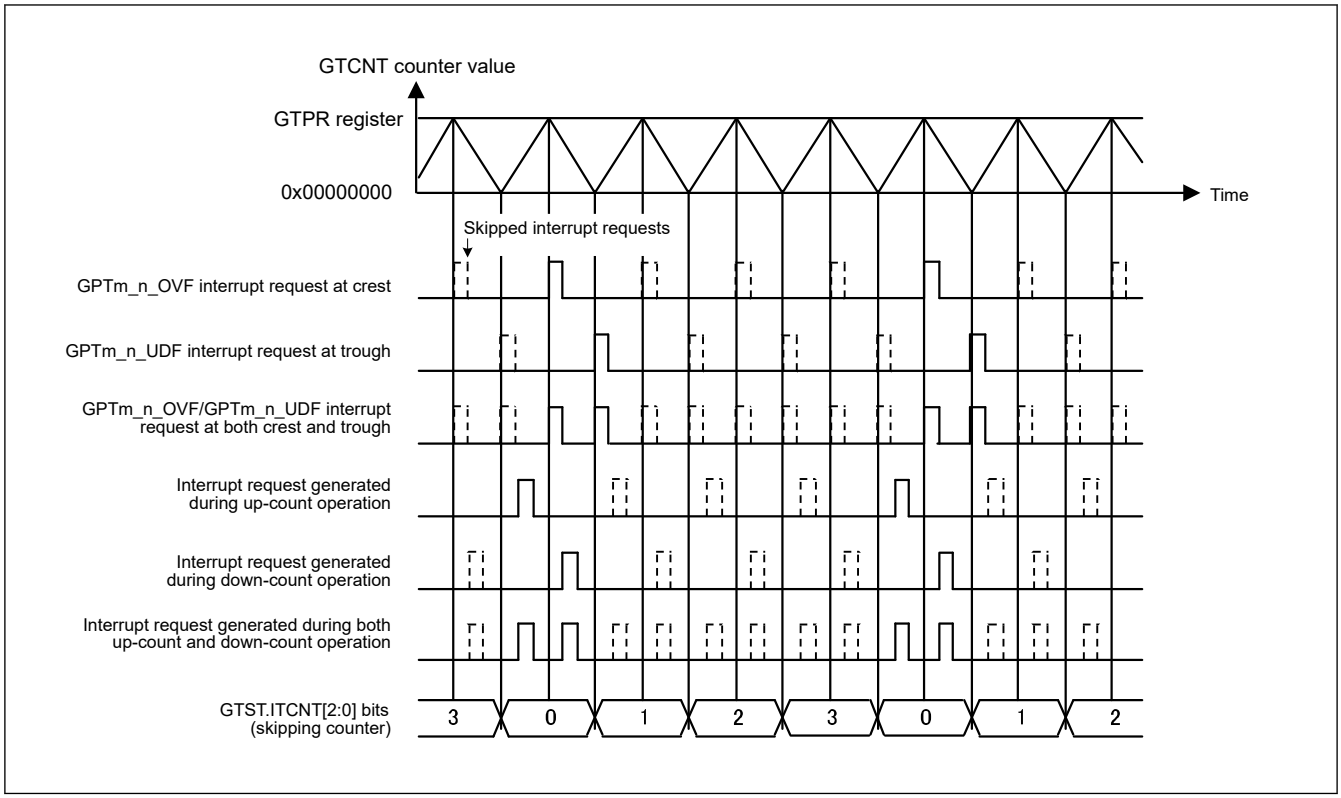

Figure 20.69 Example of interrupt skipping function operation (triangle waves, counting and skipping troughs, skipping count = 3)

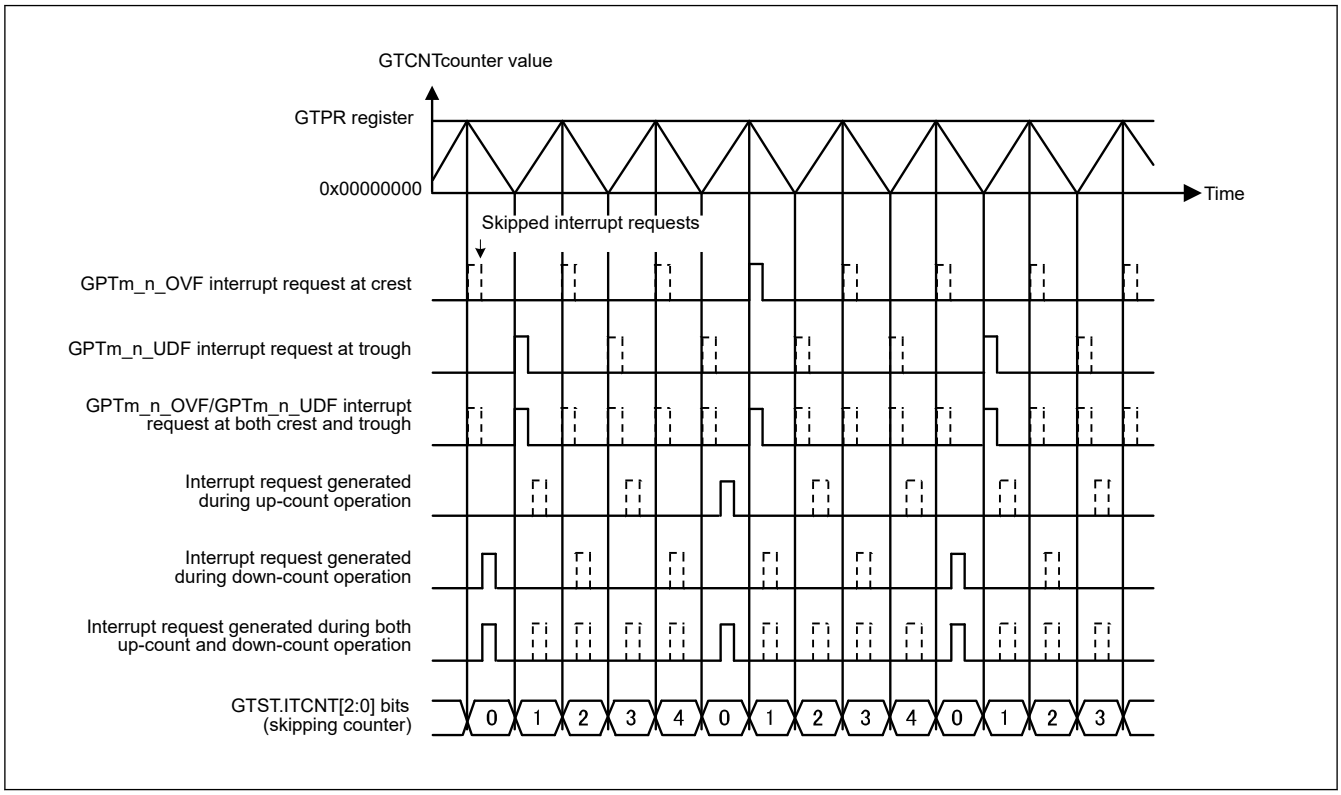

Figure 20.70 Example of interrupt skipping function operation (triangle waves, counting and skipping both troughs and crests, skipping count = 4)

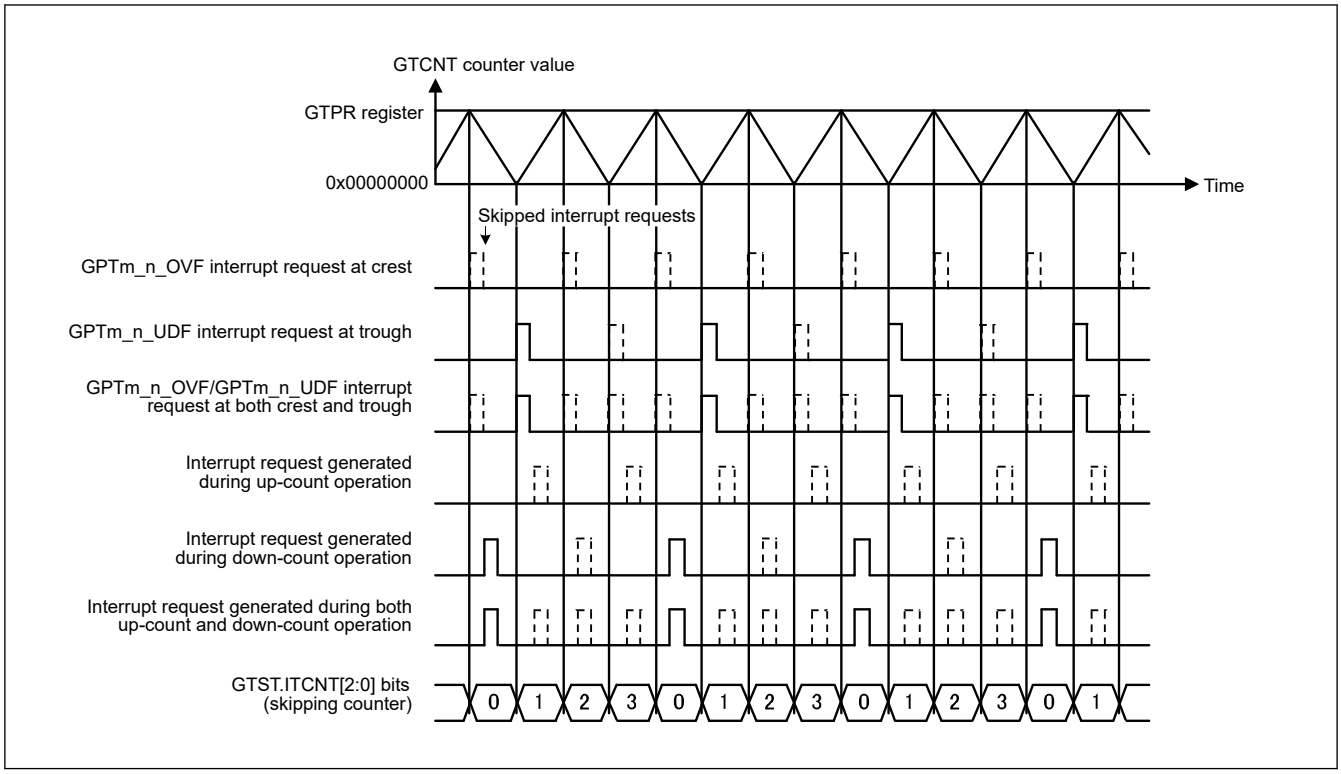

Figure 20.71 Example of interrupt skipping function operation (triangle waves, counting and skipping both troughs and crests, skipping count = 3, skipping started at up-counting)

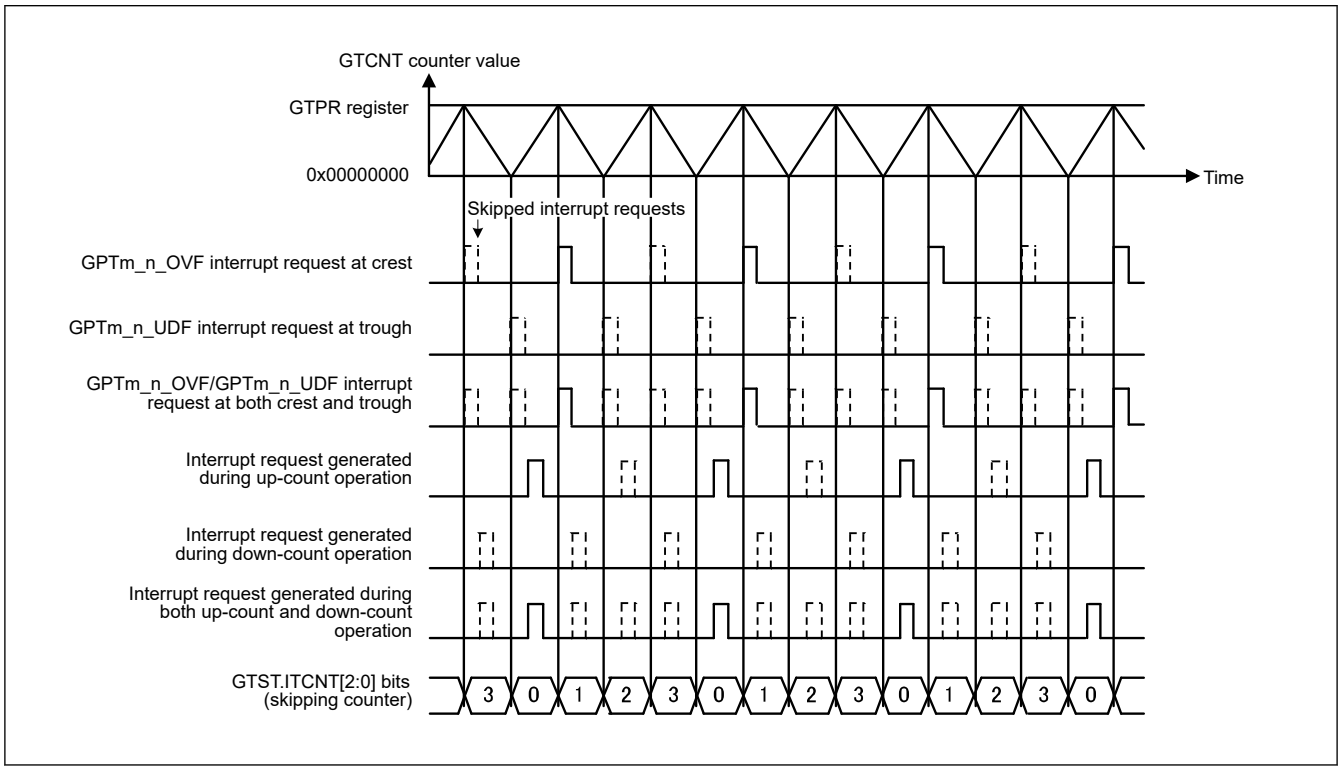

Figure 20.72 Example of interrupt skipping function operation (triangle waves, counting and skipping both troughs and crests, skipping count = 3, skipping started at down-counting)

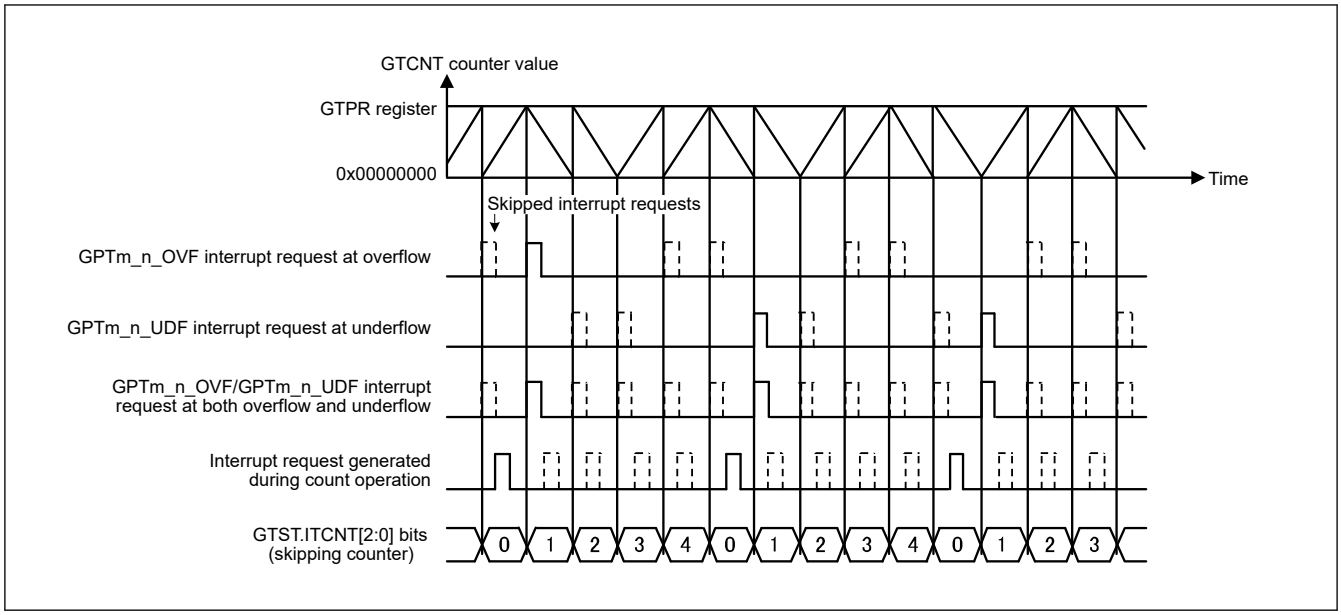

Figure 20.73 Example of interrupt skipping function operation (sawtooth waves, operation with count direction changed, counting and skipping both overflows and underflows, skipping count = 4)

20.6 A/D Converter Start Request

An A/D converter start request can be issued at a compare match between the GTCNT counter and the GTADTRA or GTADTRB register, up-counting only, down-counting only, or both up-counting and down-counting can be specified by setting the GTINTAD register.

During event count operation, the A/D converter start request cannot be generated.

The A/D converter start request is not output directly to the A/D converter but output the event signal to the ELC.

The GTADTRA and GTADTRB registers each has two buffer registers. Buffer operation with the GTADTRA register used together with the GTADTBRA and GTADTDBRA registers, and buffer operation with the GTADTRB register used together with the GTADTBRB and GTADTDBRB registers can be performed.

Figure 20.74 shows an example of A/D converter start request operation.

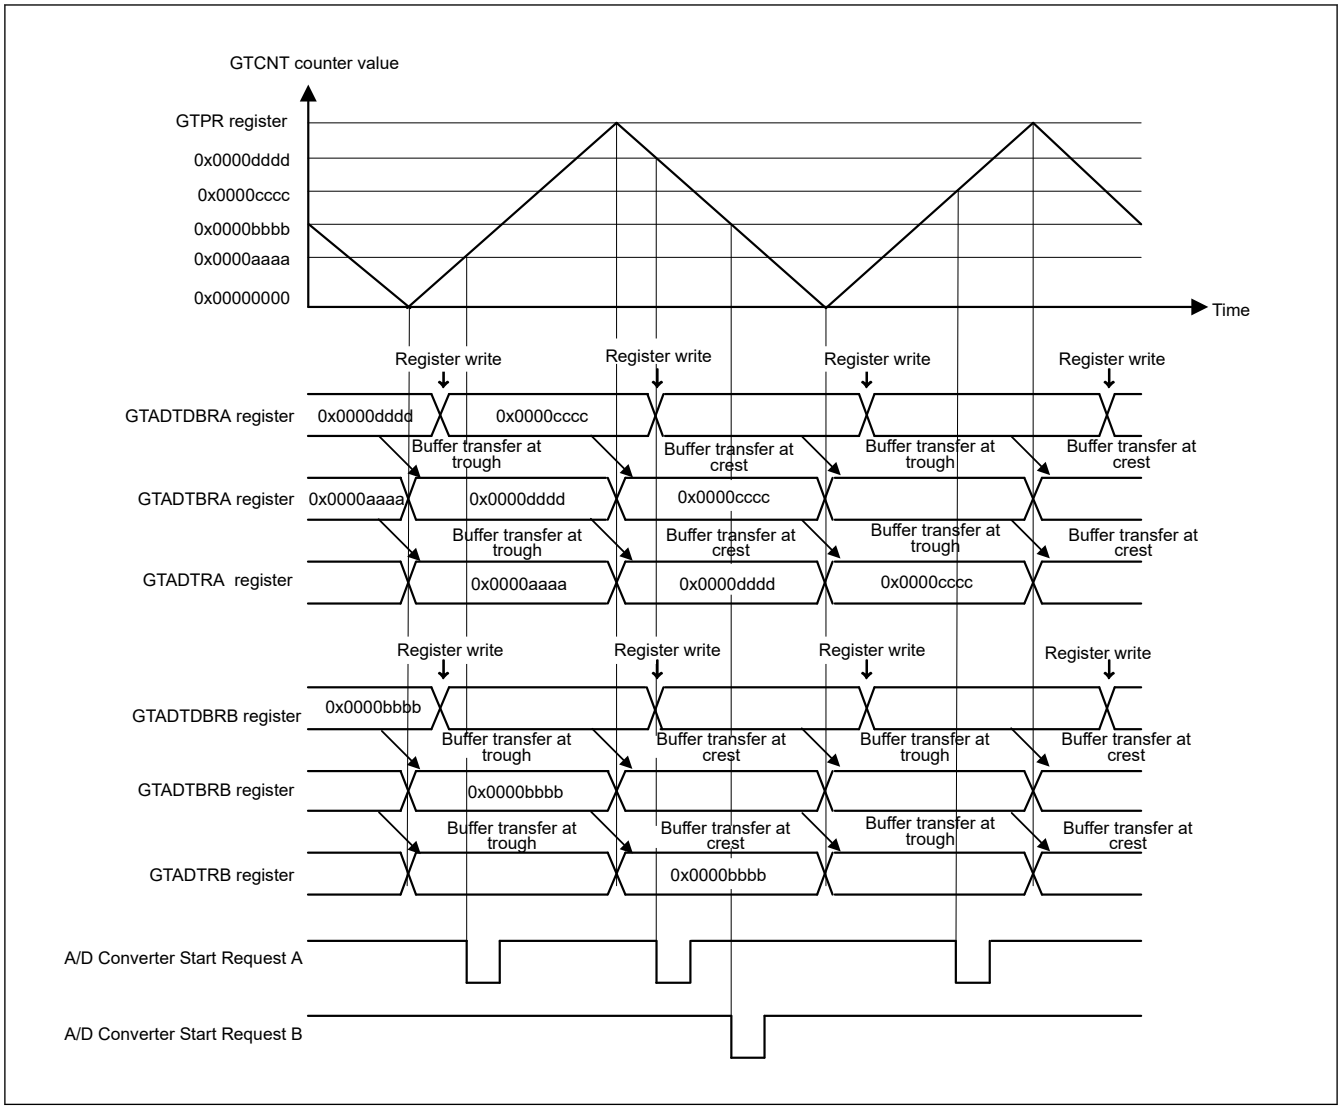

Figure 20.74 Example of A/D converter start request timing operation (triangle waves, double buffer operation, buffer transfer at both troughs and crests, A/D converter start request by GTADTRA register at both up-counting and down-counting, A/D converter start request by GTADTRB register at down-counting)

The following example shows setting for A/D converter start request operation.

1. Set operating mode
   Set the operating mode with the GTCR.MD[2:0] bits of the corresponding channel.
   In Figure 20.74, 100b, 101b, or 110b (triangle-wave PWM mode) is set.
2. Select count clock
   Select the count clock with GTCR.TPCS[3:0] bits of corresponding channel.
3. Period setting
   Set a period in the GTPR register of corresponding channel.
4. Set initial value for counter
   Set the initial value in the GTCNT counter of the corresponding channel.
5. Set buffer operation
   Set buffer operation with the ADTTA[1:0], ADTTB[1:0], ADTDA, and ADTDB bits in the GTBER register.
   In Figure 20.74, ADTTA[1:0] bits = 11b, ADTTB[1:0] bits = 11b, ADTDA bit = 1, and ADTDB bit = 1.
6. Set compare match value
   Set the A/D converter start request point in the GTADTRA and GTADTRB registers.
7. Set buffer value

For buffer operation, set the A/D converter start request point in one cycle after the current cycle (in sawtooth-wave mode or triangle-wave mode with buffer transfer at trough or crest) or half cycle after the current cycle (in triangle-wave mode with buffer transfer at both trough and crest) in the GTADTBRA and GTADTBRB registers, respectively.
For double buffer operation, set the A/D converter start request point in two cycles after the current cycle (in sawtooth-wave mode or triangle-wave mode with buffer transfer at trough or crest) or one cycle after the current cycle (in triangle-wave mode with buffer transfer at both trough and crest) in the GTADTDBRA and GTADTDBRB registers, respectively.

8. Set A/D converter start request for monitoring
   Select the A/D converter start request signal to be monitored with the ADSMS0[1:0] and ADSMS1[1:0] bits in the GTADSMR register from the GTADSM0 and GTADSM1 pins and enable output of the A/D converter start request signal being monitored to the ADSMEN0 and ADSMEN1 bits in the GTADSMR register.
9. Enable A/D converter start request
   Set to enable A/D converter start request with the ADTRAUEN, ADTRADEN, ADTRBUEN, and ADTRBDEN bits in the GTINTAD register.
   In Figure 20.74, ADTRAUEN bit = 1, ADTRADEN bit = 1, ADTRBUEN bit = 0, and ADTRBDEN bit = 1.
10. Start count operation
    Set the GTCR.CSR bit to 1 to start count operation.
11. Set buffer value by cycle
    For buffer operation, set the A/D converter start request point in one cycle after the current cycle (in sawtooth-wave mode or triangle-wave mode with buffer transfer at trough or crest) or half cycle after the current cycle (in triangle-wave mode with buffer transfer at both trough and crest) in the GTADTBRA and GTADTBRB registers, respectively.
    For double buffer operation, also set the A/D converter start request point in two cycles after the current cycle (in sawtooth-wave mode or triangle-wave mode with buffer transfer at trough or crest) or one cycle after the current cycle (in triangle-wave mode with buffer transfer at both trough and crest) in the GTADTDBRA and GTADTDBRB registers, respectively.

20.7 Operations Linked by the ELC

20.7.1 Event Signal Output to the ELC

GPT is capable of operation linked with another module set in advance when its interrupt request signal is used as an event signal by the event link controller (ELC).

The event signal can be output regardless of the setting of the corresponding interrupt request enable bits except the A/D converter start request.

The A/D converter start request during up-counting/down-counting can be enabled/disabled individually with the A/D converter start request enable bit to output both interrupts and events output to ELC.

The corresponding channels in LLPP (LLPP0 and LLPP1) and NONSAFETY respectively have 10 event signals to the ELC in the GPT, and they are shown below. A dead time error interrupt does not have a corresponding event signal.

- Generation of compare match A interrupt
- Generation of compare match B interrupt
- Generation of compare match C interrupt
- Generation of compare match D interrupt
- Generation of compare match E interrupt
- Generation of compare match F interrupt
- Generation of overflow interrupt
- Generation of underflow interrupt
- Generation of A/D converter start request A (Only used for ELC)
- Generation of A/D converter start request B (Only used for ELC)

20.7.2 Operations in Response to Receiving Event Signals from the ELC

The GPT can perform the following operations by the signals for sources A to F for unit in LLPP (LLPP0 and LLPP1) and A to H for unit in NONSAFETY which are output from the ELC. Each signal is provided to all channels. Select an event source for the desired operation by a relevant source select register in a channel:

- Operation of count start/count stop/counter clear
- Operation of switch and up-counting/down-counting
- Operation of input capture A and B

See operation by hardware sources in section 20.4. Operation for respective operations.

20.8 Noise Filter Function

Each pin for use in input capture to the GPT is equipped with a noise filter. The noise filter samples input signals at the sampling clock (Core clock) and removes the pulses of which length is less than 3 sampling cycles.

The noise filter functionality includes enabling and disabling of the noise filter for each pin and setting of the sampling clock for each channel.

Figure 20.75 shows the timing of noise filtering.

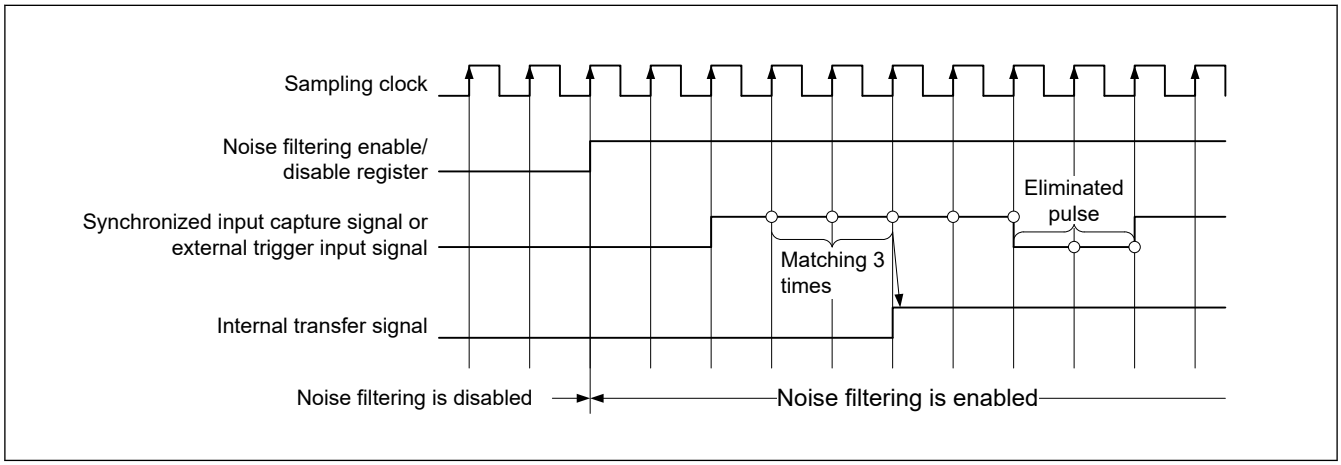

Figure 20.75 Timing of noise filtering

20.9 Protection Function

20.9.1 Write-Protection for Registers

To avoid incorrect writing to registers, write access to registers can be enabled or disabled per channel by setting the GTWP.WP bit for the given channel.

The WP bits enable or disable writing to the following registers:

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTITC, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTPDBR, GTADTRA, GTADTBRA, GTADTDBRA, GTADTRB, GTADTBRB, GTADTDBRB, GTDTCR, GTDVU, GTDVD, GTDBU, GTDBD, GTSOS, GTSOTR, GTADSMR, GTEITC, GTEITLI1, GTEITLI2, GTEITLB, GTSWSR, GTSWOS.

Every bit in registers GTSTR, GTSTP, and GTCLR, which can update the corresponding registers in other channels and can be updated by any of the corresponding registers in other channels conversely, can be protected by setting the GTWP.STRWP, STPWP, and CLRWP bits, respectively, per channel.

Likewise, writing to the GTSECSR and GTSECR registers, which can control all channel in group by writing to the GTSECSR and GTSECR registers of a given channel, can be enabled or disabled by the setting of the GTWP.CMNWP bit.

Protection by the GTWP register only targets writing operation by the CPU. Update to the register generated in related to the CPU writing is not protected.

20.9.2 Disabling of Buffer Operation

If the timing of buffer register write is too late for the buffer transfer timing, buffer operation can be suspended by setting the BD0, BD1, BD2, and BD3 bits in the GTBER register.

Specifically, buffer transfer can be temporarily disabled, even though a buffer transfer condition is generated during buffer register write, by setting the BD0, BD1, BD2, and BD3 bits to 1 (buffer operation disabled) before buffer register write, and setting the bits to 0 (buffer operation enabled) after completion of writing to all the buffer registers.

The BD0, BD1, BD2, and BD3 bits can be set on channel basis by writing directly to the GTBER register or can be set simultaneously by setting the GTSECR register for multiple channels which were set by the GTSECSR register. Figure 20.76 shows an example of operation for disabling buffer operation by writing to the GTBER register.

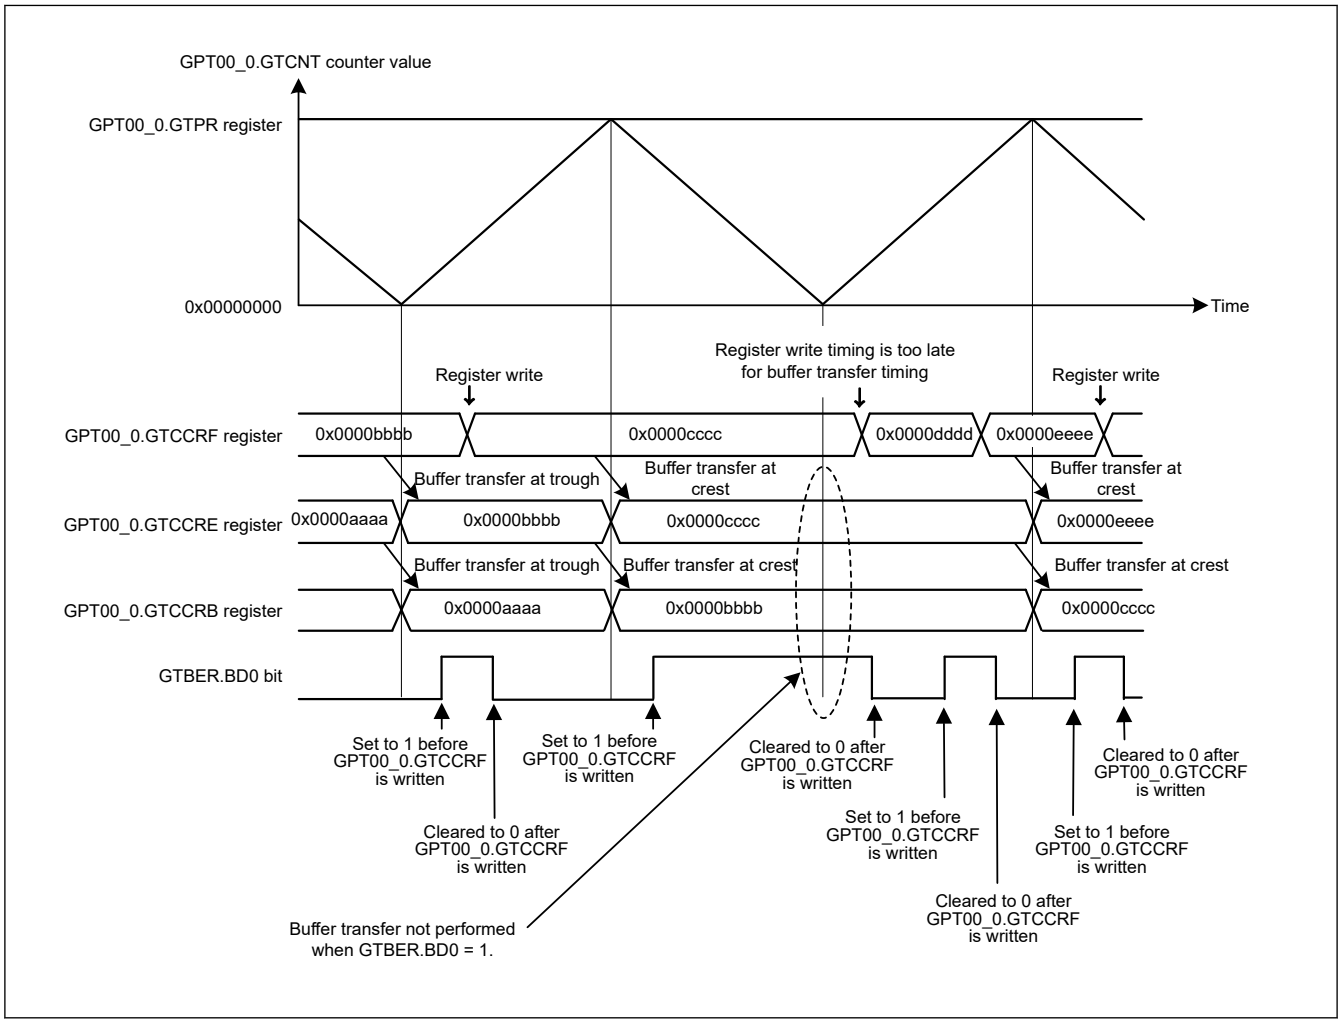

Figure 20.76 Example of operation for disabling buffer operation (triangle waves, double buffer operation, buffer transfer at both troughs and crests)

20.9.2.1 Simultaneous Control of Buffer Operations of Multiple Channels

The GTBER.BDn bit can be set by writing directly to the GTBER register per channel or by making settings in the GTSECR register for multiple channels that are already set in the GTSECSR register.

Use the following procedure to simultaneously set the GTBER.BDn bit of multiple channels.

1. Select the channels to simultaneously set the GTSECSR register
   Set the GTSECSR register so that the values at the bit positions for the corresponding channels for simultaneously setting of the GTBER.BDn bits become 1. All GTSECSR registers can be updated by writing to the GTSECSR register of any channel.
2. Simultaneously set the GTBER.BDn bits by updating the GTSECR register

In the GTSECR register, set the operation of the GTBER.BDn bit (enabling or disabling of buffer operation) that are to be simultaneously set. Writing to the GTSECR register from any channel updates the GTBER.BDn bit in all channels corresponding to the bits set as 1 in the GTSECSR register, in accordance with the value of the GTSECR register.

Figure 20.77 shows an example of simultaneously controlling the enabling or disabling of buffer operation for multiple channels.

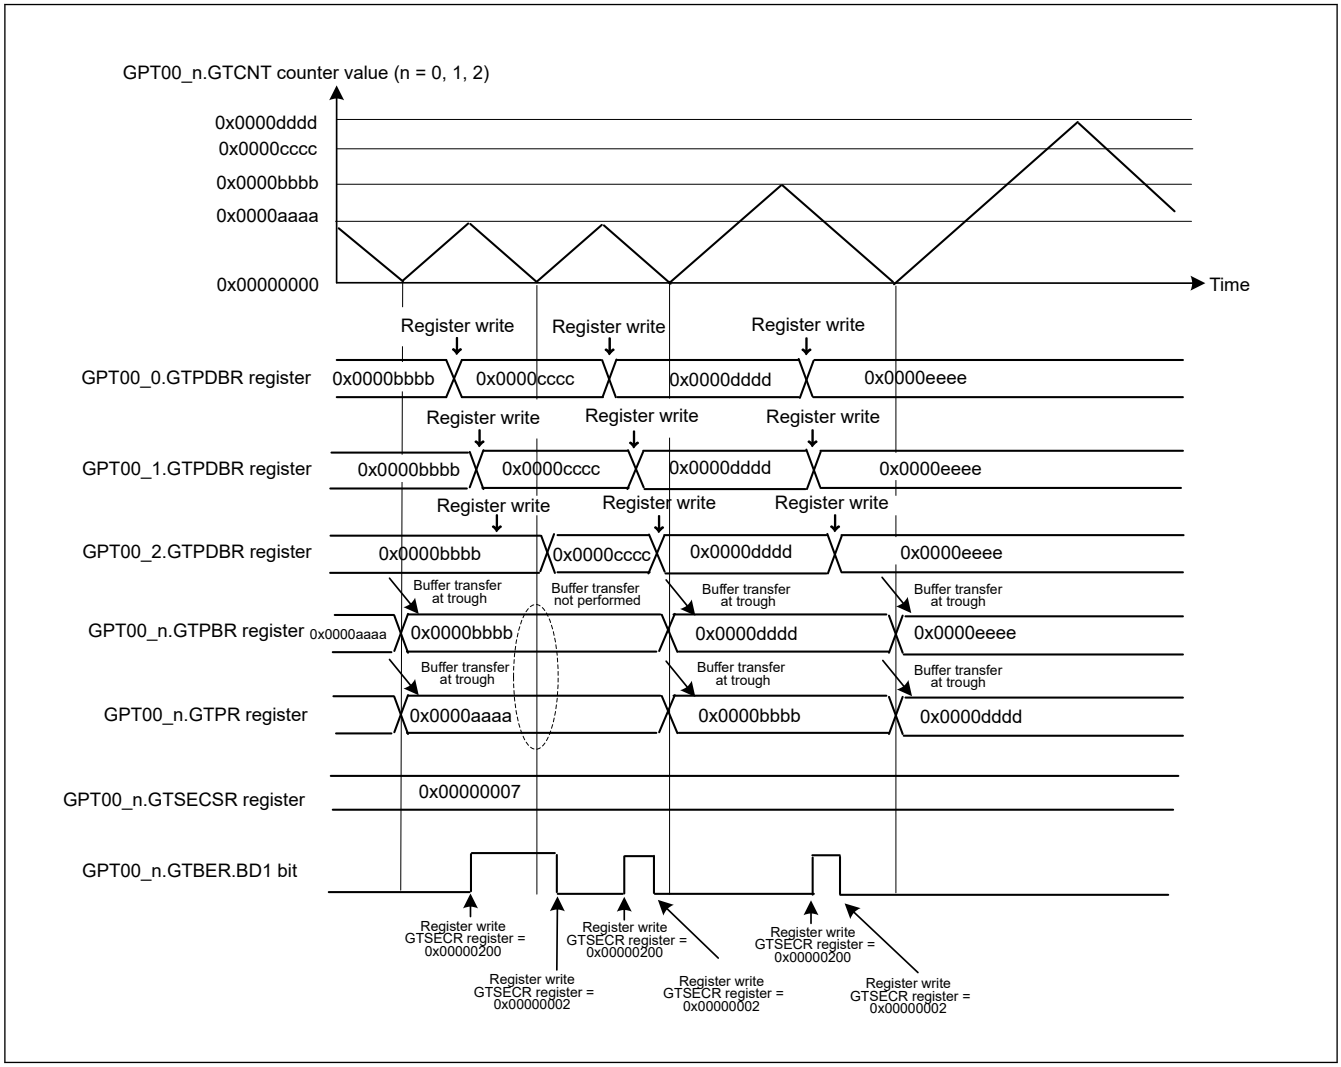

Figure 20.77 Example of multiple channel operation for disabling buffer operation (triangle waves, double buffer operation)

20.9.2.2 Repeated Double-Buffered Operation When Disabling GTCCR Buffer Transfer

When a GTBER.DBRTECm (m = A, B) bit is set to 1 in sawtooth-wave one-shot pulse mode or triangle-wave PWM mode 3, transfer from the intermediate buffer to the GTCCRm (m = A, B) register is repeated on a cyclic basis even while buffer transfer is disabled by the setting of the GTBER.BD0 bit or by the buffer transfer extended skipping function.

(1) In Sawtooth-Wave One-Shot Pulse Mode

In sawtooth-wave one-shot pulse mode, the compare match value for the first half of a waveform is stored in temporary register x (x = C, E) as the intermediate buffer for the GTCCRx (x = C, E) register and the compare match value for the second half of a waveform is stored in temporary register m (m = A, B) as the intermediate buffer for the GTCCRy (y = D, F) register, respectively, for compare match values during repeated buffer operation, and the given values are alternately transferred to the GTCCRm (m = A, B) registers.

Table 20.25 lists the types of buffer transfer of the GTCCR register during counting in sawtooth-wave one-shot pulse mode.

While counting is stopped, the setting of the value in the temporary register is transferred through forcible buffer transfer.

In forcible buffer transfer, the values of the GTCCRy (y = D, F) registers are transferred to temporary registers m (m = A, B), and the values of the GTCCRx (x = C, E) are transferred to temporary registers x (x = C, E) when the setting of the corresponding GTBER.DBRTECm (m = A, B) bit is 1, respectively.

When the setting of the GTBER.DBRTECm (m = A, B) bit is 1, values written by the CPU to the GTCCRm (m = A, B) registers are reflected as the values of temporary registers x (x = C, E).

Table 20.25 GTCCR buffer transfer operation in sawtooth-wave one-shot pulse mode during GTCNT counting

GTBER.DBRTECm	Buffer transfer	Timing of transfer				
		GTCCRx ↓ GTCCRm	GTCCRx ↓ Temporary register x	Temporary register x ↓ GTCCRm	GTCCRy ↓ Temporary register m	Temporary register m ↓ GTCCRm
0	Transfer enabled period	Overflow or underflow	No transfer	No transfer	Overflow or underflow	GTCCRm compare match
	Transfer disabled period	No transfer	No transfer	No transfer	No transfer	No transfer
1	Transfer enabled period	Overflow or underflow	Overflow or underflow	Not Transferred	Overflow or underflow	GTCCRm compare match
	Transfer disabled period	No transfer	No transfer	Overflow or underflow	No transfer	GTCCRm compare match

Note: m = A, B; x = C, E; y = D, F

Figure 20.78 shows the operation of generating transfer-disabled period by extended buffer transfer skipping as an example of repeated double buffer operations when the GTCCR buffer transfer is disabled in sawtooth-wave one-shot pulse mode.

Figure 20.79 shows the operation of generating transfer-disabled period by updating the GTBER.BD0 bit as an example of repeated double-buffer operations when the GTCCR buffer transfer is disabled in sawtooth-wave one-shot pulse mode.

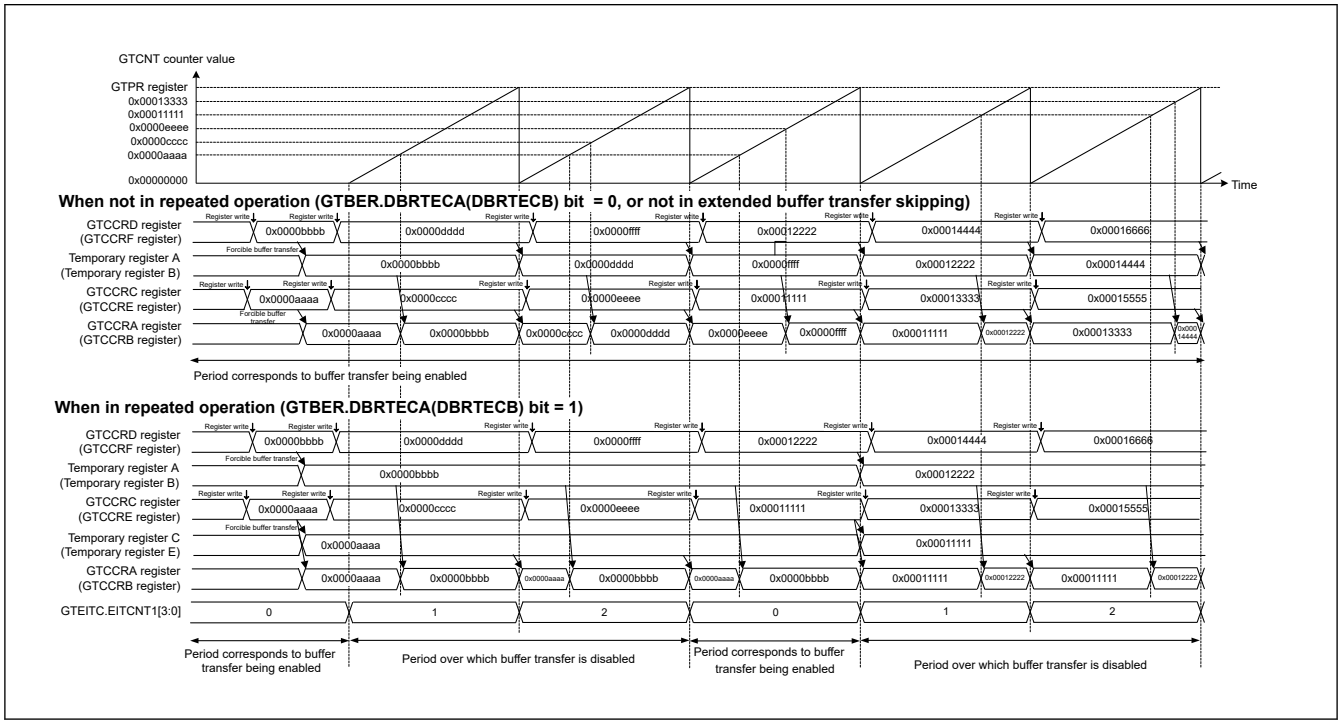

Figure 20.78 Example of repeated double-buffer operation when GTCCR buffer transfer is disabled (sawtooth-wave one-shot pulse mode, using extended buffer transfer skipping, GTBER.BD0 is constantly 0)

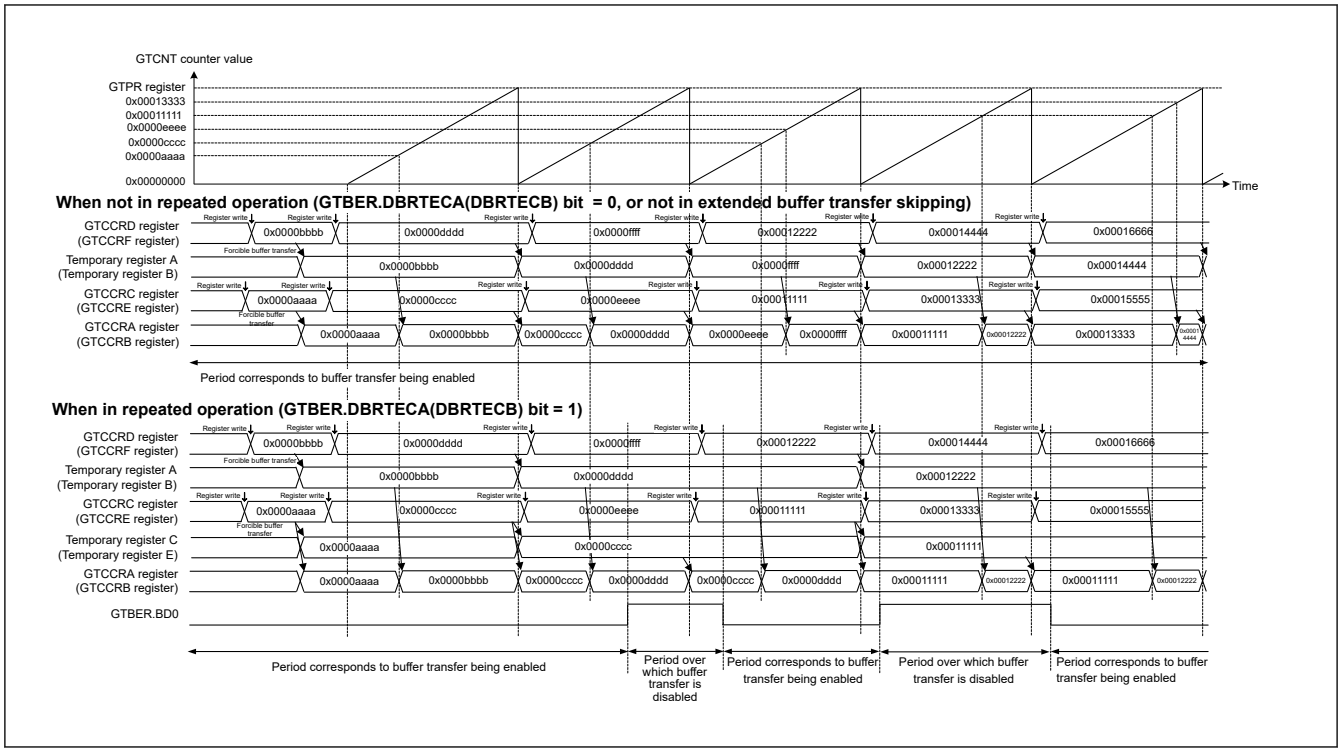

Figure 20.79 Example of repeated double-buffer operation when GTCCR buffer transfer is disabled (sawtooth-wave one-shot pulse mode, updating the GTBER.BD0 bit)

(2) In Triangle-Wave PWM Mode 3

In triangle-wave PWM mode 3, the compare match value for the first half of a waveform is stored in the temporary register x (x = C, E) as the intermediate buffer for the GTCCRx (x = C, E) register and the compare match value for the second half of a waveform is stored in temporary register m (m = A, B) as the intermediate buffer for the GTCCRy (y = D, F) register, respectively, for compare match values during repeated buffer operation, and the given values are alternately transferred to the GTCCRm (m = A, B) register.

Table 20.26 lists the types of buffer transfer of the GTCCR register during counting operation in triangle-wave PWM mode 3.

While counting is stopped, the setting of the value in the temporary register is transferred through forcible buffer transfer. In forcible buffer transfer, the values of the GTCCRy (y = D, F) registers are transferred to temporary registers m (m = A, B), and the values of the GTCCRx (x = C, E) are transferred to temporary registers x (x = C, E), when the setting of the corresponding GTBER.DBRTECm (m = A, B) bit is 1, respectively.

When the setting of the GTBER.DBRTECm (m = A, B) bit is set to 1, values written by the CPU to the GTCCRm (m = A, B) registers are reflected as the values of temporary registers x (x = C, E).

Table 20.26 GTCCR buffer transfer operation in triangle-wave PWM mode 3 during GTCNT counting

GTBER.DBRTECm	Buffer transfer	Timing of transfer				
		GTCCRx ↓ GTCCRm	GTCCRx ↓ temporary register x	temporary register x ↓ GTCCRm	GTCCRy ↓ temporary register m	temporary register m ↓ GTCCRm
0	Transfer enabled period	Trough	No transfer	No transfer	Trough	Crest
	Transfer disabled period	No transfer	No transfer	No transfer	No transfer	No transfer
1	Transfer enabled period	Trough	Trough	No transfer	Trough	Crest
	Transfer disabled period	No transfer	No transfer	Trough	No transfer	Crest

Note: m = A, B; x = C, E; y = D, F

Figure 20.80 shows the operation of generating transfer-disabled period by extended buffer transfer skipping as an example of repeated double buffer operations when the GTCCR buffer transfer is disabled in triangle-wave PWM mode 3.

Figure 20.81 shows the operation of generating transfer-disabled period by updating the GTBER.BD0 bit as an example of repeated double-buffer operations when the GTCCR buffer transfer is disabled in triangle-wave PWM mode 3.

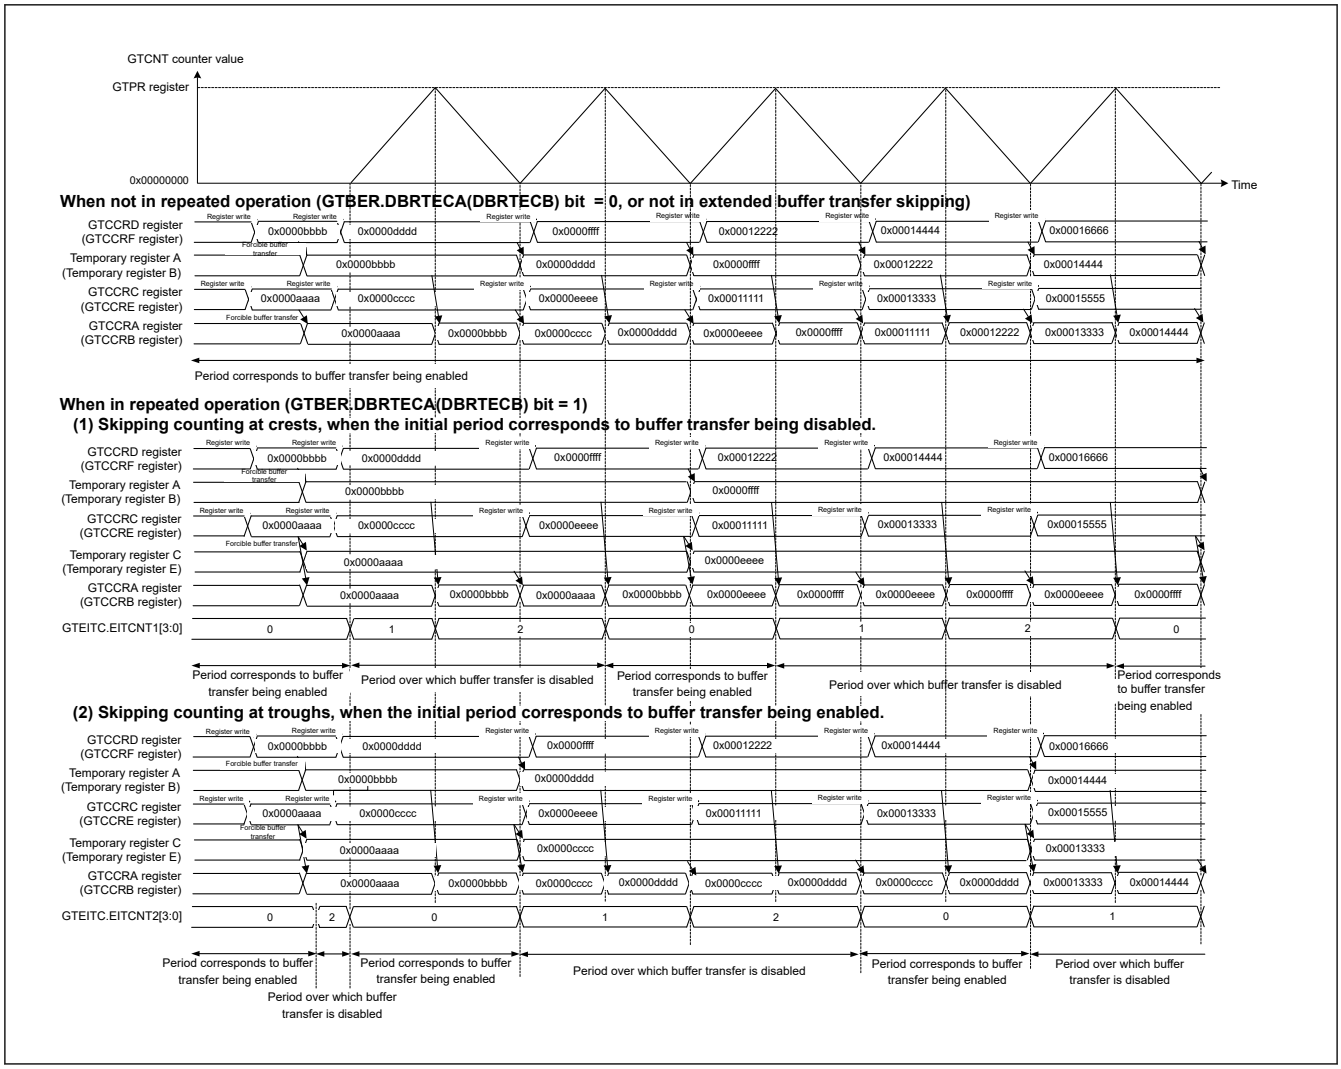

Figure 20.80 Example of repeated double-buffer operation when GTCCR buffer transfer is disabled (triangle-wave PWM mode 3, using extended buffer transfer skipping, GTBER.BD0 is constantly 0)

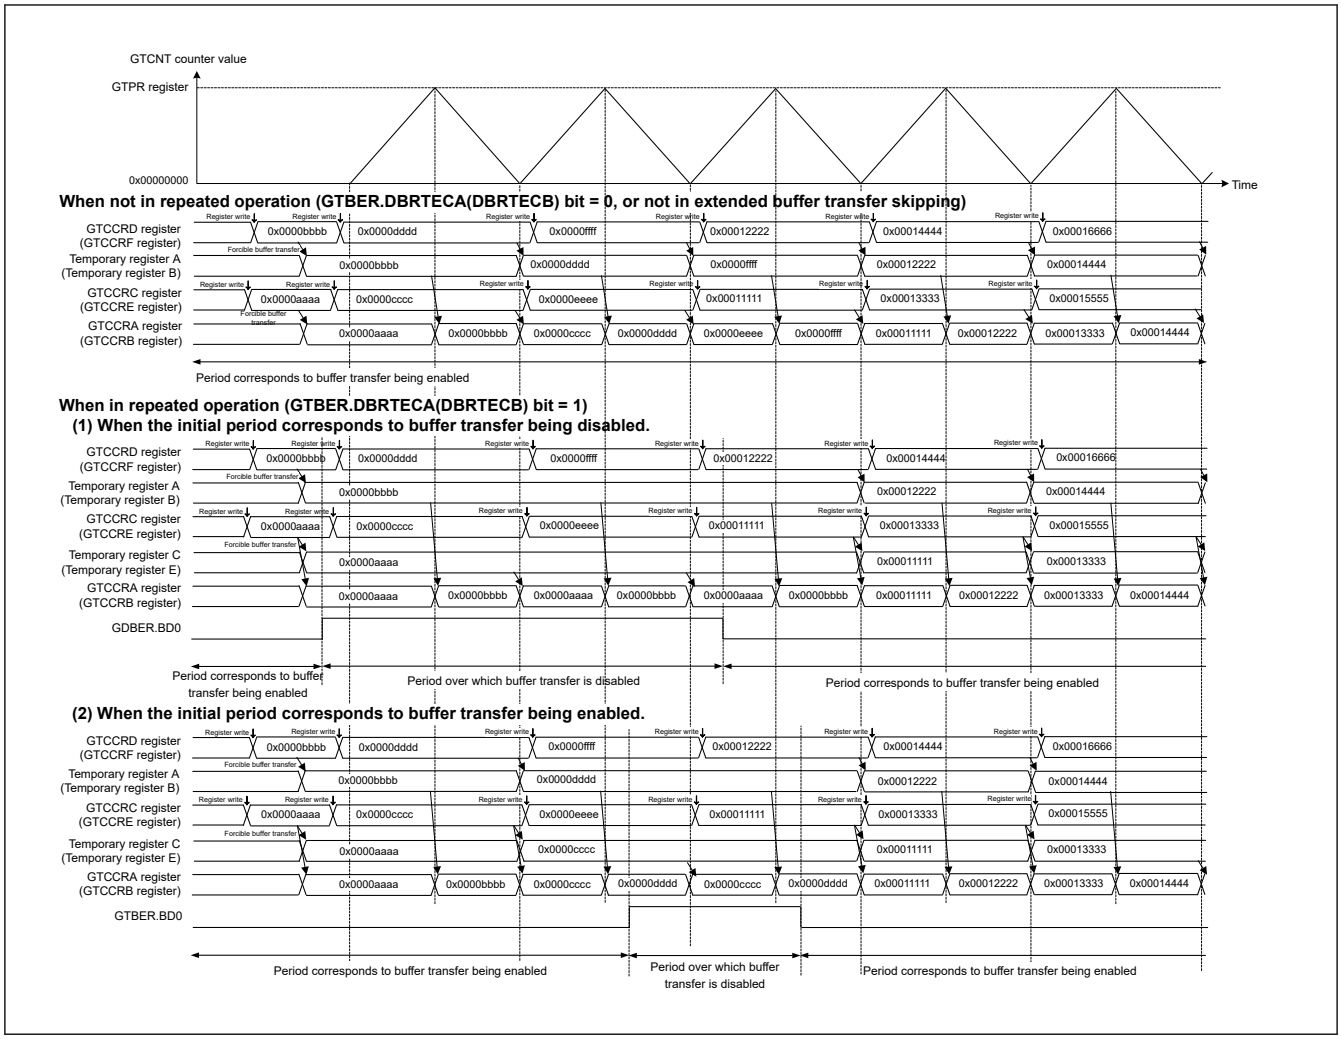

Figure 20.81 Example of repeated double-buffer operation when GTCCR buffer transfer is disabled (triangle-wave PWM mode 3, updating the GTBER.BD0 bit)

20.9.2.3 Repeated Double-Buffered Operation When Disabling GTADTR Buffer Transfer

When GTBER.DBRTEADm (m = A, B) is set to 1 for triangle waves using GTADTRm double buffer (GTBER.ADTDm bit = 1) with the buffer transfer timing of both crest and trough (GTBER.ADTTm[1:0] bits = 11b), transfer from the intermediate buffer to the GTADTRm register is repeated on a cyclic basis even while transfer is disabled by the setting of the GTBER.BD[2] bit or by the extended buffer transfer skipping function.

The A/D converter start request timing value to be transferred repeatedly are stored into the following registers:

- The A/D converter start request timing value to be used in the first half of period is stored into temporary register ADm as the intermediate buffer of the GTADTBRm register
- The compare match value to be used in the second half of period is stored into the GTADTBRm register.

These values are transferred to the GTADTRm register alternately. The GTBER.DBRTSADm bit selects either the first half or the second half of the period.

Table 20.27 lists the types of buffer transfer of the GTADTR register during counting operation in triangle waves.

While counting is stopped, set the temporary register ADm (m = A, B) to the A/D converter start request timing value of first half of period after GTCNT counting start. When the setting of the GTBER.DBRTEADm bit is set to 1, values written by the CPU to the GTADTRm registers are reflected as the values of temporary register ADm.

When the period right after GTCNT counting start is the second half, set the GTADTRm register to the A/D converter start request timing value of second half of period during GTCNT counting stop. When the period after GTCNT counting start is the second half of the period and buffer transfer is disabled, set the GTADTRm register to the same value as the GTADTBRm register.

Setting the GTADTRm register to the value of second half of period during GTCNT counting stop should be set by CPU under the condition that the GTBER.DBRTEADm bit is temporary set to 0 after setting temporary register ADm to the value of first half of the period. After setting the GTADTRm register, set the GTBER.DBRTEADm bit to 1 before GTCNT counting start.

Table 20.27 GTADTR buffer transfer operation of triangle-wave during GTCNT counting

GTBER.DBRTEADm	GTBER.DBRTSADm bit	Buffer transfer	Timing of transfer			
			GTADTDBRm ↓ GTADTBRm	GTADTBRm ↓ GTADTRm	GTADTDBRm ↓ Temporary register ADm	Temporary register ADm ↓ GTADTRm
0	—	Transfer enabled period	Both crest and trough	Both crest and trough	No transfer	No transfer
		Transfer disabled period	No transfer	No transfer	No transfer	No transfer
1	0 (trough period)	Transfer enabled period	Both crest and trough	Both crest and trough	Crest	No transfer
		Transfer disabled period	No transfer	Crest	No transfer	Trough
	1 (crest period)	Transfer enabled period	Both crest and trough	Both crest and trough	Trough	No transfer
	—	Transfer disabled period	No transfer	Trough	No transfer	Crest

Figure 20.82 shows the operation of repeated double buffer operation when the GTADTR buffer transfer disabled for triangle-wave which the period is defined by trough and the period right after GTCNT counting start is the first half.

Figure 20.83 shows the operation of repeated double buffer operation when the GTADTR buffer transfer disabled for triangle-wave which the period is defined by crest and the period right after GTCNT counting start is the second half.

Figure 20.84 shows the operation of repeated double buffer operation when the GTADTR buffer transfer disabled for triangle-wave which the period is defined by trough and the period right after GTCNT counting start is the second half.

Figure 20.85 shows the operation of repeated double buffer operation when the GTADTR buffer transfer disabled for triangle-wave which the period is defined by crest and the period right after GTCNT counting start is the first half.

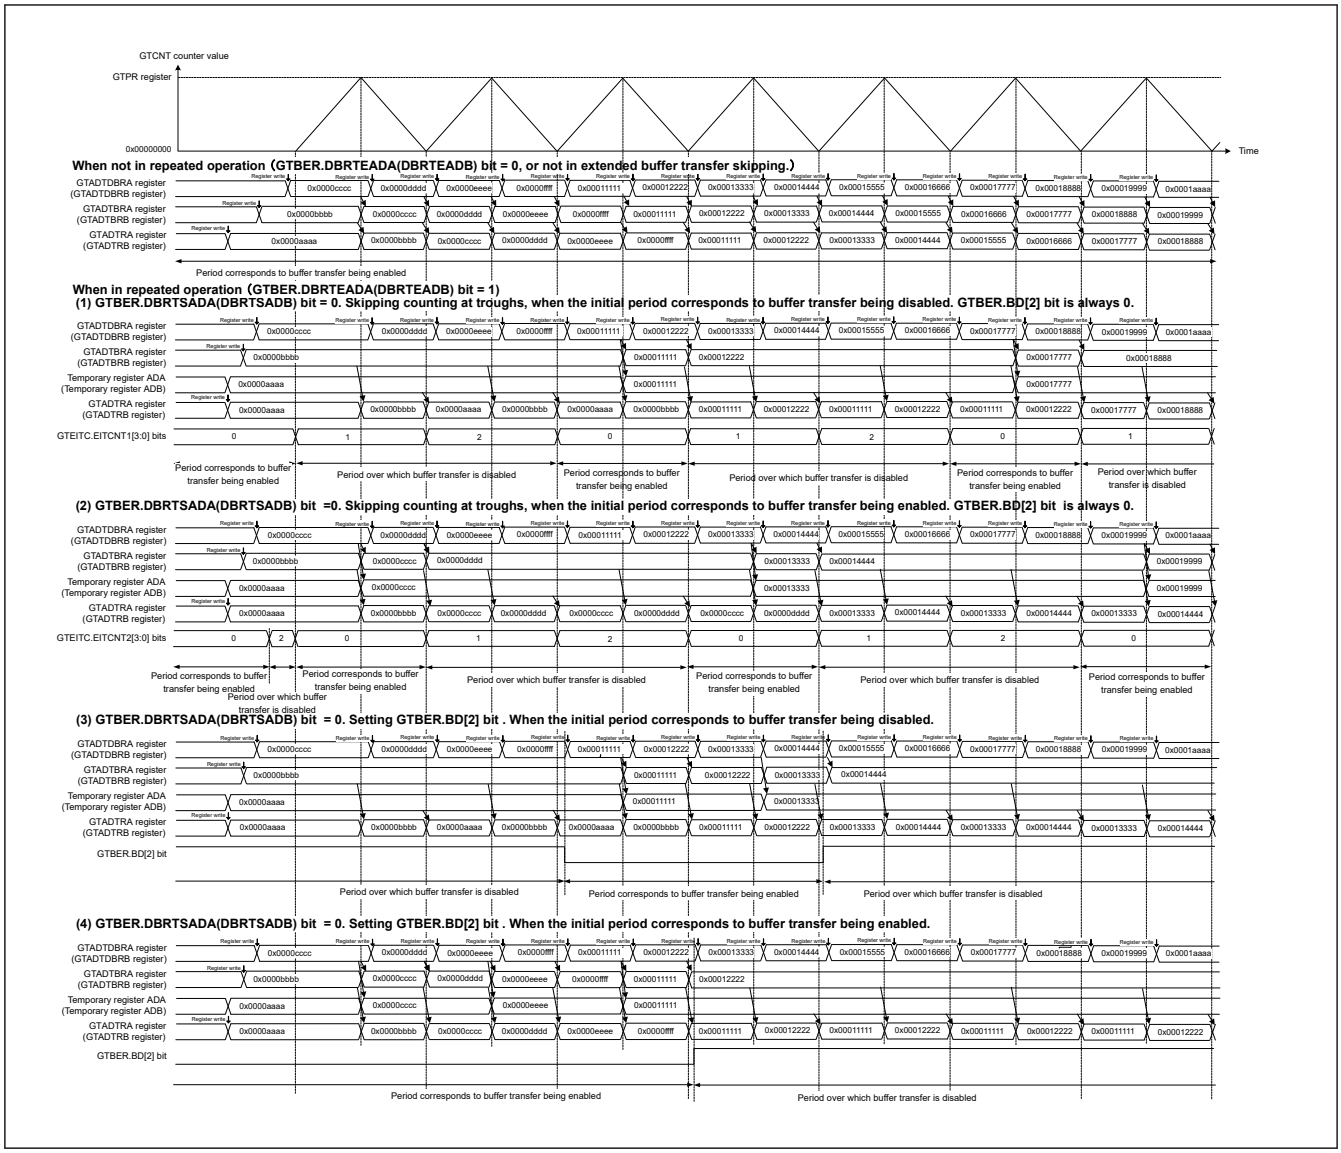

Figure 20.82 Example of repeated double-buffer operation when GTADTR buffer transfer is disabled (triangle-wave, repeating period between troughs, first half of period at GTCNT counting start)

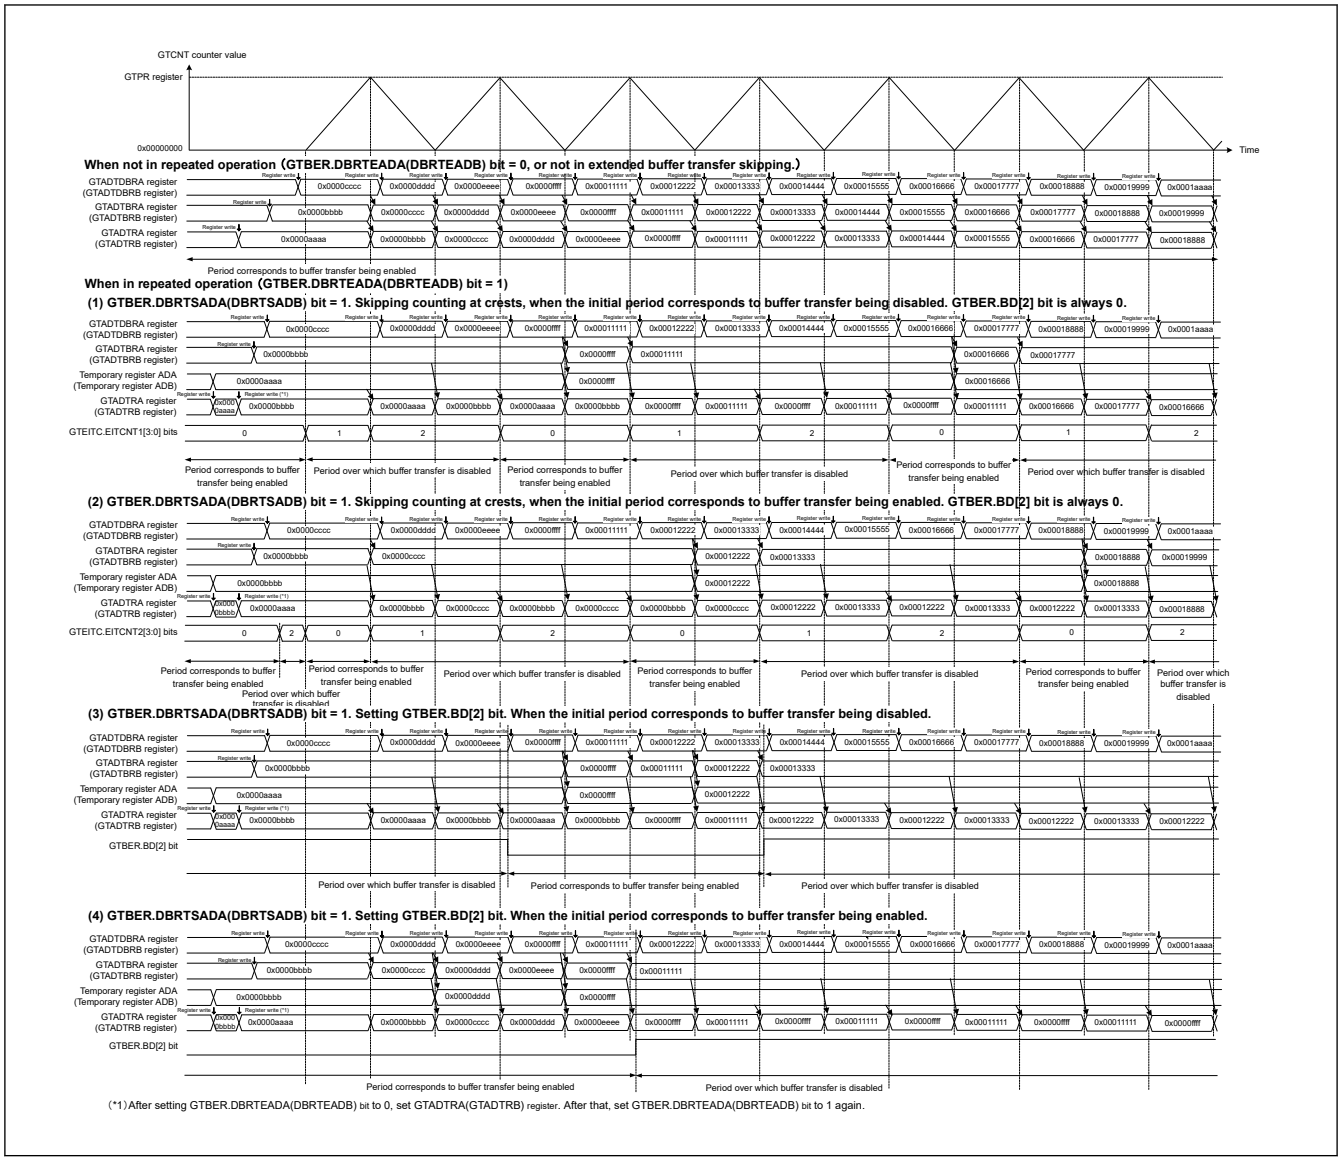

Figure 20.83 Example of repeated double-buffer operation when GTADTR buffer transfer is disabled (triangle-wave, repeating period between crests, second half of period at GTCNT counting start)

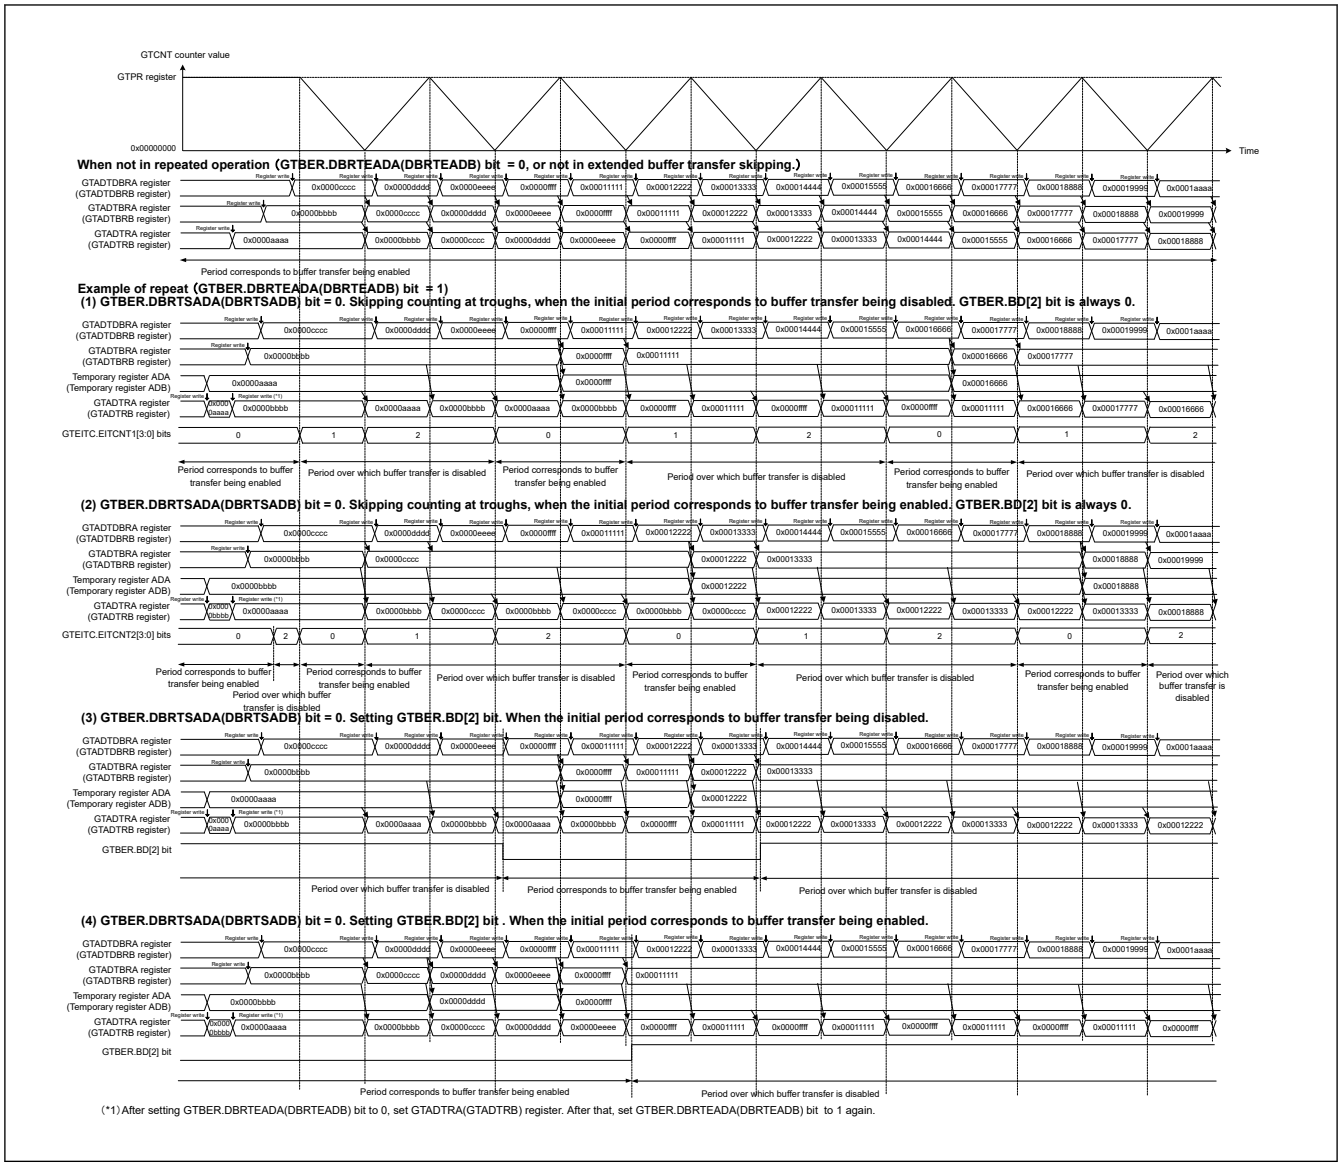

Figure 20.84 Example of repeated double-buffer operation when GTADTR buffer transfer is disabled (triangle-wave, repeating period between troughs, second half of period at GTCNT counting start)

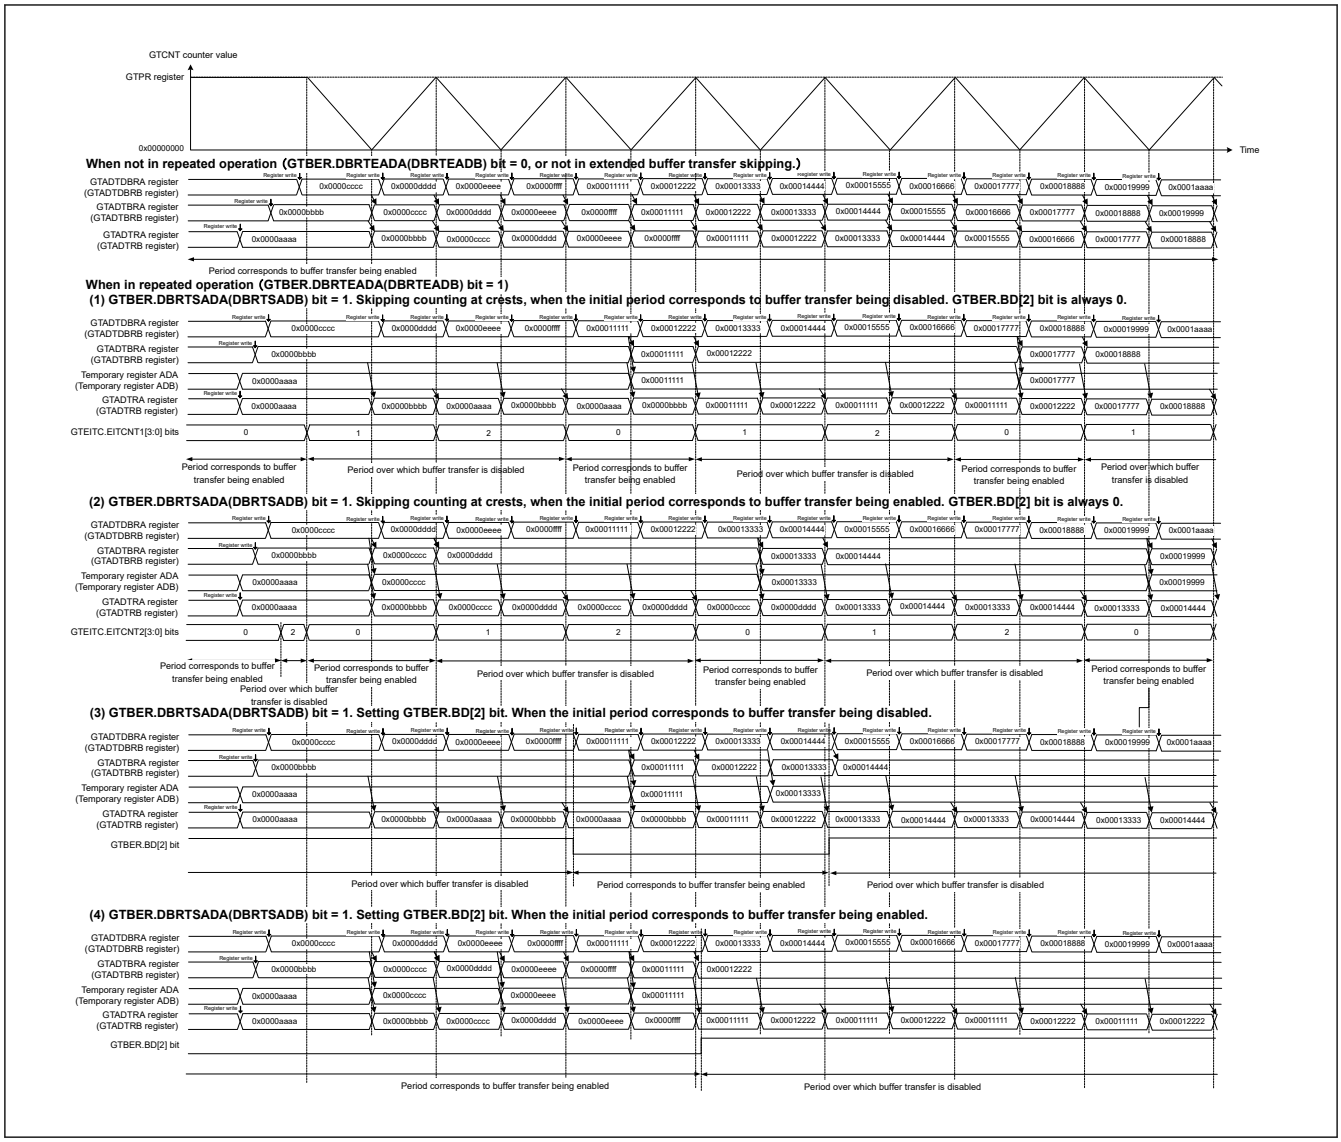

Figure 20.85 Example of repeated double-buffer operation when GTADTR buffer transfer is disabled (triangle-wave, repeating period between crests, first half of period at GTCNT counting start)

20.9.3 GTIOCm_nA and GTIOCm_nB Pin Output Negate Control ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

For protection from system failure, the output negate control that changes the GTIOCm_nA and GTIOCm_nB pin output forcibly by the output stop request from the POEG is provided.

Output protection is required when a dead-time error or the same output level on the GTIOCm_nA and GTIOCm_nB pins is detected. At that time, the detection of disabling of output is output to the group of the POEG set in the GTINTAD.GRP[1:0] bits based on the setting of the output disable detection enable bits, such as the GRPDTE, GRPABH, and GRPABL bits in the GTINTAD register. The POEG takes the logical OR of detection of the types as described and other forms of detection of the disabling of output, and outputs requests for the disabling of output to the GPT.

By setting the GTINTAD.GRP[1:0] bits, one output stop request can be selected out of four output stop requests which are input from the POEG as output stop request signal common in the GTIOCm_nA and GTIOCm_nB pins. Selected output stop request can be checked by reading the GTST.ODF flag.

The states of outputs at the time of control for their negation can be set with the GTIOR.OADF[1:0] bits for the GTIOCm_nA pin and with the GTIOR.OBDF[1:0] bits for the GTIOCm_nB pin.

Transition to the output negate condition by generating the output stop request from the POEG is performed asynchronously, while a release from the output negate condition by making the output stop request no longer satisfied is performed at the end of the cycle. It is after 3 PCLKGPTL (LLPP)/PCLKM (NONSAFETY, SAFETY) at shortest when the output negate

condition is released after the output stop request is no longer satisfied. To reliably control output negation, clear the POEG flag for which the condition of the request to disable the output is no longer satisfied after 4 PCLKGPTL (LLPP)/PCLKM (NONSAFETY, SAFETY) cycles.

To release the output stop condition during event count operation or without waiting the end of the cycle, set the OADF[1:0] bits to 00b for the GTIOCm_nA pin, and set the OBDF[1:0] bits to 00b for the GTIOCm_nB pin. Figure 20.86 shows an example of the output negate control operation for the GTIOCm_nA and GTIOCm_nB pin output.

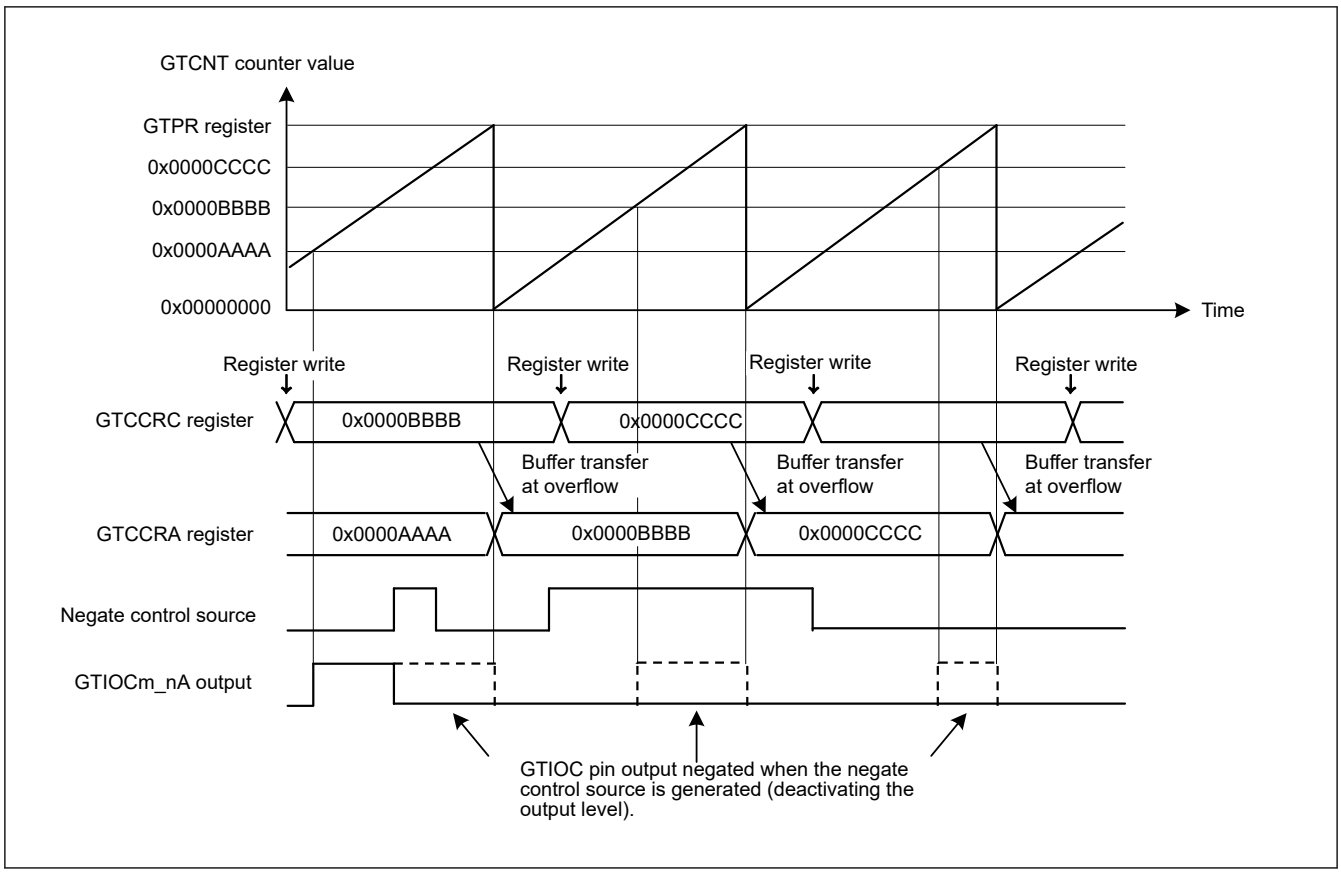

Figure 20.86 Example of operation for GTIOCm_nA and GTIOCm_nB pin output negate control (sawtooth-wave up-counting, buffer operation, active-level: high output at GTCCRA register compare match, low output at the end of the cycle, and low output at output negate) ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

20.9.4 GTIOCm_nA and GTIOCm_nB Protection Function for GTIOCm_nA and GTIOCm_nB Pin Output ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

To prepare for a case when an incorrect value (0x00000000 or a value greater than or equal to the GTPR register value) is set in the GTCCRA register, the output protection function for the GTIOCm_nA and GTIOCm_nB pin output (disabling function) is activated when the automatic dead time is set (GTDTCR.TDE bit = 1) in triangle-wave PWM mode.

The status of the output protection function can be read from the GTSOS.SOS[1:0] bits.

Figure 20.87 shows the output protection function state transition.

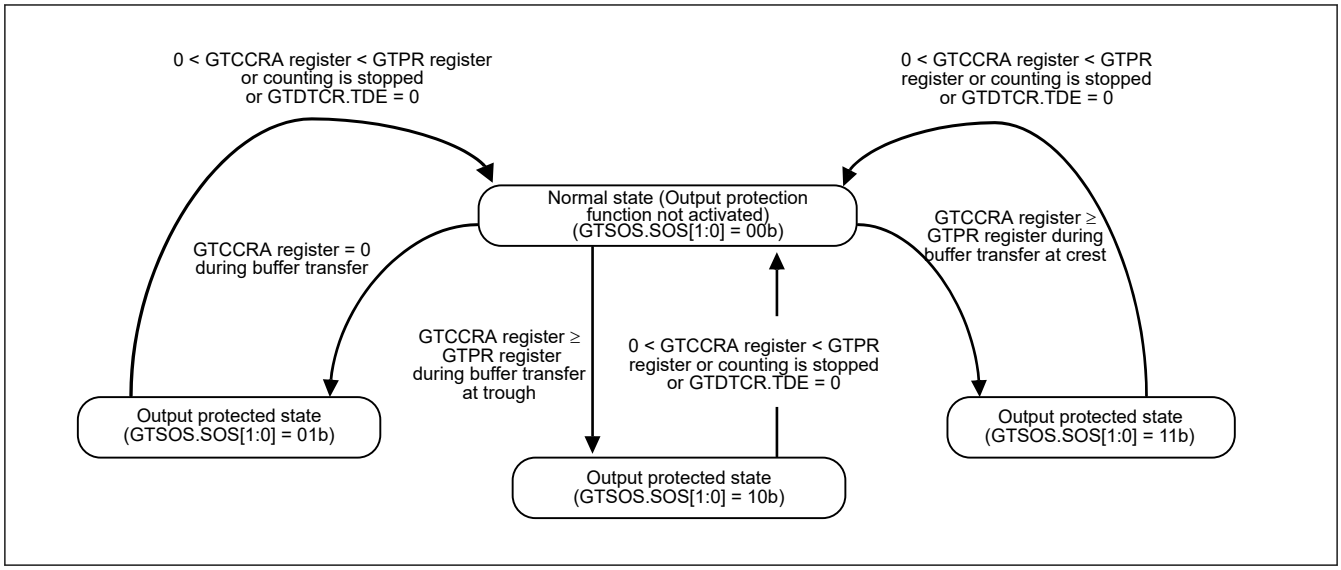

Figure 20.87 Output protection function

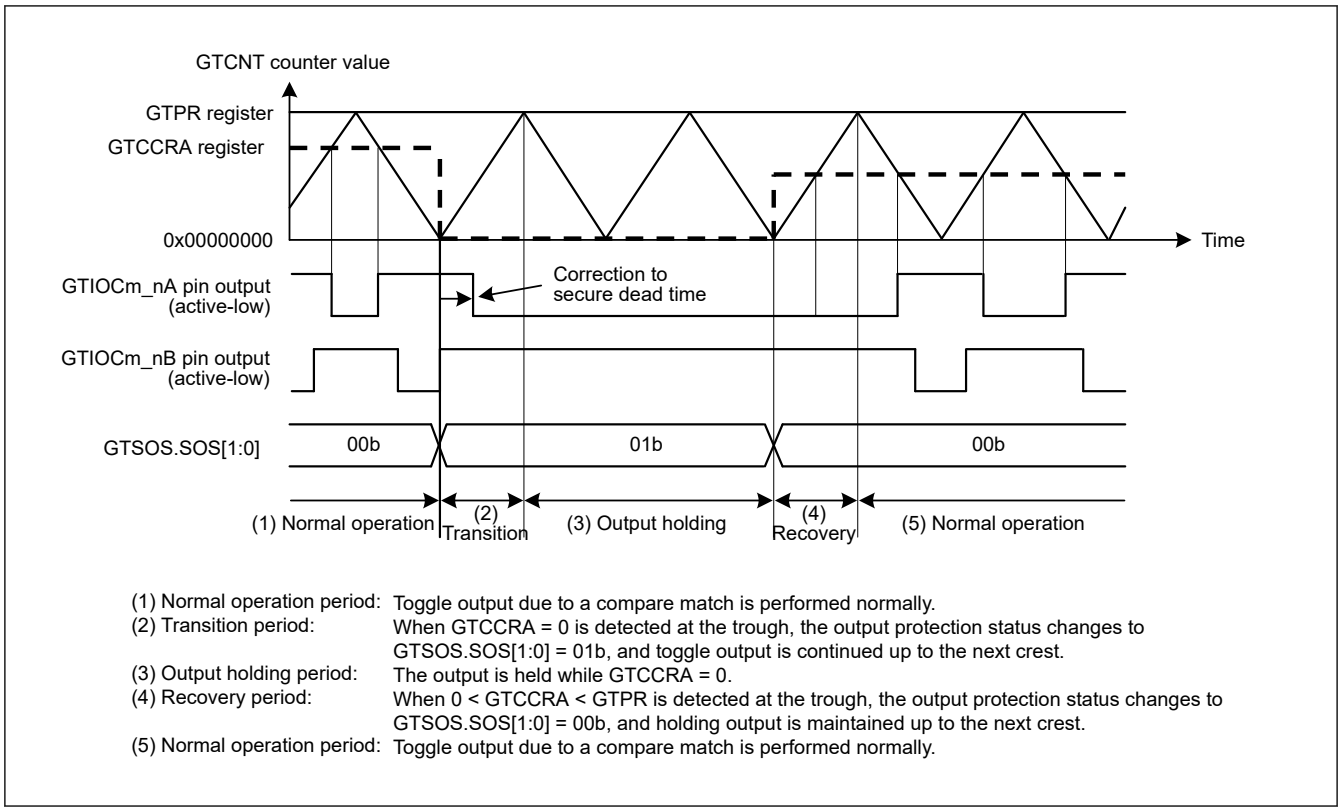
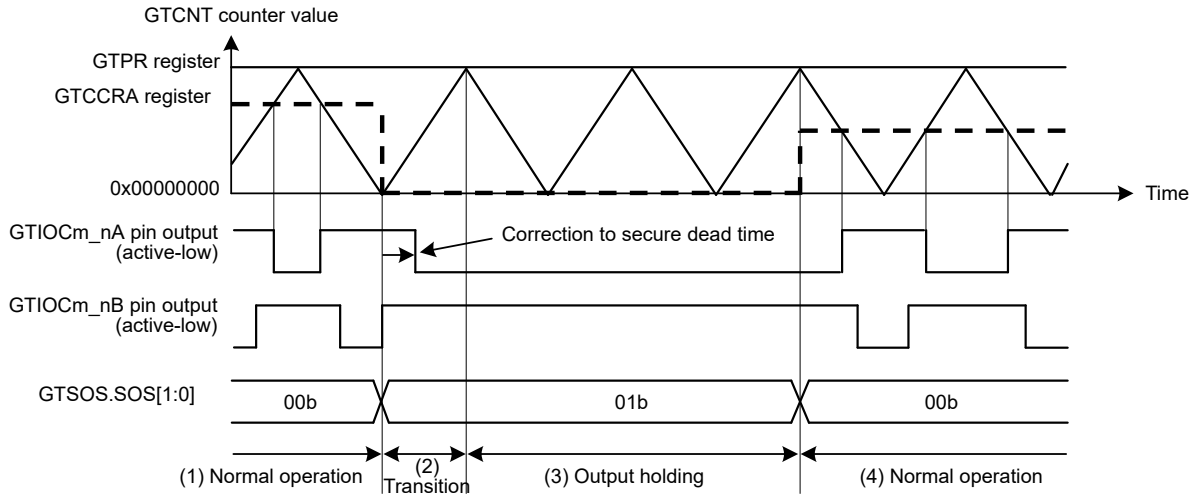
(1) Output Protection Function when the GTCCRA Register is Set to 0x00000000 during Buffer Transfer

Figure 20.88 and Figure 20.89 show examples of output protection function operation when the GTCCRA register is set to 0x00000000 during buffer transfer at troughs, and Figure 20.90 and Figure 20.91 show examples of output protection function operation when the GTCCRA register is set to 0x00000000 during buffer transfer at crests.



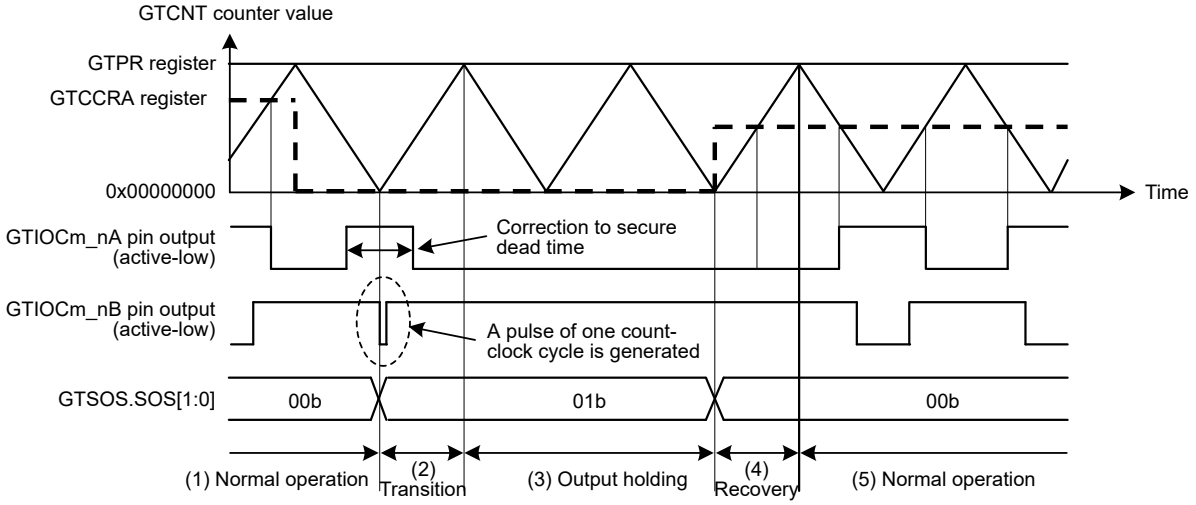
(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Transition period: When GTCCRA = 0 is detected at the trough, the output protection status changes to GTSOS.SOS[1:0] = 01b, and toggle output is continued up to the next crest.
(3) Output holding period: The output is held while GTCCRA = 0.
(4) Recovery period: When 0 < GTCCRA < GTPR is detected at the trough, the output protection status changes to GTSOS.SOS[1:0] = 00b, and holding output is maintained up to the next crest.
(5) Normal operation period: Toggle output due to a compare match is performed normally.

Figure 20.88 Example of output protection function operation when the GTCCRA register is set to 0x00000000 during buffer transfer at troughs (restored to 0 < GTCCRA register < GTPR register during buffer transfer at troughs, active-level: low) ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Transition period: When GTCCRA = 0 is detected at the trough, the output protection status changes to GTSOS.SOS[1:0] = 01b, and toggle output is continued up to the next crest.
(3) Output holding period: The output is held while GTCCRA = 0.
(4) Normal operation period: When 0 < GTCCRA < GTPR is detected at the crest, the output protection status changes to GTSOS.SOS[1:0] = 00b, and toggle output due to a compare match is performed normally.

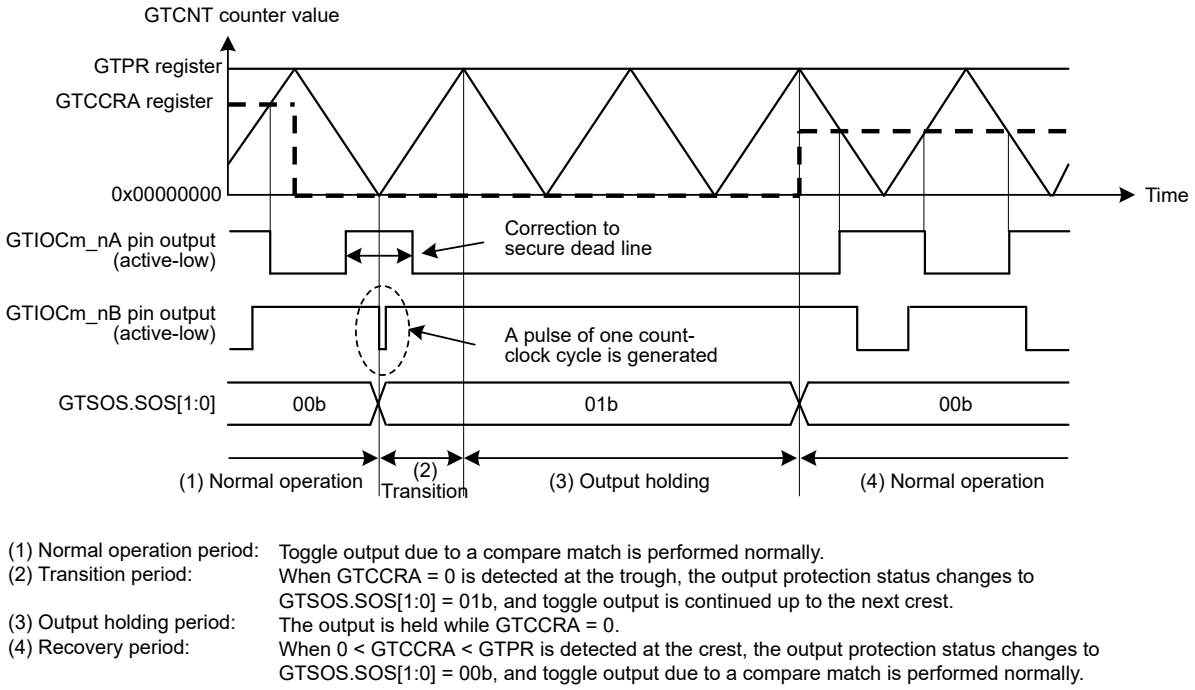
Figure 20.89 Example of output protection function operation when the GTCCRA register is set to 0x00000000 during buffer transfer at troughs (restored to 0 < GTCCRA register < GTPR register during buffer transfer at crests, active-level: low) ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Transition period: When GTCCRA = 0 is detected at the trough, the output protection status changes to GTSOS.SOS[1:0] = 01b, and toggle output is continued up to the next crest.
(3) Output holding period: The output is held while GTCCRA = 0.
(4) Recovery period: When 0 < GTCCRA < GTPR is detected at the trough, the output protection status changes to GTSOS.SOS[1:0] = 00b, and holding output is maintained up to the next crest.
(5) Normal operation period: Toggle output due to a compare match is performed normally.

Figure 20.90 Example of output protection function operation when the GTCCRA register is set to 0x00000000 during buffer transfer at crests (restored to 0 < GTCCRA register < GTPR register

during buffer transfer at troughs, active-level: low) ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

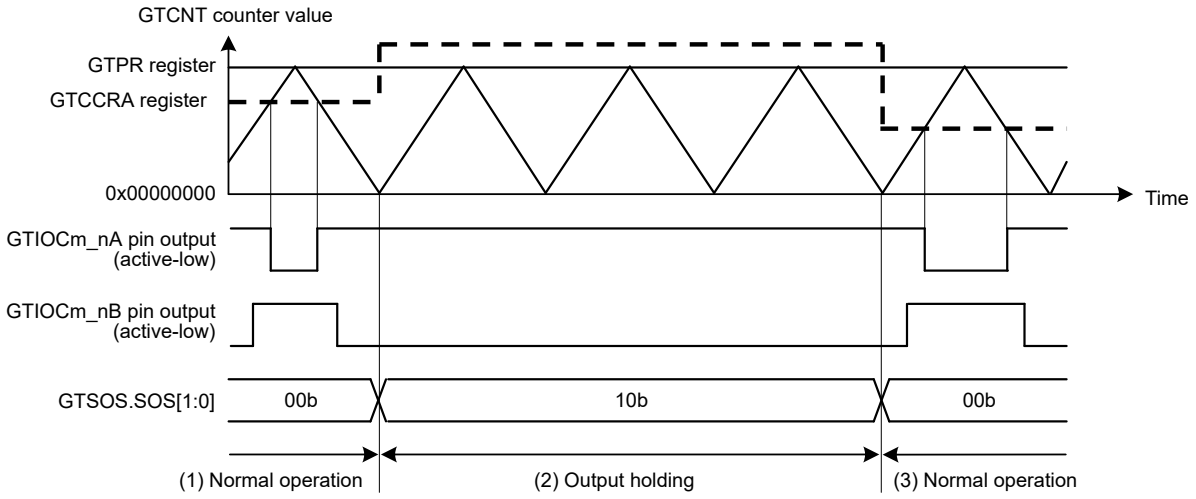


(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Transition period: When GTCCRA = 0 is detected at the trough, the output protection status changes to GTSOS.SOS[1:0] = 01b, and toggle output is continued up to the next crest.
(3) Output holding period: The output is held while GTCCRA = 0.
(4) Recovery period: When 0 < GTCCRA < GTPR is detected at the crest, the output protection status changes to GTSOS.SOS[1:0] = 00b, and toggle output due to a compare match is performed normally.

Figure 20.91 Example of output protection function operation when the GTCCRA register is set to 0x00000000 during buffer transfer at crests (restored to 0 < GTCCRA register < GTPR register during buffer transfer at crests, active-level: low) ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

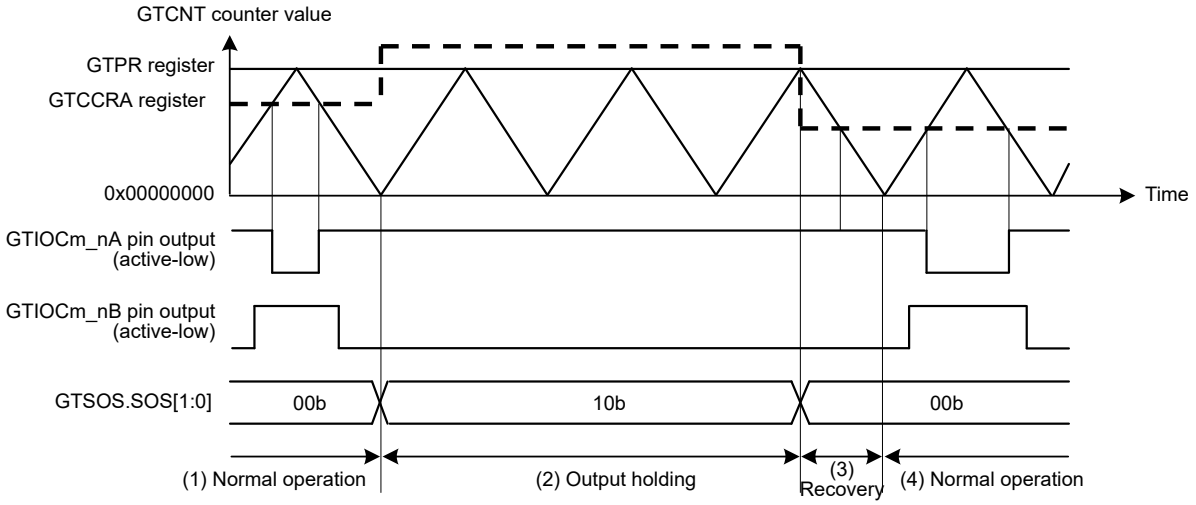
(2) Output Protection Function when GTCCRA Register ≥ GTPR Register is Set during Buffer Transfer at Troughs

Figure 20.92 and Figure 20.93 show examples of output protection function operation when GTCCRA register ≥ GTPR register is set during buffer transfer at troughs.



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA ≥ GTPR is detected at the trough, the output protection status changes to GTSOS[1:0] = 10b, and the output is held while GTCCRA ≥ GTPR.
(3) Normal operation period: When 0 < GTCCRA < GTPR is detected at the trough, the output protection status changes to GTSOS[1:0] = 00b, ant toggle output due to a compare match is performed normally.

Figure 20.92 Example of output protection function operation when GTCCRA register ≥ GTPR register is set during buffer transfer at troughs (restored to 0 < GTCCRA register < GTPR register during buffer transfer at crests, active-level: low) ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

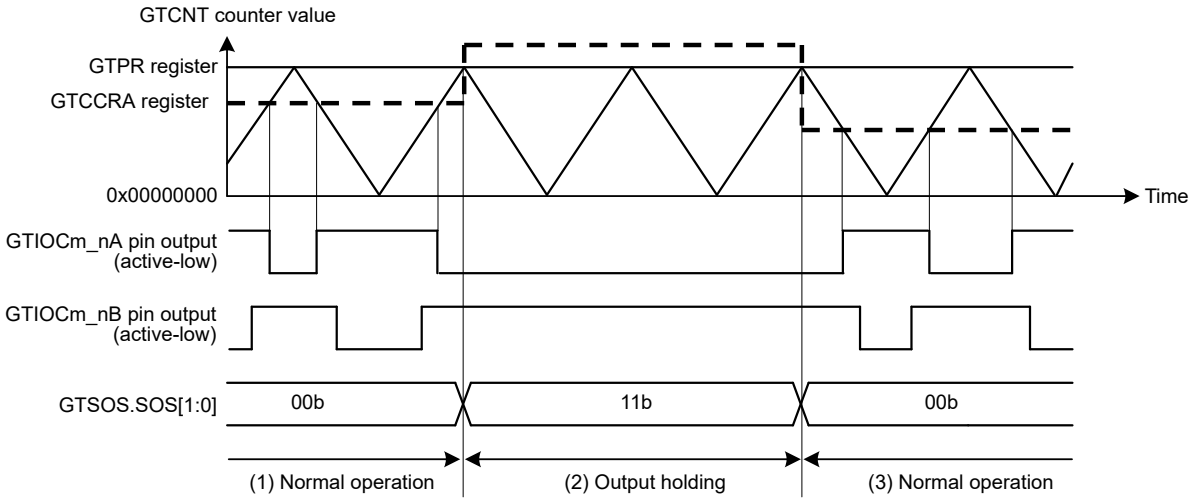


(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA ≥ GTPR is detected at the trough, the output protection status changes to GTSOS[1:0] = 10b, and the output is held while GTCCRA ≥ GTPR.
(3) Recovery period: When 0 < GTCCRA < GTPR is detected at the crest, the output protection status changes to GTSOS.SOS[1:0] = 00b, and holding output is maintained up to the next trough.
(4) Normal operation period: When 0 < GTCCRA register < GTPR register is detected in the crest, the output protection status changes to GTSOS[1:0] = 00b, and toggle output due to a compare match is performed normally.

Figure 20.93 Example of output protection function operation when GTCCRA register ≥ GTPR register is set during buffer transfer at troughs (restored to 0 < GTCCRA register < GTPR register during buffer transfer at troughs, active-level: low) ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

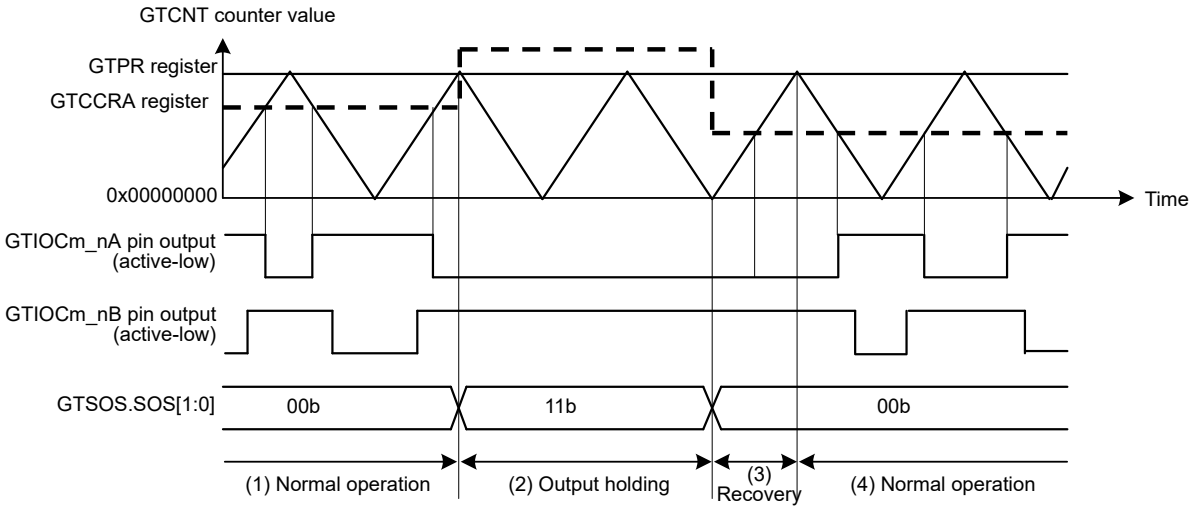
(3) Output Protection Function when GTCCRA Register ≥ GTPR Register is Set during Buffer Transfer at Crests

Figure 20.94 and Figure 20.95 show examples of output protection function operation when GTCCRA register ≥ GTPR register is set during buffer transfer at crests.



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA ≥ GTPR is detected at the crest, the output protection status changes to GTSOS[1:0] = 11b, and the output is held while GTCCRA ≥ GTPR.
(3) Normal operation period: Toggle output due to a compare match is performed normally.

Figure 20.94 Example of output protection function operation when GTCCRA register ≥ GTPR register is set during buffer transfer at crests (restored to 0 < GTCCRA register < GTPR register during buffer transfer at crests, active-level: low) ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA ≥ GTPR Is detected at the crest, the output protection status changes to GTSOS[1:0] = 11b, and the output is held while GTCCRA ≥ GTPR.
(3) Recovery period: When 0 < GTCCRA < GTPR is detected at the trough, the output protection status changes to GTSOS.SOS[1:0] = 00b, and holding output is maintained up to the next crest.
(4) Normal operation period: Toggle output due to a compare match is performed normally.

Figure 20.95 Example of output protection function operation when GTCCRA register ≥ GTPR register is set during buffer transfer at crests (restored to 0 < GTCCRA register < GTPR register during buffer transfer at troughs, active-level: low) ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

(4) Restricted Specification of Output Protection Function

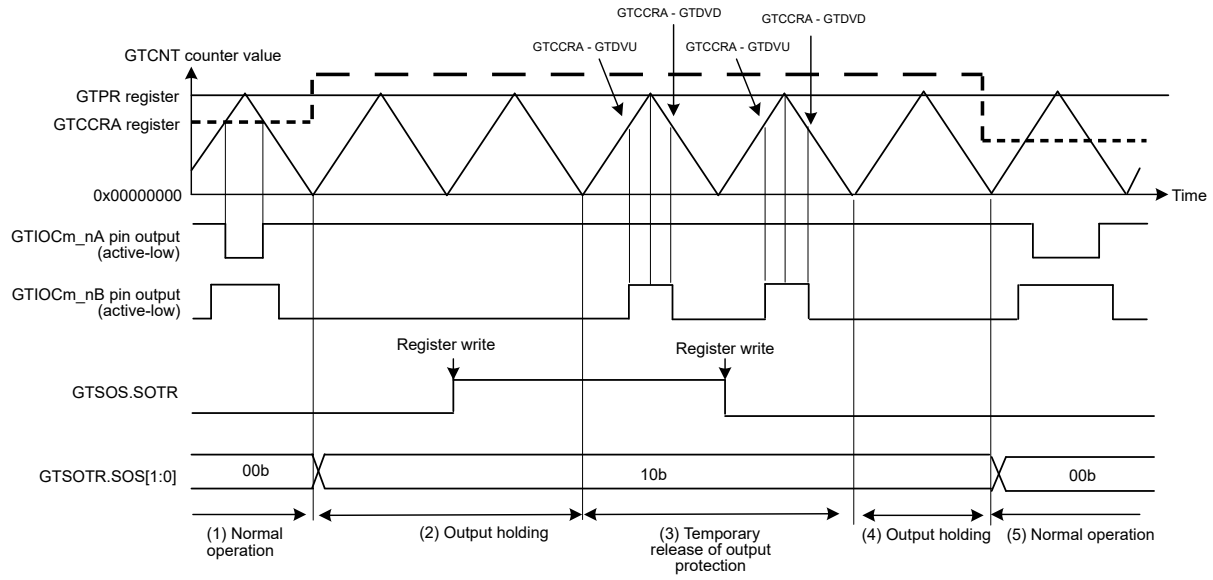
Even if an incorrect value (0x00000000 or a value greater than or equal to the GTPR register value) is set in the GTCCRA register during count operation, the output protection functions in a specific way such that one of the positive- and negative-phase outputs becomes non-active. However, the output protection does not operate normally when the GTCCRA register value at the start of count operation is greater than 0x00000000 and less than the setting value of the GTPR register.

(5) Temporary Release of Output Protection Function

When the GTSOS.SOS[1:0] bits = 10b (protected state in which GTCCRA register ≥ GTPR register occurred during transfer at trough), the protected state of the GTIOCm_nB pin output can be temporarily released by setting the GTSOTR.SOTR bit to 1. The SOS[1:0] bits retain 10b even if the output protection function is released.

When the SOTR bit is set to 0, the GTIOCm_nB pin output protection can be restarted.

Figure 20.96 shows an example of the operation of temporary release of output protection when the setting of the GTCCRA register ≥ GTPR register during buffer transfer at troughs.



(1) Normal operation period: Toggle output due to compare match is performed normally.

(2) Output holding period: When GTCCRA register ≥ GTPR register is detected in the trough, the output protection status changes to GTSOS[1:0] = 10b, and the output is held while GTCCRA register ≥ GTPR register. Even when the GTSOTR.SOTR bit is set to 1 during the output holding period, the GTIOCm_nB pin output is held until the first trough after the setting.

(3) Temporary release of output protection period: After GTSOTR.SOTR bit is set to 1, the GTIOCm_nB pin is performed normally from the first trough after the setting. Even when the GTSOTR.SOTR bit is set to 0 during the output protection releasing period, the GTIOCm_nB pin output is held until the first trough after the setting.

(4) Output holding period: The output is held until 0 < GTCCRA register < GTPR register is detected in the trough.

(5) Normal operation period: When 0 < GTCCRA register < GTPR register is detected in the trough, the output protection status changes to GTSOS[1:0] = 00b, and toggle output due to a compare match is performed normally.

Figure 20.96 Example of the operation of temporary release of output protection when the setting of the GTCCRA register ≥ GTPR register during buffer transfer at troughs (restored to 0 < GTCCRA register < GTPR register during buffer transfer at troughs, active-level: low) ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3))

20.10 Initialization Method of Output Pins

20.10.1 Pin Settings after Reset

The GPT registers are initialized at a reset. Initialize the GPT for output to the external pins by making the port mode settings and setting the OAE and OBE bits in the GTIOR register, and then start the counter counting.

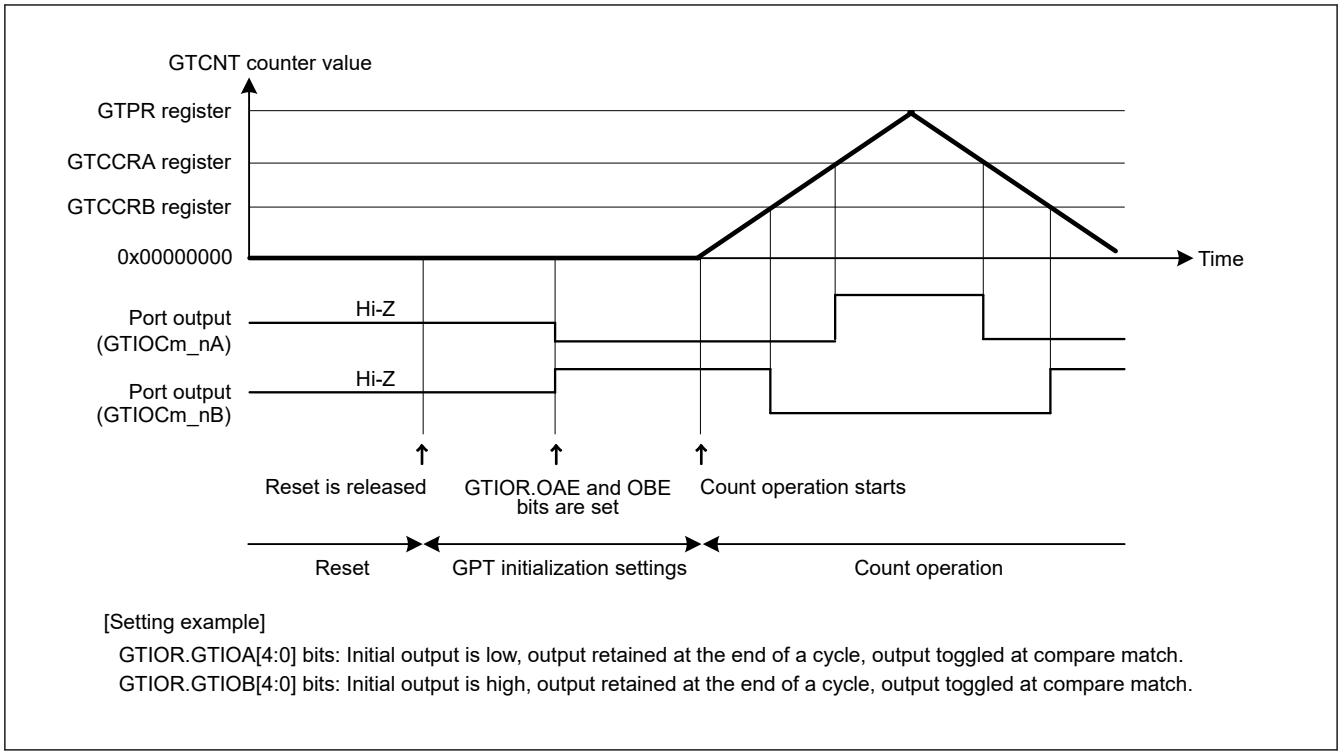


Figure 20.97 Example of pin settings after reset (n = 0 to 17)

20.10.2 Pin Initialization Due to Error during Operation

If an error occurs during GPT operation, the following four types of pin processing can be performed before pin initialization.

1. Set OAHLD and OBHLD bits in the GTIOR register to 1 and retain the outputs at count stop.
2. Set OAHLD and OBHLD bits to 0, specify arbitrary output values at OADFLT and OBDFLT bits in the GTIOR register, and output the arbitrary values at count stop.
3. Set the pin to output an arbitrary value as a general output port by setting the registers of the I/O port in advance. Set the OAE and OBE bits in the GTIOR register to 0 and the control bit in register that corresponds to the pin to allow the arbitrary values to be output from the pin set as a general output port when an error occurs.
4. Drive the output to a high impedance state using the POEG function.

When automatic dead time setting is made, set the GTDTCR.TDE bit to 0 once after counting is stopped. When counting is stopped, only the values of registers that are changed by a GPT external source change. If counting is resumed, operation carries on from where it was stopped.

If counting was stopped, registers should be initialized before counting is started.

20.11 Usage Notes

20.11.1 Module-Stop Function Setting

The Module Stop Control register can enable or disable operation of the GPT. The initial setting is to halt operation of the GPT. Register access is enabled by clearing the module-stop state. For details, see section 9, Low-Power Consumption Function.

20.11.2 Settings of the GTCCRn Register During Compare Match Operation (n = A to F)

(1) When Automatic Dead Time Setting is Made in Triangle-Wave PWM Mode

The GTCCRA register must satisfy the following conditions:

- GTCCRA register > GTDVU register

- GTCCRA register > GTDVD register
- GTCCRA register < GTPR register

When the GTCCRA register is set to 0x00000000 or a value greater than or equal to the GTPR register value during count operation, the output protection function is activated.

However, if the following conditions are not satisfied, the output protection does not operate normally.

- When the GTCCRA register value at the start of count operation is 0x00000001 or greater, and less than the setting value of the GTPR register

For details, see section 20.9.4. GTIOCm_nA and GTIOCm_nB Protection Function for GTIOCm_nA and GTIOCm_nB Pin Output ((m = 00 to 08 and n = 0 to 4), (m = 09 and n = 0 to 6), or (m = 10 and n = 0 to 3)).

(2) When Automatic Dead Time Setting is not Made in Triangle-Wave PWM Mode

Set a value greater than 0x00000000 and less than the setting value of the GTPR register in the GTCCRA register. When 0x00000000 or the same value as that of the GTPR register is set in the GTCCRA register, compare match is generated in one cycle only when [GTCCRA register = 0x00000000] or [GTCCRA register = GTPR register] is met. Furthermore, a value exceeding the setting value of the GTPR register is set in the GTCCRA register, compare match does not occur.

Similarly, set a value greater than 0x00000000, and less than the setting value of the GTPR register in the GTCCRB register. When 0x00000000 or the same value as that of the GTPR register is set in the GTCCRB register, compare match is generated in one cycle only when [GTCCRB register = 0x00000000] or [GTCCRB register = GTPR register] is met.

Furthermore, a value exceeding the setting value of the GTPR register is set in the GTCCRB register, compare match does not occur.

(3) When Automatic Dead Time Setting is Made in Sawtooth-Wave One-Shot Pulse Mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, correct output waveforms with secured dead time may not be obtained.

- In up-counting:

  GTCCRC register < GTCCRD register

  GTCCRC register > GTDVU register

  GTCCRD register < GTPR register − GTDVD register
- In down-counting:

  GTCCRC register > GTCCRD register

  GTCCRC register < GTPR register − GTDVU register

  GTCCRD register > GTDVD register

(4) When Automatic Dead Time Setting is not Made in Sawtooth-Wave One-Shot Pulse Mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRC register < GTCCRD register < GTPR register
- In down-counting: GTPR register > GTCCRC register > GTCCRD register > 0

Similarly, GTCCRE and GTCCRF registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRE register < GTCCRF register < GTPR register
- In down-counting: GTPR register > GTCCRE register > GTCCRF register > 0

(5) In Sawtooth-Wave PWM Mode

The GTCCRA register must be set with the range of 0x00000000 < GTCCRA register < GTPR register. If GTCCRA register = 0x00000000 or GTCCRA register = GTPR register is set, a compare match occurs within the cycle only when

GTCCRA register = 0x00000000 or GTCCRA register = GTPR register is satisfied. If GTCCRA register > GTPR register is set, no compare match occurs.

Similarly, GTCCRB register must be set with the range of 0x00000000 < GTCCRB register < GTPR register. If GTCCRB register = 0x00000000 or GTCCRB register = GTPR register is set, a compare match occurs within the cycle only when GTCCRB register = 0x00000000 or GTCCRB register = GTPR register is satisfied. If GTCCRB register > GTPR register is set, no compare match occurs.

20.11.3 Setting Range of the GTCNT Counter

Set the range of the GTCNT counter within the range of 0 ≤ GTCNT counter ≤ GTPR register.

20.11.4 The GTCNT Counter Start/Stop

The GTCNT counter start/stop control by the GTCR.CST bit is synchronized with the count clock selected by the GTCR.TPCS[3:0] bits. Since the GTCNT counter starts or stops after one count clock cycle selected by the GTCR.TPCS[3:0] bits following the CST bit updating, events until the GTCNT counter actually starts are ignored, where events may be accepted and the interrupt may be generated after the CST bit becomes 0.

20.11.5 Order of Priority in Events

(1) GTCNT Counter

Order of priority in events to update the GTCNT counter is shown below.

Table 20.28 Order of priority in updating GTCNT counter

The GTCNT counter updating source	Order of priority
CPU writing (GTCNT counter writing/GTCLR register writing)	High
Clearing by a hardware source set by the GTCSR register	↑
Up-counting/down-counting by a hardware source set by the GTUPSR and GTDNSR registers	↑
Count operation	Low

In case of contention between up-counting by the GTUPSR register and down-counting by the GTDNSR register, the counter value is not updated.

When updating of the GTCNT counter conflicts with reading by the CPU, the value before updating is reflected.

(2) GTCR.CST Bit

When start/stop by a hardware source set by the GTSSR and GTPSR registers conflicts with the CPU writing (GTCR register writing/GTSTR register writing/GTSTP register writing), the CPU writing takes priority.

When there is contention between start by a hardware source set by the GTSSR register and stop by a hardware source set by the GTPSR register, the state of the CST bit does not change.

When there is contention between the CST bit updating and the CPU reading (GTCR register reading/GTSTR register reading/GTSTP register reading), data before updating is read.

(3) GTCCRm Register (m = A to F)

When there is contention between the GTCCRm register writing and an input capture/buffer transfer, the GTCCRm register writing takes priority over an input capture/buffer transfer.

When an input capture conflicts with the CPU writing or the counter updating by a hardware source, the counter value before updating is captured.

When there is contention between the GTCCRm register updating and the CPU reading, data before updating is read.

(4) GTPR Register

When there is contention between a buffer transfer and the GTPR register writing, the GTPR register writing takes priority over a buffer transfer.

When there is contention between the GTPR register updating and the CPU reading, data before updating is read.

(5) GTADTRm Register (m = A, B)

When there is contention between a buffer transfer and the GTADTRm register writing, the GTADTRm register writing takes priority over a buffer transfer.

When there is contention between the GTADTRm register updating and the CPU reading, data before updating is read.

(6) GTDVm Register (m = U, D)

When there is contention between a buffer transfer and the GTDVm register writing, the GTDVm register writing takes priority over a buffer transfer.

When there is contention between the GTDVm register updating and the CPU reading, data before updating is read.

20.11.6 Input Capture Signal Select

Input capture signals for channel 4 of GPTm unit (m = 00 to 08 (LLPP0 and LLPP1)) can be selected from GTIOCm_4A / GTIOCm_4B or GTIOCm_3A / GTIOCm_3B by setting GTIOCSEL register. When GTIOCm_3A / GTIOCm_3B are selected, same input capture signals can be used for channel 3 and channel 4 in GPTm unit. It enables phase counting and pulse width measurement of the input capture signals at the same time. Note that output signals are not changed.

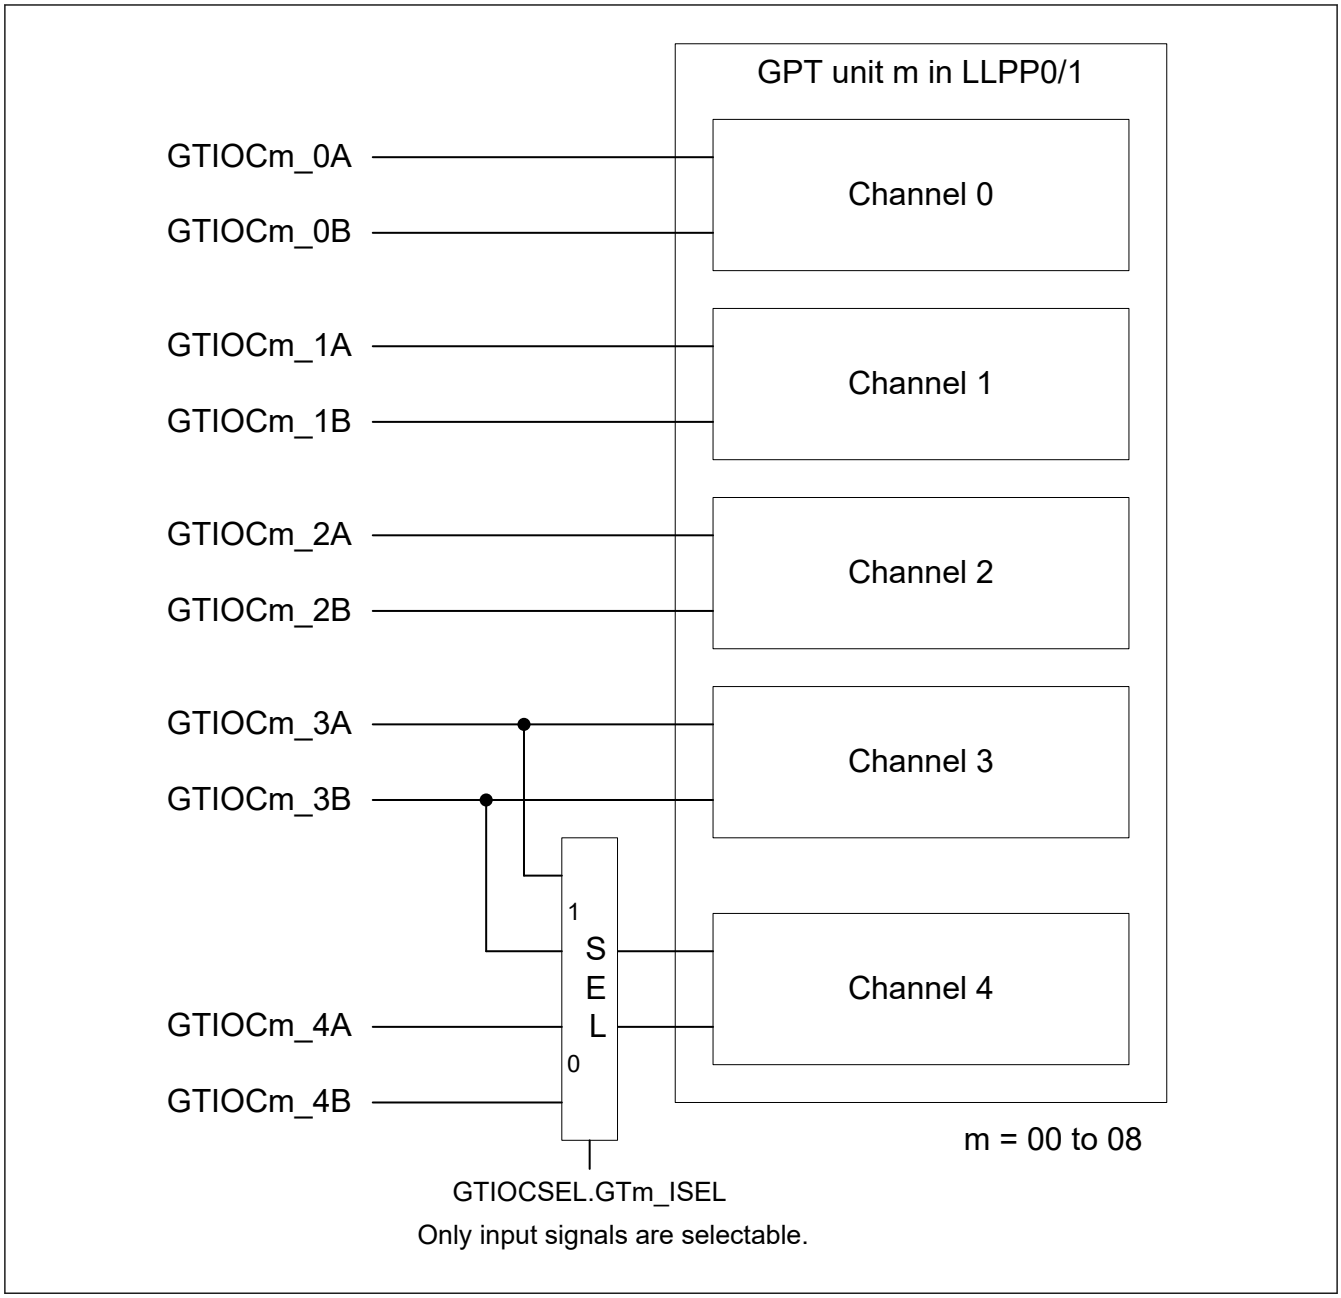

Figure 20.98 Input signal connection in unit 00 to 08

21. Port Output Enable for GPT (POEG)

21.1 Overview

The POEG issues requests to stop output from output pins of the general PWM timer (GPT). The combination of output pins of the POEG to be disabled can be specified from any channel of the GPT.

Select the method of detection for stopping the output from the list below.

- Input level detection of the GTETRGn pin (n = A to D)
- Detection from the GPT to stop output
- Detection of stopping of oscillation by the oscillation stop detection circuit for the main clock
- Register setting

The GTETRGn pin can be used for output to the external trigger input pins of the GPT.

Table 21.1 lists POEG specifications, Figure 21.1 shows a block diagram of POEG, Figure 21.4 shows POEG external trigger connections, Table 21.2 lists POEG I/O pins, and Table 21.3 lists POEG Interrupt Sources.

Table 21.1 POEG specifications

Item	Description
Number of units	Three units (LLPP (POEG0), NONSAFETY (POEG1), SAFETY (POEG2))
Number of groups	Four groups (A to D)
Output-disable control through input level detection	The GPT output pins can be disabled when a GTETRGA to GTETRGD rising edge or high level is sampled after polarity and filter selection.
Output-disable request from the GPT	• When the GTIOCA pin and the GTIOCB pin are driven to an active level simultaneously, the GPT generates an output-disable request to the POEG. Through reception of these requests, the POEG can control whether the GTIOCA and GTIOCB pins are output-disabled. • GPT output pins can be set to be disabled when the GPT output pins detect a dead time error.
Output-disable control through oscillation stop detection	The GPT output pins can be disabled when oscillation of the clock generation circuit stops.
Output-disable control by software (registers)	The GPT output pins can be disabled by modifying the register settings.
Output-disable control through DSMIF error detection	The GPT output pins can be disabled when DSMIF error 0 or 1 occurs (LLPP only).
Interrupt	• Allows output-disable control by the input level detection • Allows output-disable requests from the GPT
External trigger output to the GPT (count start, count stop, count clear, up-count, down-count, or input capture function)	The GTETRGA to GTETRGD signals can be output to the GPT after polarity and filter selection.
Noise filtering	• Three times sampling for every PCLK/1, PCLK/8, PCLK/32, or PCLK/128 can be set for any of the input pins GTETRGA to GTETRGD. (PCLK is PCLKH for LLPP and PCLKL for NONSAFETY and SAFETY). • Positive or negative polarity can be selected for any of the input pins, GTETRGA to GTETRGD. • Signal state after polarity and filter selection can be monitored.

Table 21.2 POEG I/O pins

Pin name	I/O	Function
GTETRGA	Input	GPT output pin output-disable request signal and GPT external trigger input pin A for channels in LLPP and NONSAFETY
GTETRGB	Input	GPT output pin output-disable request signal and GPT external trigger input pin B for channels in LLPP and NONSAFETY
GTETRGC	Input	GPT output pin output-disable request signal and GPT external trigger input pin C for channels in LLPP and NONSAFETY
GTETRGD	Input	GPT output pin output-disable request signal and GPT external trigger input pin D for channels in LLPP and NONSAFETY
GTETRGSA	Input	GPT output pin output-disable request signal and GPT external trigger input pin A for channels in SAFETY
GTETRGSB	Input	GPT output pin output-disable request signal and GPT external trigger input pin B for channels in SAFETY

Table 21.3 POEG interrupt sources (1 of 2)

Name	Interrupt Sources
POEG0_GROUP0	POEG group A interrupt for channels in LLPP
POEG0_GROUP1	POEG group B interrupt for channels in LLPP

Table 21.3 POEG interrupt sources (2 of 2)

Name	Interrupt Sources
POEG0_GROUP2	POEG group C interrupt for channels in LLPP
POEG0_GROUP3	POEG group D interrupt for channels in LLPP
POEG1_GROUP0	POEG group A interrupt for channels in NONSAFETY
POEG1_GROUP1	POEG group B interrupt for channels in NONSAFETY
POEG1_GROUP2	POEG group C interrupt for channels in NONSAFETY
POEG1_GROUP3	POEG group D interrupt for channels in NONSAFETY
POEG2_GROUP0	POEG group A interrupt for channels in SAFETY
POEG2_GROUP1	POEG group B interrupt for channels in SAFETY
POEG2_GROUP2	POEG group C interrupt for channels in SAFETY
POEG2_GROUP3	POEG group D interrupt for channels in SAFETY

21.2 Register Descriptions

21.2.1 POEG0Gn0 : POEG0 Group n Setting Register 0 (n = A to D)

Base address: POEG0 = 0x9001_9000

Offset address: 0x000 (POEG0GA0)
0x400 (POEG0GB0)
0x800 (POEG0GC0)
0xC00 (POEG0GD0)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	NFCS[1:0]		NFEN	INV	—	—	—	—	—	—	—	—	—	—	—	ST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	OSTPE	IOCE	PIDE	SSF	OSTPF	IOCF	PIDF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PIDF	Port Input Detection Flag 0: The selected input level was not detected on the GTETRGn pin 1: The selected input level was detected on the GTETRGn pin	R/W*1
1	IOCF	GPT Output Stop Request Detection Flag 0: Stopping of GPT output was not detected 1: Stopping of GPT output was detected	R/W*1
2	OSTPF	Oscillation Stop Detection Flag 0: Stopping of oscillation was not detected 1: Stopping of oscillation was detected	R/W*1
3	SSF	Software Stop Flag 0: Software has not stopped output 1: Software has stopped output	R/W
4	PIDE	Port Input Detection Enable 0: Detection of input levels on the corresponding GTETRGn pin is disabled 1: Detection of input levels on the corresponding GTETRGn pin is enabled	R/W*2
5	IOCE	GPT Output Stop Request Enable 0: Detection of stopping of output from the GPT is disabled 1: Detection of stopping of output from the GPT is enabled	R/W*2

Bit	Symbol	Function	R/W
6	OSTPE	Enable Stopping Output on Stopping of Oscillation 0: Detection of stopping of oscillation is disabled 1: Detection of stopping of oscillation is enabled	R/W*2
15:7	—	These bits are read as 0. The write value should be 0.	R/W
16	ST	GTETRGn Input Status Flag 0: GTETRGn input after filtering was 0 1: GTETRGn input after filtering was 1	R
27:17	—	These bits are read as 0. The write value should be 0.	R/W
28	INV	GTETRGn Input Inverting 0: Input on the GTETRGn pin is not inverted 1: Input on the GTETRGn pin is inverted	R/W
29	NFEN	Noise filter Enable 0: Digital noise filter on the GTETRGn pin is disabled 1: Digital noise filter on the GTETRGn pin is enabled	R/W
31:30	NFCS[1:0]	Noise filter Clock Select 0 0: Samples the input level of GTETRGn pin three times per PCLKH clock 0 1: Samples the input level of GTETRGn pin three times per PCLKH/8 clock 1 0: Samples the input level of GTETRGn pin three times per PCLKH/32 clock 1 1: Samples the input level of GTETRGn pin three times per PCLKH/128 clock	R/W

Note 1. Only 0 to clear the flag can be written.
Note 2. Can write only once after reset.

The POEG0Gn0 register (n = A to D) controls requests for stopping output and an external trigger for the GPT based in response to the detection of various signals.

21.2.2 POEG0Gn1 : POEG0 Group n Setting Register 1 (n = A to D)

Base address: POEG0 = 0x9001_9000

Offset address: 0x004 (POEG0GA1)
0x404 (POEG0GB1)
0x804 (POEG0GC1)
0xC04 (POEG0GD1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

5	IOCE	GPT Output Stop Request Enable 0: Detection of stopping of output from the GPT is disabled 1: Detection of stopping of output from the GPT is enabled	R/W*2
6	OSTPE	Enable Stopping Output on Stopping of Oscillation 0: Detection of stopping of oscillation is disabled 1: Detection of stopping of oscillation is enabled	R/W*2
15:7	—	These bits are read as 0. The write value should be 0.	R/W
16	ST	GTETRGn Input Status Flag 0: GTETRGn input after filtering was 0 1: GTETRGn input after filtering was 1	R
27:17	—	These bits are read as 0. The write value should be 0.	R/W
28	INV	GTETRGn Input Inverting 0: Input on the GTETRGn pin is not inverted 1: Input on the GTETRGn pin is inverted	R/W
29	NFEN	Noise filter Enable 0: Digital noise filter on the GTETRGn pin is disabled 1: Digital noise filter on the GTETRGn pin is enabled	R/W
31:30	NFCS[1:0]	Noise filter Clock Select 0 0: Samples the input level of GTETRGn pin three times per PCLKL clock 0 1: Samples the input level of GTETRGn pin three times per PCLKL/8 clock 1 0: Samples the input level of GTETRGn pin three times per PCLKL/32 clock 1 1: Samples the input level of GTETRGn pin three times per PCLKL/128 clock	R/W

Note 1. Only 0 to clear the flag can be written.
Note 2. Can write only once after reset.

The POEGmGn0 register (m = 1, 2), (n = A to D) controls requests for stopping output and an external trigger for the GPT based in response to the detection of various signals.

21.3 Operation

21.3.1 Output-Disable Control Operation

If any of the following conditions is satisfied, the GTIOCxA, GTIOCxB, and the three-phase PWM output for motor control pins can be set to output-disable:

- Input level or edge detection of the GTETRGA to GTETRGD pins
  When POEGmGn0.PIDE = 1 (m = 0 to 2, n = A to D), the POEGmGn0.PIDF flag is set to 1.
- Output-disable request from the GPT
  When POEGmGn0.IOCE = 1 (m = 0 to 2, n = A to D), the POEGmGn0.IOCF flag is set to 1 if the output-disable request is enabled in GTINTAD. The GTINTAD.GRPDTE, GTINTAD.GRPABH, and GTINTAD.GRPABL settings apply to the group selected in GPT register GTINTAD.GRP[1:0] and OPSCR.GRP[1:0].
- Oscillation stop detection for the Clock Generation Circuit
  When POEGmGn0.OSTPE = 1 (m = 0 to 2, n = A to D), the POEGmGn0.OSTPF flag is set to 1.
- SSF bit setting
  When POEGmGn0.SSF (m = 0 to 2, n = A to D) is set to 1.

The state of output-disable is controlled in the GPT module. The output-disable of the GTIOCxA and GTIOCxB pins are set in the GTINTAD.GRP[1:0] bits, GTIOR.OADF[1:0] bits, and GTIOR.OBDF[1:0] bits in GPTx. The output-disable of the PWM output for motor control pins are set in the OPSCR.GRP[1:0] bits and OPSCR.GODF bit in GPT_OPS.

21.3.1.1 Pin Input Level Detection Operation

If the input conditions set in POEGmGn0.PIDE, POEGmGn0.NFCS[1:0], POEGmGn0.NFEN, and POEGmGn0.INV (m = 0 to 2, n = A to D) occur on the GTETRGA to GTETRGD pins, the GPT output pins are output-disabled.

(1) Digital Noise Filter

Figure 21.5 shows high-level detection by the digital filter. When a high level associated with the POEGmGn0.INV (m = 0 to 2, n = A to D) polarity setting is detected three times consecutively with the sampling clock selected in POEGmGn0.NFCS[1:0] and POEGmGn0.NFEN, the detected level is recognized as high, and the GPT output pins are output-disabled. If even one low level is detected during this interval, the detected level is not recognized as high. In addition, in an interval where the sampling clock is not being output, changes of the levels on the GTETRGA to GTETRGD pins are ignored.

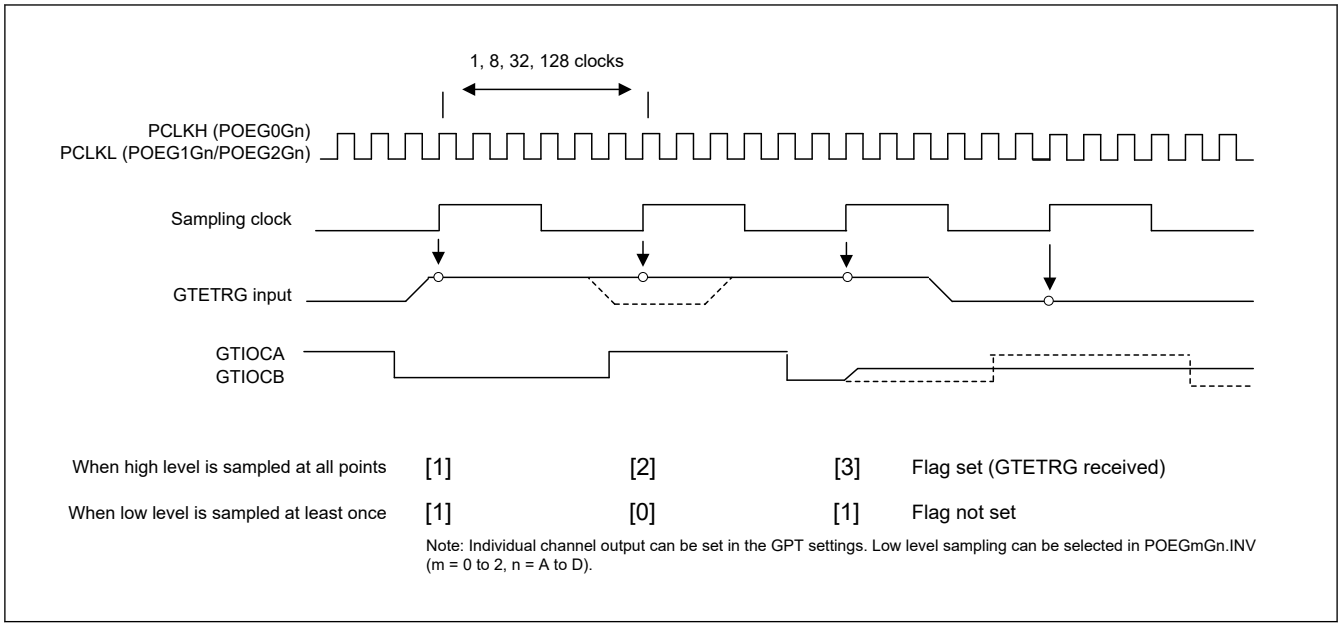

Figure 21.5 Example of digital noise filter operation

21.3.2 Output-Disable Requests from the GPT

For details on this operation, see the description of output-disable control for GTIOC pin outputs in section 20, General PWM Timer (GPT).

21.3.3 Output-Disable Control Using Detection of Stopped Oscillation

When the oscillation stop detection function in the Clock Generation Circuit detects stopped oscillation while POEGmGn0.OSTPE = 1 (m = 0 to 2, n = A to D), the GPT output pins are output-disabled for each group.

21.3.4 Output-Disable Control Using DSMIF Error Detection

When the DSMIF detects error while POEG0Gn.DmERR0E =1 or POEG0Gn.DmERR1E = 1 (m = 0, 1), the GPT output pins in the LLPP region can be output-disabled. Target DSMIF error can be selected in POEG0Gn2 register (n = A to D).

21.3.5 Output-Disable Control Using Registers

The GPT output pins can be directly controlled by writing to the software stop flag, POEGmGn0.SSF.

21.3.6 Release from Output-Disable

To release the GPT output pins placed in the output-disable state, either return them to their initial state with a reset, clear all of the following (n = A to D), or DSMIF error flag in DSMIFn.DSCESR:

- POEGmGn0.PIDF flag
- POEGmGn0.IOCF flag
- POEGmGn0.OSTPF flag
- POEGmGn0.SSF flag

Writing 0 to the POEGmGn0.PIDF (n = A to D) flag is ignored (the flag is not cleared) if the external input pins, GTETRGA to GTETRGD, are not disabled and the POEGmGn0.ST bit is not set to 0.

Writing 0 to the POEGmGn0.IOCF (n = A to D) flag is valid (the flag is cleared) only if all of the GTST.DTEF, GTST.OABHF, and GTST.OABLF flags in the GPT are set to 0.

Figure 21.6 shows the release timing for output-disable. The output-disable is released at the beginning of the next count cycle of the GPT after the flag is cleared.

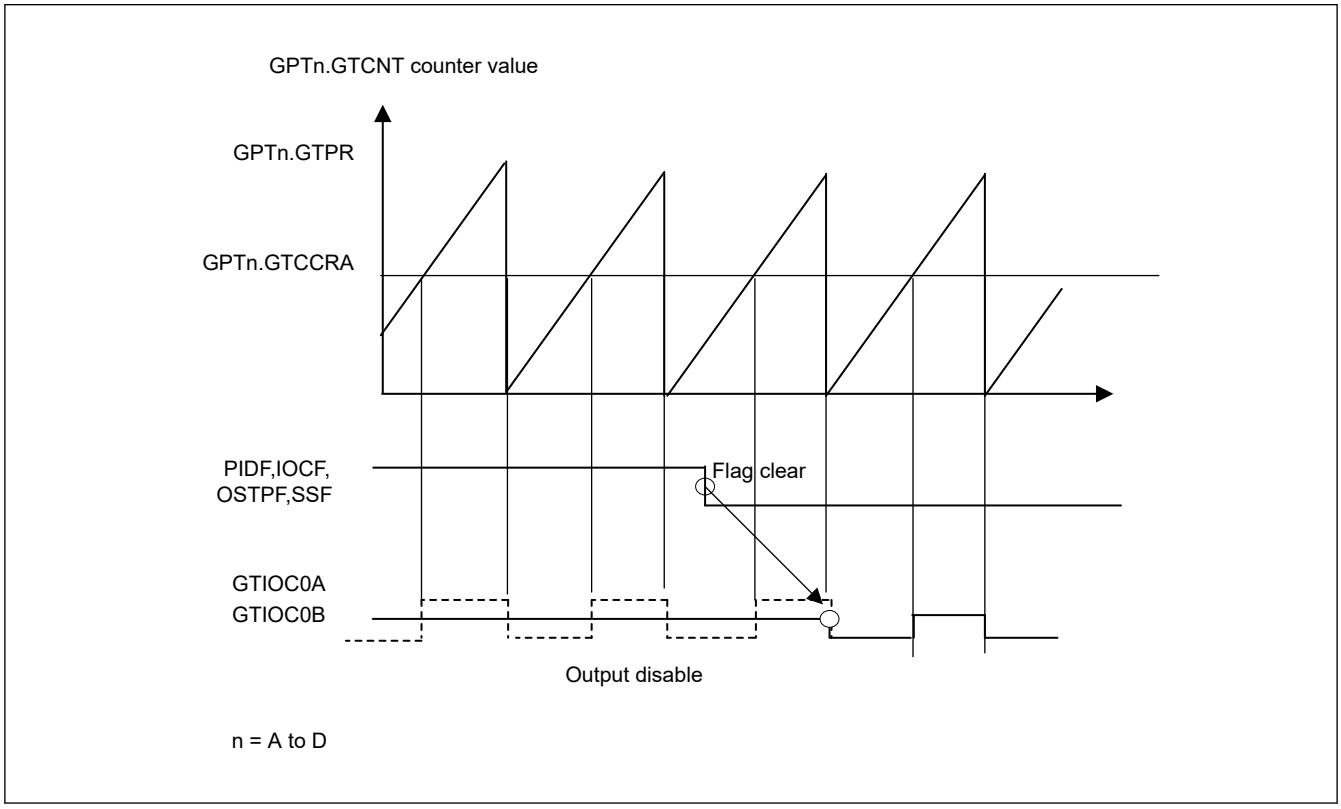

Figure 21.6 Output-disable release timing for GPT pin outputs

22. Trigonometric Function Unit (TFU)

22.1 Overview

A trigonometric Function Unit (TFU) handles the high-speed calculation for sinf, cosf, atan2f, and hypotf functions.

The PCLKH is used as the operating clock for the TFU.

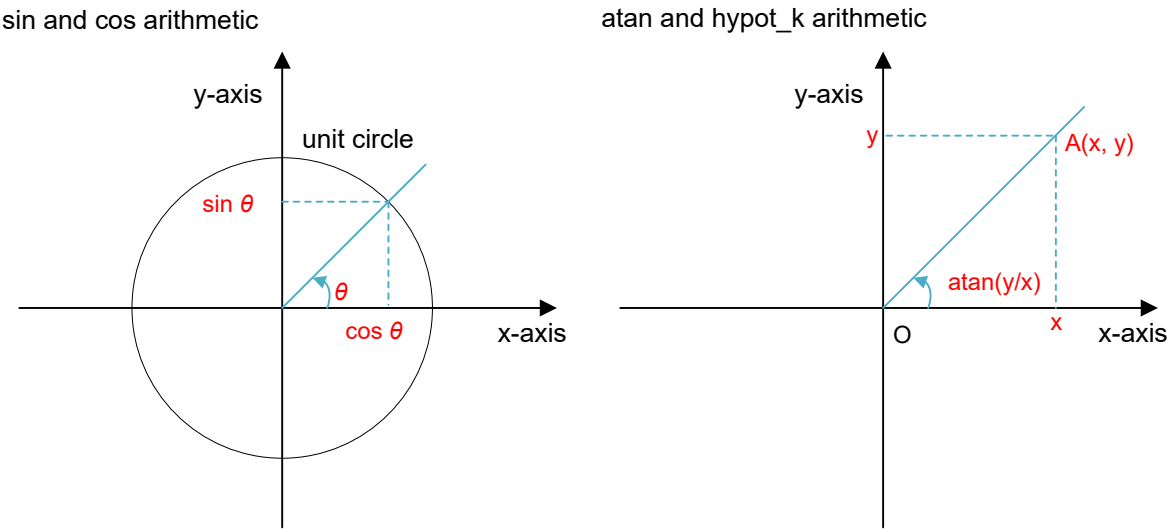
Table 22.1 lists the specifications of the TFU.

Table 22.1 TFU specifications

Item	Description			
Number of unit	2 units			
Arithmetic Processing	Calculation of sine, cosine, arctangent, and hypot_k ($\sqrt{x^2+y^2}/k$) • A sine and cosine can be simultaneously calculated. • An arctangent and hypot_k can be simultaneously calculated.			
Range and Unit of Values	**Floating-point**	**I/O**		**Range**	**Unit**
	Calculating sine	Input	Angle θ	$-\text{float\_max} \le \theta \le \text{float\_max}$ *1	radian
		Output	$\sin\theta$	$-1.0 \le \sin\theta \le 1.0$	—
	Calculating cosine	Input	Angle θ	$-\text{float\_max} \le \theta \le \text{float\_max}$ *1	radian
		Output	$\cos\theta$	$-1.0 \le \cos\theta \le 1.0$	—
	Calculating arctangent	Input	x and y coordinates	$-\text{float\_max} \le x \le \text{float\_max}$ *1 $-\text{float\_max} \le y \le \text{float\_max}$ *1	—
		Output	$\text{atan}(y/x)$	$-\pi \le \text{atan}(y/x) \le \pi$	radian
	Calculating hypot_k	Input	x and y coordinates	$-\text{float\_max} \le x \le \text{float\_max}$ *1 $-\text{float\_max} \le y \le \text{float\_max}$ *1	—
		Output	$\sqrt{x^2+y^2}/k$	$0 \le \sqrt{x^2+y^2}/k \le \infty$	—
	Fixed-point	**I/O**		**Range**	**Unit**
	Calculating sine	Input	Angle θ	$-1.0 \le \theta < 1.0$	turn
				$-4.0 \le \theta < 4.0$	radian
		Output	$\sin\theta$	$-1.0 \le \sin\theta \le 1.0$	—
	Calculating cosine	Input	Angle θ	$-1.0 \le \theta < 1.0$	turn
				$-4.0 \le \theta < 4.0$	radian
		Output	$\cos\theta$	$-1.0 \le \cos\theta \le 1.0$	—
	Calculating arctangent	Input	x and y coordinates	$-1.0 \le x < 1.0$ $-1.0 \le y < 1.0$	—
		Output	$\text{atan}(y/x)$	$-0.5 \le \text{atan}(y/x) \le 0.5$	turn
				$-\pi \le \text{atan}(y/x) \le \pi$	radian
	Calculating hypot_k	Input	x and y coordinates	$-1.0 \le x < 1.0$ $-1.0 \le y < 1.0$	—
		Output	$\sqrt{x^2+y^2}/k$	$0 \le \sqrt{x^2+y^2}/k \le \sqrt{2}/k$	—
Data Type for Processing	Single-precision floating-point, Fixed-point (two's complement)			
Number of cycles for calculation	Sine: 5 Cosine: 5 Arctangent: 14 hypot_k: 14			

Note: k is a constant. See section 22.4.1. Arithmetic Processing.

Note 1. float_max is the maximum value that can be expressed as single-precision floating-point: $(2 - 2^{-23}) \times 2^{127}$.



Note: sin and cos arithmetic:
Operation to find $\sin\theta$ and $\cos\theta$, which are the triangular ratios of the input angle values θ.
atan arithmetic:
Operation to find the angle value between the vector OA (O is the origin and A is the point indicated by the input coordinates x and y) and the positive part of the x-axis.
hypot_k arithmetic:
Operation to find a value proportional to the distance from the point A indicated by the input coordinates x and y to the origin O.

Note: By multiplying the TFU output result hypot_k by the constant k, the distance between OA ($\sqrt{x^2+y^2}$) can be obtained. for details about k, see section 22.4.1. Arithmetic Processing.

Figure 22.1 Explanation for operations

22.1.1 Precautions on Use of the Trigonometric Function Unit

This section describes precautions on use of the trigonometric function unit.

22.1.1.1 General Precautions

If another operation is started after the operation is started and before the result is read, the result of the preceding operation will be discarded.

22.2 Register Map

Table 22.2 TFU register map (1 of 2)

Table 22.3 TFU related system control register

Unit	Module Reset Control Register	Module Stop Control Register	Slave Access Control Register
0	—	MSTPCRC.MSTPCRC05	SLVACCCTL7.LLPP_SL*1
1	—	MSTPCRC.MSTPCRC24	SLVACCCTL7.LLPP_SL*1

Note 1. Access from Cortex-R52 CPU0 and CPU1 is not protected by TrustZone. This slave access control is applied to access from other masters.

22.3 Register Descriptions

22.3.1 FXSCIOC : Fixed-point Sine Cosine Input/Output Setting Register

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	OF[1:0]		—	—	—	IUF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IUF	Input unit and format setting Specify the unit and format for input value of fixed-point sincos operation 0: unit, format = turn, Q1.31 1: unit, format = radian, Q3.29	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
5:4	OF[1:0]	Output format setting 0 0: Q1.31 0 1: Q2.30 1 0: Q3.29 1 1: Setting prohibited	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

IUF bit (Input unit and format setting)

The IUF bit specifies the unit and format for input value of fixed-point sincos operation.

OF[1:0] bits (Output format setting)

The OF[1:0] bits specify the format for output value of fixed-point sincos operation.

When Q1.31 is selected, +1.0 cannot be expressed accurately. If $\sin\theta$ or $\cos\theta$ is +1.0 ordinally when Q1.31, $+1.0 - 2^{-31}$ will be read out from the FXSCDT0 and FXSCDT1 registers.

This register should be set before the calculation start. If this register is changed during the calculation, the operation is not guaranteed.

22.3.2 FXATIOC : Fixed-point Arctangent hypot_k Input/Output Setting Register

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	OUF	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	OUF	Output unit and format setting Specify the unit and format for output value of fixed-point arctangent operation 0: unit, format = turn, Q1.31 1: unit, format = radian, Q3.29	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

OUF bit (Output unit and format setting)

The OUF bit specifies the unit and format for output value when arctangent calculation is executed by fixed-point atanhypot_k operation. The output format of hypot_k calculation executed with arctangent calculation in parallel is Q3.29 regardless of this bit setting.

This register should be set before the calculation start. If this register is changed during the calculation, the operation is not guaranteed.

22.3.3 TRGSTS : Trigonometric Status Register

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ERRF	BSYF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BSYF	Calculation in progress flag 0: No calculating 1: Calculating	R/W*1
1	ERRF	Input error flag 0: No input error occurred 1: Input error occurred	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to this bit is invalid.

BSYF bit (Calculation in progress flag)

The BSYF bit specifies the calculation in progress flag. Writing to this bit is ignored.

[Setting condition]

- When calculation started

[Clearing condition]

- When calculation completed

ERRF bit (Input error flag)

The ERRF bit specifies the input error flag.

Do not write to this bit except error flag restoration procedure shown in section 22.4.5. Relationship Between Input and Output Values for Atan Operation.
[Setting condition]

- When input error occurred or 1 wrote to this bit. For details on input error, see Table 22.10.

[Clearing condition]

- When the next calculation started or 0 wrote to this bit

22.3.4 FPSCDT0 : Floating-point Sine Cosine Data Register 0

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x10

Bit position:	31																												0
Bit field:	FPSCDT0[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FPSCDT0[31:0]	Floating-point Sine Cosine Data Register 0	R/W

For the floating-point sincos operation, the FPSCDT0 register is dedicated for the output value $\cos\theta$ of the trigonometric function unit. See Table 22.4 for detail. In terms of usage of this register, see section 22.4.7. Procedure for Trigonometric Function Operation.

Writing to this register is prohibited even during any operations.

If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

For calculations except the floating-point sincos operation, do not access this register. If other data register 0 such as FPATDT0, FXSCDT0, and FXATDT0 registers is written, this register value will be uncertainty.

When the DTSR0 register is written, this register value will be the same as DTSR0 register writing value.

22.3.5 FPSCDT1 : Floating-point Sine Cosine Data Register 1

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x14

Bit position:	31																												0
Bit field:	FPSCDT1[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FPSCDT1[31:0]	Floating-point Sine Cosine Data Register 1	R/W

For the floating-point sincos operation, the FPSCDT1 register is shared for the input angle value θ and the output value $\sin\theta$ of the trigonometric function unit. See Table 22.4 for detail. Writing to this register starts the floating-point sincos operation. In terms of usage of this register, see section 22.4.7. Procedure for Trigonometric Function Operation.

Writing to this register is prohibited even during any operations.

If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

For calculations except the floating-point sincos operation, do not access this register. If other data register 1 such as FPATDT1, FXSCDT1, and FXATDT1 registers is written, this register value will be uncertainty.

When the DTSR1 register is written, this register value will be the same as DTSR1 register writing value.

Table 22.4 Input/Output value of FPSCDT0 and FPSCDT1

Register	Input value	Output value
FPSCDT0	—	$\cos\theta$
FPSCDT1	Angle θ	$\sin\theta$

22.3.6 FPATDT0 : Floating-point Arctangent hypot_k Data Register 0

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x18

Bit position:	31																												0
Bit field:	FPATDT0[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FPATDT0[31:0]	Floating-point Arctangent hypot_k Data Register 0	R/W

For the floating-point atanhypot_k operation, the FPATDT0 register is shared for the input coordinate value x and the output value $\sqrt{x^2+y^2}/k$ of the trigonometric function unit. See Table 22.5 for detail. In terms of usage of this register, see section 22.4.7. Procedure for Trigonometric Function Operation.

Writing to this register is prohibited even during any operations.

If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

For calculations except the floating-point atanhypot_k operation, do not access this register. If other data register 0 such as FPSCDT0, FXSCDT0, and FXATDT0 registers is written, this register value will be uncertainty.

When the DTSR0 register is written, this register value will be the same as DTSR0 register writing value.

22.3.7 FPATDT1 : Floating-point Arctangent hypot_k Data Register 1

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x1C

Bit position:	31																												0
Bit field:	FPATDT1[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FPATDT1[31:0]	Floating-point Arctangent hypot_k Data Register 1	R/W

For the floating-point atanhypot_k operation, the FPATDT1 register is shared for the input coordinate value y and the output value atan(y/x) of the trigonometric function unit. See Table 22.5 for detail. Writing to this register starts the floating-point atanhypot_k operation. In terms of usage of this register, see section 22.4.7. Procedure for Trigonometric Function Operation.

Writing to this register is prohibited even during any operations.

If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

For calculations except the floating-point atanhypot_k operation, do not access this register. If other data register 1 such as FPSCDT1, FXSCDT1, and FXATDT1 registers is written, this register value will be uncertainty.

When the DTSR1 register is written, this register value will be the same as DTSR1 register writing value.

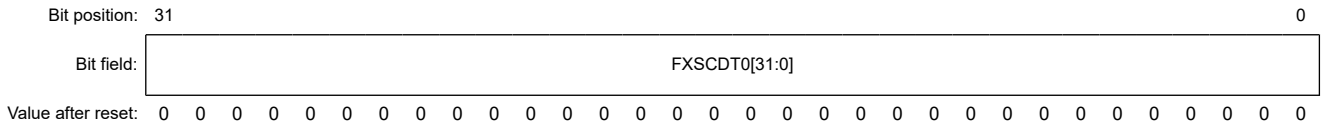
Table 22.5 Input/Output value of FPATDT0 and FPATDT1

Register	Input value	Output value
FPATDT0	Coordinates x	hypot_k
FPATDT1	Coordinates y	atan(y/x)

22.3.8 FXSCDT0 : Fixed-point Sine Cosine Data Register

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x20



Bit	Symbol	Function	R/W
31:0	FXSCDT0[31:0]	Fixed-point Sine Cosine Data Register 0	R/W

For the fixed-point sincos operation, the FXSCDT0 register is dedicated for the output value $\cos\theta$ of the trigonometric function unit. See Table 22.6 for detail. In terms of usage of this register, see section 22.4.7. Procedure for Trigonometric Function Operation.

Writing to this register is prohibited even during any operations.

If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

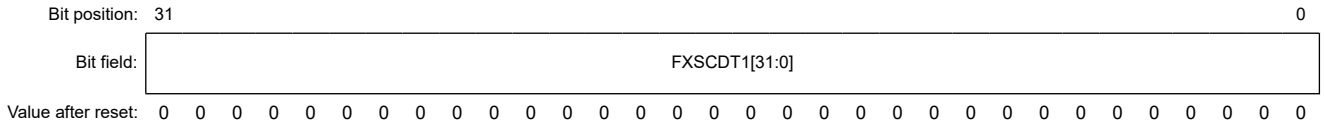
For calculations except the fixed-point sincos operation, do not access this register. If other data register 0 such as FPSCDT0, FPATDT0, and FXATDT0 registers is written, this register value will be uncertainty.

When the DTSR0 register is written, this register value will be the same as DTSR0 register writing value.

22.3.9 FXSCDT1 : Fixed-point Sine Cosine Data Register 1

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x24



Bit	Symbol	Function	R/W
31:0	FXSCDT1[31:0]	Fixed-point Sine Cosine Data Register 1	R/W

For the fixed-point sincos operation, the FXSCDT1 register is shared for the input angle value θ and the output value $\sin\theta$ of the trigonometric function unit. See Table 22.6 for detail. Writing to this register starts the fixed-point sincos operation. In terms of usage of this register, see section 22.4.7. Procedure for Trigonometric Function Operation.

Writing to this register is prohibited even during any operations.

If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

For calculations except the fixed-point sincos operation, do not access this register. If other data register 1 such as FPSCDT1, FPATDT1, and FXATDT1 registers is written, this register value will be uncertainty.

When the DTSR1 register is written, this register value will be the same as DTSR1 register writing value.

Table 22.6 Input/Output value of FXSCDT0 and FXSCDT1

Register	Input value	Input unit and format	Output value	Output format
FXSCDT0	Unused	—	$\cos\theta$	Depends on FXSCIOC.OF[1:0] setting: Q1.31, Q2.30, or Q3.29
FXSCDT1	Angle θ	When FXSCIOC.IUF = 0: [turn], Q1.31 When FXSCIOC.IUF = 1: [radian], Q3.29	$\sin\theta$	Same as $\cos\theta$

When Q1.31 is selected, +1.0 cannot be expressed accurately. If $\sin\theta$ or $\cos\theta$ is +1.0 ordinally when Q1.31, +1.0 - 2^{-31} will be read out from the FXSCDT0 and FXSCDT1 registers.

22.3.10 FXATDT0 : Fixed-point Arctangent hypot_k Data Register 0

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x28

Bit	Symbol	Function	R/W
31:0	FXATDT0[31:0]	Fixed-point Arctangent hypot_k Data Register 0	R/W

For the fixed-point atanhypot_k operation, the FXATDT0 register is shared for the input coordinate value x and the output value $\sqrt{x^2+y^2}/k$ of the trigonometric function unit. See Table 22.7 for detail. In terms of usage of this register, see section 22.4.7. Procedure for Trigonometric Function Operation.

Writing to this register is prohibited even during any operations.

If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

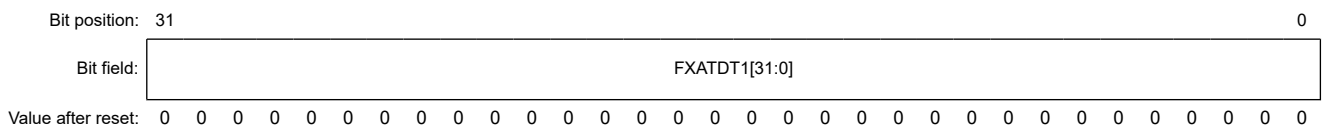
For calculations except the fixed-point atanhypot_k operation, do not access this register. If other data register 0 such as FPSCDT0, FPATDT0, and FXSCDT0 registers is written, this register value will be uncertainty.

When the DTSR0 register is written, this register value will be the same as DTSR0 register writing value.

22.3.11 FXATDT1 : Fixed-point Arctangent hypot_k Data Register 1

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x2C



Bit	Symbol	Function	R/W
31:0	FXATDT1[31:0]	Fixed-point Arctangent hypot_k Data Register 1	R/W

For the fixed-point atanhypot_k operation, the FXATDT1 register is shared for the input coordinate value y and the output value atan(y/x) of the trigonometric function unit. See Table 22.7 for detail. Writing to this register starts the fixed-point atanhypot_k operation. In terms of usage of this register, see section 22.4.7. Procedure for Trigonometric Function Operation.

Writing to this register is prohibited even during any operations.

If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

For calculations except the fixed-point atanhypot_k operation, do not access this register. If other data register 1 such as FPSCDT1, FPATDT1, and FXSCDT1 registers is written, this register value will be uncertainty.

When the DTSR1 register is written, this register value will be the same as DTSR1 register writing value.

Table 22.7 Input/Output value of FXATDT0 and FXATDT1

Register	Input value	Input format	Output value	Output unit and format
FXATDT0	Coordinates x	Q1.31	hypot_k	[—], Q3.29
FXATDT1	Coordinates y	Q1.31	atan(y/x)	When FXATIOC.OUF = 0: [turn], Q1.31 When FXATIOC.OUF = 1: [radian], Q3.29

22.3.12 DTSR0 : Data Save Restore Register 0

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x30

Bit position:	31																												0
Bit field:	DTSR0[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DTSR0[31:0]	Data Save Restore Register 0	R/W

The DTSR0 register is used to save and restore data in the data register 0 such as FPSCDT0, FPATDT0, FXSCDT0, and FXATDT0.

When read this register, the last written value into data register 0 or the result of the last arithmetic operation for data register 0 will be read.

When write to this register, the value for all data register 0 will be set to the written data of this register.

Writing to this register is prohibited during the operation.

If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

In terms of usage of this register, see section 22.4.8. Usage of Interrupt.

22.3.13 DTSR1 : Data Save Restore Register 1

Base address: TFUm = 0x9001_0000 + 0x10_0000 × m (m = 0, 1)

Offset address: 0x34

Bit position:	31																												0
Bit field:	DTSR1[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DTSR1[31:0]	Data Save Restore Register 1	R/W

The DTSR1 register is used to save and restore data in the data register 1 such as FPSCDT1, FPATDT1, FXSCDT1, and FXATDT1.

When read this register, the last written value into data register 1 or the result of the last arithmetic operation for data register 1 will be read.

When write to this register, the value for all data register 1 will be set to the written data of this register.

Writing to this register is prohibited during the operation.

If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

In terms of usage of this register, see section 22.4.8. Usage of Interrupt.

22.4 Operation

22.4.1 Arithmetic Processing

The trigonometric function unit has two arithmetic operations, the sincos operation and the atanhypot_k operation. See Table 22.8 for detail.

Table 22.8 Arithmetic processing

Operation	Input value	Output value
sincos	Angle value θ	$\cos\theta$ and $\sin\theta$
atanhypot_k	Coordinates x and y	atan(y/x) and hypot_k

The value of scaling factor k is:

$$k = \prod_{i=0}^{\infty} \frac{1}{\sqrt{1 + 2^{-2i}}} \approx 0.607252935008881256169 4$$

22.4.2 Input and Output Value Formats

The input/output value of the TFU supports single-precision floating-point and fixed-point. For the single-precision floating-point in detail, see Table 22.4 and Table 22.9. For the fixed-point in detail, see Table 22.5. As a side of note, fixed-point input/output data is in 32-bit format, but it is performed with less than 32 bits of precision.

- Floating-point
  Support single-precision floating-point specified by the IEEE754 standard.
  - Single-precision floating-point

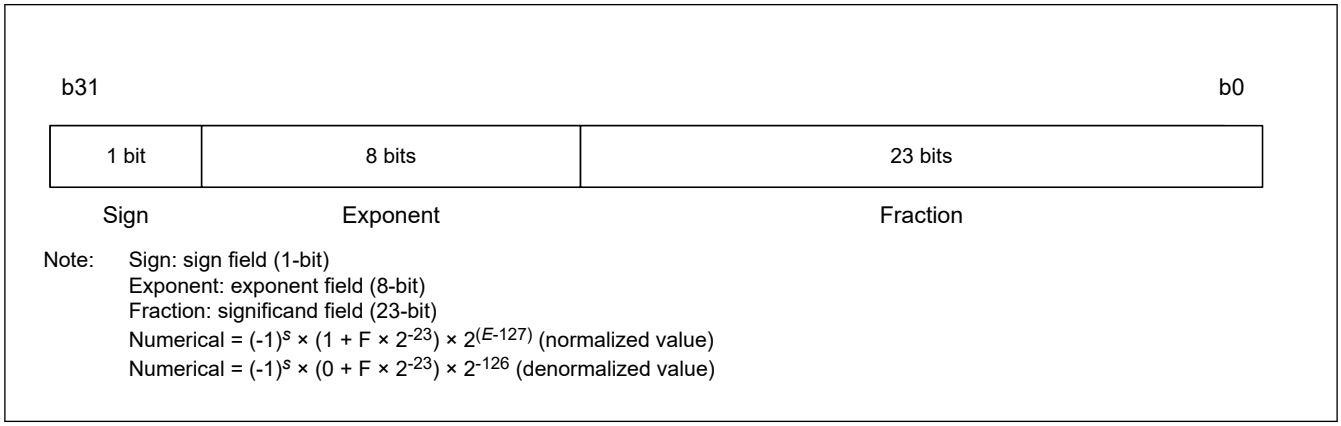


Figure 22.2 Input and output value formats

Table 22.9 Support single-precision floating-point (1 of 2)

S	E	F	Numerical
Any value	0 < E < 255	Any value	$(-1)^s \times 1.F \times 2^{(E-127)}$ (normalized value — Normal Numbers)
Any value	E = 0	F > 0	$(-1)^s \times 0.F \times 2^{-126}$ (denormalized value — Subnormal Numbers)

Table 22.9 Support single-precision floating-point (2 of 2)

S	E	F	Numerical
S = 0	E = 0	F = 0	$(-1)^0 \times 0.0$ (positive zero — +0)
S = 1	E = 0	F = 0	$(-1)^{-1} \times 0.0$ (negative zero — -0)
S = 0	E = 255	F = 0	(positive infinity — +∞)
S = 1	E = 255	F = 0	(negative infinity — -∞)
Any value	E = 255	$2^{22} > F > 0$	(non-number — SNaN: Signaling Not a Number)
Any value	E = 255	$F \geq 2^{22}$	(non-number — QNaN: Quiet Not a Number)

- Fixed-point
  Format of two's complement representation shown in Figure 22.3 is used.

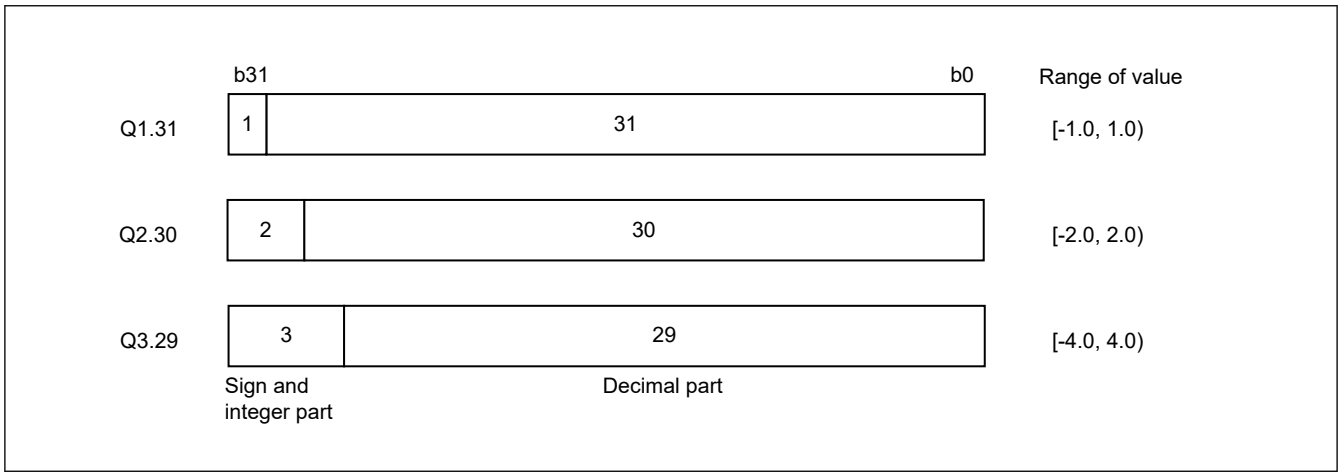

Figure 22.3 Fixed-point

22.4.3 Angle Unit

The units of angle used in the TFU are radian and turn. The radian is one rotation expressed as 0 to 2π. The turn is one rotation expressed as 0 to 1.

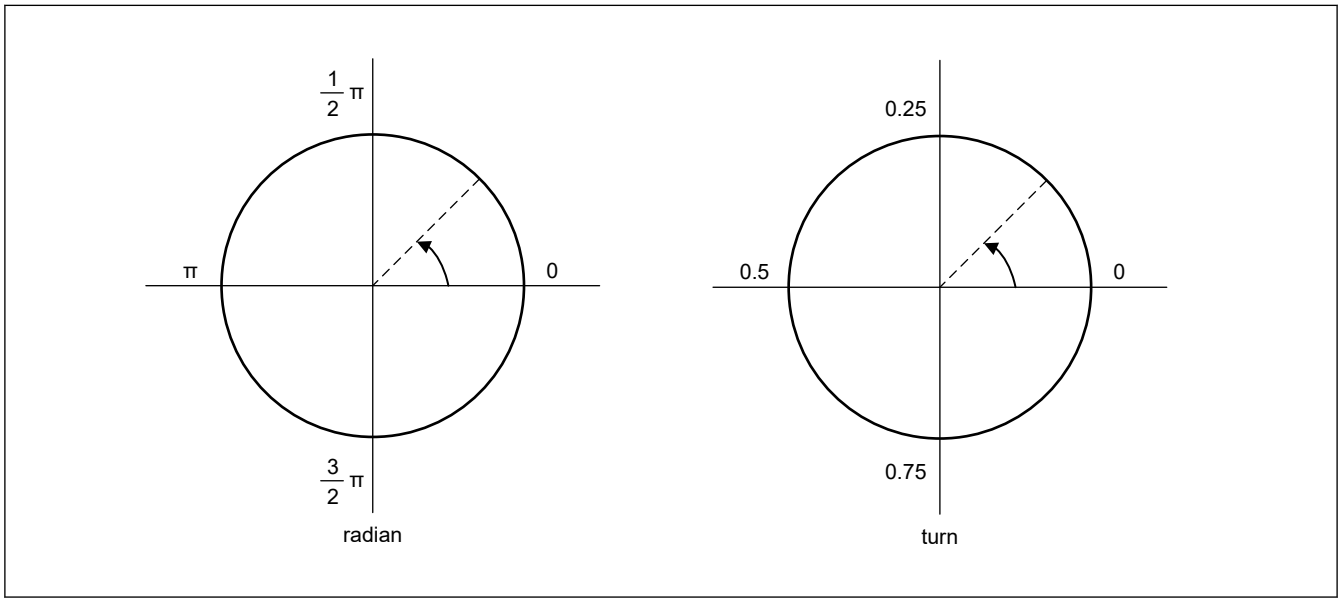

Figure 22.4 Angle unit

22.4.4 Relationship Between Input and Output Values for Sincos Operation

When the input values in the floating-point sincos operation are ±0, ±∞, SNaN (Signaling Not a Number), and QNaN (Quiet Not a Number), a fixed value is output as shown in Table 22.10.

Table 22.10 Relationship between special input value and its output value (for floating-point sincos operation)

Input (θ)	Output ($\cos\theta$)	Output ($\sin\theta$)
-∞	QNaN	QNaN
-0	+1	-0
+0	+1	+0
+∞	QNaN	QNaN
SNaN/QNaN	QNaN	QNaN

Note: The output value of QNaN is 0xFFC0_0000.

22.4.5 Relationship Between Input and Output Values for Atan Operation

When either the input values x or y in the floating-point atan operation are ±0, ±∞, SNaN (Signaling Not a Number), and QNaN (Quiet Not a Number), a fixed value is output as shown in Table 22.11.

If both input values are ±0, it is determined as an input error.

Table 22.11 Relationship between special input value and its output value (for floating-point atan operation)

		x						
		-∞	Negative value	-0	+0	Positive value	+∞	SNaN/QNaN
y	-∞	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN
	Negative value	QNaN	—	-π/2	-π/2	—	QNaN	QNaN
	-0	QNaN	-π	QNaN*1	QNaN*1	-0	QNaN	QNaN
	+0	QNaN	+π	QNaN*1	QNaN*1	+0	QNaN	QNaN
	Positive value	QNaN	—	+π/2	+π/2	—	QNaN	QNaN
	+∞	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN
	SNaN/QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN

Note 1. An input error occurs for the special input value, and the input error flag (TRGSTS.ERRF) is set.

For fixed-point atan operation, when both x and y input values are 0, it is determined as an input error. When an input error happens, output value of atan operation is 0.

22.4.6 Relationship Between Input and Output Values for hypot_k Operation

When either the input values x or y in the floating-point hypot_k operation are ±0, ±∞, SNaN (Signaling Not a Number), and QNaN (Quiet Not a Number), or when both x and y are ± 0, a fixed value is output as shown in Table 22.12.

If both input values are ±0, it is determined as an input error.

Table 22.12 Relationship between special input value and its output value (for floating-point hypot_k operation)

		x						
		-∞	**Negative value**	**-0**	**+0**	**Positive value**	**+∞**	**SNaN/QNaN**
y	**-∞**	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN
	Negative value	QNaN	—	—	—	—	QNaN	QNaN
	-0	QNaN	—	+0[*1]	+0[*1]	—	QNaN	QNaN
	+0	QNaN	—	+0[*1]	+0[*1]	—	QNaN	QNaN
	Positive value	QNaN	—	—	—	—	QNaN	QNaN
	+∞	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN
	SNaN/QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN

Note 1. An input error occurs for the special input value, and the input error flag (TRGSTS.ERRF) is set.

For fixed-point hypot_k operation, when both x and y input values are 0, it is determined as an input error. Because atan operation becomes error, although it is no problem for hypot_k operation. When an input error happens, output value of hypot_k is 0.

22.4.7 Procedure for Trigonometric Function Operation

Figure 22.5 shows the procedure for sincos operation. There are two procedures. The advantages and disadvantages of each are shown in Table 22.13. For floating-point sincos operation, replace SCDTn in the figure with FPSCDTn. And for fixed-point sincos operation, replace with FXSCDTn. (n = 0 or 1)

Figure 22.6 shows the procedure for atanhypot_k operation. There are two procedures. The advantages and disadvantages of each are shown in Table 22.13. For floating-point atanhypot_k operation, replace ATDTn in the figure with FPATDTn. And for fixed-point atanhypot_k operation, replace with FXATDTn. (n = 0 or 1)

Table 22.13 Advantages and disadvantages of sincos and atanhypot_k operations

Method	Advantages	Disadvantages
Procedure 1	Not occupy the bus.	Operation end determination is required by checking TRGSTS.BSYF.
Procedure 2	Operation end determination is not required by checking TRGSTS.BSYF. (reduced number of execution cycles)	Occupy the bus while waiting for the number of execution cycles when the result of the operation is read.

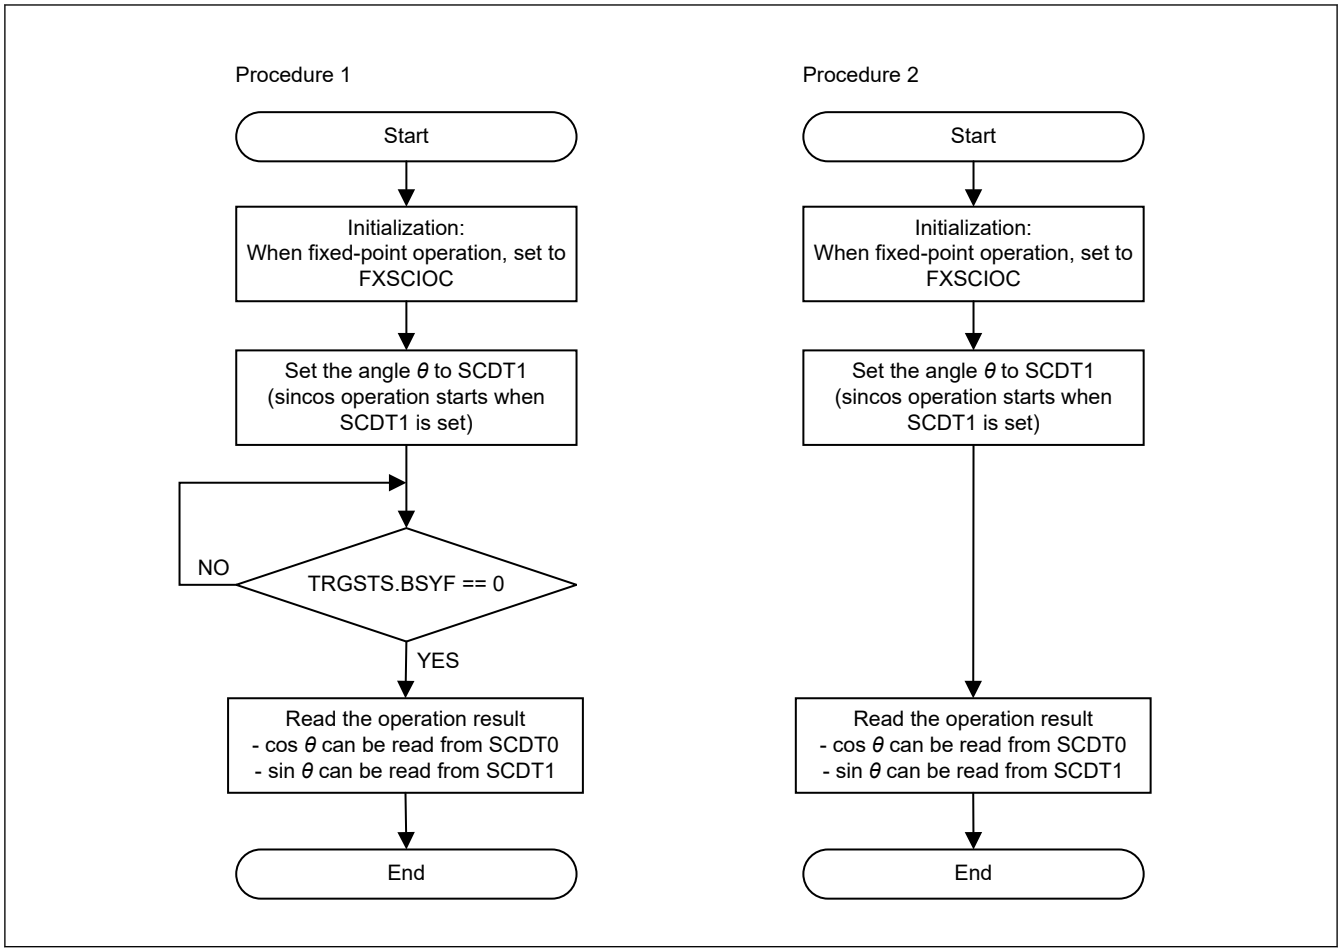

Figure 22.5 Procedure for using TFU (sincos operation)

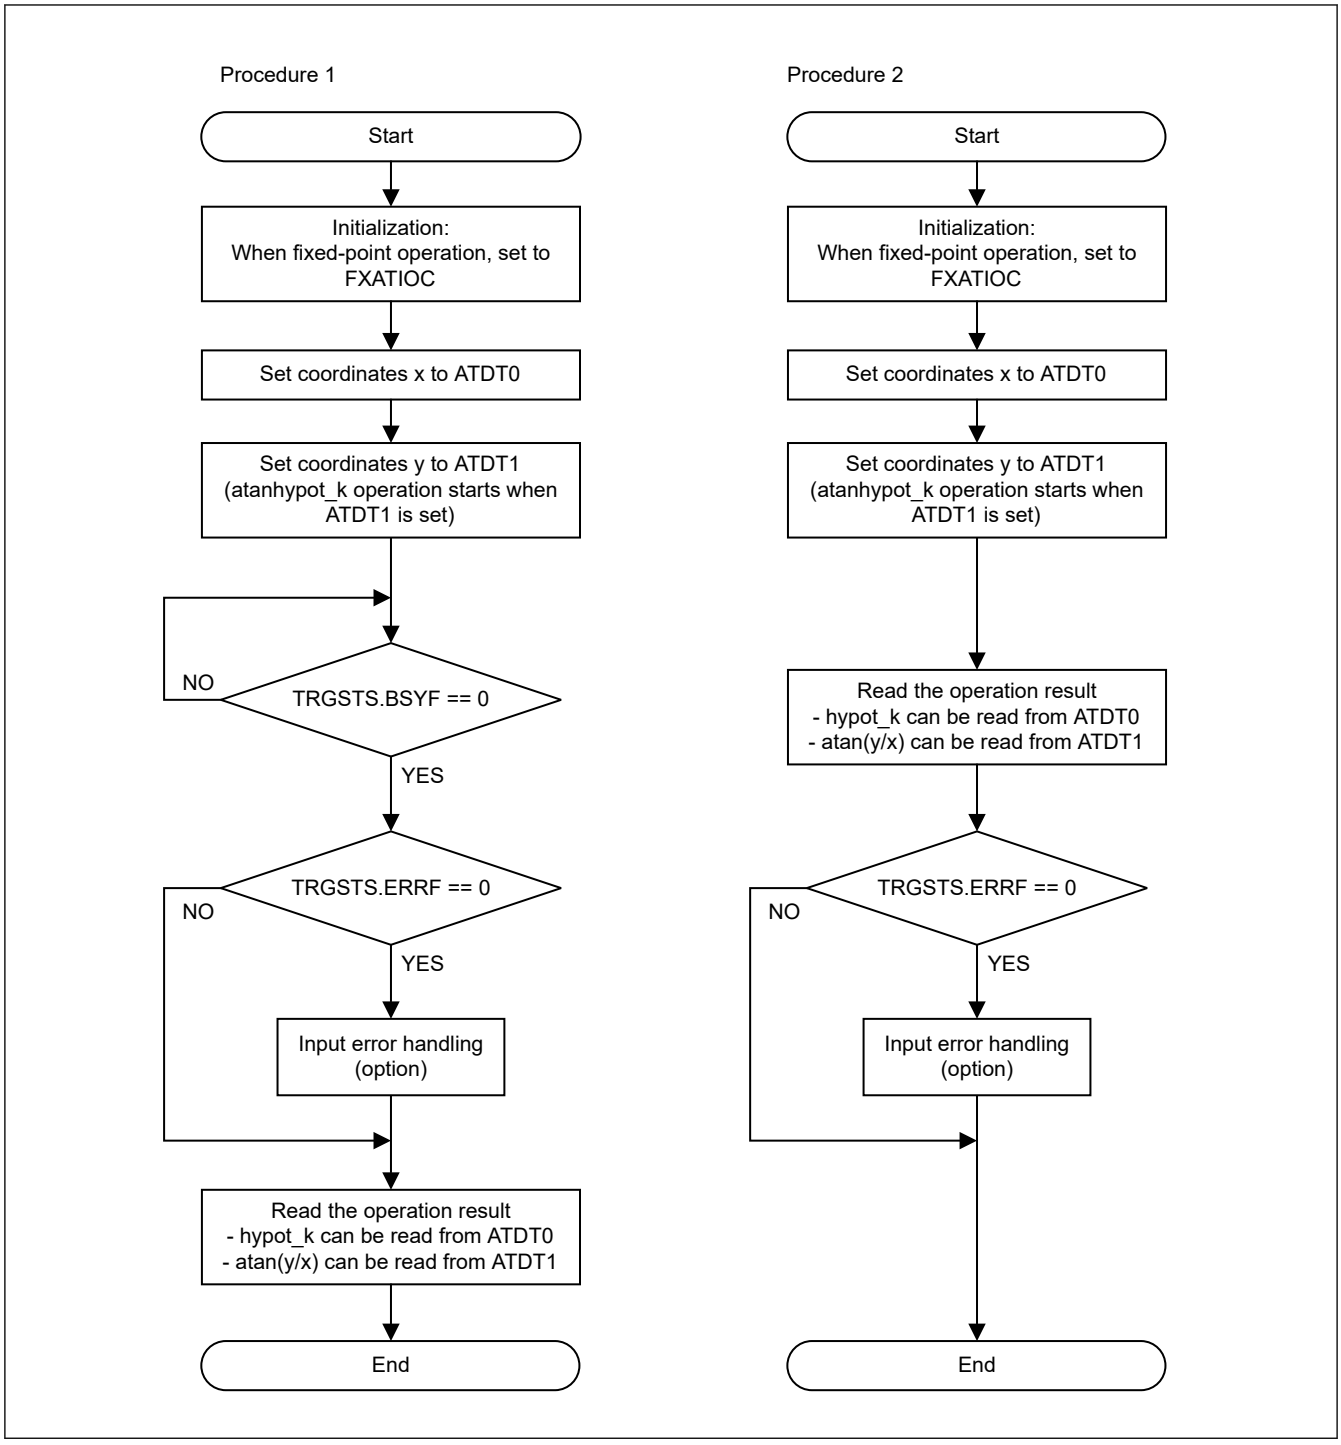

Figure 22.6 Procedure for using TFU (atanhypot_k operation)

22.4.8 Usage of Interrupt

In the middle of procedure for trigonometric function operation, when an interrupt occurs between a data register write and an error flag/data register read and trigonometric function operation is executed in the interrupt handler, malfunction occurs after returning from the interrupt handler.

Therefore, the following measures are required so that malfunction does not occur when multiple interrupts are used, and multiple interrupt handlers use TFU module.

1. Disable interrupts on the process from a data register write to an error flag and data register read
2. Save and restore an error flag and data registers in an interrupt handler

The latter measure is described as below.

Regardless of a kind of an operation in the interrupt handler and an operation being performed before the interrupt is received, data registers and error flag should be saved/restored by using DTSR0, DTSR1, and TRGSTS registers. Figure 22.7 shows the data save/restore procedure. By following this procedure, the operation before the interrupt is received can be continued without malfunction after returning from the interrupt handler.

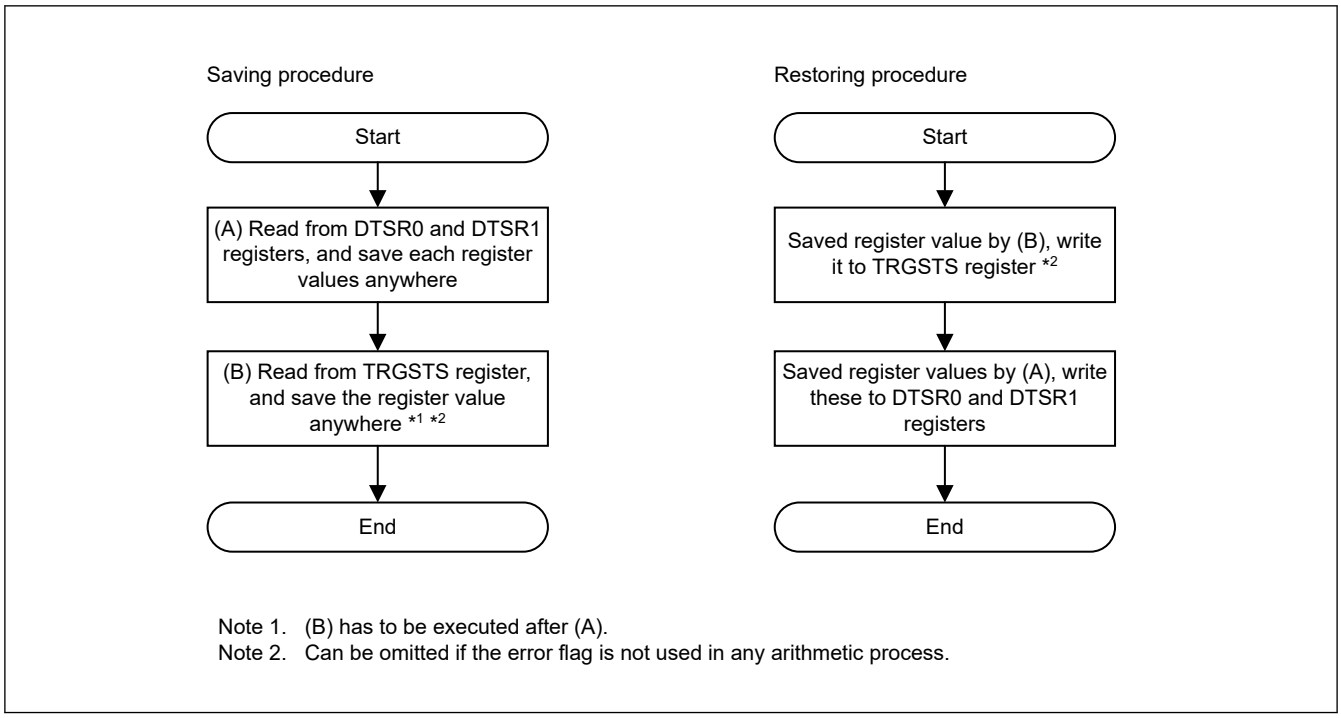

Figure 22.7 Data save/restore procedure in exception handler

When a setting will be changed in the interrupt handler and an arithmetic processing will be performed, in addition to the data registers and error flag, setting registers such as FXSCIOC and FXATIOC need to be saved and restored as well. Save and restore the setting registers as necessary. When saving the setting registers, be sure to do so after saving (A).

23. Compare Match Timer (CMT)

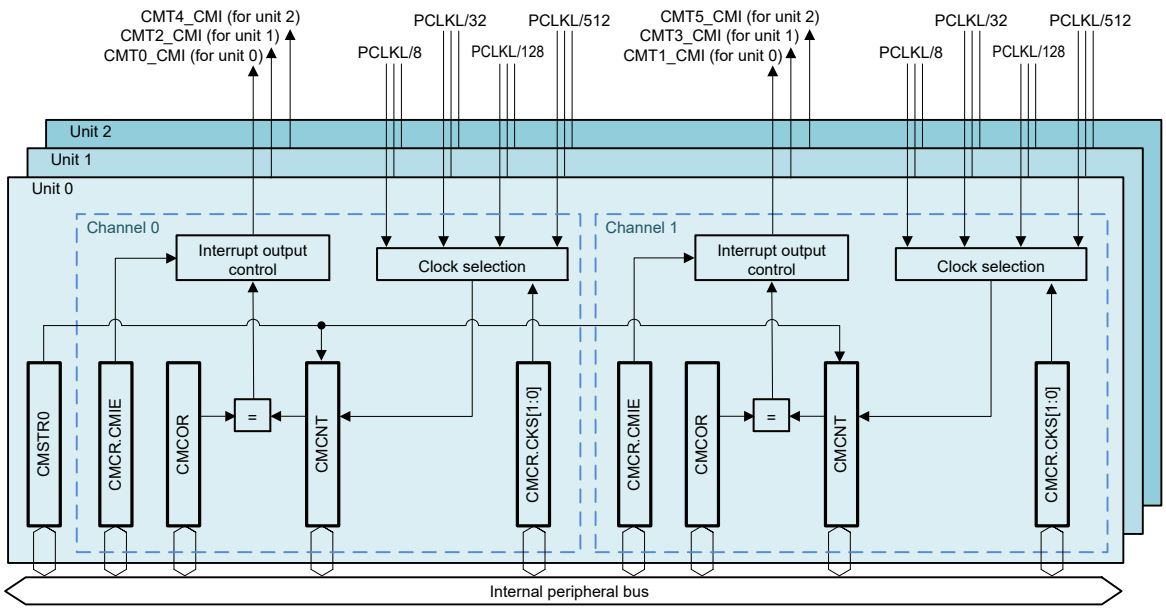
23.1 Overview

The LSI has three on-chip compare match timer (CMT) units, each consisting of a 2-channel 16-bit timer, for a total of six channels. The CMT has a 16-bit counter and can generate interrupts at set intervals.

Table 23.1 lists the specifications for the CMT and Figure 23.1 shows a block diagram of the CMT.

Table 23.1 CMT specifications

Item	Description
Number of internal channels	6 channels (2 channels × 3 units)
Timer counter (per channel)	16-bit up counter (counted according to the count enable signal output by the prescaler.) Returned to 0x0000 after compare match.
Prescaler (per channel)	9-bit counter (linked with enabling/disabling of timer counter operation.) ● Outputs four types of count clocks. The type can be selected from PCLKL/8, PCLKL/32, PCLKL/128, and PCLKL/512.
Interrupt	A compare match interrupt can be requested for each channel.
Module-stop function	Module-stop state can be set to reduce power consumption



CMSTRn: Compare match timer start register (n = 0, 2, 4)
CMCR: Compare match timer control register
CMCOR: Compare match timer constant register
CMCNT: Compare match timer counter register

23.3 Register Descriptions

23.3.1 CMSTRn : Compare Match Timer Start Register (n = 0, 2, 4)

Base address: CMTC = 0x8008_0000

Offset address: 0x000 + 0x200 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STR1	STR0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STR0	CMT Channel n Count Start This bit selects starting or stopping of the CMTn.CMCNT counter operation. The corresponding prescaler starts or stops according to the setting of this bit. 0: The CMTn.CMCNT counter is stopped. 1: The CMTn.CMCNT counter is started.	R/W
1	STR1	CMT Channel n+1 Count Start This bit selects starting or stopping of the CMTn+1.CMCNT counter operation. The corresponding prescaler starts or stops according to the setting of this bit. 0: The CMTn+1.CMCNT counter is stopped. 1: The CMTn+1.CMCNT counter is started.	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W

The CMSTR0 register sets starting or stopping of the CMT0.CMCNT and CMT1.CMCNT counters of unit 0.

The CMSTR2 register sets starting or stopping of the CMT2.CMCNT and CMT3.CMCNT counters of unit 1.

The CMSTR4 register sets starting or stopping of the CMT4.CMCNT and CMT5.CMCNT counters of unit 2.

23.3.2 CMCR : Compare Match Timer Control Register

Base address: CMT0 = 0x8008_0002, CMT2 = 0x8008_0402, CMT4 = 0x8008_0802
CMT1 = 0x8008_0008, CMT3 = 0x8008_0408, CMT5 = 0x8008_0808

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	CMIE	—	—	—	—	CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	x	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CKS[1:0]	Clock Select 0 0: PCLKL/8 0 1: PCLKL/32 1 0: PCLKL/128 1 1: PCLKL/512	R/W
5:2	—	These bits are read as 0. The write value should be 0.	R/W
6	CMIE	Compare Match Interrupt Enable 0: Compare match interrupt (CMTn_CMI) disabled 1: Compare match interrupt (CMTn_CMI) enabled	R/W
7	—	The read value is undefined. The write value should be 0.	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W

The CMCR register specifies a clock used for count-up operation.

CKS[1:0] bits (Clock Select)

These bits select a clock to be input to the CMTn.CMCNT counter from the internal clocks obtained by dividing the frequency of the low-speed peripheral module clock (PCLKL) (n = 0 to 5). Setting the CMSTRm.STRn bit to 1 starts count-up operation of the corresponding CMCNT counter by using the clock selected in the CKS[1:0] bits (m = 0, 2, 4; n = 0, 1).

CMIE bit (Compare Match Interrupt Enable)

This bit selects whether to enable or disable generation of a compare match interrupt (CMTn_CMI) when the values in the CMCNT counter and in the CMCOR register match (n = 0 to 5).

23.3.3 CMCNT : Compare Match Timer Counter Register

Base address: CMT0 = 0x8008_0002, CMT2 = 0x8008_0402, CMT4 = 0x8008_0802
CMT1 = 0x8008_0008, CMT3 = 0x8008_0408, CMT5 = 0x8008_0808

Offset address: 0x002

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CMCNT counter (the main unit of the compare match timer) is a readable/writable up-counter. When an internal clock is selected by the CMCR.CKS[1:0] bits and the CMSTRm.STRn (m = 0, 2, 4; n = 0, 1) bit is set to 1, the CMCNT counter starts counting up using the selected clock.

When the value in the CMCNT counter and the value in the CMCOR register match, the CMCNT counter is cleared to 0x0000. At the same time, a compare match interrupt (CMTn_CMI) is generated (n = 0 to 5).

23.3.4 CMCOR : Compare Match Timer Constant Register

Base address: CMT0 = 0x8008_0002, CMT2 = 0x8008_0402, CMT4 = 0x8008_0802
CMT1 = 0x8008_0008, CMT3 = 0x8008_0408, CMT5 = 0x8008_0808

Offset address: 0x004

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The CMCOR register is a readable/writable register to set a cycle for compare match with the CMCNT counter. The cycle for compare matches is as follows:

Compare-match cycle = (setting of the CMCOR register + 1) × counter-clock cycle*1

Note 1. This is a clock cycle set by the CMCR.CKS[1:0] bits.

23.4 Operation

23.4.1 Periodic Count Operation

When an internal clock is selected by the CMCR.CKS[1:0] bits and the CMSTRm.STRn (m = 0, 2, 4; n = 0, 1) bit is set to 1, the CMCNT counter starts counting up using the selected clock.

When the value in the CMCNT counter and the value in the CMCOR register match, the CMCNT counter is cleared to 0x0000, and then a compare match interrupt (CMTn_CMI) is generated (n = 0 to 5). The CMCNT counter then starts counting up again from 0x0000. Figure 23.2 shows the operation of the CMCNT counter.

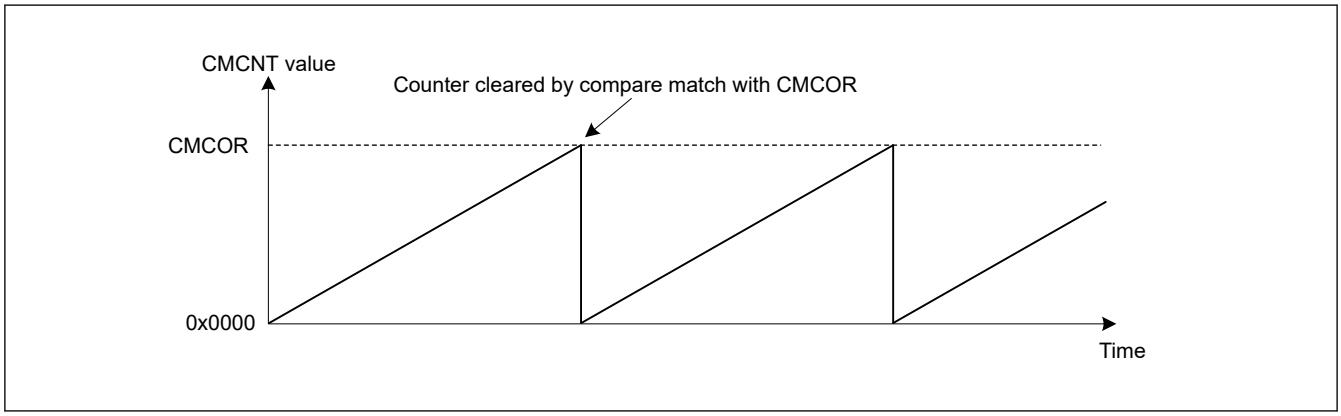

Figure 23.2 Counter operation

23.4.2 CMCNT Count Timing

As the count clock, one of four internal clocks (PCLKL/8, PCLKL/32, PCLKL/128, and PCLKL/512) obtained by dividing the low-speed peripheral module clock (PCLKL) can be selected with the CMCR.CKS[1:0] bits. Figure 23.3 shows the timing of the CMCNT counter.

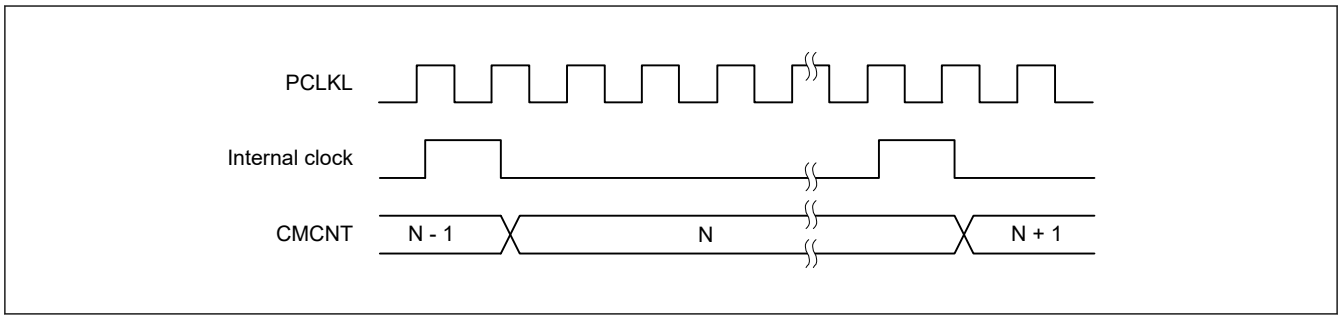

Figure 23.3 CMCNT count timing

23.5 Interrupts

23.5.1 Interrupt Sources

For each CMT channel, a compare-match interrupt (CMTn_CMI) is allocated and has a different event number. The priority of channels can be changed by the interrupt controller settings.

Table 23.4 CMT interrupt sources (1 of 2)

Name	Interrupt Sources	CPU0 GIC request	CPU1 GIC request	DMAC activation
CMT0_CMI	Compare match between the CMT0.CMCNT counter and CMT0.CMCOR register	Possible	Possible	Possible

Table 23.4 CMT interrupt sources (2 of 2)

Name	Interrupt Sources	CPU0 GIC request	CPU1 GIC request	DMAC activation
CMT1_CMI	Compare match between the CMT1.CMCNT counter and CMT1.CMCOR register	Possible	Possible	Possible
CMT2_CMI	Compare match between the CMT2.CMCNT counter and CMT2.CMCOR register	Possible	Possible	Possible
CMT3_CMI	Compare match between the CMT3.CMCNT counter and CMT3.CMCOR register	Possible	Possible	Possible
CMT4_CMI	Compare match between the CMT4.CMCNT counter and CMT4.CMCOR register	Possible	Possible	Possible
CMT5_CMI	Compare match between the CMT5.CMCNT counter and CMT5.CMCOR register	Possible	Possible	Possible

23.5.2 Timing of Compare Match Interrupt Generation

When the CMCNT counter and the CMCOR register match, a compare match interrupt (CMTn_CMI) is generated.

A compare match signal is generated at the last state in which the values match (the timing when the CMCNT counter updates the matched count value). That is, after a match between the CMCOR register and the CMCNT counter, the compare match signal is not generated until the CMCNT counter input clock is generated (n = 0 to 5).

Figure 23.4 shows the timing of a compare match interrupt.

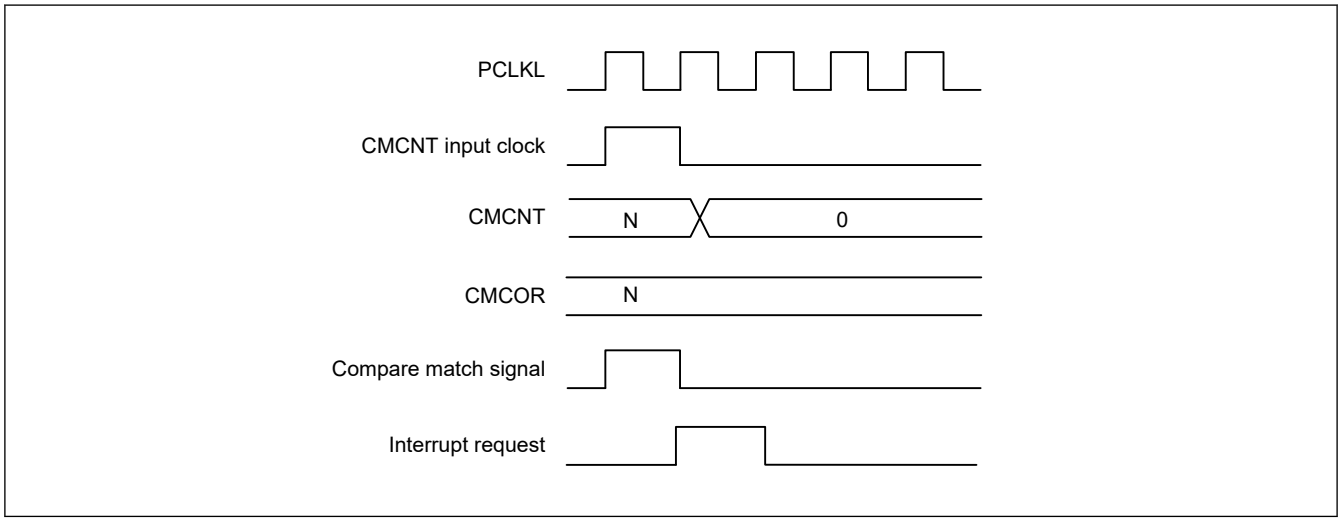

Figure 23.4 Timing a compare match interrupt is set

23.6 Usage Notes

23.6.1 Setting the Module Stop Function

The CMT can be enabled or disabled using the Module Stop Control register. After a reset, the CMT is in the module-stop state. The registers can be accessed by canceling the module-stop state. For details, see section 9, Low-Power Consumption Function.

23.6.2 Conflict between Write and Compare-Match Processes of CMCNT

When the compare match signal is generated while writing to the CMCNT counter, clearing the CMCNT counter is given priority over the writing to it. In this case, the CMCNT counter is not written to. Figure 23.5 shows the timing to clear the CMCNT counter.

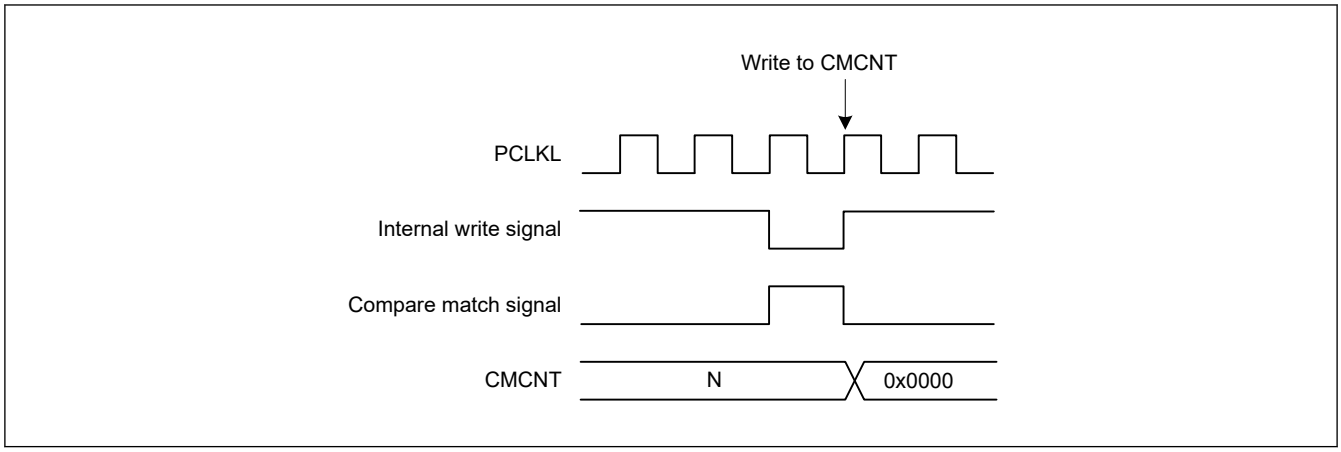

Figure 23.5 Conflict between write and compare match processes of CMCNT

23.6.3 Conflict between Write and Count-Up Processes of CMCNT

If count-up occurs during the write access to the CMCNT counter, that writing has priority over the count-up. Figure 23.6 shows the timing to write the CMCNT counter.

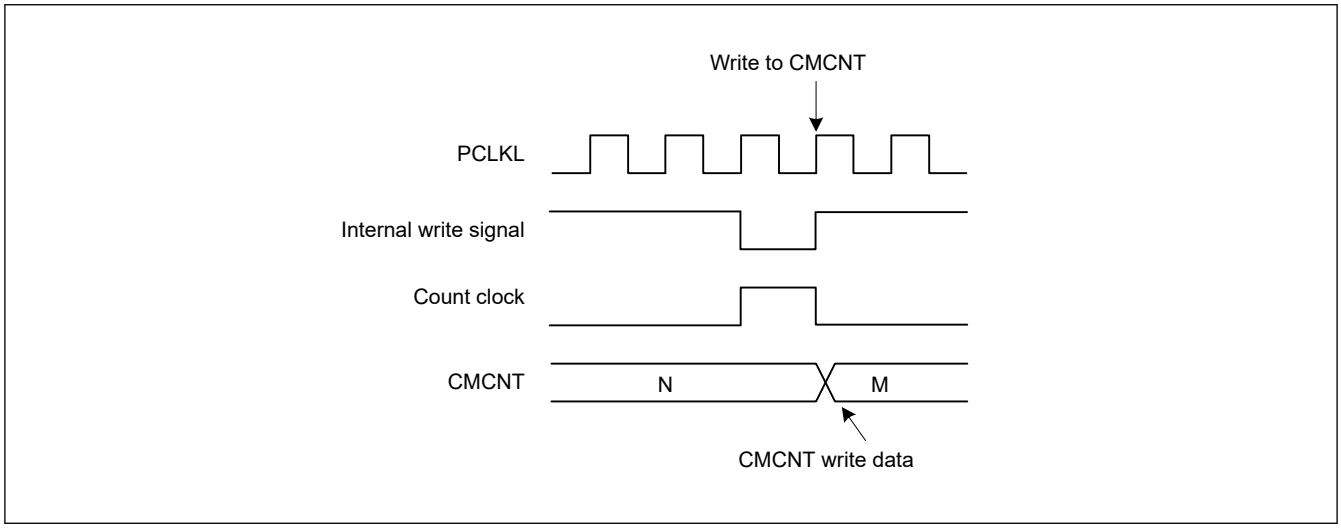

Figure 23.6 Conflict between write and count-up processes of CMCNT

24. Compare Match Timer W (CMTW)

24.1 Overview

The LSI has two channels (1 channel × 2 units) of 32-bit compare match timer W (CMTW). CMTW has a 32-bit counter and can generate interrupts each time a set period elapses.

Table 24.1 shows the specifications of the CMTW and Figure 24.1 shows a block diagram of the CMTW.

Table 24.1 CMTW specifications

Item	Description
Number of channel	Two channels (1 channel × 2 units)
Timer counter	16-bit/32-bit selectable up-counter. The counter returns to 0x00000000 after a compare match.
Prescaler	Four dividing clocks are output. Selectable from any of PCLKL/8, PCLKL/32, PCLKL/128, or PCLKL/512.
Input capture	Up to two input capture input signals available per unit
Output compare	Up to two output compare output signals available per unit
Compare match	One compare match available (no output compare output pin used)
Interrupt	Compare match interrupt Input capture 0 and 1 interrupts per unit Output compare 0 and 1 interrupts per unit
Module-stop function	Module-stop state can be set to reduce power consumption

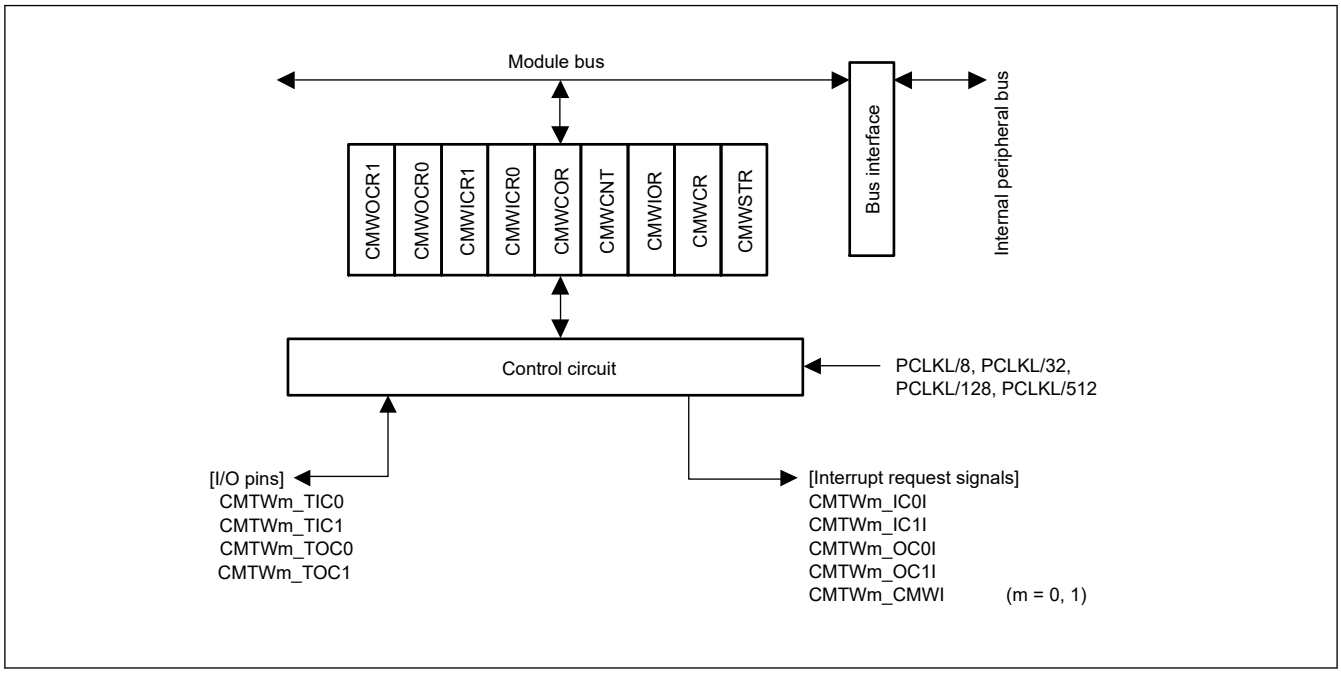

Figure 24.1 Block diagram of CMTW (units 0 to 1)

Table 24.2 shows the CMTW pin configuration.

Table 24.2 Input/Output pins of CMTW

Unit	Pin name	I/O	Description
CMTWm (m = 0, 1)	CMTWm_TIC0	Input	CMTWm input capture input 0
	CMTWm_TIC1	Input	CMTWm input capture input 1
	CMTWm_TOC0	Output	CMTWm output compare output 0
	CMTWm_TOC1	Output	CMTWm output compare output 1

Note: For convention, pin names within this chapter are written without "CMTWm_" (m = 0, 1) notation except this table and the block diagram.

24.2 Register Map

Table 24.3 CMTW register map

Address	Register symbol	Register name	Write protection

24.3 Register Descriptions

24.3.1 CMWSTR : Timer Start Register

Base address: CMTWm = 0x8008_1000 + 0x0400 × m (m = 0, 1)

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STR	Counter Start 0: The CMWCNT counter stops counting. The value immediately before a stop of counting is retained and counting is stopped. 1: The CMWCNT counter starts counting.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

The CMWSTR register is used to start or stop the CMWCNT counter.

STR bit (Counter Start)

Specifies whether the timer counter operates or is stopped. The relevant prescaler operates or is stopped according to the settings of STR bit.

24.3.2 CMWCR : Timer Control Register

Base address: CMTWm = 0x8008_1000 + 0x0400 × m (m = 0, 1)

Offset address: 0x004

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CCLR[2:0]			—	—	—	CMS	—	OC1IE	OC0IE	IC1IE	IC0IE	CMWIE	—	CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CKS[1:0]	Clock Select 0 0: PCLKL/8 0 1: PCLKL/32 1 0: PCLKL/128 1 1: PCLKL/512	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CMWIE	Compare Match Interrupt Enable 0: Disables a compare match interrupt request (CMTWm_CMWI). 1: Enables a compare match interrupt request (CMTWm_CMWI).	R/W
4	IC0IE	Input Capture 0 Interrupt Enable 0: Disables an interrupt request by the input capture 0 (CMTWm_IC0I). 1: Enables an interrupt request by the input capture 0 (CMTWm_IC0I).	R/W
5	IC1IE	Input Capture 1 Interrupt Enable 0: Disables an interrupt request by the input capture 1 (CMTWm_IC1I). 1: Enables an interrupt request by the input capture 1 (CMTWm_IC1I).	R/W
6	OC0IE	Output Compare 0 Interrupt Enable 0: Disables an interrupt request by the output compare 0 (CMTWm_OC0I). 1: Enables an interrupt request by the output compare 0 (CMTWm_OC0I).	R/W
7	OC1IE	Output Compare 1 Interrupt Enable 0: Disables an interrupt request by the output compare 1 (CMTWm_OC1I). 1: Enables an interrupt request by the output compare 1 (CMTWm_OC1I).	R/W
8	—	This bit is read as 0. The write value should be 0.	R/W
9	CMS	Timer Counter Size 0: 32 bits 1: 16 bits	R/W
12:10	—	These bits are read as 0. The write value should be 0.	R/W
15:13	CCLR[2:0]	Counter Clear 0 0 0: The CMWCNT counter is cleared by CMWCOR register compare match. 0 0 1: The CMWCNT counter is not cleared. 0 1 0: The CMWCNT counter is not cleared. 0 1 1: The CMWCNT counter is not cleared. 1 0 0: The CMWCNT counter is cleared by CMWICR0 register input capture. 1 0 1: The CMWCNT counter is cleared by CMWICR1 register input capture. 1 1 0: The CMWCNT counter is cleared by CMWOCR0 register compare match. 1 1 1: The CMWCNT counter is cleared by CMWOCR1 register compare match.	R/W

The CMWCR register selects the counter clearing source and the counter input clock, and enables or disables interrupts.

The CMWCR register should be set while the timer counter (CMWCNT) operation is stopped.

CKS[1:0] bits (Clock Select)

Select the clock to be input to the CMWCNT counter among four internal clocks obtained by dividing the peripheral clock (PCLKL). When the CMWSTR.STR bit is set to 1, the CMWCNT counter starts counting up based on the clock selected with the CMWCR.CKS[1:0] bits.

CMWIE bit (Compare Match Interrupt Enable)

Enables or disables compare match interrupt (CMTWm_CMWI) request generation when the CMWCNT counter and CMWCOR register values match.

IC0IE bit (Input Capture 0 Interrupt Enable)

Enables or disables input capture interrupt 0 (CMWm_IC0I) request generation when input capture is generated in the CMWICR0 register.

IC1IE bit (Input Capture 1 Interrupt Enable)

Enables or disables input capture interrupt 1 (CMWm_IC1I) request generation when input capture is generated in the CMWICR1 register.

OC0IE bit (Output Compare 0 Interrupt Enable)

Enables or disables compare match interrupt 0 (CMWm_OC0I) request generation when the CMWCNT counter and CMWOCR0 register values match.

OC1IE bit (Output Compare 1 Interrupt Enable)

Enables or disables compare match interrupt 1 (CMWm_OC1I) request generation when the CMWCNT counter and CMWOCR1 register values match.

CMS bit (Timer Counter Size)

Selects either 16 or 32 bits as the size of the timer counter (CMWCNT). The size selected with the CMS bit is valid in the compare match constant register (CMWCOR), input capture registers (CMWICR0 and CMWICR1), and output compare registers (CMWOCR0 and CMWOCR1).

CCLR[2:0] bits (Counter Clear)

Selects the CMWCNT counter clearing source.

24.3.3 CMWIOR : Timer I/O Control Register

Base address: CMTWm = 0x8008_1000 + 0x0400 × m (m = 0, 1)

Offset address: 0x008

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMWE	—	OC1E	OC0E	OC1[1:0]		OC0[1:0]		—	—	IC1E	IC0E	IC1[1:0]		IC0[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	IC0[1:0]	Input Capture Control 0 0 0: Input capture at the rising edge on the TIC0 pin. 0 1: Input capture at the falling edge on the TIC0 pin. 1 0: Input capture at both edges on the TIC0 pin. 1 1: Setting prohibited	R/W
3:2	IC1[1:0]	Input Capture Control 1 0 0: Input capture at the rising edge on the TIC1 pin. 0 1: Input capture at the falling edge on the TIC1 pin. 1 0: Input capture at both edges on the TIC1 pin. 1 1: Setting prohibited	R/W
4	IC0E	Input Capture Enable 0 0: Disables the input capture operation of the CMWICR0 register. 1: Enables the input capture operation of the CMWICR0 register.	R/W
5	IC1E	Input Capture Enable 1 0: Disables the input capture operation of the CMWICR1 register. 1: Enables the input capture operation of the CMWICR1 register.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
9:8	OC0[1:0]	Output Compare Control 0 0 0: Retains the output value.*1 0 1: Initially outputs 0 and toggles the output value upon compare match. 1 0: Initially outputs 1 and toggles the output value upon compare match. 1 1: Setting prohibited	R/W
11:10	OC1[1:0]	Output Compare Control 1 0 0: Retains the output value.*1 0 1: Initially outputs 0 and toggles the output value upon compare match. 1 0: Initially outputs 1 and toggles the output value upon compare match. 1 1: Setting prohibited	R/W
12	OC0E	Compare Match Enable 0 0: Disables the compare match operation using the CMWOCR0 register. 1: Enables the compare match operation using the CMWOCR0 register.	R/W
13	OC1E	Compare Match Enable 1 0: Disables the compare match operation using the CMWOCR1 register. 1: Enables the compare match operation using the CMWOCR1 register.	R/W
14	—	This bit is read as 0. The write value should be 0.	R/W
15	CMWE	Compare Match Enable 0: Disables the compare match operation using the CMWCOR register. 1: Enables the compare match operation using the CMWCOR register.	R/W

Note 1. After reset, 0 is output until the CMWIOR register is set.

The CMWIOR register controls the CMWCOR, CMWICR0, CMWICR1, CMWOCR0, and CMWOCR1 registers.

CMWIOR should be set while the timer counter (CMWCNT) operation is stopped.

IC0[1:0] bits (Input Capture Control 0)

Selects the input capture operation of the CMWICR0 register.

IC1[1:0] bits (Input Capture Control 1)

Selects the input capture operation of the CMWICR1 register.

IC0E bit (Input Capture Enable 0)

Enables or disables the input capture operation of the CMWICR0 register.

IC1E bit (Input Capture Enable 1)

Enables or disables the input capture operation of the CMWICR1 register.

OC0[1:0] bits (Output Compare Control 0)

Sets the output compare operation using the CMWOCR0 register.

OC1[1:0] bits (Output Compare Control 1)

Sets the output compare operation using the CMWOCR1 register.

OC0E bit (Compare Match Enable 0)

Enables or disables the compare match operation using the CMWOCR0 register.

OC1E bit (Compare Match Enable 1)

Enables or disables the compare match operation using the CMWOCR1 register.

CMWE bit (Compare Match Enable)

Enables or disables the compare match operation using the CMWCOR register.

24.3.4 CMWCNT : Timer Counter

Base address: CMTWm = 0x8008_1000 + 0x0400 × m (m = 0, 1)

Offset address: 0x010

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Timer Counter	R/W

The CMWCNT counter is used as a readable/writable up-counter.

Before starting counter operation, the timer control register (CMWCR) should be set. When the 16-bit counter size is selected with the CMS bit in the timer control register (CMWCR), bits 15 to 0 in the CMWCNT counter are valid. Since access to this register is in 32-bit units, when writing, write 32-bit values to it with 0x0000 in the higher-order bits. If a value other than 0x0000 is set in the higher-order bits, a value greater than 0x0000FFFF may be read when this register is read.

When the STR bit is set to 1, the CMWCNT counter starts counting. When the STR bit is set to 0, the CMWCNT counter retains the value immediately before a stop of counting and stops counting.

24.3.5 CMWCOR : Compare Match Constant Register

Base address: CMTWm = 0x8008_1000 + 0x0400 × m (m = 0, 1)

Offset address: 0x014

Bit position:	31																												0
Bit field:																													
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
31:0	n/a	The CMWCOR register is a readable/writable register that specifies the time up to a compare match between the timer counter (CMWCNT) value and CMWCOR value. When the 16-bit counter size is selected with the CMS bit in the timer control register (CMWCR), bit 15 to bit 0 in this register are valid. Since access to this register is in 32-bit units, when writing, write 32-bit values to it with 0x0000 in the higher-order bits.	R/W

The cycle for compare matches is as follows:

Compare-match cycle = (setting of the CMWCOR register + 1) × counter-clock cycle[*1]

Note 1. This is a clock cycle set by the CMWCR.CKS[1:0] bits.

24.3.6 CMWICRn : Input Capture Registers (n = 0, 1)

Base address: CMTWm = 0x8008_1000 + 0x0400 × m (m = 0, 1)

Offset address: 0x018 + 0x004 × n

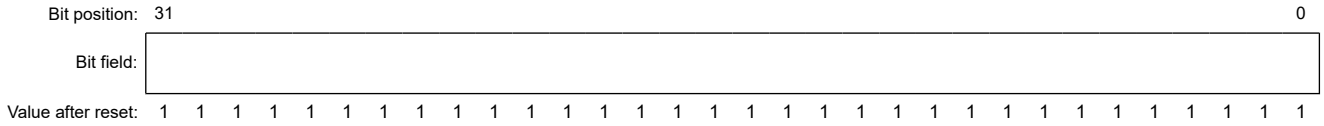
Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	The CMWICR0 and CMWICR1 registers are read-only registers in which the CMWCNT counter value is stored when an input capture is generated. When the 16-bit counter size is selected with the CMS bit in the timer control register (CMWCR), bits 15 to 0 in these registers are valid. Writing to these registers is invalid.	R

24.3.7 CMWOCRn : Output Compare Registers (n = 0, 1)

Base address: CMTWm = 0x8008_1000 + 0x0400 × m (m = 0, 1)

Offset address: 0x020 + 0x004 × n



Bit	Symbol	Function	R/W
31:0	n/a	The CMWOCR0 and CMWOCR1 registers are readable/writable registers that set the value to be compared when an output compare is generated. When the 16-bit counter size is selected with the CMS bit in the timer control register (CMWCR), bits 15 to 0 of these registers become valid. Since access to this register is in 32-bit units, when writing, write 32-bit values to it with 0x0000 in the higher-order bits.	R/W

24.4 Operation

When the CMWCR register is set and then the STR bit in CMWCR is set to 1, the CMTW starts counter operation.

Setting the CMWSTR.STR bit to 0 enables the CMWCNT counter to retain the value immediately before a stop of counting and stop counting. Setting CMWIOR register enables using the compare match function, input capture input function, and output compare output function.

24.4.1 Period Counting Operation

When the internal clock is selected by using the CMWCNT.CKS[1:0] bits and the CMWSTR.STR bit is set to 1, the CMWCNT counter starts counting up cycles of the selected clock. When the CCLR[2:0] bits in CMWCR are set so that CMWCNT should be cleared by a specific counter clearing source and the counter clearing source is generated, the CMWCNT counter is cleared to 0x00000000 and continues incrementing. When the CCLR[2:0] bits are set so that CMWCNT should not be cleared by any specific counter clearing source, the CMWCNT counter is cleared to 0x00000000 only when an overflow is generated (0xFFFFFFFF → 0x00000000 (when the counter size is 32 bits) or 0x0000FFFF → 0x00000000 (when the counter size is 16 bits)) and continues incrementing.

24.4.2 Compare Match Function

When the values of the CMWCNT counter and CMWCOR register match, a compare match interrupt (CMTWm_CMWI) is generated. The CMWCNT counter operates as follows according to the setting of CMWCR.CCLR[1:0].

1. When CMWCR.CCLR[2:0] = 000b
   When the values of the CMWCNT counter and CMWCOR register match, the CMWCNT counter is cleared to 0x00000000. The CMWCNT counter then restarts counting up from 0x00000000.
2. When CMWCR.CCLR[2:0] ≠ 000b
   Even when the values of the CMWCNT counter and CMWCOR register match, the CMWCNT counter is not cleared to 0x00000000 but continues counting up until the clearing condition set in CMWCR.CCLR[1:0] is satisfied or the value of the counter reaches 0xFFFFFFFF (when the size of the counter is 32 bits) or 0x0000FFFF (when the size of the counter is 16 bits).
   The CMWCNT counter is then cleared to 0x00000000 and restarts counting up from 0x00000000.

Figure 24.2 shows an example of procedure for setting compare match operation.

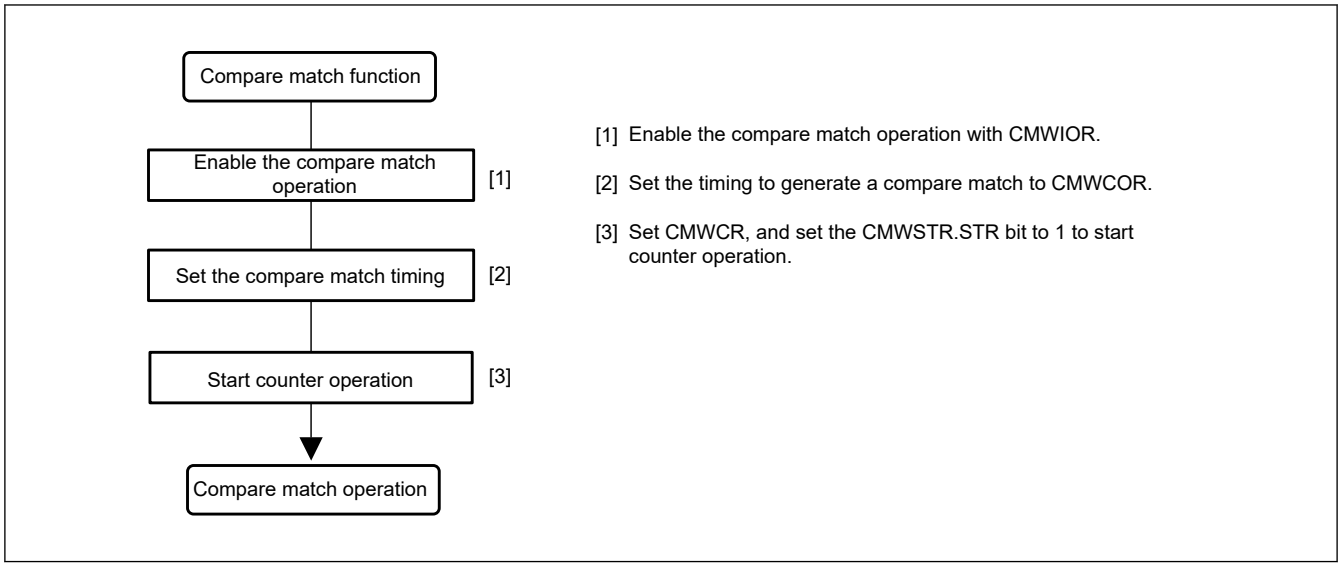


Figure 24.2 Procedure for setting compare match operation

Figure 24.3 shows an example when compare match with CMWCOR is set as a counter clearing source.

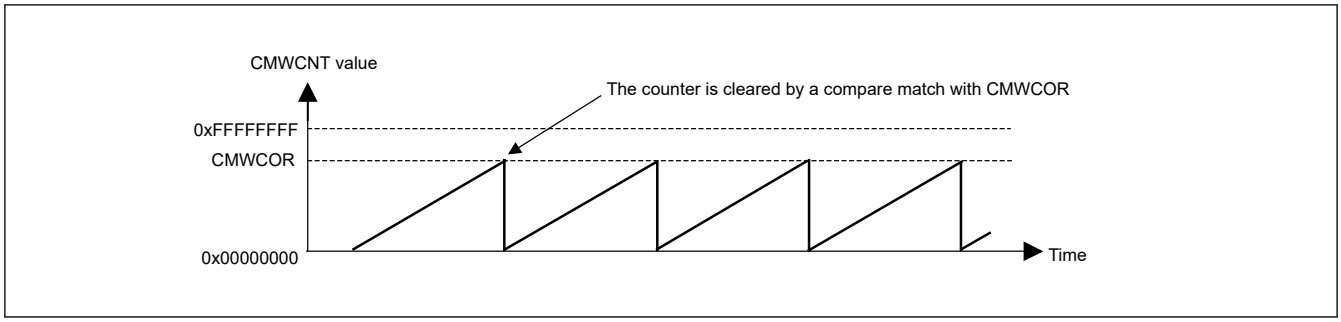

Figure 24.3 Example of compare match operation

Figure 24.4 shows an example when CMWCOR is set to 0xFFFFFFFF and detected as overflow.

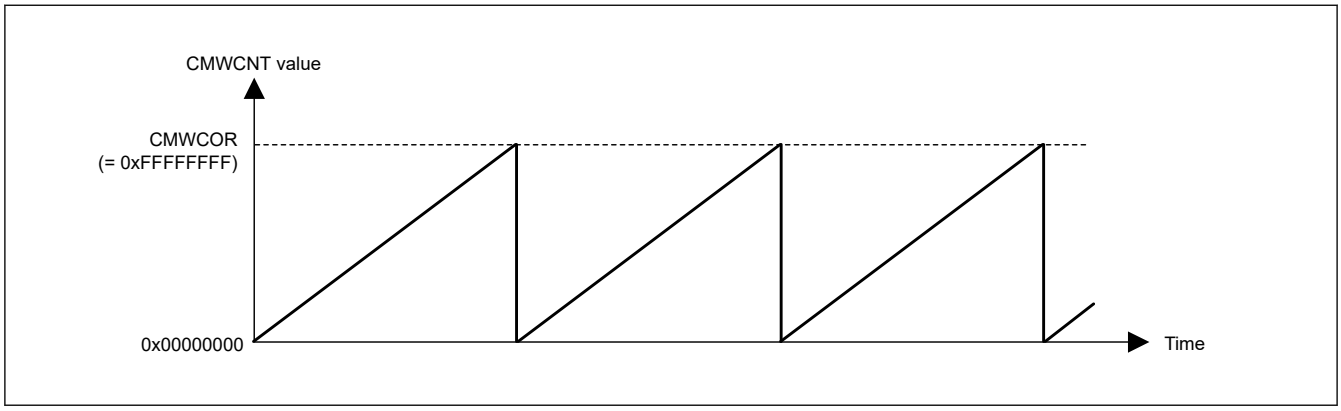

Figure 24.4 Example of compare match operation (overflow detected)

24.4.3 Output Compare Function

Using the output compare function, toggle output from the relevant output pins can be provided. When the CMWCNT counter value matches either of the values of CMWOCR0 or CMWOCR1 register, the output compare interrupt (CMTWm_OC0I or CMTWm_OC1I (m = 0, 1)) is generated. The CMWCNT counter operates as follows according to the setting of CMWCR.CCLR[2:0].

1. When CMWCR.CCLR[2:0] = 110b
   When the values of the CMWCNT counter and CMWOCR0 register match, the CMWCNT counter is cleared to 0x00000000. The CMWCNT counter then restarts counting up from 0x00000000.

2. When CMWCR.CCLR[2:0] = 111b
   When the values of the CMWCNT counter and CMWOCR1 register match, the CMWCNT counter is cleared to 0x00000000. The CMWCNT counter then restarts counting up from 0x00000000.
3. When CMWCR.CCLR[2:0] = others except 110b and 111b
   Even when the values of the CMWCNT counter and CMWOCR0 or CMWOCR1 register match, the CMWCNT counter is not cleared to 0x00000000 but continues counting up until the clearing condition set in CMWCR.CCLR[2:0] is satisfied or the value of the counter reaches 0xFFFFFFFF (when the size of the counter is 32 bits) or 0x0000FFFF (when the size of the counter is 16 bits). The CMWCNT counter is then cleared to 0x00000000 and restarts counting up from 0x00000000.

Figure 24.5 shows an example of procedure for setting output compare operation.

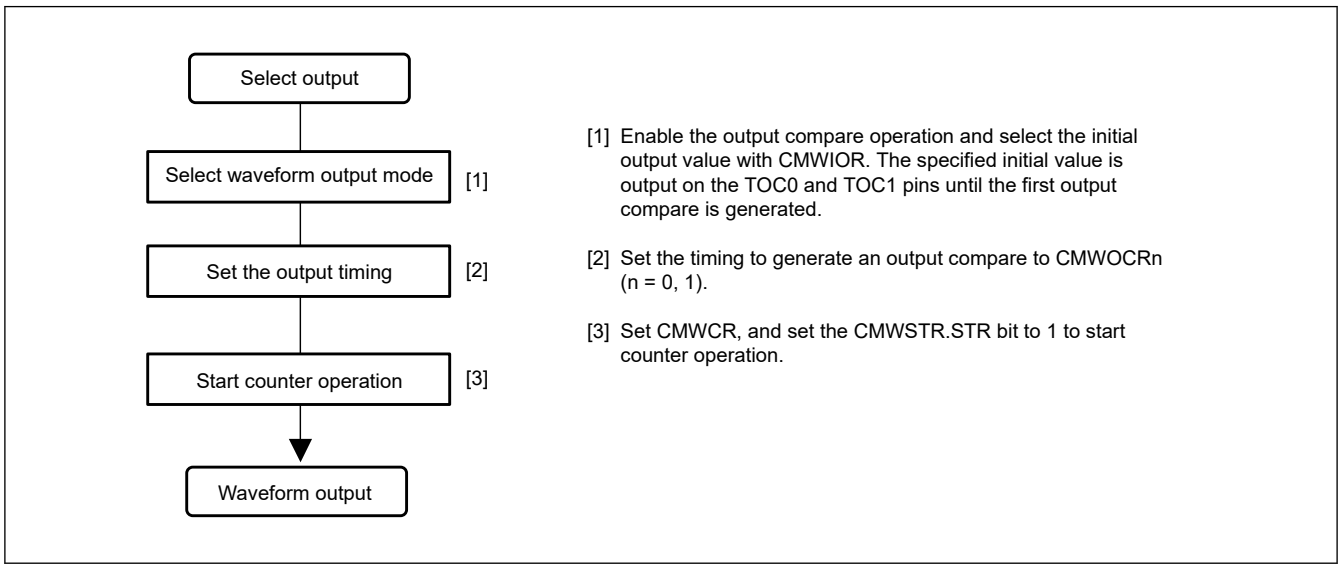

Figure 24.5 Procedure for setting output compare operation

Figure 24.6 shows an example when the counter is cleared upon compare match with CMWOCR1 register and toggle outputs are provided from the TOC0 and TOC1 pins.

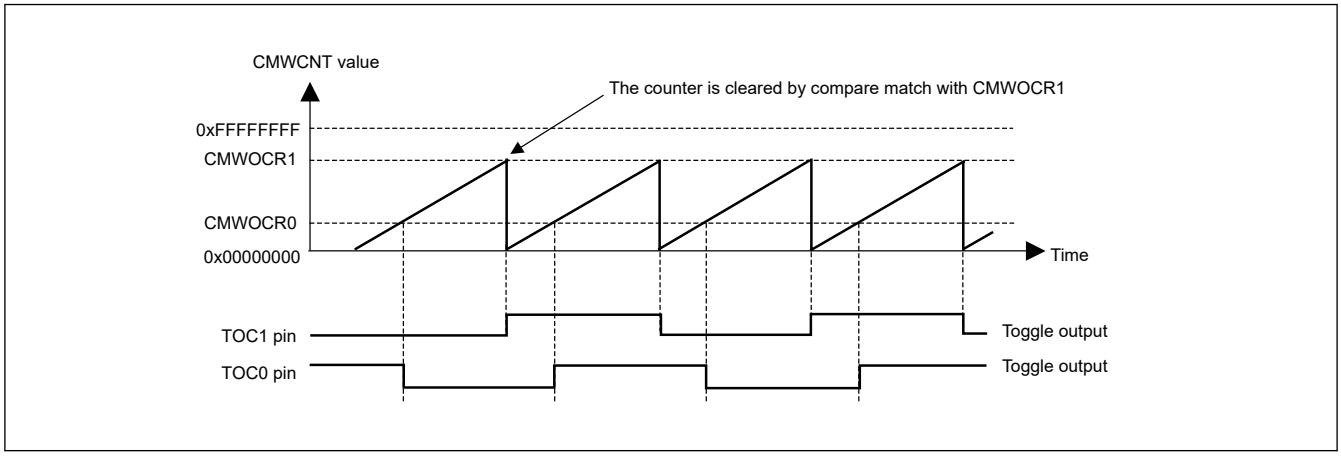

Figure 24.6 Example of output compare operation

24.4.4 Input Capture Function

Through detecting the edge on the TIC0 and TIC1 pin input, the CMWCNT counter value can be transferred to CMWICR0 and CMWICR1 registers, respectively. The edges to be detected can be selected from among the rising edge alone, falling edge alone, and both the rising and falling edges. When the CMWCNT counter value is transferred to CMWICR0 or CMWICR1 register using the input capture function, an input capture interrupt (CMTWm_IC0I or CMTWm_IC1I (m = 0, 1)) is generated. The CMWCNT counter operates as follows according to the setting of CMWCR.CCLR[2:0].

1. When CMWCR.CCLR[2:0] = 100b
   When the CMWCNT counter value is transferred to CMWICR0 using the input capture operation, the CMWCNT counter is cleared to 0x00000000.
   The CMWCNT counter then restarts counting up from 0x00000000.
2. When CMWCR.CCLR[2:0] = 101b
   When the CMWCNT counter value is transferred to CMWICR1 using the input capture operation, the CMWCNT counter is cleared to 0x00000000.
   The CMWCNT counter then restarts counting up from 0x0000000.
3. When CMWCR.CCLR[2:0] = others except 110b and 111b
   Even when the CMWCNT counter value is transferred to CMWICR0 or CMWICR1 using the input capture operation, the CMWCNT counter is not cleared to 0x00000000 but continues counting up until the clearing condition set in CMWCR.CCLR[2:0] is satisfied or the value of the counter reaches 0xFFFFFFFF (when the size of the counter is 32 bits) or 0x0000FFFF (when the size of the counter is 16 bits). The CMWCNT counter is then cleared to 0x00000000 and restarts counting up from 0x00000000.

Figure 24.7 shows an example of procedure for setting input capture operation.

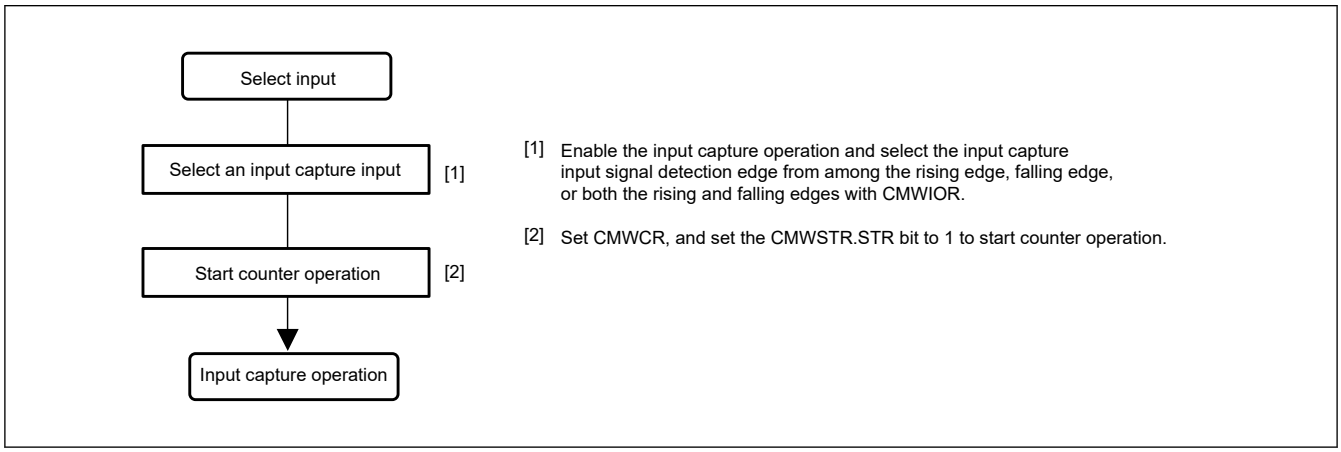

Figure 24.7 Procedure for setting input capture operation

Figure 24.8 shows an example in which both the rising and falling edges are selected for the TIC0 pin input capture input edge and the falling edge for the TIC1 pin, and the CMWCNT counter is cleared by a CMWICR1 register input capture.

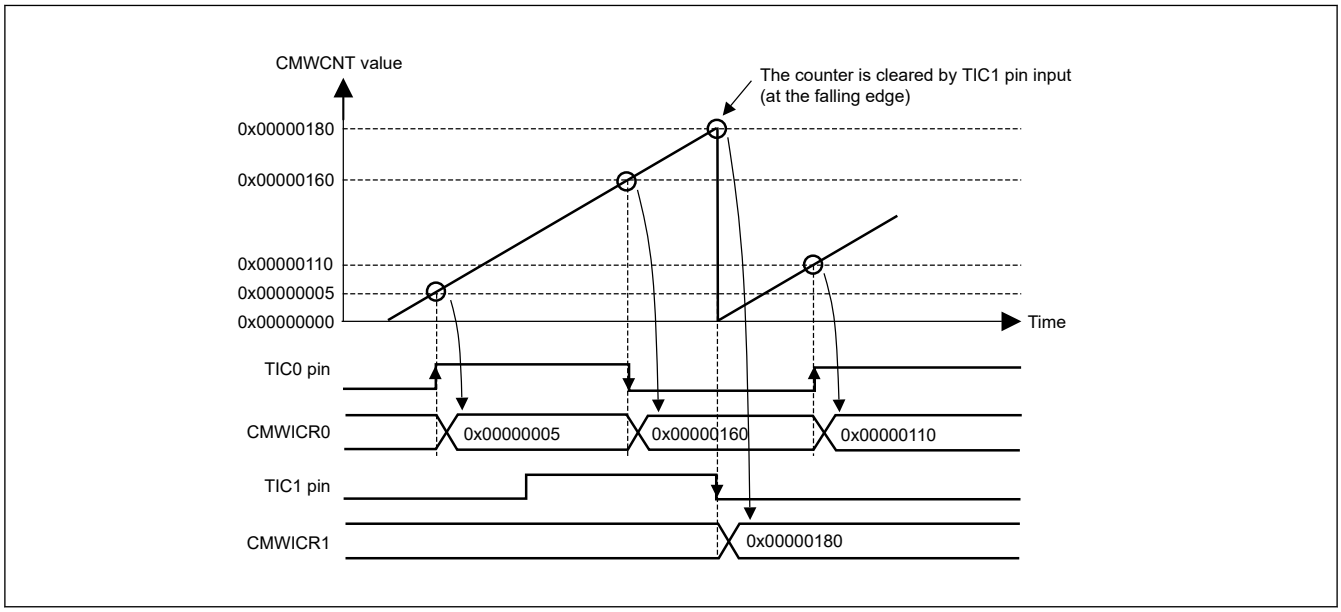

Figure 24.8 Example of input capture operation

24.4.5 Counter Size

With the CMTW, either 16 or 32 bits can be selected as the counter size by using the CMWCR.CMS bit. When the counter is used as a 32-bit counter, set the CMWCOR, CMWOCR0, or CMWOCR1 register to the desired values in 32-bit units. In reading, all 32 bits of CMWICR0 and CMWICR1 are valid. When the counter is used as a 16-bit counter, a 32-bit value should be set to the CMWCOR register with 0x0000 in the higher-order bits. Similarly, a 32-bit value should be set to CMWOCR0 and CMWOCR1 registers with 0x0000 in the higher-order bits.

A 32-bit value with 0x0000 in the higher-order bits is read from CMWICR0 and CMWICR1 registers.

24.4.6 Count Timing Based on CMWCNT

One of four clocks (PCLKL/8, PCLKL/32, PCLKL/128, and PCLKL/512) obtained by dividing the peripheral clock (PCLKL) can be selected with the CMWCR.CKS[1:0] bits. Figure 24.9 shows the timing.

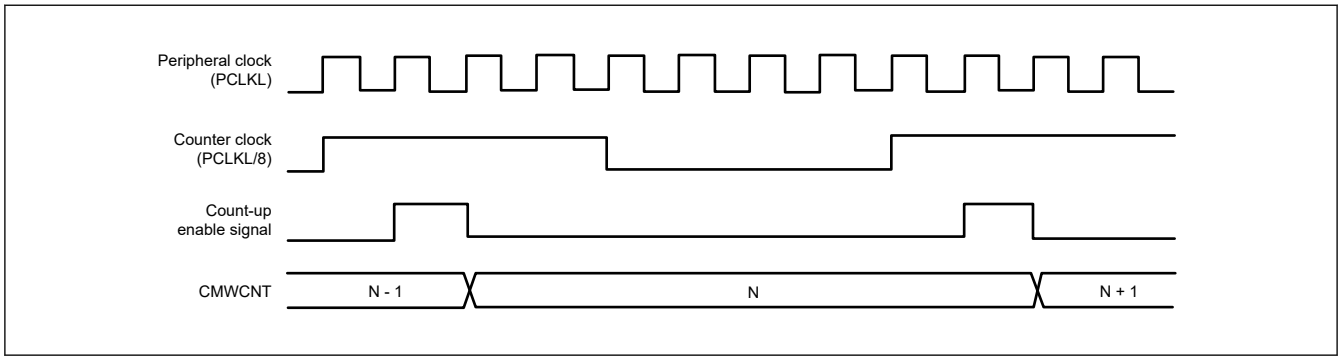

Figure 24.9 Count timing (PCLKL/8)

24.4.7 Output Compare Output Timing

A compare match signal is generated in the last state in which the CMWOCRn (n = 0, 1) register and CMWCNT counter values match (the CMWCNT counter value is updated immediately after the state). That is, the compare match signal is not generated if the CMWCNT counter clock is not input after a match between the CMWOCRn register and CMWCNT counter values. When a compare match signal is generated, the output compare output pin (TOC) changes in accord with the setting of the OC0[1:0] or OC1[1:0] bits in the CMWIOR register. Figure 24.10 shows output compare output timing.

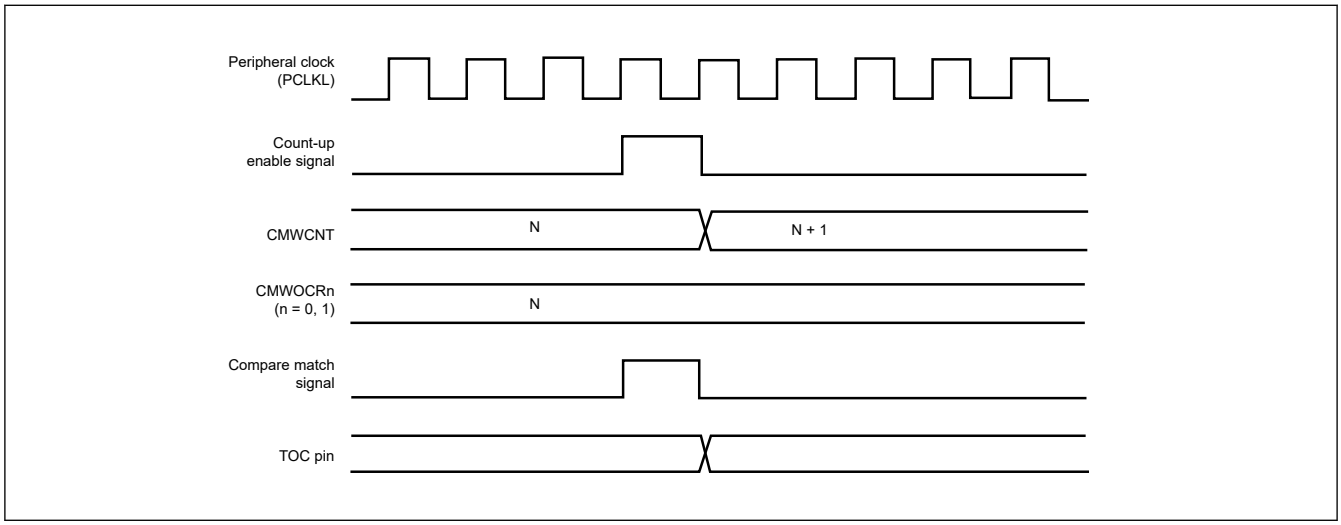

Figure 24.10 Output compare output timing

24.4.8 Input Capture Signal Timing

Figure 24.11 shows the input capture timing.

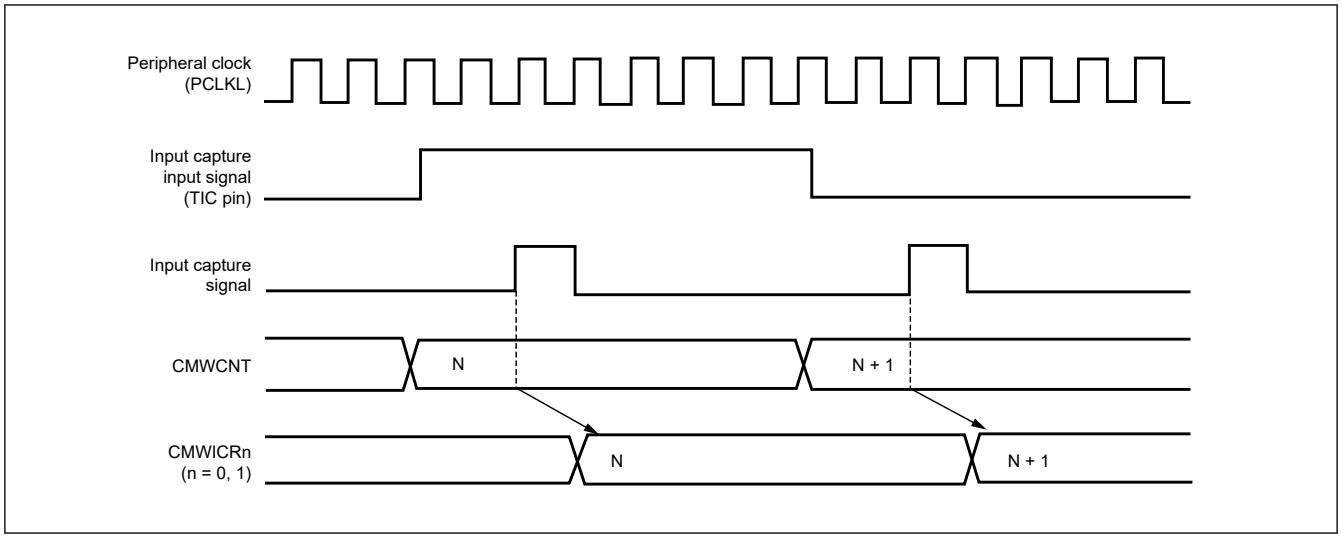

Figure 24.11 Input capture input signal timing

24.5 Interrupts

24.5.1 CMTW Interrupt Sources and DMAC Transfer Requests

The CMTW has five interrupt sources: two input capture interrupt requests (CMTWm_IC0I and CMTWm_IC1I), two output compare interrupt requests (CMTWm_OC0I and CMTWm_OC1I), and a compare match interrupt request (CMTWm_CMWI) (m = 0, 1).

Table 24.5 shows the interrupt sources and priority. The interrupt sources can be enabled or disabled using the IC0IE, IC1IE, OC0IE, OC1IE, and CMWIE bits in CMWCR and are separately issued to the interrupt controller.

Table 24.5 CMTW interrupt sources

Interrupt source	Interrupt	Interrupt enable bit	CPU0 GIC request	CPU1 GIC request	DMAC activation	Priority
CMTWm_CMWI	Interrupt caused by compare match	CMWIE	Possible	Possible	Possible	High
CMTWm_IC0I	Interrupt caused by input capture 0	IC0IE	Possible	Possible	Possible	↑
CMTWm_IC1I	Interrupt caused by input capture 1	IC1IE	Possible	Possible	Possible	↑
CMTWm_OC0I	Interrupt caused by output compare 0	OC0IE	Possible	Possible	Possible	↑
CMTWm_OC1I	Interrupt caused by output compare 1	OC1IE	Possible	Possible	Possible	Low

24.5.2 Timing of Compare Match Interrupt Generation

When the values of the CMWCNT counter and CMWCOR register match, a compare match interrupt (CMTWm_CMWI (m = 0, 1)) is generated. The compare match signal is generated at the end of the cycle where the values matched (i.e. when the CMWCNT counter is updated from the matching counter value). The compare match signal, therefore, is not generated until a further cycle of the input clock (PCLKL/8, PCLKL/32, PCLKL/128, or PCLKL/512) for the CMWCNT counter arrives after the values of the CMWCNT counter and CMWCOR register have matched. Figure 24.12 shows the timing of compare match interrupt generation.

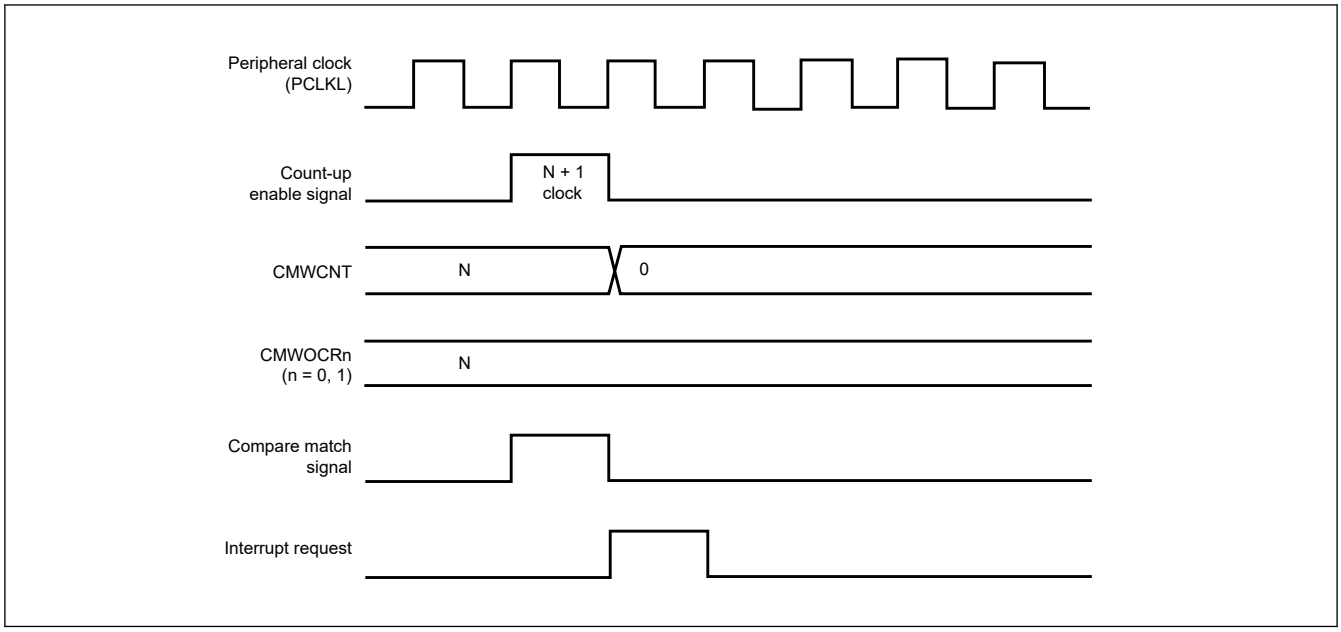

Figure 24.12 Timing of compare match interrupt generation

24.5.3 Timing of Output Compare Interrupt Generation

Figure 24.13 shows the timing of output compare interrupt generation.

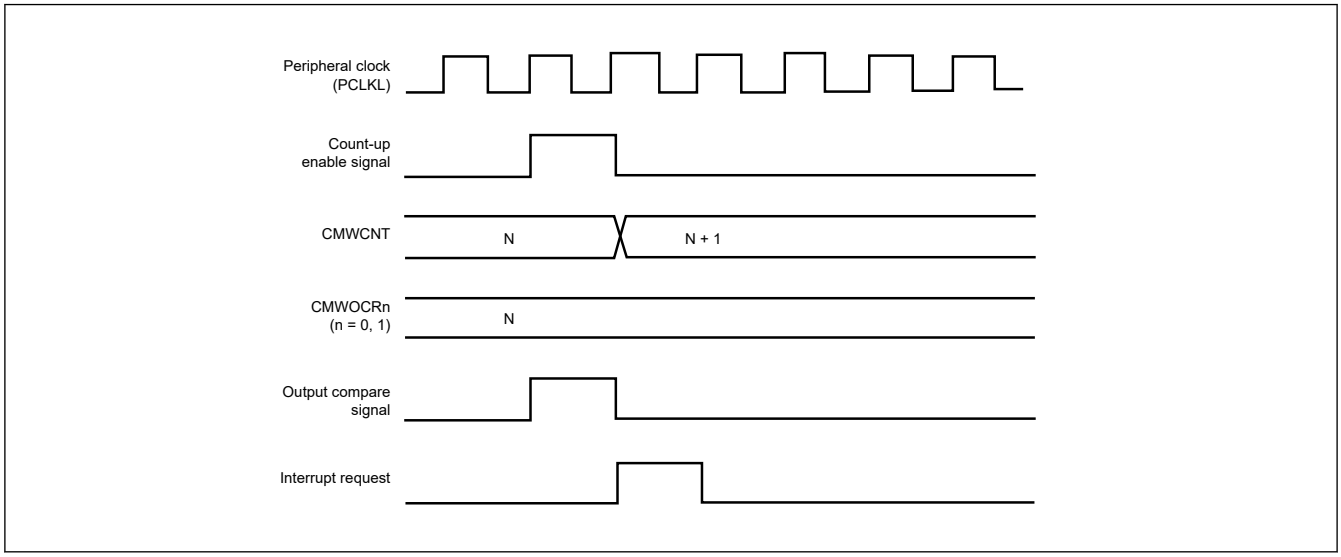

Figure 24.13 Timing of output compare interrupt generation

24.5.4 Timing of Input Capture Interrupt Generation

Figure 24.14 shows the timing of input capture interrupt generation.

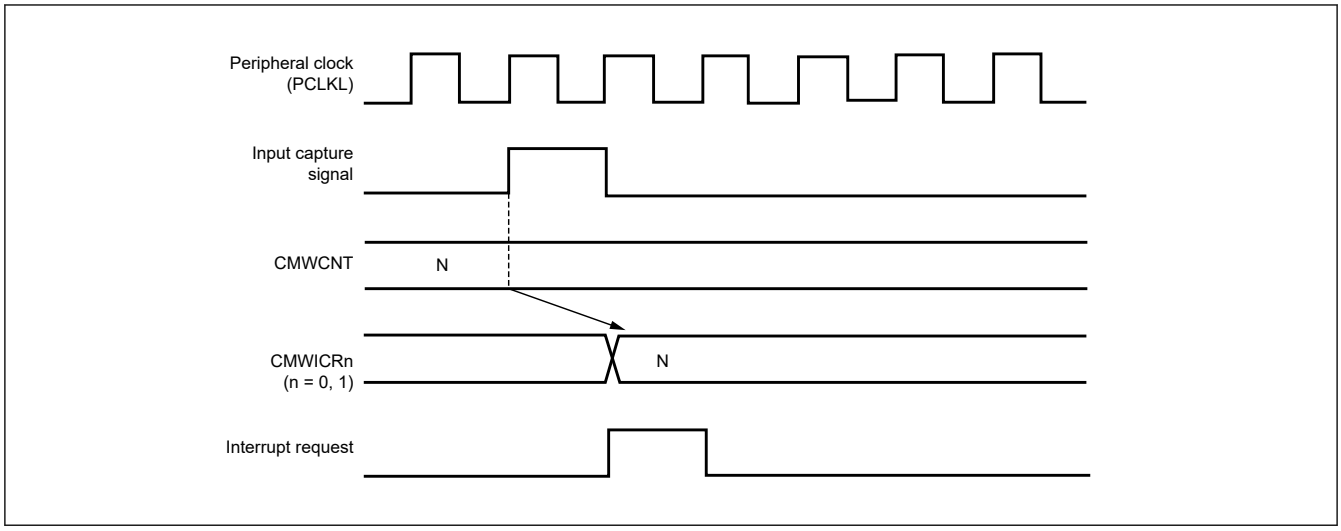

Figure 24.14 Timing of input capture interrupt generation

24.6 Usage Notes

24.6.1 Module-Stop Function

The CMTW operation can be enabled and disabled using the Module-Stop Control Register (MSTPCRD). With the initial value, the CMTW is in module-stop state. Register access is enabled by release from the module-stop state. For details, see section 9, Low-Power Consumption Function.

24.6.2 Contention Between CMWCNT Counter Writing and Compare Match

If the compare match signal is generated during CPU writing to the CMWCNT counter, the compare match interrupt request is output but the counter is not cleared since the CPU writing to the counter is given priority.

Figure 24.15 shows the timing of contention between CMWCNT counter writing and compare match.

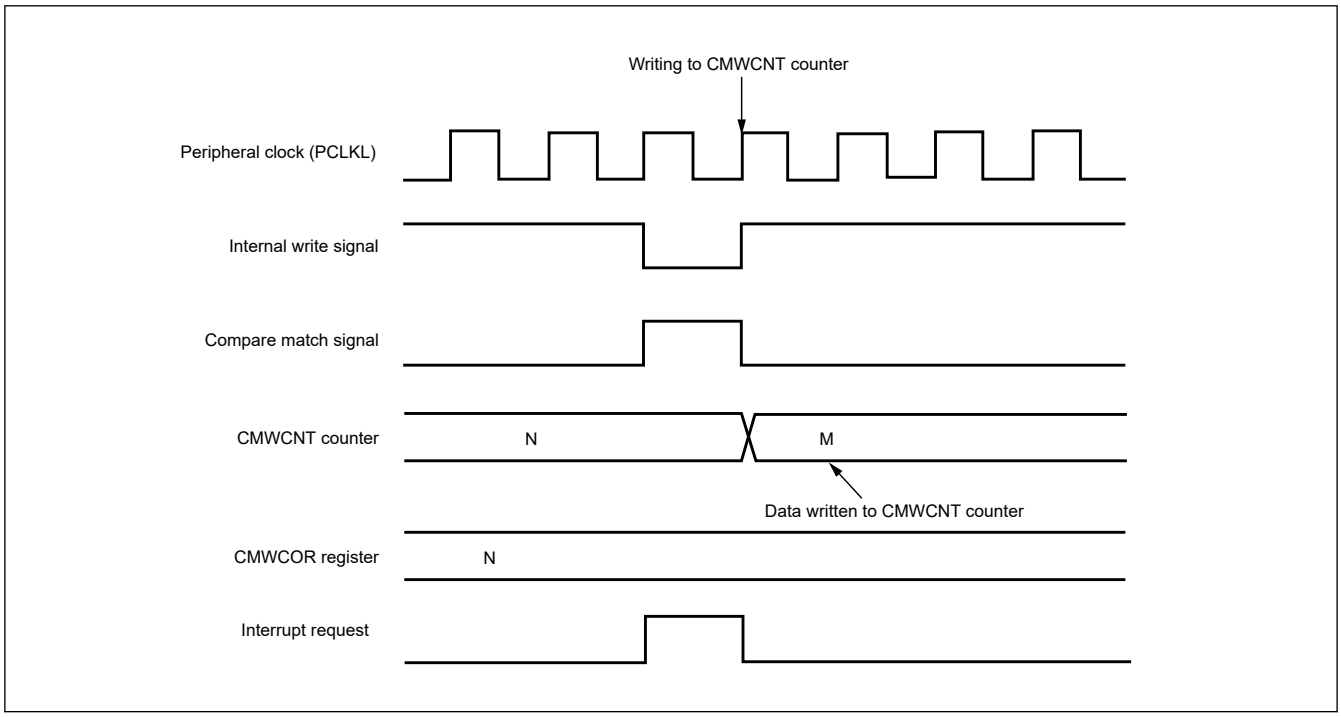

Figure 24.15 Contention between CMWCNT counter writing and compare match

24.6.3 Contention Between CMWCNT Counter Writing and Incrementing or Clearing

In case of contention between incrementation or clearing of the CMWCNT counter and CPU writing to the counter, the counter is not actually incremented or cleared since the CPU writing to the CMWCNT counter is given priority.

Figure 24.16 shows the timing in the case of contention between writing to the CMWCNT counter and incrementation or clearing.

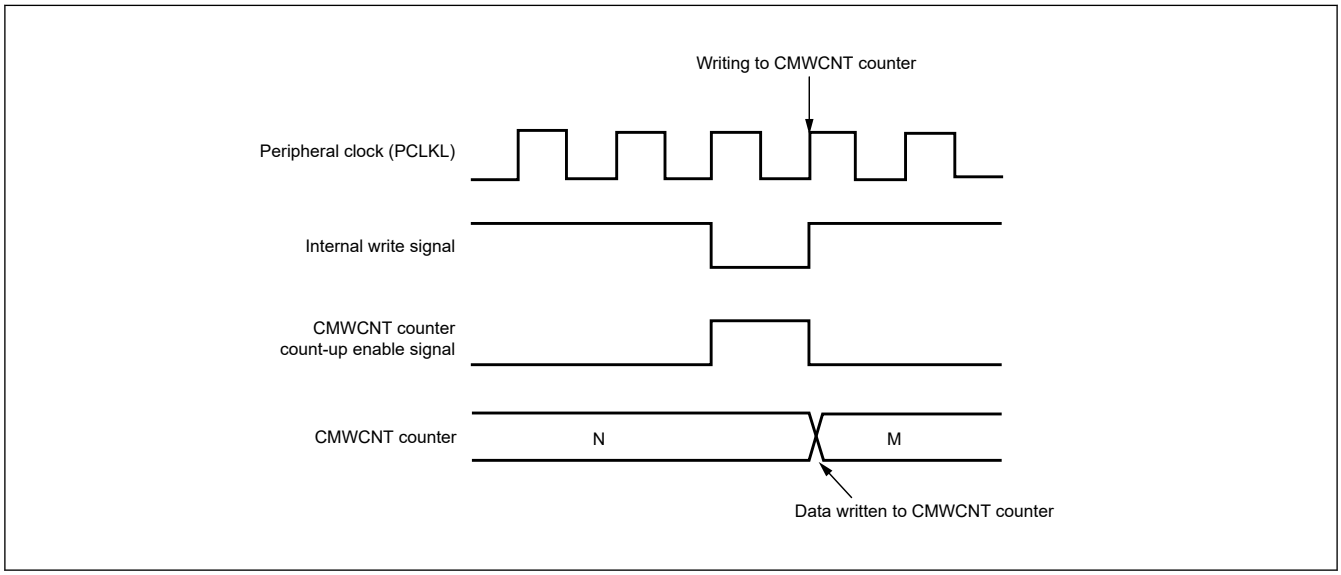

Figure 24.16 Contention between CMWCNT counter writing and incrementing

24.6.4 Contention Between CMWCOR Register Writing and Compare Match

If the compare match is generated during CPU writing to the CMWCOR register, the CPU writing to the CMWCOR register proceeds and also the compare match signal is output.

Figure 24.17 shows the timing of contention between CMWCOR register writing and compare match.

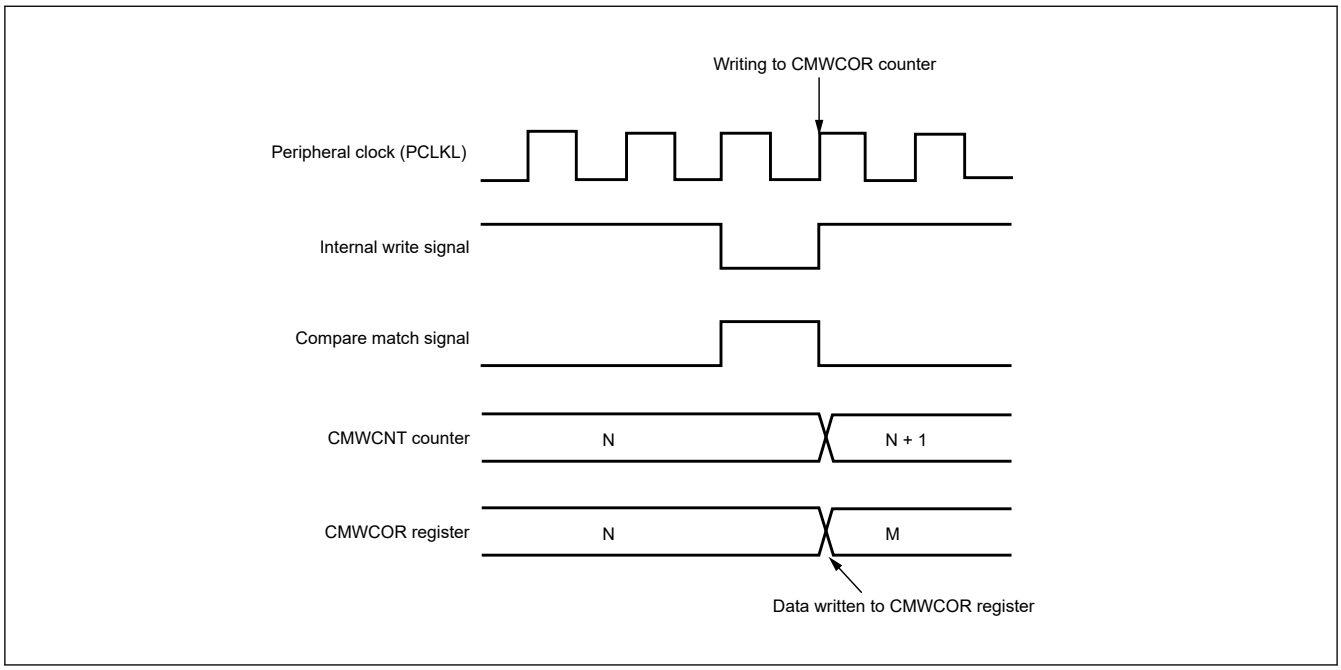

Figure 24.17 Contention between CMWCOR register writing and compare match

24.6.5 Contention Between CMWOCRn Register Writing and Compare Match

If the compare match is generated during CPU writing to the CMWOCRn register, the CPU writing to the CMWOCRn register proceeds and also the compare match signal is output (n = 0, 1).

Figure 24.18 shows the timing of contention between CMWOCRn register writing and compare match.

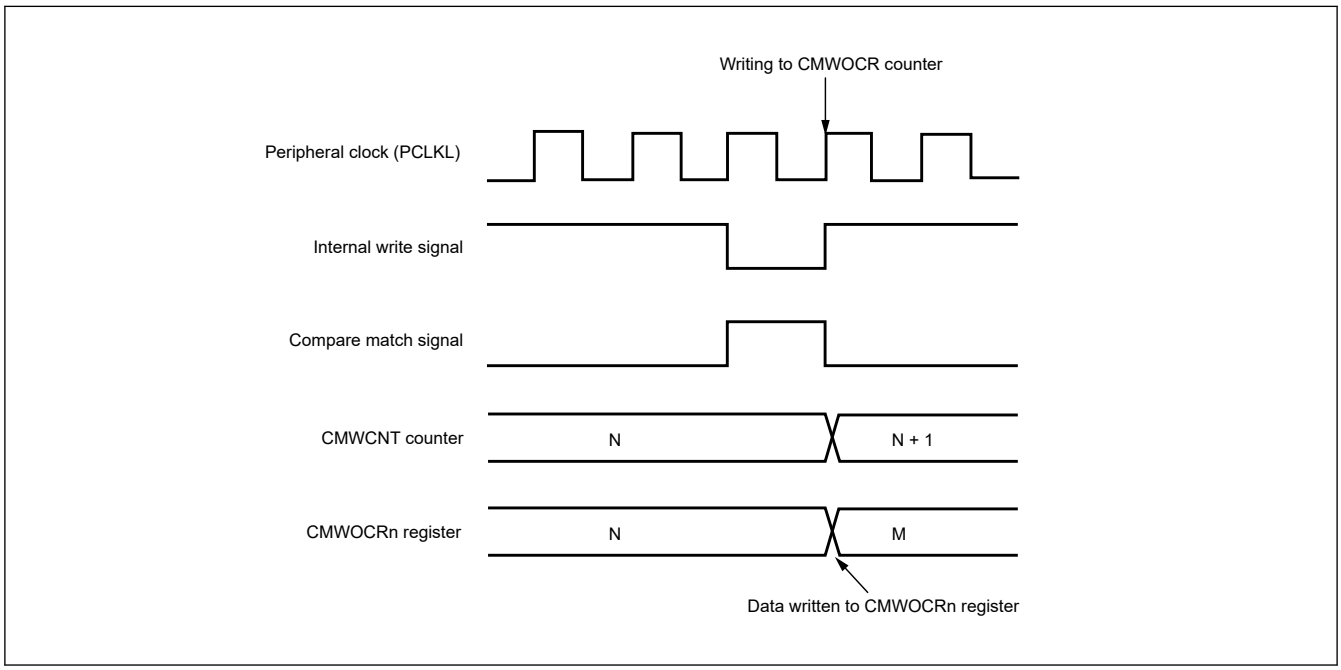

Figure 24.18 Contention between CMWOCRn register writing and compare match

24.6.6 Contention Between CMWCNT Counter Reading and Incrementing or Clearing

If the CMWCNT counter incrementing or clearing process occurs at the same time that the data of the CMWCNT counter is read, the value having been in the CMWCNT counter before incremented or cleared is read.

Figure 24.19 shows the timing of contention between the CMWCNT counter reading and incrementing.

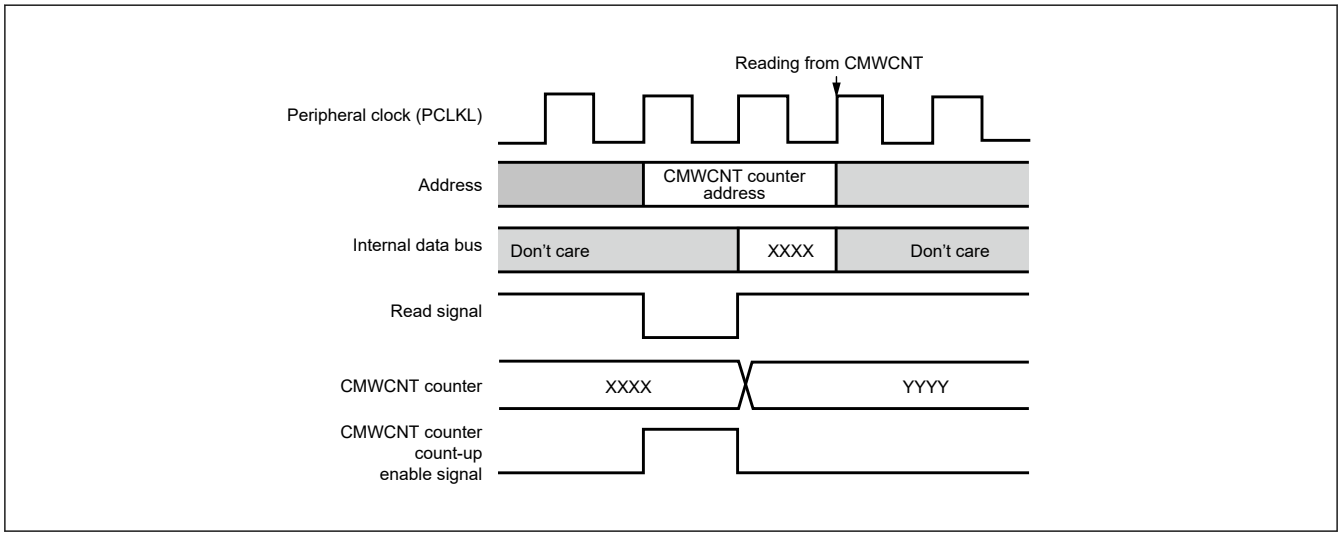

Figure 24.19 Contention between CMWCNT counter reading and incrementing (when the data reading and incrementing process occur simultaneously)

24.6.7 Contention Between CMWICRn Register Reading and Input Capture

If the input capture signal is generated at the same time that the data of CMWICRn register is read, the value having been in CMWICRn register before updated by input capture transfer is read (n = 0, 1).

Figure 24.20 shows the timing of contention between CMWICRn register reading and input capture.

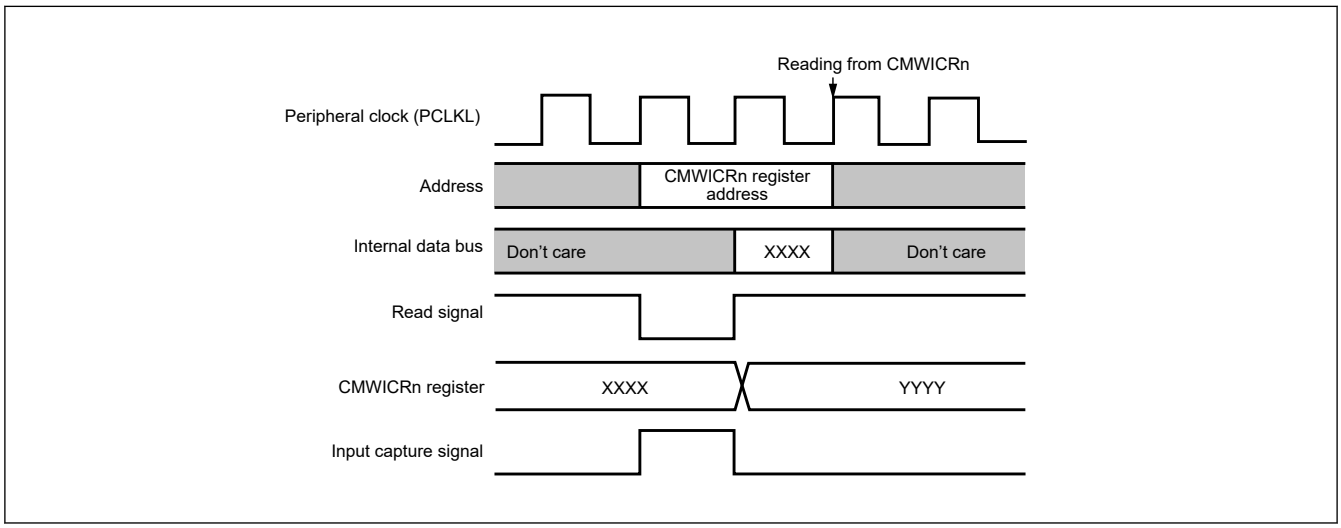

Figure 24.20 Contention between CMWICRn register reading and input capture (when the input capture signal and read signal are generated simultaneously)

Table 24.6 Summary of contention between operations due to the access to registers and changes to the counter's state

Register access	CMWCNT state	CMWICR0/1 state	Operation to be performed
Writing to CMWCNT	Compare match	—	Output of compare match interrupt request / Writing to CMWCNT
	Counting up	—	Writing to CMWCNT
Writing to CMWCOR	Compare match	—	Compare match
Writing to CMWOCR0	Output compare 0	—	Output compare 0
Writing to CMWOCR1	Output compare 1	—	Output compare 1
Reading from CMWCNT	Counting up	—	Counting up and reading of the previous value
Reading from CMWICR0	—	Input capture 0	Input capture 0 and reading of the value before transfer
Reading from CMWICR1	—	Input capture 1	Input capture 1 and reading of the value before transfer

25. Watchdog Timer (WDT)

25.1 Overview

The watchdog timer (WDT) is a 14-bit down-counter and can be used to inform error events to ICU when the counter underflows because the system has run out of control and is unable to refresh the WDT. The refresh-permitted period can be set to refresh the counter and to detect when the system runs out of control.

Table 25.1 lists the specifications of the WDT and Figure 25.1 shows a block diagram of the WDT.

Table 25.1 WDT specifications

Parameter	Specifications
Number of units	6 units (2 units for Cortex-R52 and 4 units for Cortex-A55)
Count source	Peripheral clock (PCLKL)
Clock division ratio	Divide by 4, 64, 128, 512, 2048, or 8192
Counter operation	Counting down using a 14-bit down-counter
Conditions for starting the counter	Register start mode: Counting is started by refresh on a write to the WDTRR register
Conditions for stopping the counter	• Reset (the down-counter and other registers return to their initial values) • A counter underflows or a refresh error occurs • Cortex-R52 and Cortex-A55 debug state
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods)
WDT error events	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error)
Reading the counter value	The down-counter value can be read by the WDTSR register.
Output signal (internal signal)	Interrupt request output

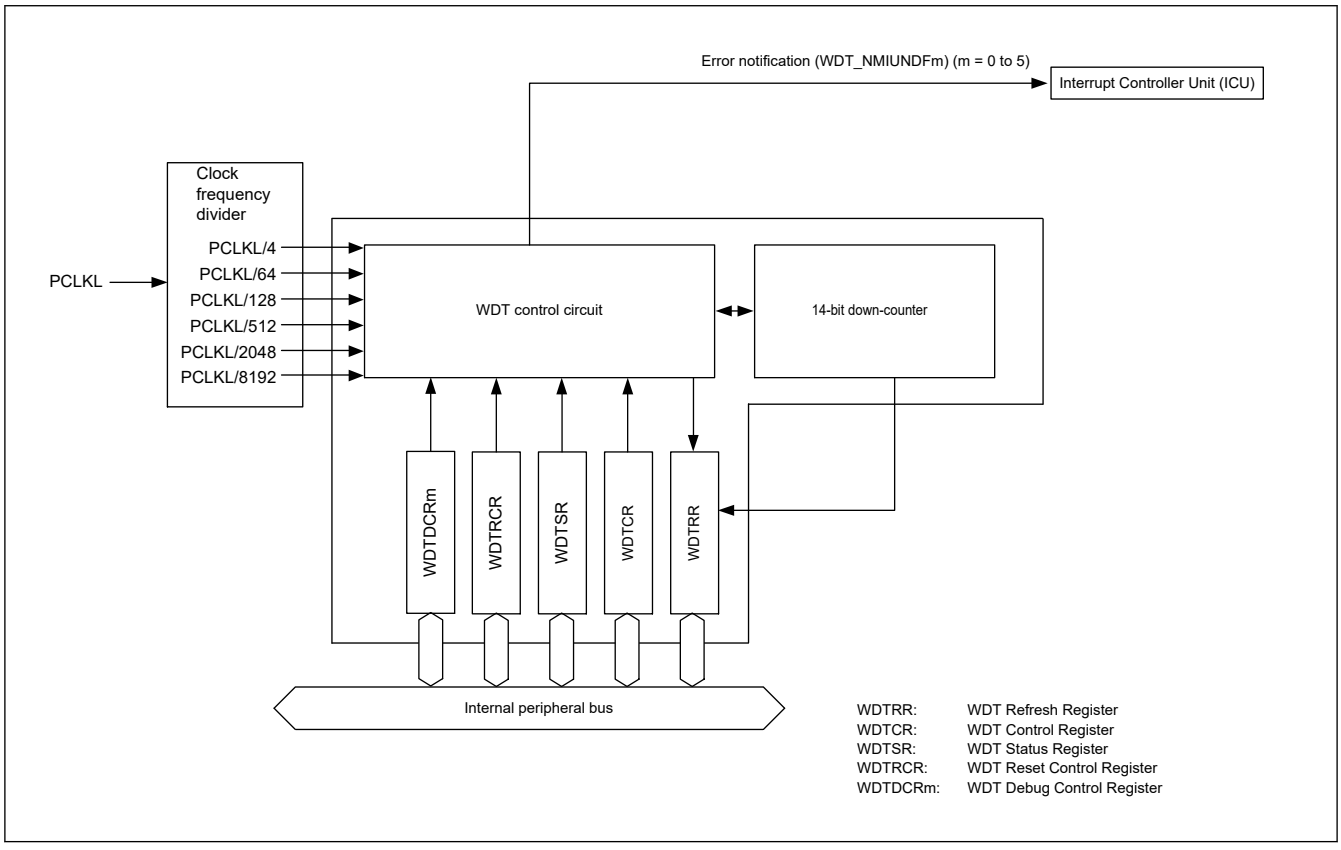

Figure 25.1 WDT block diagram

Table 25.2 WDT interrupt sources

Name	Interrupt sources
WDT_NMIUNDF0	Down-counter underflow/Refresh error for Cortex-R52 CPU0
WDT_NMIUNDF1	Down-counter underflow/Refresh error for Cortex-R52 CPU1
WDT_NMIUNDF2	Down-counter underflow/Refresh error for Cortex-A55 Core0
WDT_NMIUNDF3	Down-counter underflow/Refresh error for Cortex-A55 Core1
WDT_NMIUNDF4	Down-counter underflow/Refresh error for Cortex-A55 Core2
WDT_NMIUNDF5	Down-counter underflow/Refresh error for Cortex-A55 Core3

25.2 Register Map

25.3 Register Descriptions

25.3.1 WDTRR : WDT Refresh Register

Base address: WDTm = 0x8008_2000 + 0x0400 × m (m = 0 to 5)

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	n/a	The down-counter is refreshed by writing 0x00 and then 0xFF to this register.	R/W

WDTRR register refreshes the down-counter of the WDT.

The down-counter of the WDT is refreshed by writing 0x00 and then 0xFF to WDTRR (refresh operation) within the refresh-permitted period. After being refreshed, the down-counter starts counting down from the value specified with the WDTCR.TOPS[1:0] bits.

When 0x00 is written, the read value is 0x00, when a value other than 0x00 is written, the read value is 0xFF. For details of the refresh operation, see section 25.4.3. Refresh Operation.

25.3.2 WDTCR : WDT Control Register

Base address: WDTm = 0x8008_2000 + 0x0400 × m (m = 0 to 5)

Offset address: 0x02

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	RPSS[1:0]		—	—	RPES[1:0]		CKS[3:0]				—	—	TOPS[1:0]	
Value after reset:	0	0	1	1	0	0	1	1	1	1	1	1	0	0	1	1

Bit	Symbol	Function	R/W
1:0	TOPS[1:0]	Timeout Period Selection 0 0: 1024 cycles (0x03FF) 0 1: 4096 cycles (0x0FFF) 1 0: 8192 cycles (0x1FFF) 1 1: 16384 cycles (0x3FFF)	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
7:4	CKS[3:0]	Clock Division Ratio Selection 0x1: PCLKL/4 0x4: PCLKL/64 0xF: PCLKL/128 0x6: PCLKL/512 0x7: PCLKL/2048 0x8: PCLKL/8192 Others: Setting prohibited.	R/W
9:8	RPES[1:0]	Window End Position Selection 0 0: 75% 0 1: 50% 1 0: 25% 1 1: 0% (window end position is not specified.)	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
13:12	RPSS[1:0]	Window Start Position Selection 0 0: 25% 0 1: 50% 1 0: 75% 1 1: 100% (window start position is not specified.)	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

The WDTCR register allows the selecting of a timeout period before the down-counter underflows, a clock division ratio, and a window start/end position for refreshing. There are some restrictions for writing to this register. For details, see section 25.4.2. Control over Writing to the WDTCR and WDTRCR Registers.

TOPS[1:0] bits (Timeout Period Selection)

These bits select a timeout period (period before the down-counter underflows) from among 1024, 4096, 8192, and 16384 cycles, taking the divided clock specified by the CKS[3:0] bits as one cycle.

After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the time (number of PCLKL cycles) before the counter underflows.

Table 25.5 lists the relationship between the CKS[3:0] and TOPS[1:0] bit settings, the timeout period, and the number of PCLKL cycles.

CKS[3:0] bits (Clock Division Ratio Selection)

These bits specify the division ratio of the clock used for the down-counter. The division ratio can be selected from among the peripheral module clock (PCLKL) divided by 4, 64, 128, 512, 2048, and 8192. Combined with the TOPS[1:0] bit setting, a count period between 4,096 and 134,217,728 cycles of the PCLKL clock can be selected for the WDT.

RPES[1:0] bits (Window End Position Selection)

These bits allow selection of the window end position of the down counter from among 75%, 50%, 25%, and 0% of the counting period. The selected window end position should be a value smaller than the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is valid.

The counter values of the window start and end positions specified by the RPES[1:0] and RPSS[1:0] bit settings vary according to the TOPS[1:0] bit setting.

Table 25.6 lists the counter values of the window start and end positions corresponding to the TOPS[1:0] bit setting.

RPSS[1:0] bits (Window Start Position Selection)

These bits allow the selection of the window start position of the down counter from among 100%, 75%, 50%, and 25% of the counting period (assuming that the count start position as 100% and underflow occurrence as 0%). The period from the window start position to the window end position is the refresh-permitted period, any other periods are the refresh-prohibited periods.

Table 25.6 lists the counter values for the window start and end positions and Figure 25.2 shows the relationship between the settings of the RPSS[1:0] and RPES[1:0] bits, including the refresh-permitted and refresh-prohibited periods.

Table 25.5 Timeout period settings

CKS[3:0] bits				TOPS[1:0] bits		Clock division ratio	Timeout period (number of cycles)	No. of Peripheral clock (PCLKL) cycles @Count clock = PCLKL
b7	b6	b5	b4	b1	b0			
0	0	0	1	0	0	Count clock/4	1024	4096
				0	1		4096	16384

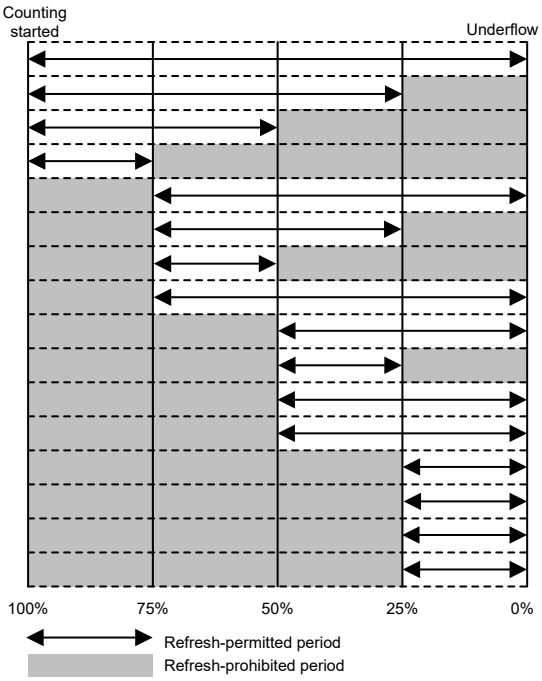
0	0	1	1	25	0
		1	0		25
		0	1		50
		0	0		75



Note: If window end setting ≥ window start setting, the window end setting is set to 0%.

Figure 25.2 RPSS[1:0] and RPES[1:0] bit settings and the refresh-permitted period

25.3.3 WDTSR : WDT Status Register

Base address: WDTm = 0x8008_2000 + 0x0400 × m (m = 0 to 5)

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	REFEF	UNDF	CNTVAL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	CNTVAL[13:0]	Down-Counter Value Value counted by the down-counter	R
14	UNDFF	Underflow Flag 0: No underflow occurred 1: Underflow occurred	R/W*1

Bit	Symbol	Function	R/W
15	REFEF	Refresh Error Flag 0: No refresh error occurred 1: Refresh error occurred	R/W*1

Note 1. Only 0 can be written to clear the flag.

The WDTSR register displays the counter value of the down-counter and the states of underflow and refresh error occurrences.

CNTVAL[13:0] bits (Down-Counter Value)

Read these bits to confirm the value of the down-counter, but note that the read value may differ from the actual count by a value of one count.

UNDFF flag (Underflow Flag)

Read this flag to confirm whether an underflow has occurred in the down-counter.

The value 1 indicates that the down-counter has underflowed. The value 0 indicates that the down-counter has not underflowed.

Write 0 to the UNDFF flag to set the value to 0. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N + 1) PCLKL cycles. In addition, clearing of the flag is ignored for (N + 1) PCLKL cycles after an underflow. N is specified in the WDTCR.CKS[3:0] bits as follows:

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

REFEF flag (Refresh Error Flag)

Read this flag to confirm whether a refresh error (performing a refresh operation during a refresh-prohibited period) has occurred.

The value 1 indicates that a refresh error has occurred. The value 0 indicates that no refresh error has occurred.

Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

Clearing of the REFEF flag takes (N + 1) PCLKL cycles. In addition, clearing of the flag is ignored for (N + 1) PCLKL cycles after a refresh error. N is specified in the WDTCR.CKS[3:0] bits as follows:

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

25.3.4 WDTRCR : WDT Reset Control Register

Base address: WDTm = 0x8008_2000 + 0x0400 × m (m = 0 to 5)

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RSTIRQS	—						
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	RSTIRQS	Reset Interrupt Request Selection 0: Error notification to ICU is permitted 1: Error notification to ICU is not performed	R/W

The WDTRCR register controls whether to send an error notification when underflow occurs in the down-counter of WDT.

There are some restrictions for writing to the WDTRCR register. For details, see section 25.4.2. Control over Writing to the WDTCR and WDTRCR Registers.

RSTIRQS bit (Reset Interrupt Request Selection)

The RSTIRQS bit specifies whether an error notification should be sent to the ICU module when an underflow or refresh error occurs in the down-counter. Set this bit to 0 to enable error notification from the WDT module.

25.3.5 WDTDCRm : WDT Debug Control Register m (m = 0 to 5)

Base address: WDT_DBG = 0x8129_5100

Offset address: 0x00 + 0x04 × m

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WDTSTOPMASK
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WDTSTOPCTRL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	WDTSTOPCTRL	WDT Count Stop Control 0: WDT count is enabled, and interrupt is enabled. 1: WDT count is stopped, and interrupt is disabled.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W
16	WDTSTOPMASK	WDT Debug Break Mask 0: haltdbg is not masked 1: haltdbg is masked	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

The WDTDCRm is used to stop WDT count and to mask haltdbg from CoreSight.

25.4 Operation

25.4.1 Count Operation in Start Mode

Counting starts by a refresh operation of the WDT Refresh Register (WDTRR) when the WDT Control Register (WDTCR) and WDT Reset Control Register (WDTRCR) are set.

25.4.1.1 Register Setting

After the reset state is released, set the clock division ratio, window start and end positions, and timeout period in the WDTCR register. The value specified by the WDTCR.TOPS[1:0] bits is then set in the down-counter by a refresh operation to start counting down.

Thereafter, the value in the counter is reset at each refresh operation and count-down continues if the program runs normally and the counter is refreshed in the refresh-permitted period.

Figure 25.3 shows an example of operation under the following conditions:

- Reset Interrupt Request bit (RSTIRQS): 0b (error notification to ICU is permitted)
- Window Start Position Selection bits (RPSS[1:0]): 10b (75%)
- Window End Position Selection bits (RPES[1:0]): 10b (25%)

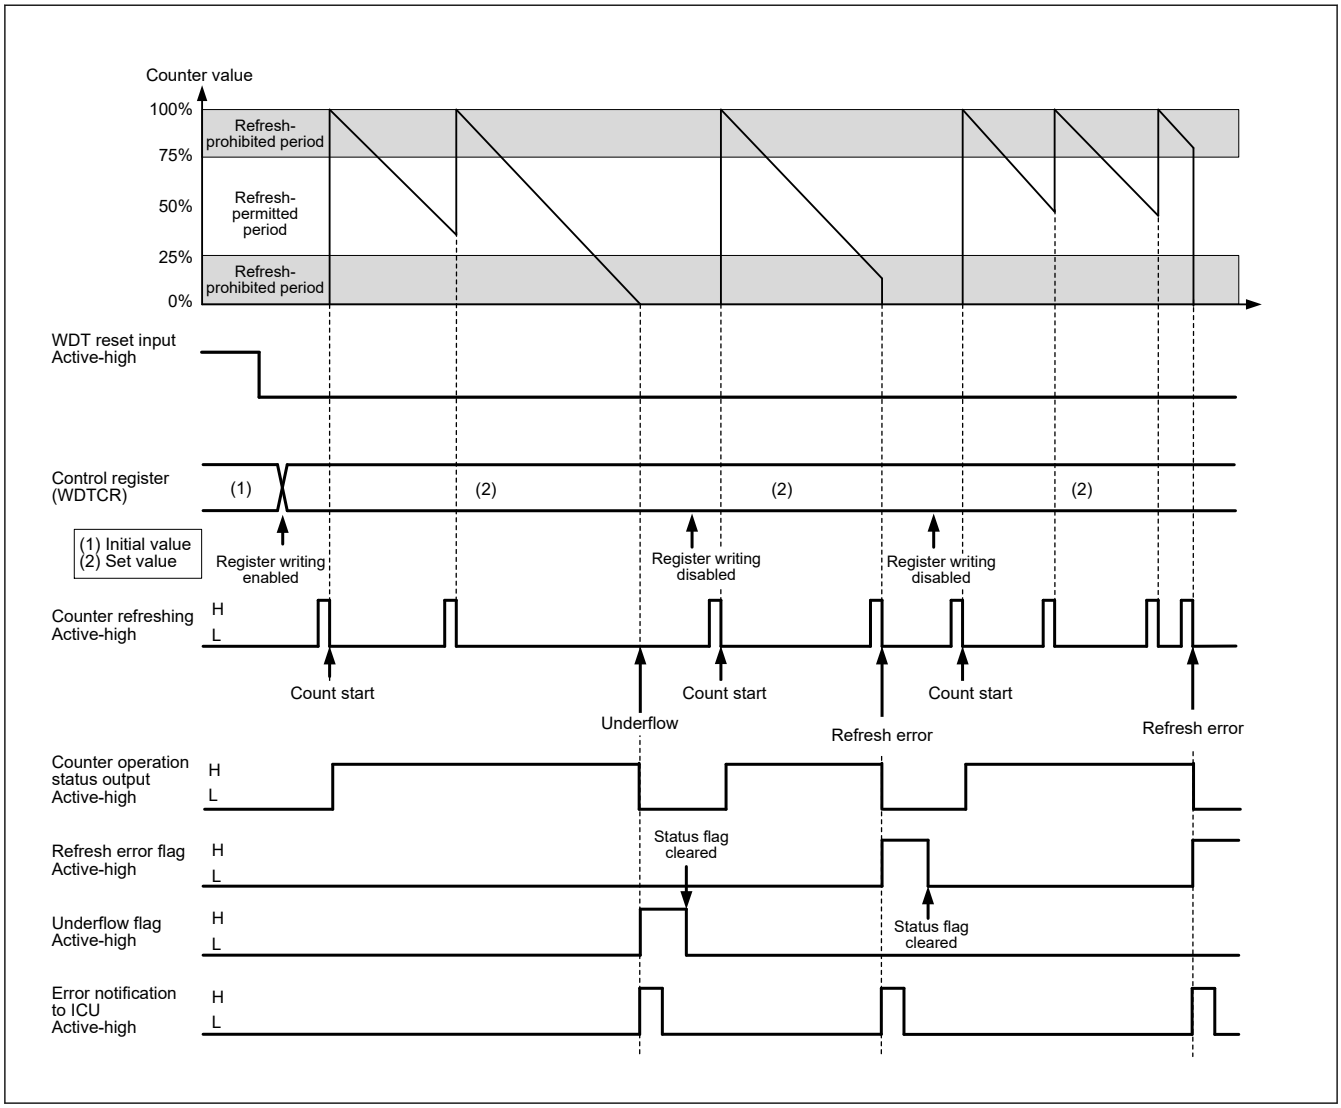


Figure 25.3 Operation example in register start mode

25.4.2 Control over Writing to the WDTCR and WDTRCR Registers

Writing to the WDT Control Register (WDTCR) is only possible once between the release from the reset state and the first refresh operation.

After a refresh operation (counting starts) or by writing to the WDTCR register, the protection signal in the WDT becomes 1 to protect the WDTCR register against subsequent attempts at writing.

Writing to the WDT Reset Control Register (WDTRCR) is also controlled similarly.

This protection is released by the reset source of the WDT. Any other reset sources cannot release the protection. Figure 25.4 shows control waveforms produced in response to writing to the WDTCR register.

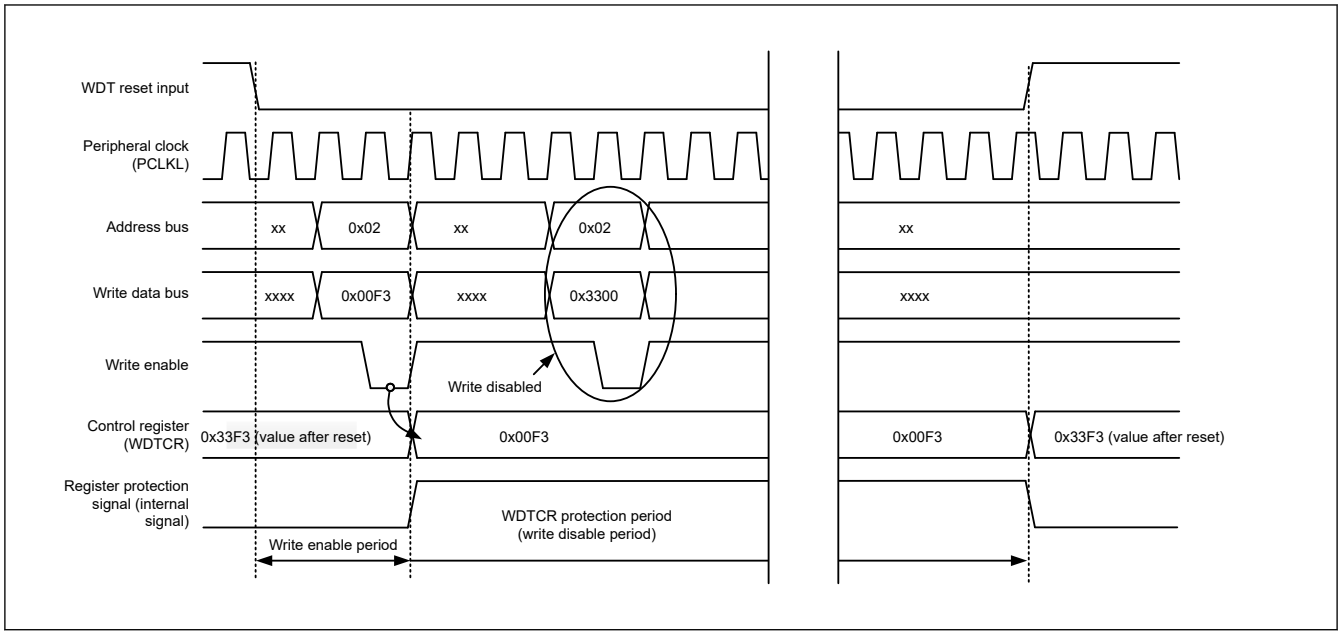

Figure 25.4 Control waveforms produced in response to writing to the WDTCR register

25.4.3 Refresh Operation

To refresh the down-counter and to start the down-counter operation (count start due to refreshing), write the values 0x00 and then 0xFF to the WDT Refresh Register (WDTRR). If a value other than 0xFF is written after 0x00, the down-counter is not refreshed. To perform refreshing after an invalid write, write 0x00 and then 0xFF again to the WDTRR register.

If 0x00 is written twice in succession, writing 0xFF after the second 0x00 refreshes the down-counter because the 0x00 → 0xFF condition is satisfied. The write sequence of 0x00 (n-1th) → 0x00 (nth) → 0xFF also satisfies the refreshing condition and thus refreshes the down-counter.

Even if a register other than WDTRR is accessed or WDTRR is read between writing 0x00 and writing 0xFF to WDTRR, correct refreshing will be done.

[Sample sequences of writing that are valid for refreshing the counter]

- 0x00 → 0xFF
- 0x00 (n - 1th time) → 0x00 (nth time) → 0xFF
- 0x00 → access to another register or read from the WDTRR register → 0xFF

[Sample sequences of writing that are not valid for refreshing the counter]

- 0x23 (a value other than 0x00) → 0xFF
- 0x00 → 0x54 (a value other than 0xFF)
- 0x00→ 0xAA (0x00 and a value other than 0xFF) → 0xFF

If 0xFF is written to the WDTRR register during the refresh-permitted period after 0x00 is written outside of the period, write operation is acknowledged and down-counter is refreshed. Whether writing is made within the refresh-permitted period is determined by when 0xFF is written.

After 0xFF is written to the WDT Refresh Register (WDTRR), refreshing the down-counter requires up to 4 counting cycles. The number of peripheral clock (PCLKL) cycles in a single counting cycle differs depending on the setting of the Clock Division Ratio Selection bits (WDTCR.CKS[3:0]).

Therefore, writing 0xFF to the WDTRR register should be completed within 4 count cycles before the refresh-permitted period end position or before the down-counter underflows. Confirm the down-counter value with the down-counter value bits (WDTSR.CNTVAL[13:0]).

[Sample of refresh operation timing]

- When the window start position is 0x1FFF, if 0x00 is written to the WDTRR register before 0x1FFF (for example, 0x2002), the down-counter can be refreshed by writing 0xFF to the WDTRR register after the value of WDTSR.CNTVAL[13:0] becomes 0x1FFF.
- When the window end position is 0x1FFF, if the value of WDTSR.CNTVAL[13:0] is 0x2003 (4 counts before 0x1FFF) or more immediately after 0x00 and 0xFF are written to the WDTRR register, the down-counter will be refreshed.
- If the refresh-permitted period goes down to 0x0000, refreshing is possible until just before underflow. In this case, if the value of WDTSR.CNTVAL[13:0] is 0x0003 (4 count cycles before underflow) or more immediately after 0x00 and 0xFF are written to the WDTRR register, underflow does not occur and the down-counter is refreshed.

Figure 25.5 shows WDT refresh-operation waveforms when the clock division ratio is PCLKL/64.

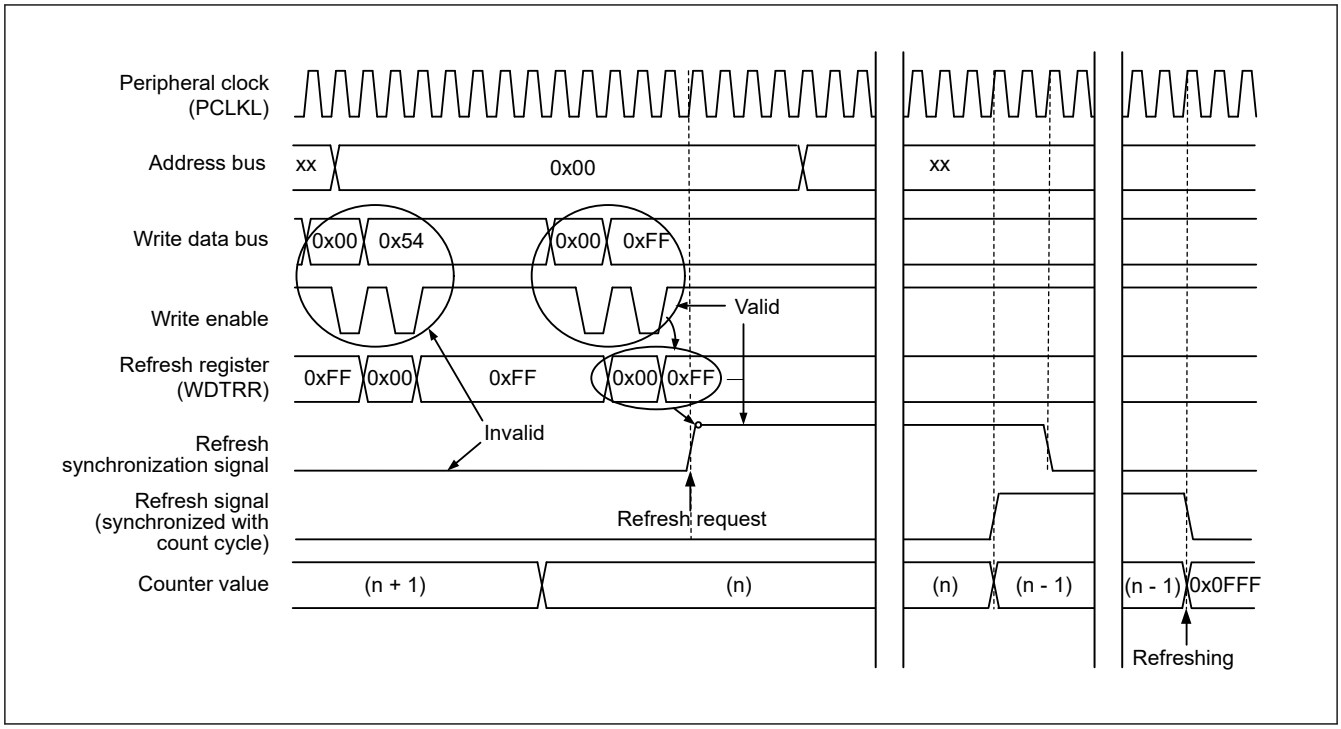

Figure 25.5 WDT refresh operation waveforms (WDTCR.CKS[3:0] = 0x4, WDTCR.TOPS[1:0] = 01b)

25.4.4 Status Flag

The Refresh Error flag (WDTSR.REFEF) and the Underflow flag (WDTSR.UNDFF) retain the error causes after error notifications are output to the Interrupt Controller (ICU).

Occurrence state of error notifications to ICU can be confirmed by reading the WDTSR.REFEF flag or the WDTSR.UNDFF flag after reset is released or on occurrence of an error notification to ICU.

To clear these flags, write 0. Writing 1 is ignored.

If these flags are not cleared, there is no effect on the operation. On occurrence of the next error notification to ICU, the previous error notification is automatically cleared and a new notification to ICU is written.

25.4.5 Count Stop Control

WDT count can be stopped by debug event (haltdbg) from CoreSight through TSGCNT HALTREQ or RESTARTREQ to prevent unintentional WDT overflow during debug operation, or by WDTSTOPCTRL bit in WDTDCRm register during normal operation. Assert or de-assert of haltdbg needs to be controlled by connecting stop/re-start event of CPU (e.g. cross halt trigger event etc.) to TSGCNT HALTREQ or RESTARTREQ via CTI. Stop control by haltdbg is maskable by setting WDTSTOPMASK bit in WDTDCRm register. When setting 1 to WDTSTOPMASK bit in WDTDCRm register, WDT continues to count even during debug operation.

26. Real Time Clock (RTC)

26.1 Overview

The RTC module can count a 100-year calendar from 2000 to 2099 and automatically adjust dates for leap years. The RTC uses an internal clock acquired by dividing the main clock oscillator or PLL output by a prescaler. Year, month, date, day-of-week, a.m./p.m. (in 12-hour mode), hour, minute, second is counted. No external oscillator is required but battery backup is not supported.

Table 26.1 lists the RTC specifications and Figure 26.1 shows a block diagram. Table 26.2 lists the RTC I/O pin and Table 26.3 lists the interrupt sources.

Table 26.1 RTC specifications

Parameter	Specifications
Number of units	1 unit
Count mode	Calendar count mode
Count source	Main clock oscillator divided by 128 (195.3125 kHz)
Clock and calendar functions	• Year, month, day of the week, day, hour, minute, second counters and sub-counters, counting up to 99 years are supported • Year, month, day of the week, day, hour, minute, and second counters: BCD code display • 12 hours/24 hours mode switching function • Automatic adjustment function for leap years • Start/stop function • 1 Hz pulse output
Interrupts	• Alarm interrupt (RTC_ALM) As an alarm interrupt condition, day-of-week, hour and minute can be selected • 1 second interrupt (RTC_1S) Interrupt can be generated every 1 second • Fixed interval interrupt (RTC_PRD) 0.25 second, 0.5 second, 1 second, 1 minute, 1 hour, 1 day, or 1 month can be selected as an interrupt period
Module-stop function	Module-stop state can be set to reduce power consumption.

26.3 Register Descriptions

26.3.1 RTCA0CTL0 : RTC Control Register 0

Base address: RTC = 0x8100_9000

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	RTCA0CE	RTCA0CEST	RTCA0AMPM	RTCA0SLSB	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	RTCA0SLSB	RTCA0SCMP enable/disable setting Set this bit to 1, see the RTCA0SCMP register description. When setting this bit, be sure to follow the flow described in section 26.4.1.1. Initial Setting. It is prohibited to change the setting of this bit while the clock counter operation is enabled (RTCA0CE = 1). If the setting of this bit is changed during clock counter operation, the operation of RTC Controller cannot be guaranteed. When changing the setting of this bit, first perform initialization according to section 26.4.1.5. Initialization of RTC While Clock Counter Operation is Enabled, and then perform the setting of this bit again according to the flow described in section 26.4.1.1. Initial Setting.	R/W
5	RTCA0AMPM	RTCA0HOUR, RTCA0ALH display format selection bit 0: 12-hour display 1: 24-hour display	R/W
6	RTCA0CEST	RTC Controller Enable Status 0: Clock counter operation stopped status 1: Clock counter operation enabled status (the clock counter counts up)	R
7	RTCA0CE	RTC Controller Enable Bit Setting this bit to 0 initializes the internal circuit of RTC Controller other than the control registers*1. Moreover, interrupts (RTC_ALM, RTC_1S, RTC_PRD) are cleared. 0: Clock counter operation stopped 1: Clock counter operation enabled (the clock counter counts up)	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Status flags RTCA0WST, RTCA0RSST, and RTCA0WSST, which cannot be written by the user, are cleared.

26.3.2 RTCA0CTL1 : RTC Control Register 1

Base address: RTC = 0x8100_9000

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	RTCA01HZE	RTCA0ALME	RTCA01SE	RTCA0CT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	RTCA0CT[2:0]	Fixed interval interrupt (RTC_PRD) output setting bit See section 26.4.1.7. Changing the Setting of Fixed Interval Interrupt During Clock Counter Operation for changing the setting of this field. RTCA0CT[2]/RTCA0CT[1]/RTCA0CT[0] 0 0 0: Fixed interval interrupt output stop 0 0 1: Interrupt once every 0.25 seconds (in synchronization with second count-up) 0 1 0: Interrupt once every 0.5 seconds (in synchronization with second count-up) 0 1 1: Interrupt once every 1 second (in synchronization with second count-up) 1 0 0: Interrupt once every 1 minute (every 1 minute 00 seconds) 1 0 1: Interrupt once every 1 hour (every 1 hour 00 minutes 00 seconds) 1 1 0: Interrupt once every 1 day (every 1 day 00 hours 00 minutes 00 seconds) 1 1 1: Interrupt once every 1 month (every 1 month first day 00 hours 00 minutes 00 seconds a.m.)	R/W
3	RTCA01SE	1 second interrupt (RTC_1S) output enable bit 0: Stop interrupt output at every 1 second 1: Enable interrupt output at every 1 second	R/W
4	RTCA0ALME	Alarm interrupt (RTC_ALM) output enable bit 0: Disable 1: Enable	R/W
5	RTCA01HZE	This bit enables/disables 1 Hz pulse output (RTCAT1HZ). 0: Disable 1 Hz pulse output (RTCAT1HZ fixed to 0) 1: Enable 1 Hz pulse output	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

26.3.3 RTCA0CTL2 : RTC Control Register 2

Base address: RTC = 0x8100_9000

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	RTCA0WSST	RTCA0RSST	RTCA0RSUB	RTCA0WST	RTCA0WAIT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RTCA0WAIT	RTC Controller Counter Wait Control This bit controls the count-up operation of the counters. Be sure to write 1 to this bit when reading and writing counter values while the clock counter operation is enabled (RTCA0CE = 1). When this bit is 1, on occurrence of RTCA0SUBC overflow, the overflow information is held internally, and after 0 is written to this bit, RTCA0SEC is counted up. However, when the value of the second counter is written while RTCA0WAIT = 1, the overflow information that was held is discarded. 0: Counter operation 1: Count-up operation of RTCA0SEC, RTCA0MIN, RTCA0HOUR, RTCA0WEEK, RTCA0DAY, RTCA0MONTH, RTCA0YEAR is stopped (count-up operation of second, minute, hour, week, day, month, and year count registers is stopped)	R/W
1	RTCA0WST	RTC Controller Counter Wait Status When 1 is written to RTCA0WAIT, the value of this bit becomes 1 when the count-up operation of RTCA0SEC, RTCA0MIN, RTCA0HOUR, RTCA0WEEK, RTCA0DAY, RTCA0MONTH, RTCA0YEAR has stopped completely. Before reading and writing clock counters (RTCA0SEC, RTCA0MIN, RTCA0HOUR, RTCA0WEEK, RTCA0DAY, RTCA0MONTH, RTCA0YEAR) during clock counter operation (RTCA0CE = 1), check that the value of this register is 1. Also, when write to a clock counter (RTCA0SEC, RTCA0MIN, RTCA0HOUR, RTCA0WEEK, RTCA0DAY, RTCA0MONTH, RTCA0YEAR) occurred, the value written to RTCA0WAIT is reflected only when the write operation has completed (status hold). 0: Count-up status of RTCA0SECC, RTCA0MINC, RTCA0HOURC, RTCA0WEEKC, RTCA0DAYC, RTCA0MONC, RTCA0YEARC 1: Count-up stopped status of RTCA0SECC, RTCA0MINC, RTCA0HOURC, RTCA0WEEKC, RTCA0DAYC, RTCA0MONC, RTCA0YEARC (count-up operation of second, minute, hour, week, day, month, and year count registers is stopped)	R
2	RTCA0RSUB	RTCA0SUBC Data Transfer Control This is a control bit for transferring the value of RTCA0SUBC of RTCA0SRBU. Use it when reading the value of RTCA0SRBU while the clock counter operation is enabled (RTCA0CE = 1). When 1 is written to this bit, the value of RTCA0SUBC is loaded to RTCA0SRBU in synchronization with PCLKRTC. For the usage method, see section 26.4.1.4. Reading RTCA0SRBU While Clock Counter Operation is Enabled. 0: RTCA0SRBU data hold 1: Transfer of value of RTCA0SUBC to RTCA0SRBU	R/W
3	RTCA0RSST	RTCA0SRBU Transfer Status When 1 is written to RTCA0RSUB, the value of this bit becomes 1 when the value of RTCA0SUBC is loaded to RTCA0SRBU. Before reading RTCA0SRBU during clock counter operation (RTCA0CE = 1), check that the value of this register is 1. 0: RTCA0SRBU data hold status 1: Transfer of the value of RTCA0SUBC to RTCA0SRBU completed	R
4	RTCA0WSST	RTCA0SCMP Write Status This bit is set to 1 when RTCA0SCMP is written to while the clock counter operation is enabled (RTCA0CE = 1). It is then cleared to 0 on completion of RTCA0SCMP write (RTCA0SUBC overflow). Do not write to RTCA0SCMP while the value of this bit is 1 because write to RTCA0SCMP is in progress. 0: RTCA0SCMP write completed 1: RTCA0SCMP write in progress	R
31:5	—	These bits are read as 0. The write value should be 0.	R/W

26.3.4 RTCA0SUBC : RTC Sub Count Register

Base address: RTC = 0x8100_9000

Offset address: 0x0C

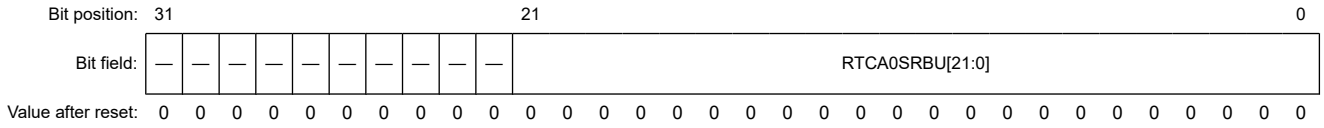
Bit position:	31										21																				0
Bit field:	—	—	—	—	—	—	—	—	—	—	RTCA0SUBC[21:0]																				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
21:0	RTCA0SUBC[21:0]	Register that counts the 1 second reference time This register is cleared on reset or on write to the RTCA0SEC (RTC Sec Count Buffer register) or RTCA0TIME (RTC Time Set register), and arbitrary values cannot be written to this register. Count-up occurs on clock input when the clock counter operation is enabled (RTCA0CE = 1). When this register is read while the clock counter operation is enabled (RTCA0CE = 1), the register value, which changes in synchronization with PCLKRTC, is read asynchronously, so that the read value is not guaranteed. To check the value of this register while the clock counter operation is enabled (RTCA0CE = 1), use the RTCA0SRBU register. The count-up operation starts from 0x0, and on matching the value set to RTCA0SCMP, an overflow signal is output to RTCA0SEC (Second Count Buffer register), and this register is cleared. [Example] Operation using 195.3 kHz clock 195312 - 1 = 195311 (decimal code) = 0x2FAEF is set to RTCA0SCMP. Counting up is performed each time a 195.3 kHz clock is input, taking on values from 0x0 to 0x2FAEF. 1 second is counted when the value changes from 0x2FAEF to 0x0.	R
31:22	—	These bits are read as 0.	R

26.3.5 RTCA0SRBU : RTC Sub Count Register Read Buffer

Base address: RTC = 0x8100_9000

Offset address: 0x10

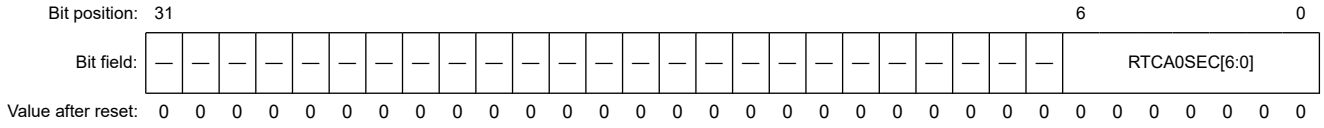


Bit	Symbol	Function	R/W
21:0	RTCA0SRBU[21:0]	Read buffer register of RTCA0SUBC This register is cleared when reset, at which time arbitrary values cannot be written. When 1 is written to the RTCA0RSUB bit while the clock counter operation is enabled (RTCA0CE = 1), the value of RTCA0SUBC is loaded to this register in synchronization with PCLKRTC clock. Be sure to perform RTCA0SRBU read according to the flow described in section 26.4.1.4. Reading RTCA0SRBU While Clock Counter Operation is Enabled.	R
31:22	—	These bits are read as 0.	R

26.3.6 RTCA0SEC : RTC Sec Count Buffer Register

Base address: RTC = 0x8100_9000

Offset address: 0x14



Bit	Symbol	Function	R/W
6:0	RTCA0SEC[6:0]	Buffer register to read/write RTC Second Count register (RTCA0SECC). This register is used when Second Count register is read and written. When setting this register, a decimal value of 00 to 59 must be set in BCD code.	R/W
31:7	—	These bits are read as 0. The write value should be 0.	R/W

26.3.7 RTCA0MIN : RTC Min Count Buffer Register

Base address: RTC = 0x8100_9000

Offset address: 0x18

Bit position:	31																							6						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCA0MIN[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	RTCA0MIN[6:0]	Buffer register to read/write RTC Minute Count register (RTCA0MINC). This register is used when Minute Count register is read and written. When setting this register, a decimal value of 00 to 59 must be set in BCD code.	R/W
31:7	—	These bits are read as 0. The write value should be 0.	R/W

26.3.8 RTCA0HOUR : RTC Hour Count Buffer Register

Base address: RTC = 0x8100_9000

Offset address: 0x1C

Bit position:	31																								5					0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCA0HOUR[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	0

Bit	Symbol	Function	R/W
5:0	RTCA0HOUR[5:0]	Buffer register to read/write RTC Hour Count register (RTCA0HOURC). This register is used when Hour Count register is read and written. When setting this register, a decimal value of 01 to 12 or 21 to 32 must be set when RTCA0AMPM = 0, or a decimal value of 0 to 23 when RTCA0AMPM = 1, in BCD code in both cases. Display of RTCA0HOUR is 12-hour display when the RTCA0AMPM bit is set to 0, and 24-hour display when it is 1. In the case of 12-hour display, am/pm is indicated by the 5th bit of RTCA0HOUR. During am, RTCA0HOUR[5] = 0, and during pm, RTCA0HOUR[5] = 1.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

12-hour display		24-hour display	
Time	RTCA0HOUR display	Time	RTCA0HOUR display
0 am	0x12	0	0x00
1 am	0x01	1	0x01
⋮	⋮	⋮	⋮
9 am	0x09	9	0x09
10 am	0x10	10	0x10
11 am	0x11	11	0x11
0 pm	0x32	12	0x12
1 pm	0x21	13	0x13
⋮	⋮	⋮	⋮
9 pm	0x29	21	0x21
10 pm	0x30	22	0x22
11 pm	0x31	23	0x23

26.3.9 RTCA0WEEK : RTC Week Count Buffer Register

Base address: RTC = 0x8100_9000

Offset address: 0x20

Bit position:	31																										2	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCA0WEEK[2:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	RTCA0WEEK[2:0]	Buffer register to read/write RTC Week Count register (RTCA0WEEKC). This register is used when Week Count register is read and written. When setting this register, a decimal value of 00 to 06 must be set in BCD code. There is no particular correspondence between the value of RTCA0WEEK and the day of the week. Set the correspondence according to the application to be used. [Example] 0 → Sunday, 1 → Monday, …, 6 → Saturday	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

26.3.10 RTCA0DAY : RTC Day Count Buffer Register

Base address: RTC = 0x8100_9000

Offset address: 0x24

Bit position:	31																									5	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCA0DAY[5:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
5:0	RTCA0DAY[5:0]	Buffer register to read/write RTC Day Count register (RTCA0DAYC). This register is used when Day Count register is read and written. When setting this register, a decimal value of 01 to 31 must be set in BCD code. ● 01 to 31 (January, March, May, July, August, October, December) ● 01 to 30 (April, June, September, November) ● 01 to 29 (February, leap year) ● 01 to 28 (February, non-leap year)	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

26.3.11 RTCA0MONTH : RTC Month Count Buffer Register

Base address: RTC = 0x8100_9000

Offset address: 0x28

Bit position:	31																									4	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCA0MONTH[4:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
4:0	RTCA0MONTH[4:0]	Buffer register to read/write RTC Month Count register (RTCA0MONC). This register is used when Month Count register is read and written. When setting this register, a decimal value of 01 to 12 must be set in BCD code.	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

26.3.12 RTCA0YEAR : RTC Year Count Buffer Register

Base address: RTC = 0x8100_9000

Offset address: 0x2C

Bit position:	31																						7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCA0YEAR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RTCA0YEAR[7:0]	Buffer register to read/write RTC Year Count register (RTCA0YEARC). This register is used when Year Count register is read and written. When setting this register, a decimal value of 00 to 99 must be set in BCD code.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

26.3.13 RTCA0TIME : RTC Time Set Register

Base address: RTC = 0x8100_9000

Offset address: 0x30

Bit position:	31								23							16	15							8	7						0
Bit field:	—	—	—	—	—	—	—	—	RTCA0HOUR[7:0]								RTCA0MIN[7:0]								RTCA0SEC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RTCA0SEC[7:0]	See RTCA0SEC register	R/W
15:8	RTCA0MIN[7:0]	See RTCA0MIN register	R/W
23:16	RTCA0HOUR[7:0]	See RTCA0HOUR register	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

The RTCA0TIME register is a register for accessing the RTCA0HOUR, RTCA0MIN, and RTCA0SEC registers simultaneously. By using this register, the RTCA0HOUR, RTCA0MIN, and RTCA0SEC registers can be read or written simultaneously.

26.3.14 RTCA0CAL : RTC Calendar Set Register

Base address: RTC = 0x8100_9000

Offset address: 0x34

Bit position:	31							24	23							16	15							8	7						0
Bit field:	RTCA0YEAR[7:0]								RTCA0MONTH[7:0]								RTCA0DAY[7:0]								RTCA0WEEK[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RTCA0WEEK[7:0]	See RTCA0WEEK register	R/W
15:8	RTCA0DAY[7:0]	See RTCA0DAY register	R/W
23:16	RTCA0MONTH[7:0]	See RTCA0MONTH register	R/W
31:24	RTCA0YEAR[7:0]	See RTCA0YEAR register	R/W

The RTCA0CAL register is a register for accessing the RTCA0YEAR, RTCA0MONTH, RTCA0DAY, and RTCA0WEEK registers simultaneously. By using this register, the RTCA0YEAR, RTCA0MONTH, RTCA0DAY, and RTCA0WEEK registers can be read or written simultaneously.

26.3.15 RTCA0SCMP : RTC Sub Count Compare Register

Base address: RTC = 0x8100_9000

Offset address: 0x3C

Bit position:	31										21																				0
Bit field:	—	—	—	—	—	—	—	—	—	—	RTCA0SCMP[21:0]																					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
21:0	RTCA0SCMP[21:0]	Register that sets the compare value of RTCA0SUBC (sub-counter). The setting of this register is valid when RTCA0SLSB = 1. When RTCA0SLSB = 1 is set, RTCA0SUBC starts counting up from 0, and when the value set to this register is matched, an overflow signal is output to RTCA0SEC (Second Count Buffer register), and the register is cleared. Set the value for this register according to the frequency of the selected input clock. Accurate one second counting can be performed to PCLKRTC through the value set to this register. [Example] Setting of 195,312 (decimal) - 1 = 195,311 (decimal) = 0x2FAEF to RTCA0SCMP When performing write to this register during clock counter operation (RTCA0CE = 1), be sure to check that RTCA0WSST = 0. When writing to this register during clock counter operation (RTCA0CE = 1), write ends at the timing of RTCA0SUBC overflow. Be sure to perform RTCA0SCMP write according to the flows described in section 26.4.1.1. Initial Setting and section 26.4.1.6. Writing to RTCA0SCMP During Clock Counter Operation.	R/W
31:22	—	These bits are read as 0. The write value should be 0.	R/W

26.3.16 RTCA0ALM : RTC Alarm Min Set Register

Base address: RTC = 0x8100_9000

Offset address: 0x40

Bit position:	31																								6						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCA0ALM[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	RTCA0ALM[6:0]	RTCA0ALM is a register that performs the minute setting for the alarm interrupt. Set a decimal value of 00 to 59 in BCD code (alarm detection is not performed if an out-of-range value is set.)	R/W
31:7	—	These bits are read as 0. The write value should be 0.	R/W

26.3.17 RTCA0ALH : RTC Alarm Hour Set Register

Base address: RTC = 0x8100_9000

Offset address: 0x44

Bit position:	31																								5		0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCA0ALH[5:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	0

Bit	Symbol	Function	R/W
5:0	RTCA0ALH[5:0]	RTCA0ALH is a register that performs the hour setting for the alarm interrupt. When RTCA0AMPM = 0, set a decimal value of 01 to 12 or 21 to 32, and when RTCA0AMPM = 1, set a decimal value of 00 to 23, in BCD code in both cases (alarm detection is not performed if an out-of-range value is set.)	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

26.3.18 RTCA0ALW : RTC Alarm Week Set Register

Base address: RTC = 0x8100_9000

Offset address: 0x48

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	RTCA0ALW6	RTCA0ALW5	RTCA0ALW4	RTCA0ALW3	RTCA0ALW2	RTCA0ALW1	RTCA0ALW0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RTCA0ALW0	Alarm interrupt day of the week setting bit 0 0: Disable alarm 1: Enable alarm	R/W
1	RTCA0ALW1	Alarm interrupt day of the week setting bit 1 0: Disable alarm 1: Enable alarm	R/W
2	RTCA0ALW2	Alarm interrupt day of the week setting bit 2 0: Disable alarm 1: Enable alarm	R/W
3	RTCA0ALW3	Alarm interrupt day of the week setting bit 3 0: Disable alarm 1: Enable alarm	R/W
4	RTCA0ALW4	Alarm interrupt day of the week setting bit 4 0: Disable alarm 1: Enable alarm	R/W
5	RTCA0ALW5	Alarm interrupt day of the week setting bit 5 0: Disable alarm 1: Enable alarm	R/W
6	RTCA0ALW6	Alarm interrupt day of the week setting bit 6 0: Disable alarm 1: Enable alarm	R/W
31:7	—	These bits are read as 0. The write value should be 0.	R/W

The RTCA0ALW register enables the alarm corresponding to RTCA0WEEK value. For example, if RTCA0WEEK = 0 is Sunday, RTCA0ALW0 bit functions as Sunday alarm. If RTCA0WEEK = 6 is Saturday, RTCA0ALW6 bit functions as Saturday alarm.

26.3.19 RTCA0SECC : RTC Second Count Register

Base address: RTC = 0x8100_9000

Offset address: 0x4C

Bit position:	31																								6						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCA0SECC[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	RTCA0SECC[6:0]	Counts up the seconds This register counts from 00 to 59, and when its value changes from 59 to 00 in BCD code, an overflow signal is output to RTCA0MINC.	R
31:7	—	These bits are read as 0.	R

26.3.20 RTCA0MINC : RTC Minute Count Register

Base address: RTC = 0x8100_9000

Offset address: 0x50

Bit position:	31																								6						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCA0MINC[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	RTCA0MINC[6:0]	Counts up the minutes This register counts from 00 to 59, and when its value changes from 59 to 00 in BCD code, an overflow signal is output to RTCA0HOURC.	R
31:7	—	These bits are read as 0.	R

26.3.21 RTCA0HOURC : RTC Hour Count Register

Base address: RTC = 0x8100_9000

Offset address: 0x54

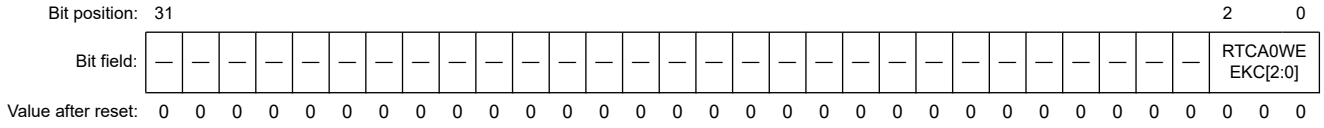
Bit position:	31																									5					0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCA0HOURC[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	0

Bit	Symbol	Function	R/W
5:0	RTCA0HOURC[5:0]	Counts up the hours This register counts from 00 to 23, or 01 to 12, or 21 to 32 in BCD code depending on the setting of RTCA0AMPM, and when its value changes from 23 to 00 or from 32 to 01, an overflow signal is output to RTCA0DAY and RTCA0WEEK.	R
31:6	—	These bits are read as 0.	R

26.3.22 RTCA0WEEKC : RTC Week Count Register

Base address: RTC = 0x8100_9000

Offset address: 0x58

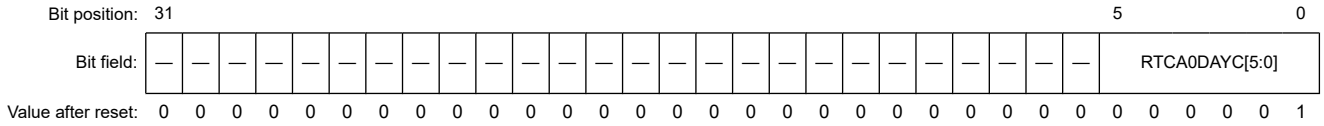


Bit	Symbol	Function	R/W
2:0	RTCA0WEEKC[2:0]	Counts up the weeks This register counts up on occurrence of RTCA0HOURC overflow when the clock counter operation is enabled (RTCA0CE = 1).	R
31:3	—	These bits are read as 0.	R

26.3.23 RTCA0DAYC : RTC Day Count Register

Base address: RTC = 0x8100_9000

Offset address: 0x5C

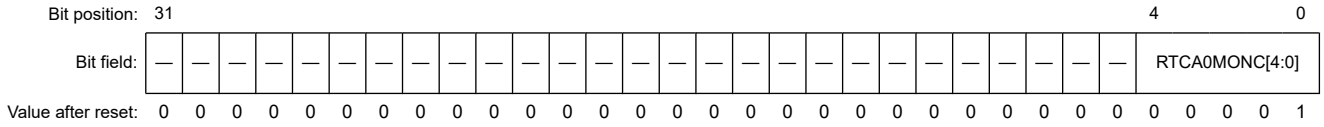


Bit	Symbol	Function	R/W
5:0	RTCA0DAYC[5:0]	Counts up the days This register counts up on occurrence of RTCA0HOURC overflow when the clock counter operation is enabled (RTCA0CE = 1). This register counts according to the value of RTCA0MONC, and on occurrence of an overflow, an overflow signal is output to RTCA0MONC.	R
31:6	—	These bits are read as 0.	R

26.3.24 RTCA0MONC : RTC Month Count Register

Base address: RTC = 0x8100_9000

Offset address: 0x60

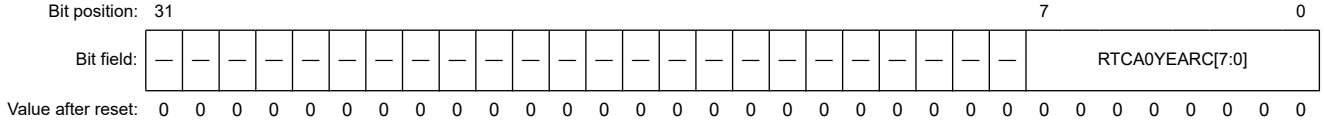


Bit	Symbol	Function	R/W
4:0	RTCA0MONC[4:0]	Counts up the months This register counts up on occurrence of RTCA0DAYC overflow while the clock counter operation is enabled (RTCA0CE = 1). This register counts from 01 to 12 in BCD code, and when its value changes from 12 to 01, an overflow signal is output to RTCA0YEARC.	R
31:5	—	These bits are read as 0.	R

26.3.25 RTCA0YEARC : RTC Year Count Register

Base address: RTC = 0x8100_9000

Offset address: 0x64

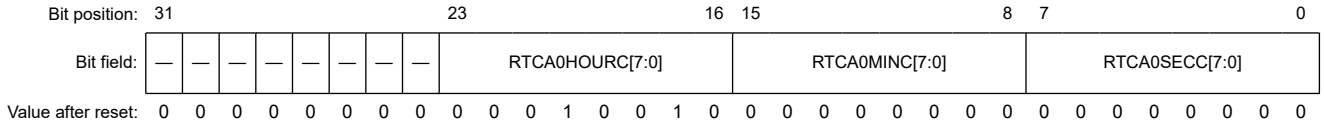


Bit	Symbol	Function	R/W
7:0	RTCA0YEARC[7:0]	Counts up the years This register counts up on occurrence of RTCA0MONC overflow while the clock counter operation is enabled (RTCA0CE = 1). This register counts from 00 to 99 in BCD code.	R
31:8	—	These bits are read as 0.	R

26.3.26 RTCA0TIMEC : RTC Time Count Register

Base address: RTC = 0x8100_9000

Offset address: 0x68



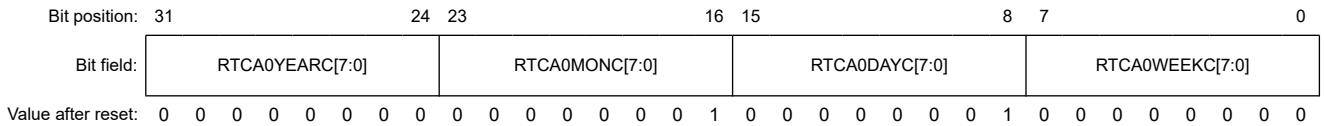
Bit	Symbol	Function	R/W
7:0	RTCA0SECC[7:0]	See RTCA0SECC register	R
15:8	RTCA0MINC[7:0]	See RTCA0MINC register	R
23:16	RTCA0HOURC[7:0]	See RTCA0HOURC register	R
31:24	—	These bits are read as 0.	R

This register is for reading the RTCA0HOURC, RTCA0MINC, and RTCA0SECC simultaneously.

26.3.27 RTCA0CALC : RTC Calendar Count Register

Base address: RTC = 0x8100_9000

Offset address: 0x6C



Bit	Symbol	Function	R/W
7:0	RTCA0WEEKC[7:0]	See RTCA0WEEKC register	R
15:8	RTCA0DAYC[7:0]	See RTCA0DAYC register	R
23:16	RTCA0MONC[7:0]	See RTCA0MONC register	R
31:24	RTCA0YEARC[7:0]	See RTCA0YEARC register	R

The RTCA0CALC register is for reading the RTCA0YEARC, RTCA0MONC, RTCA0DAYC, and RTCA0WEEKC simultaneously.

26.4 Operation

26.4.1 Programming RTC

26.4.1.1 Initial Setting

Perform initial setting of RTC according to the flow in Figure 26.2.

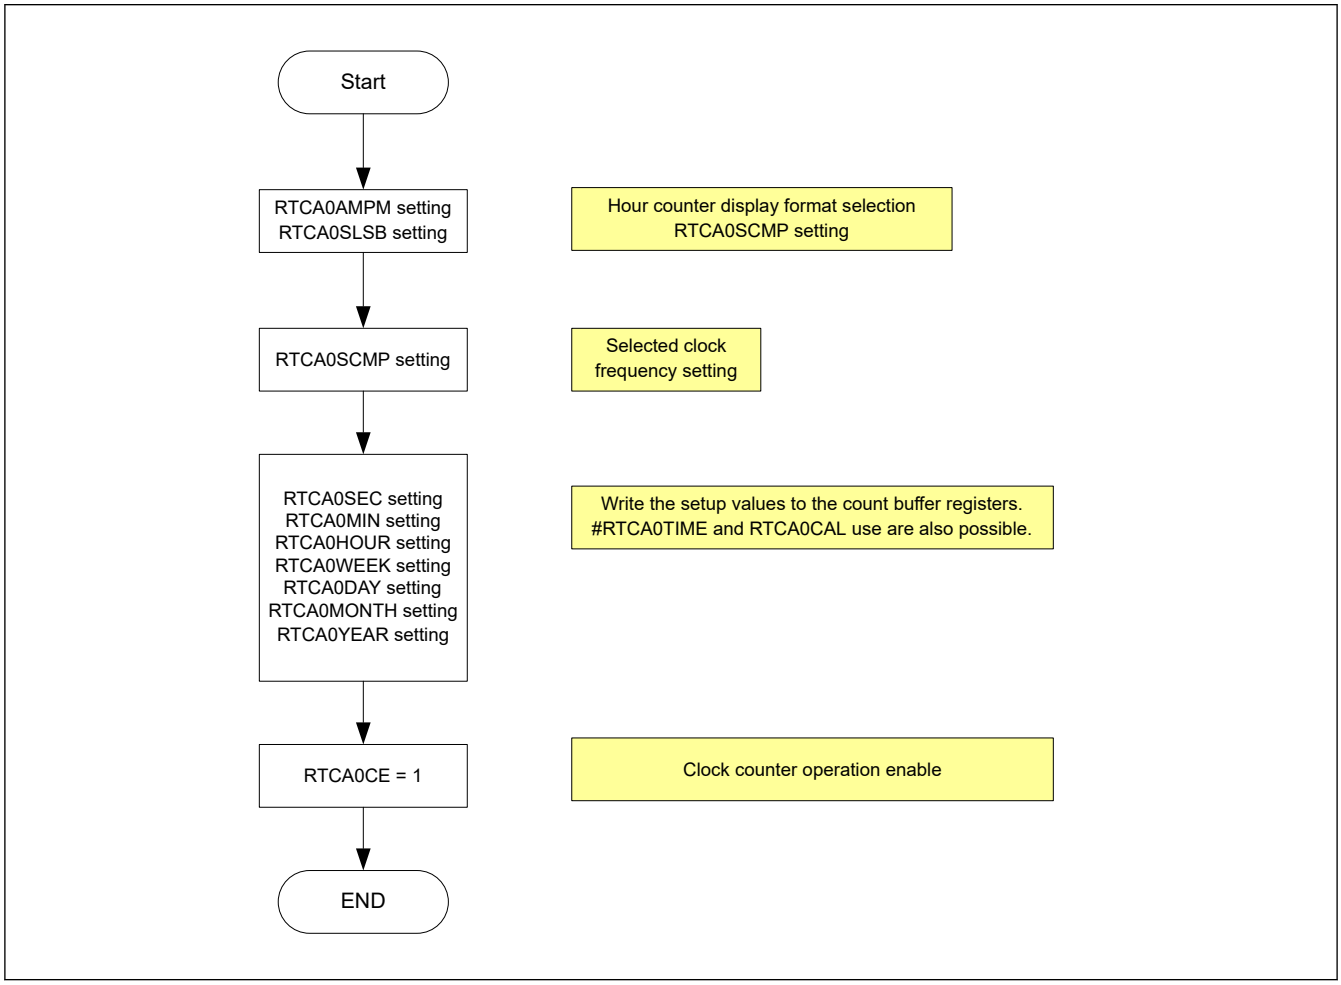


Figure 26.2 Setting RTC when clock counter is disabled

The internal clock counter operates in synchronization with PCLKRTC, and two PCLKRTC cycles are required until completion of the initial value setting procedure described in Figure 26.2. Therefore, PCLKL must be continuously supplied until completion of the initial value setting procedure. To stop PCLKL supply after the initial value setting procedure, check first that RTCA0CEST = 1 (clock counter operation enabled status).

26.4.1.2 Writing to Clock Counters While Clock Counter Operation is Enabled

Be sure to write to the RTCA0SEC, RTCA0MIN, RTCA0HOUR, RTCA0WEEK, RTCA0DAY, RTCA0MONTH, and RTCA0YEAR counters while the clock counter operation is enabled (RTCA0CE = 1) according to the flow in Figure 26.3.

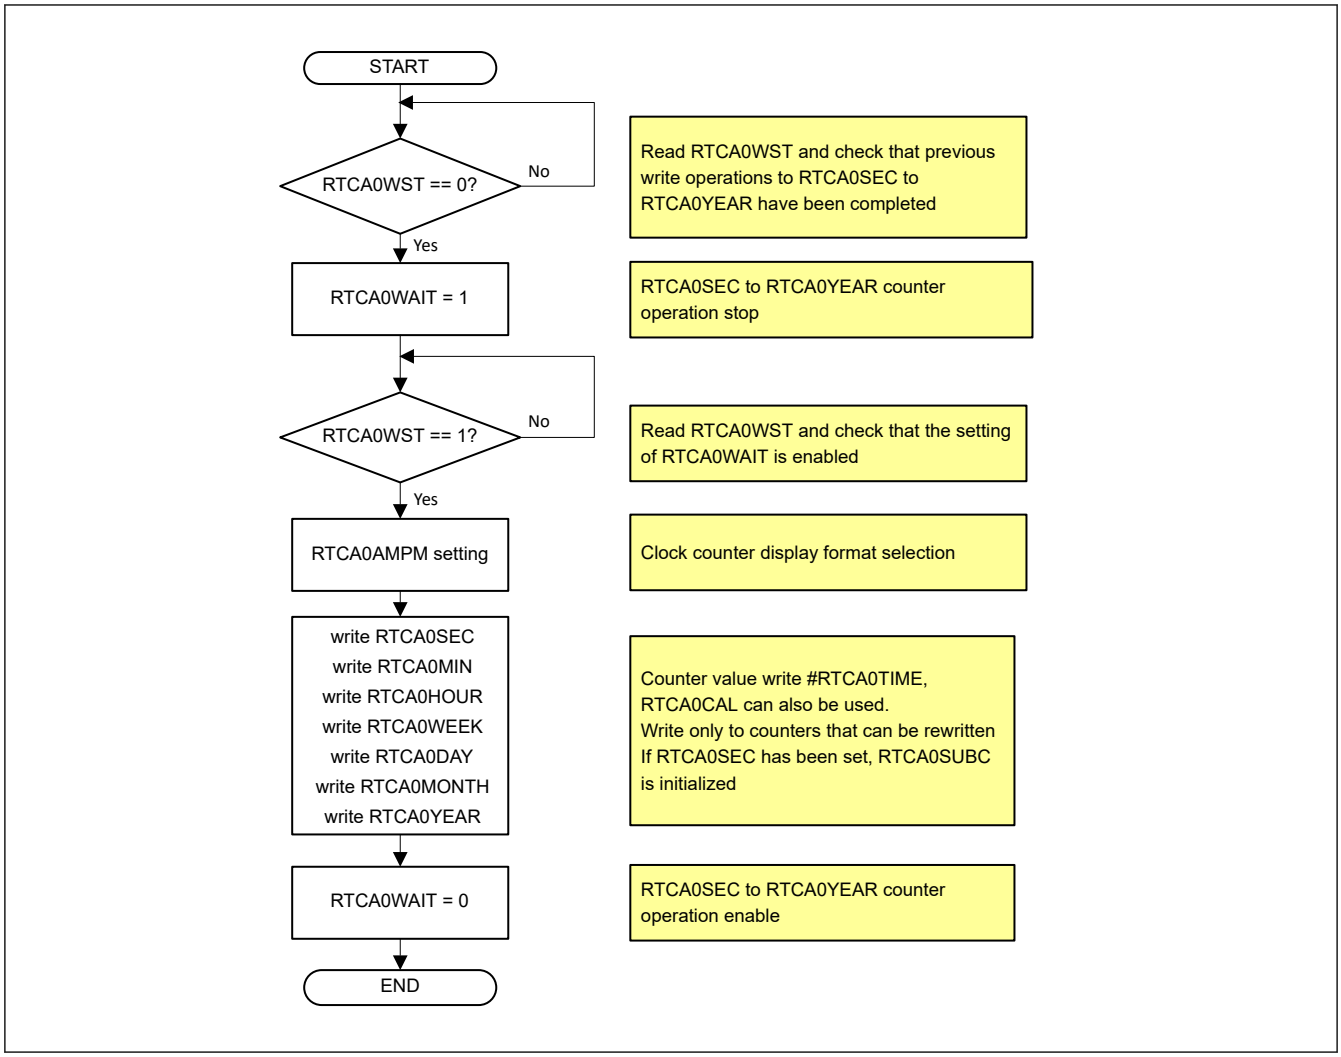

Figure 26.3 Setting RTC when clock counter is enabled

It is prohibited to write two or more times to the same register in the flow described in Figure 26.3. For example, it is prohibited to write twice to the second counter. End the programming flow within 1 second.

When RTCA0WAIT = 1 is set, the operation of RTCA0SEC (second counter buffer) stops. If RTCA0SUBC overflow occurs while RTCA0WAIT = 1, one overflow is held internally. However, if overflow occurs two or more times, the overflow count cannot be held.

The internal clock counter operates in synchronization with PCLKRTC. Two PCLKRTC cycles are required until completion of the above-described initial value setting procedure. Therefore, PCLKL must be continuously supplied until completion of the initial value setting procedure.

To stop PCLKL supply after the initial value setting procedure, check first that RTCA0WST = 0 (clock counter count-up status).

26.4.1.3 Reading Clock Counters While Clock Counter Operation is Enabled

There are two methods to read clock counters while clock counter operation is enabled (RTCA0CE = 1):

- Using Count Buffer Registers
- Reading Count Registers

The advantages and disadvantages of the two methods are mentioned in the next table.

Method	Advantage	Disadvantage
(1) Using count buffer registers	It is unnecessary to read clock counter several times such as in method (2), because clock counters are read synchronously.	Program wait*1 occurs from setting RTCA0WAIT = 1 to completion of data transfer.
(2) Reading count registers	Program wait does not occur.	When the reading of counter and overflow of RTCA0SUBC competed with each other, the clock counters are read several times again*2.

Note 1. The maximum of program wait is 3 clock cycles of PCLKL + 2 clock cycles of PCLKRTC.
Note 2. When reading of counter and overflow of sub-counter competed with each other, unknown value might be read.

(1) Using Count Buffer Registers

This is how to read clock counter value by using buffer registers. The value of clock count registers are transferred to count buffer registers by writing 1 in RTCA0WAIT. The count buffer registers are read after that. In this method, program wait occurs from setting RTCA0WAIT = 1 to completion of data transfer.

Reading clock counters while clock counter operation is enabled (RTCA0CE = 1)

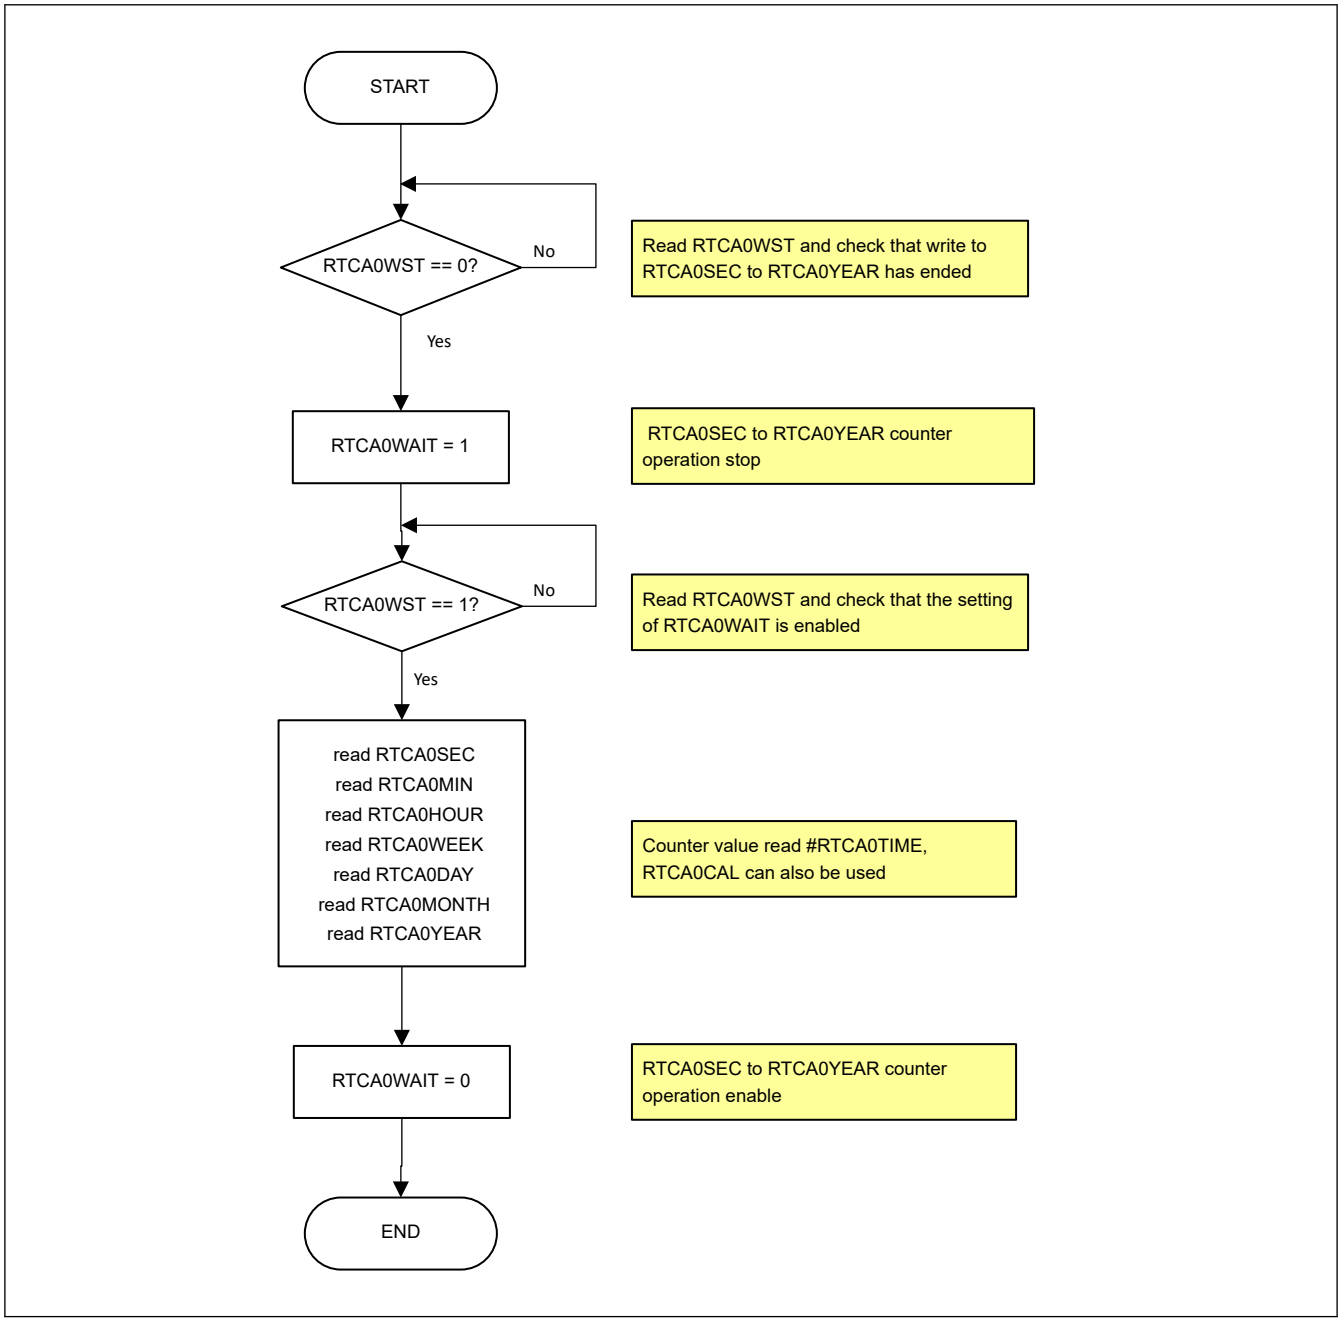

Figure 26.4 Reading RTC using count buffer registers

End this flow within 1 second.

When RTCA0WAIT = 1 is set, the operation of RTCA0SEC (second counter buffer) stops. If RTCA0SUBC overflow occurs while RTCA0WAIT = 1, one overflow is held internally. However, if overflow occurs two or more times, the overflow count cannot be held.

(2) Reading Count Registers

This is how to read clock counter immediately. RTCA0SECC (RTC Second Count Register) is read twice in the beginning and in the end. This is because it confirms whether overflow of sub-counter does not occur while counter is read. After that, the first read value is compared with the second read value. If the first read value is the same as the second read value, it is determined that overflow of sub-counter did not occur during counter read flow. If the first read value is not the same as the second read value, it is determined that overflow of sub-counter occurred during counter read flow, and it begins to read the clock counter again.

Reading clock counters while clock counter operation is enabled (RTCA0CE = 1)

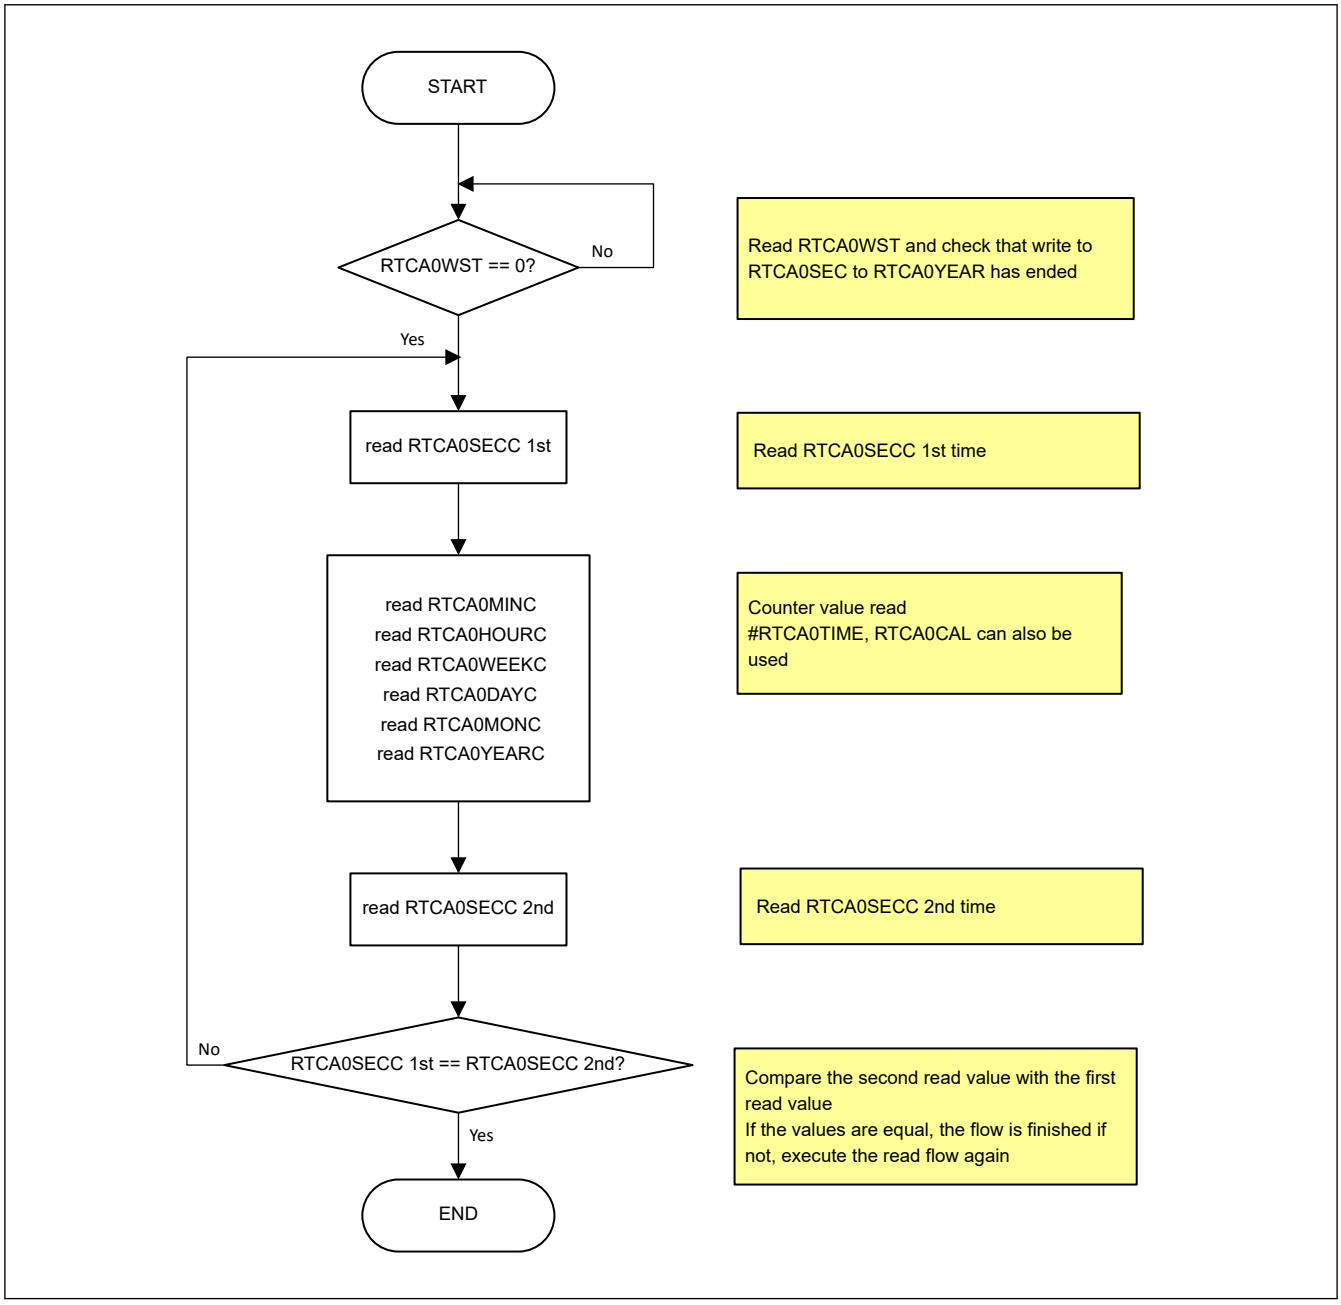

Figure 26.5 Reading RTC using the counting registers

End this flow within 1 second.

When it is not finished within one second, read clock counter value cannot be assured.

26.4.1.4 Reading RTCA0SRBU While Clock Counter Operation is Enabled

Be sure to read RTCA0SRBU while the clock counter operation is enabled (RTCA0CE = 1) according to the flow in Figure 26.6.

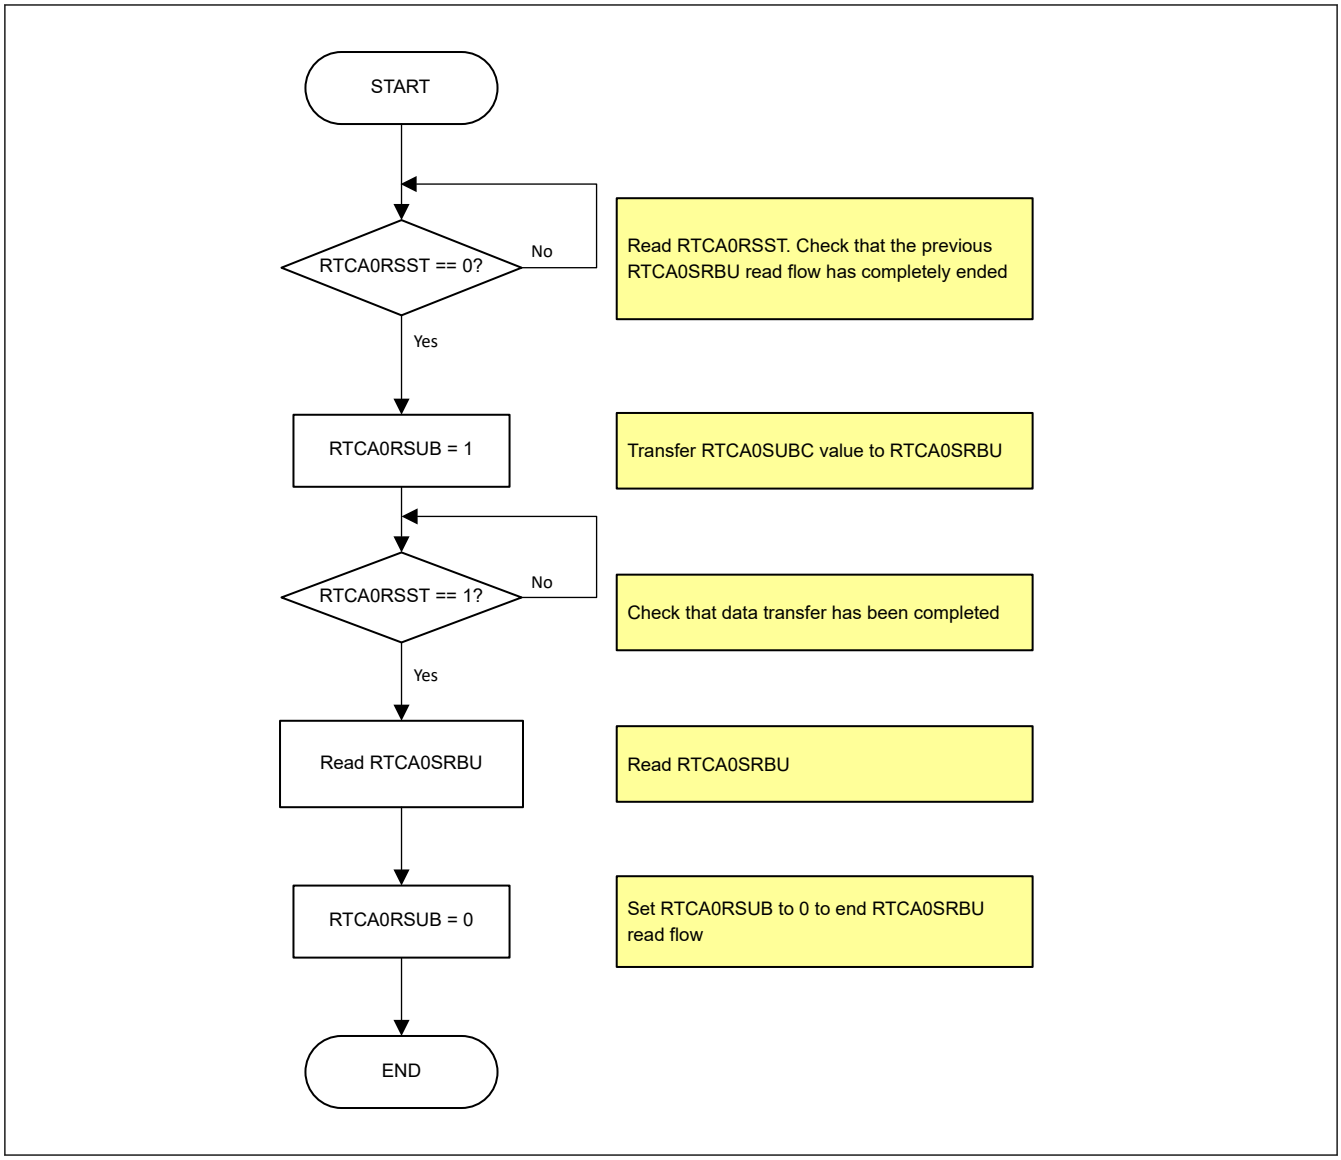

Figure 26.6 Reading RTCA0SRBU

26.4.1.5 Initialization of RTC While Clock Counter Operation is Enabled

Be sure to perform initialization of the RTC controller while the clock counter operation is enabled (RTCA0CE = 1) according to the flow in Figure 26.7. To restart the RTC controller operation at the end of the flow, implement the flow as described in section 26.4.1.1. Initial Setting.

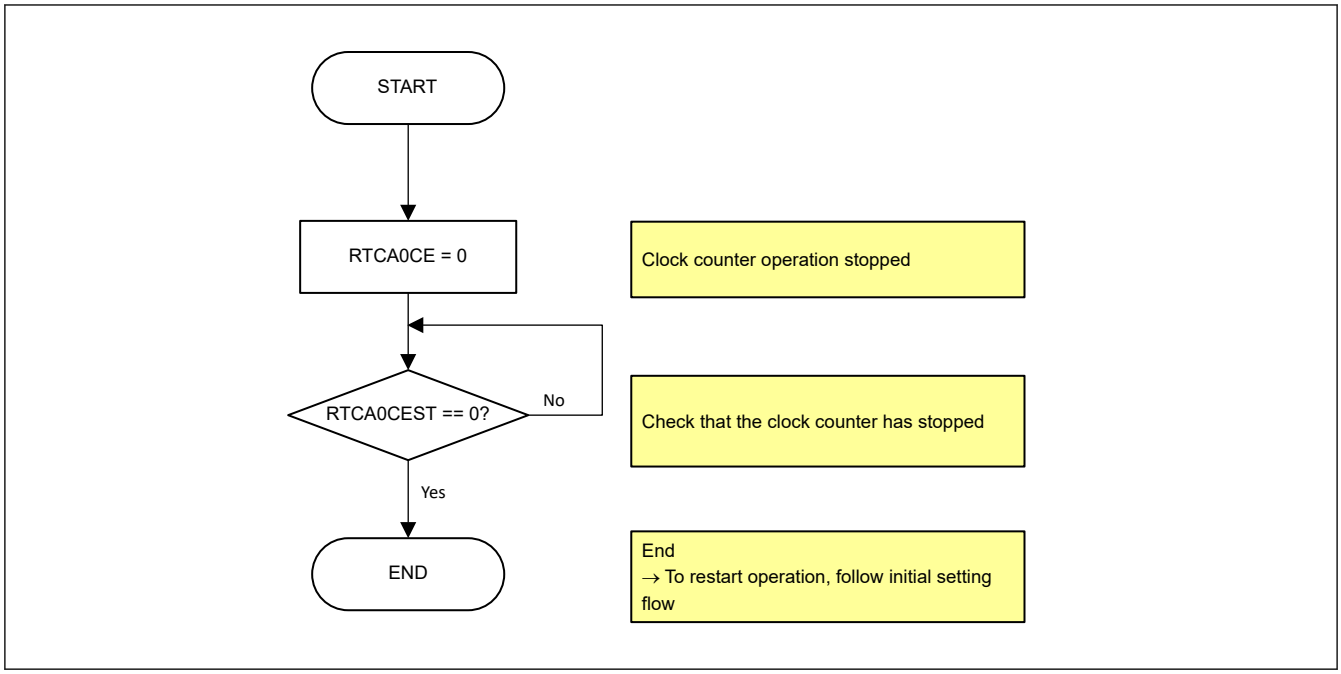

Figure 26.7 Initialization of RTC while clock counter operation is enabled

26.4.1.6 Writing to RTCA0SCMP During Clock Counter Operation

Be sure to write to RTCA0SCMP while the clock counter operation is enabled (RTCA0CE = 1) according to the flow in Figure 26.8.

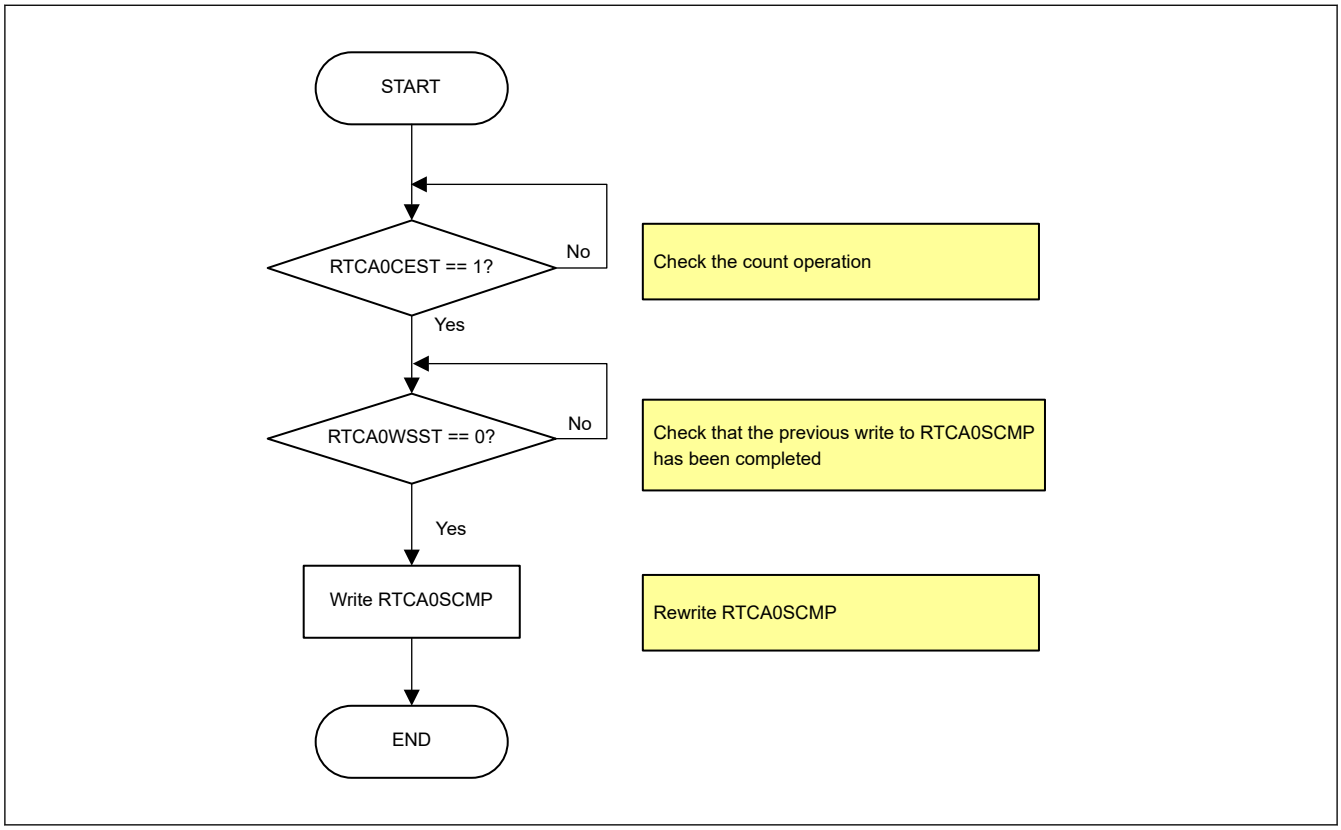

Figure 26.8 Writing to RTCA0SCMP

RTCA0WSST is set to 1 when RTCA0SCMP is written to while the clock counter operation is enabled (RTCA0CE = 1), and on completion of RTCA0SCMP write (RTCA0SUBC overflow), RTCA0WSST is cleared to 0. Because RTCA0WSST displays 1 for up to 1 second for this reason, caution is required when polling RTCA0WSST.

26.4.1.7 Changing the Setting of Fixed Interval Interrupt During Clock Counter Operation

Be sure to change the fixed interval interrupt setting while the clock counter operation is enabled (RTCA0CE = 1) according to the flow in Figure 26.9.

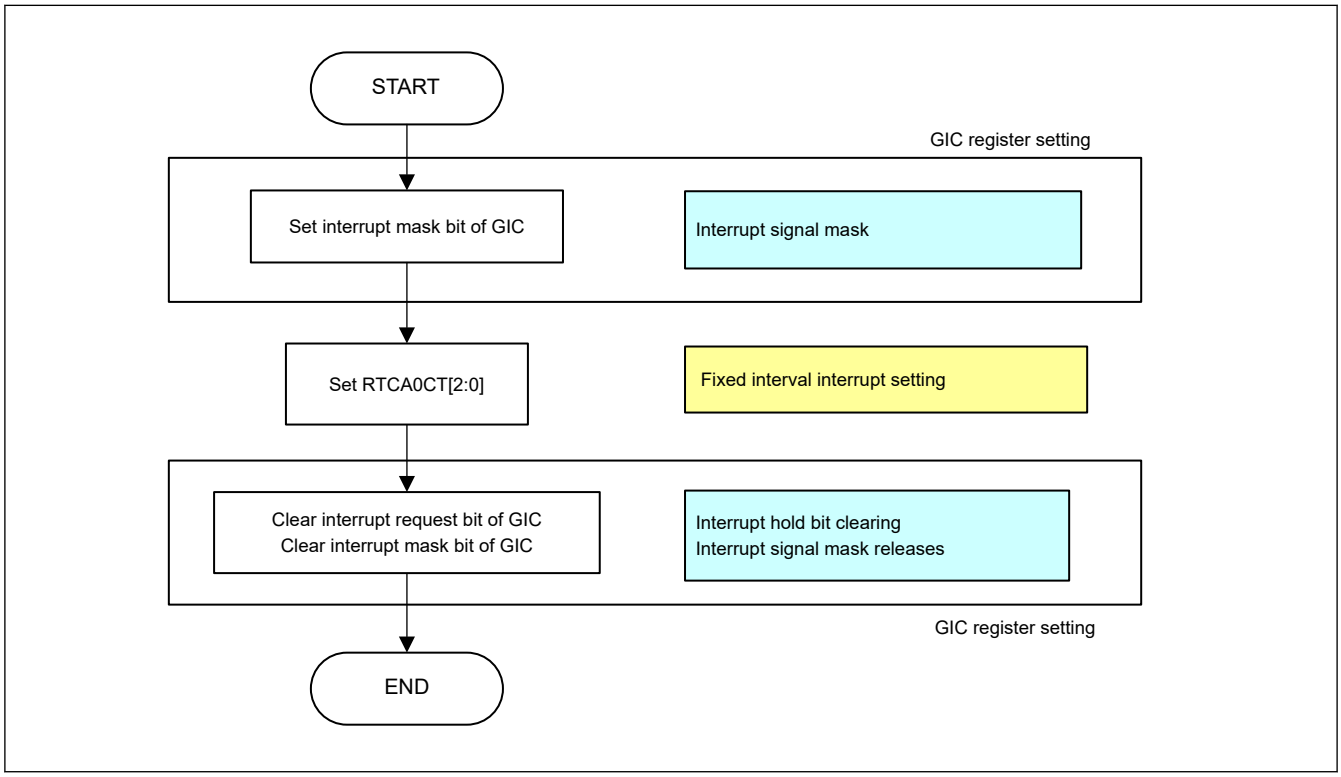

Figure 26.9 Setting of fixed interval interrupt during clock counter operation

26.4.1.8 Changing Alarm Setting During Clock Counter Operation

Be sure to change the alarm interrupt setting while the clock counter operation is enabled (RTCA0CE = 1) according to the flow in Figure 26.10.

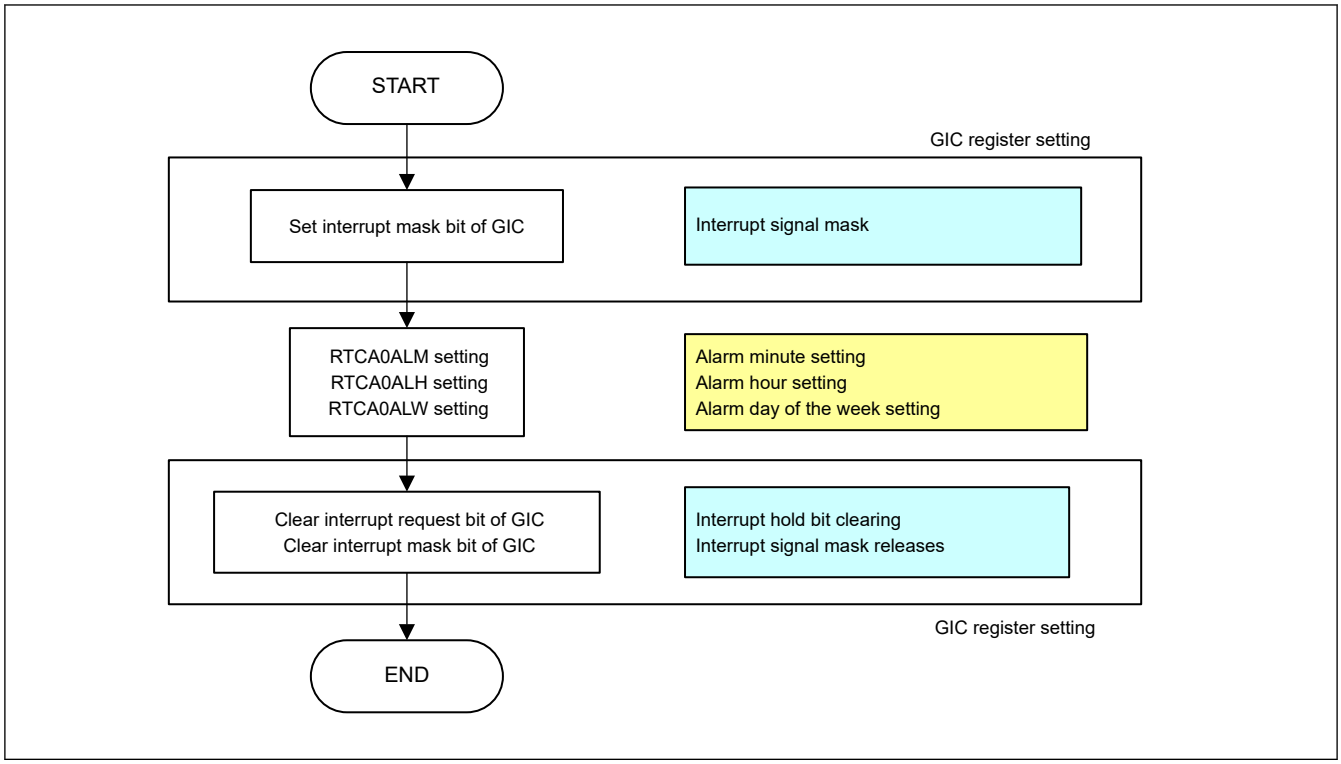

Figure 26.10 Changing the alarm setting during clock counter operation

27. Ethernet Subsystem

27.1 Overview

Ethernet Subsystem (Ethernet_SS) consists of Ethernet MAC (GMAC), Ethernet Switch (ETHSW), EtherCAT Slave Controller (ESC), and RGMII/RMII converters. Four MAC-PHY interfaces supporting RGMII, MII, and RMII are shared with these functions.

Table 27.1 lists the specification of the Ethernet Subsystem and Figure 27.1 shows a block diagram of the Ethernet Subsystem.

Table 27.1 Ethernet Subsystem specifications

Parameter	Description
Ethernet function	• Gigabit Ethernet MAC (GMAC0 to GMAC2) • Ethernet Switch supporting TSN (ETHSW) • EtherCAT Slave Controller (ESC)
MAC-PHY interface	Supported interface by RGMII/RMII converter • RGMII (2.5 MHz/25 MHz/125 MHz) • RMII (50 MHz) • MII (2.5 MHz/25 MHz)
Clock output for PHY	• 25 MHz reference clock output • 50 MHz reference clock output for RMII
Event link (input)	• GMAC PTP Timer capture • EtherCAT DC capture (LATCH0/1)
Event link (output)	• Ethernet Switch PTP Timer pulse event • Ethernet Switch TDMA scheduler event • EtherCAT DC event (SYNC0/1)
Module-stop function	Module-stop state can be set to reduce power consumption each module

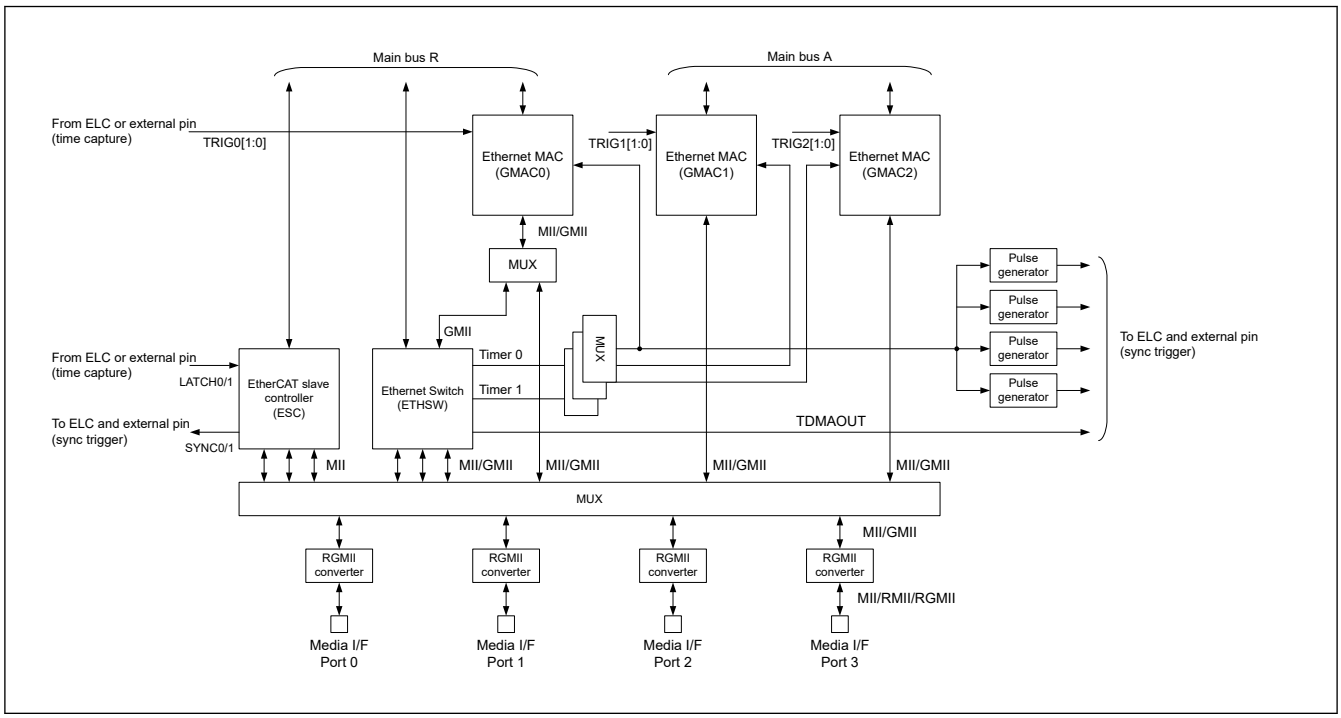

Figure 27.1 Block diagram of Ethernet Subsystem

Table 27.2 Ethernet Subsystem I/O pins (common PHY interface only)

Channel	Pin Name	I/O	Function
ETHn	ETHn_TXCLK	I/O	TX clock input pin (MII mode)/TX clock output pin (RGMII mode)
	ETHn_TXD0	Output	TX data 0 output pin (RGMII, RMII, and MII modes)
	ETHn_TXD1	Output	TX data 1 output pin (RGMII, RMII, and MII modes)
	ETHn_TXD2	Output	TX data 2 output pin (RGMII and MII modes)
	ETHn_TXD3	Output	TX data 3 output pin (RGMII and MII modes)
	ETHn_TXEN	Output	TX data enable pins (RMII and MII modes) TX data enable/TX data error (TX_CTL) pin (RGMII mode)
	ETHn_TXER	Output	TX data error output pin (MII mode)
	ETHn_RXCLK	Input	RX clock input pin (RGMII, RMII, and MII modes)
	ETHn_RXD0	Input	RX data 0 input pin (RGMII, RMII, and MII modes)
	ETHn_RXD1	Input	RX data 1 input pin (RGMII, RMII, and MII modes)
	ETHn_RXD2	Input	RX data 2 input pin (RGMII and MII modes)
	ETHn_RXD3	Input	RX data 3 input pin (RGMII and MII modes)
	ETHn_RXDV	Input	RX data valid pins (MII mode) Carrier sense/RX data valid (CRS_DV) pin (RMII mode) RX data valid/RX error (RX_CTL) pin (RGMII mode)
	ETHn_RXER	Input	RX data error pins (RMII and MII modes)
	ETHn_CRS	Input	Carrier sense pins (MII mode)
	ETHn_COL	Input	Collision detection pins (MII mode)

Note: n = 0 to 3

Table 27.3 Combination of MAC-PHY interface

Pin name	I/O	MII mode	RMII mode (REF_CLK input)	RMII mode (REF_CLK output)	RGMII mode
ETHn_TXCLK	I/O	TX_CLK (Input)	—	—	TXC (Output)
ETHn_TXD0	Output	TXD0	TXD0	TXD0	TXD0
ETHn_TXD1	Output	TXD1	TXD1	TXD1	TXD1

Table 27.4 MAC-PHY interface mode

Combination	ETH0	ETH1	ETH2	ETH3
No.0*1	ETHSW Port 0	ETHSW Port 1	ETHSW Port 2	GMAC1
No.1	ESC Port 0	ESC Port 1	GMAC2	GMAC1
No.2*1	ESC Port 0	ESC Port 1	ETHSW Port 2	GMAC1
No.3	ESC Port 0	ESC Port 1	ESC Port 2	GMAC1
No.4*1 *2	ETHSW Port 0	ESC Port 1	ESC Port 2	GMAC1
No.5*1 *2	ETHSW Port 0	ESC Port 1	ETHSW Port 2	GMAC1
No.6*1	ETHSW Port 0	ETHSW Port 1	GMAC2	GMAC1
No.7	GMAC0	GMAC1	GMAC2	—

Note: This is the pin connection inside the Ethernet Subsystem. For example, if GMAC2 in ETH2 is not required for No.1, pins which are assigned to ETH2 can be used as another peripheral by pin mux. GMAC2 can be put to the module stop state (clock is stopped).
Note 1. In case using ETHSW, GMAC0 is used as management port.
Note 2. ETHSW Port 1 is connected to ESC Port 0 internally.

27.2 Register Map

Table 27.5 ETHSS register map

Address	Register symbol	Register name	Write protect
0x8011_0000	PRCMD	Ethernet Protect Register	—

27.3 Register Descriptions

27.3.1 PRCMD : Ethernet Protect Register

Base address: ETHSS = 0x8011_0000

Offset address: 0x000

Bit position:	31																												0
Bit field:	PRCMD[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PRCMD[31:0]	Permit write access to protected registers For detail, see Figure 27.2. 0x0000 00A5: DLE to STATE1 at IDLE 0x0000 0001: STATE1 to STATE2 at STATE1 0x0000 FFFE: STATE2 to STATE3 at STATE2 0x0000 0001: STATE3 to Release Protect at STATE3 0x0000 0000: Clear at Release Protect	R/W

The PRCMD register is used to permit write access to protected registers. The PRCMD register mitigates the risk when application system carries out unusual operations by software runaways.

Before setting the PRCMD register to 0x00000001, protected registers are denied write access (no error occurs and the registers are not updated by write data).

[Setting procedure]

1. Writing 0x000000A5 to PRCMD register
2. Writing 0x00000001 to PRCMD register
3. Writing 0x0000FFFE to PRCMD register
4. Writing 0x00000001 to PRCMD register

[Clearing condition]

- Writing 0x00000000 to PRCMD register

Figure 27.2 shows an ethernet protect command sequence.

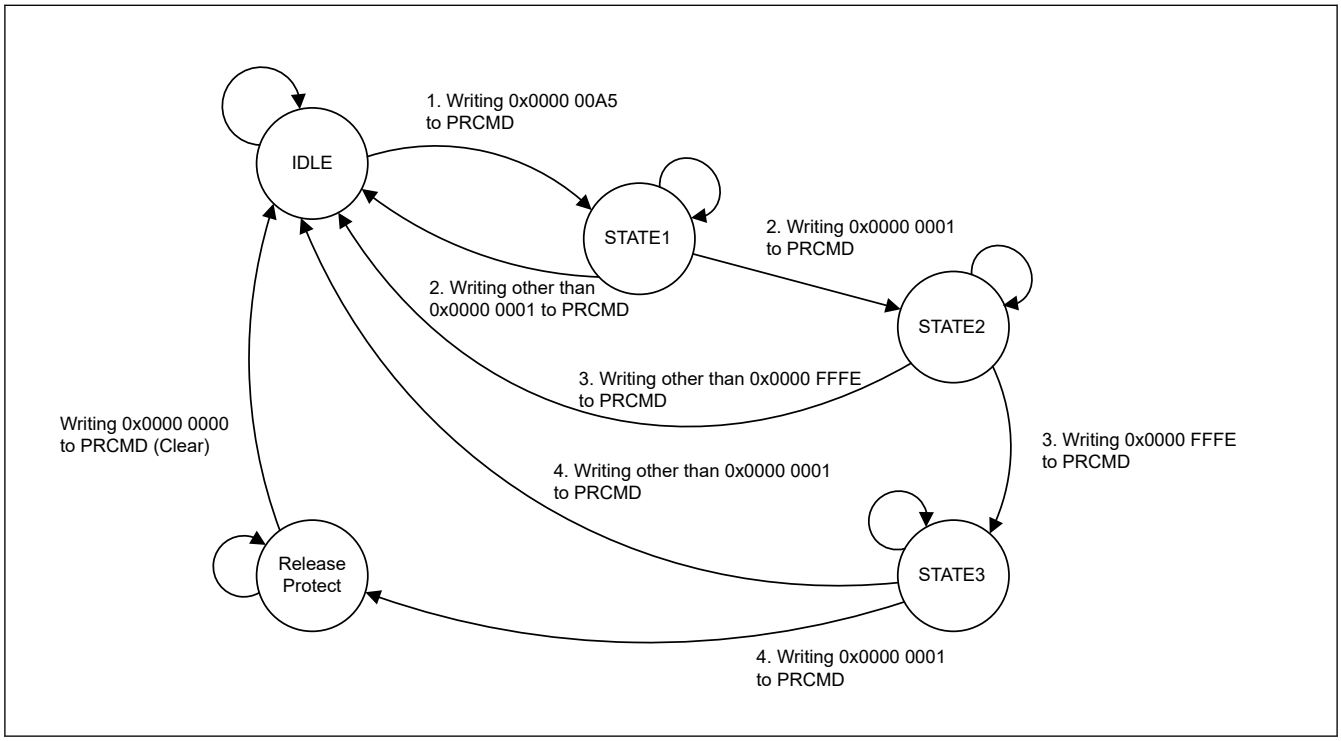

Figure 27.2 Ethernet protect command sequence

27.3.2 MODCTRL : Mode Control Register

Base address: ETHSS = 0x8011_0000

Offset address: 0x008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

111b	ETH0	ETH1	ETH2	—	—	—	—	—	—	—

Note 1. Inter-module connection between GMAC0 and ETHSW MPort
Note 2. Inter-module connection between ETHSW Port 1 and ESC Port 0

Bit	Symbol	Function	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

The MODCTRL register is used to switch the operation control of Switch mode. See Figure 27.1.

27.3.3 PTPMCTRL : PTP Mode Control Register

Base address: ETHSS = 0x8011_0000

Offset address: 0x00C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PTP_PLS_RSTn
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	PTP_MODE2	PTP_MODE1	PTP_MODE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PTP_MODE0	Select the unit number of PTP Timer for GMAC0 and Pulse Generator (unit 0 - 3) 0: Ethernet Switch Timer 0 1: Ethernet Switch Timer 1	R/W
1	PTP_MODE1	Select the unit number of PTP Timer for GMAC1 0: Ethernet Switch Timer 0 1: Ethernet Switch Timer 1	R/W
2	PTP_MODE2	Select the unit number of PTP Timer for GMAC2 0: Ethernet Switch Timer 0 1: Ethernet Switch Timer 1	R/W
15:3	—	These bits are read as 0. The write value should be 0.	R/W
16	PTP_PLS_RSTn	Reset control for Pulse Generator (unit 0 - 3) 0: Assert RESET 1: Release RESET	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

The PTPMCTRL register is used to select the unit number of PTP timer.

27.3.4 PHYLNK : Ethernet PHY Link Mode Register

Base address: ETHSS = 0x8011_0000

Offset address: 0x014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	CATLNK[2:0]			—	SWLINK[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	1	1	1	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SWLINK[2:0]	Specify the active level of the ETHSW_PHYLINKn signal using the Ethernet switch interface SWLINK[n] control ETHSW_PHYLINKn signal (n = 0 to 2) If not used, set the initial value. 0: Active-High PHYLINK signal 1: Active-Low PHYLINK signal	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
6:4	CATLNK[2:0]	Specify the active level of the ESC_PHYLINKn signal using the EtherCAT interface CATLNK[n] control ESC_PHYLINKn signal (n = 0 to 2) If not used, set the initial value. 0: Active-Low PHYLINK signal 1: Active-High PHYLINK signal	R/W
31:7	—	These bits are read as 0. The write value should be 0.	R/W

The PHYLNK register is used to switch the polarity of the Ethernet Switch and EtherCAT Link.

27.3.5 CONVCTRLn : RGMII/RMII Converter n Control Register (n = 0 to 3)

Base address: ETHSS = 0x8011_0000

Offset address: 0x100 + 0x004 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RGMII_SPEED[1:0]		RGMII_DUPLEX	RGMII_LINK	—	RMII_CRS_MODE	RMII_RX_ER_EN	FULLD	—	—	—	CONV_MODE[4:0]				
Value after reset:	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	CONV_MODE[4:0]	Converter operation mode **CONV_MODE[4:0] / Description** x0000b: MII mode (through mode) 00100b: RMII mode 10 Mbps REF_CLK input 00101b: RMII mode 100 Mbps REF_CLK input 10100b: RMII mode 10 Mbps REF_CLK output 10101b: RMII mode 100 Mbps REF_CLK output x1000b: RGMII mode 10 Mbps x1001b: RGMII mode 100 Mbps x1010b: RGMII mode 1000 Mbps Others: Setting prohibited	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	FULLD	Duplex mode (for RMII/RGMII mode) 0: Half-duplex 1: Full-duplex	R/W
9	RMII_RX_ER_EN	ETHn_RXER pin input control (only for RMII mode) 0: RX_ER is always 0 1: RX_ER signal	R/W
10	RMII_CRS_MODE	CRS detection mode (only for RMII mode) 0: CRS | TX_EN 1: CRS | TX_EN | RX_DV	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
12	RGMII_LINK	Indicates link status (only for RGMII mode) 0: Down 1: Up	R

Bit	Symbol	Function	R/W
13	RGMII_DUPLEX	Indicates duplex status (only for RGMII mode) 0: Half-duplex 1: Full-duplex	R
15:14	RGMII_SPEED[1:0]	Indicates link speed (only for RGMII mode) 0 0: 2.5 MHz 0 1: 25 MHz 1 0: 125 MHz 1 1: Reserved	R
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The CONVCTRLn register is used to select the mode for RGMII/RMII.

Table 27.7 Ethernet interface support mode

Ethernet interface mode	Module			
		ETHSW		
	GMAC	Store and forward / cut through	Hub mode	EtherCAT (Port 0 / 1 / 2)
MII mode, 10 Mbps, Half-duplex	Supported	Supported	Not supported	Not supported
MII mode, 10 Mbps, Full-duplex	Supported	Supported	Not supported	Not supported
MII mode, 100 Mbps, Half-duplex	Supported	Supported	Supported	Not supported
MII mode, 100 Mbps, Full-duplex	Supported	Supported	Not supported	Supported*1
RMII mode, 10 Mbps, Half-duplex, Reference clock input	Supported	Supported	Not supported	Not supported
RMII mode, 10 Mbps, Full-duplex, Reference clock input	Supported	Supported	Not supported	Not supported
RMII mode, 100 Mbps, Half-duplex, Reference clock input	Supported	Supported	Supported	Not supported
RMII mode, 100 Mbps, Full-duplex, Reference clock input	Supported	Supported	Not supported	Supported*2
RMII mode, 10 Mbps, Half-duplex, Reference clock output	Supported	Supported	Not supported	Not supported
RMII mode, 10 Mbps, Full-duplex, Reference clock output	Supported	Supported	Not supported	Not supported
RMII mode, 100 Mbps, Half-duplex, Reference clock output	Supported	Supported	Supported	Not supported
RMII mode, 100 Mbps, Full-duplex, Reference clock output	Supported	Supported	Not supported	Supported*3
RGMII mode, 10 Mbps, Half-duplex	Supported	Supported	Not supported	Not supported
RGMII mode, 10 Mbps, Full-duplex	Supported	Supported	Not supported	Not supported
RGMII mode, 100 Mbps, Half-duplex	Supported	Supported	Supported	Not supported
RGMII mode, 100 Mbps, Full-duplex	Supported	Supported	Not supported	Supported
RGMII mode, 1000 Mbps, Half-duplex	Supported	Not supported	Not supported	Not supported
RGMII mode, 1000 Mbps, Full-duplex	Supported	Supported	Not supported	Not supported

Note 1. When using EtherCAT in MII mode with 100 Mbps and Full-duplex, ETHn_REFCLK (n = 0 to 2) output needs to be used for the reference clock of the external Ethernet PHY. And the PHY must synchronize the ETHn_TXCLK (n = 0 to 2) output with the ETHn_REFCLK.

Note 2. When using EtherCAT in RMII mode with 100 Mbps, Full-duplex, and Reference clock input, RMIIn_REFCLK (n = 0 to 2) output needs to be used for the reference clock of the external Ethernet PHY. And the PHY must synchronize the ETHn_RXCLK (n = 0 to 2) output with the RMIIn_REFCLK.

Note 3. When using EtherCAT in RMII mode with 100 Mpbs, Full-duplex, and Reference clock output, RMIIn_REFCLK (n = 0 to 2) output needs to be used for the reference clock of the external Ethernet PHY.

27.3.6 CONVRST : RGMII/RMII Converter Reset Control Register

Base address: ETHSS = 0x8011_0000

Offset address: 0x114

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	PHYIR[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	PHYIR[3:0]	Release reset of RGMII/RMII Converter. Bit 0 = port 0, bit 1= port 1, bit 2 = port 2, bit 3 = port 3. 0: Reset RGMII/RMII Converter 1: Activate RGMII/RMII Converter	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

The CONVRST register is used to control the reset for RGMII/RMII Converter.

27.3.7 SWCTRL : Switch Core Control Register

Base address: ETHSS = 0x8011_0000

Offset address: 0x304

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STRAP_HUB_ENB	STRAP_SX_ENB
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	SET1000[2:0]			—	SET10[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SET10[2:0]	Port control to select use of 10 Mbps. Bit 0 = port 0, bit 1 = port 1, bit 2 = port 2. 0: Not 10 Mbps 1: 10 Mbps	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
6:4	SET1000[2:0]	Port control to select use of 1000 Mbps. Bit 0 = port 0, bit 1 = port 1, bit 2 = port 2. 0: Not 1000 Mbps 1: 1000 Mbps	R/W
15:7	—	These bits are read as 0. The write value should be 0.	R/W
16	STRAP_SX_ENB	Initialize switch after reset (set during module reset of ETHSW) Wiring both STRAP_SX_ENB and STRAP_HUB_ENB to 1 enables all ports including the management port. 0: Switch stay uninitialized 1: Switch initialized (line port)	R/W

Bit	Symbol	Function	R/W
17	STRAP_HUB_ENB	Initialize switch port 0 and 1 (set during module reset of ETHSW) Wiring both STRAP_SX_ENB and STRAP_HUB_ENB to 1 enables all ports including the management port. When STRAP_SX_ENB is 0: 0: Port 0 and 1 stay uninitialized 1: Port 0 and 1 initialized	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The SWCTRL register is used to control the Ethernet switch.

27.3.8 SWDUPC : Switch Core Duplex Mode Register

Base address: ETHSS = 0x8011_0000

Offset address: 0x308

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PHY_DUPLEX[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	PHY_DUPLEX[2:0]	Configure the MAC of each port for full-duplex or half-duplex operation. Bit 0 = port 0, bit 1 = port 1, bit 2 = port 2. This bit is ignored if HD_ENA bit of COMMAND_CONFIG_P[n] register is 0. It is recommended that these bits are set to 0. Use HD_ENA bit of COMMAND_CONFIG_Pn register instead. 0: Half-duplex 1: Full-duplex	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

The SWDUPC register is used to switch the core duplex mode.

27.4 Operation

27.4.1 Ethernet Initializing Operation

For initializing operation, complete the following flowchart.

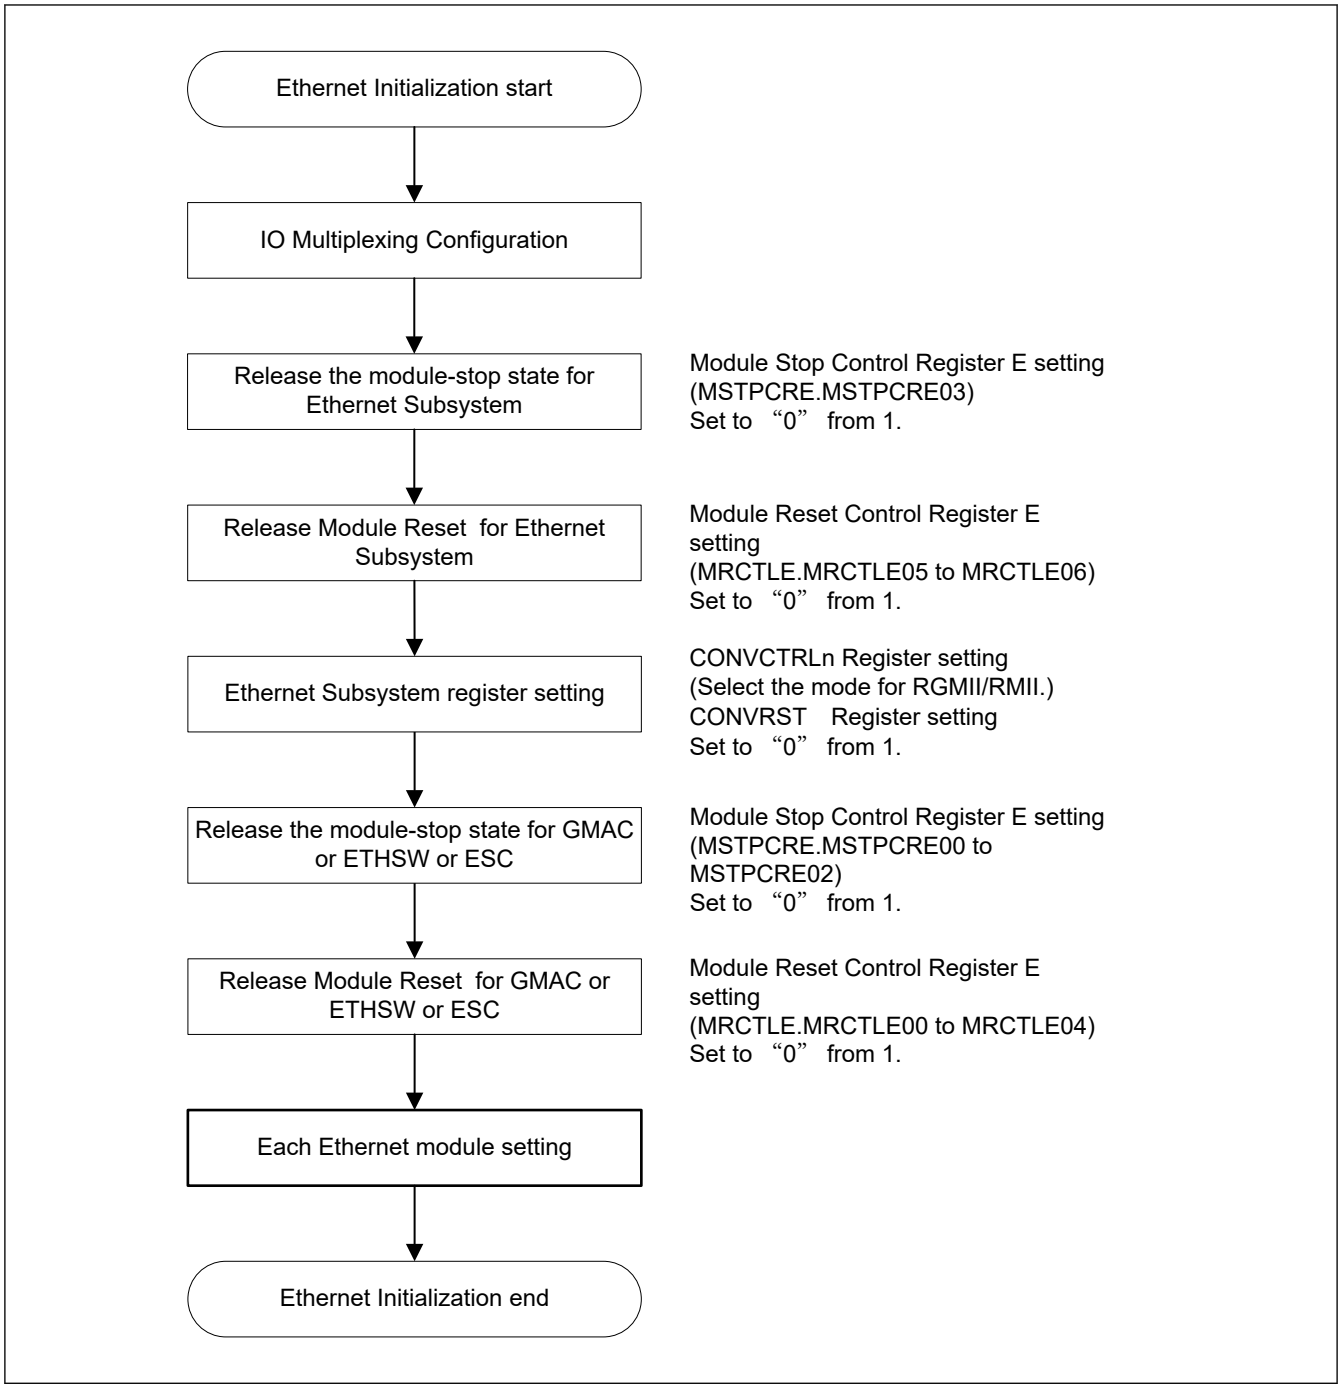

Figure 27.3 Ethernet initializing flowchart

27.5 Usage Notes

When MODCTRL.SW_MODE[2:0] is 100b or 101b (inter-module connection between ETHSW Port 1 and ESC Port 0), PHY Link signals for ETHSW Port 1 and ESC Port 0 should be handled as bellows,

- Do not select ESC_PHYLINK0 and ETHSW_PHYLINK1 as multiplexed pin configuration for any ports.
- Set PHYLINK.CATLNK[0] and PHYLINK.SWLINK[1] to the inverted value of reset value.

28. Ethernet MAC (GMAC)

28.1 Overview

The LSI includes three Ethernet GMAC.

Table 28.1 GMAC specifications

Item	Description
Number of units	• 3 Units
Features	• Compliance with the following standards: – IEEE 802.3-2008 for Ethernet MAC, Gigabit Media Independent Interface (GMII) & Media Independent Interface (MII) – IEEE 1588-2008 v2 standard for precision networked clock synchronization, IEEE 1588-2008 v2 is compliant with Power IEEE-C37.238 profile – IEEE 802.3-az, version D2.0 for Energy Efficient Ethernet (EEE) – Time Sensitive Networking • Enhancement to Scheduled Traffic (EST, 802.1Qbv) • Frame Preemption (FPE, 802.1Qbu / 802.3br) • Time-Based Scheduling • Support for 10/100/1000 Mbps data transfer rates • Support for both half-duplex and full-duplex operation • Programmable frame length to support both standard and "jumbo" ethernet frames with size up to 16 KB – Jumbo mode support in cut through mode only (not implemented in store & forward due to TX & RX fifo size) • 32 MAC Address registers for the Address Filter block • Variety of flexible addresses filtering modes are supported – Perfect (DA) address filters with masks for each byte – SA address comparison check with masks for each byte – 256-bit Hash filter for multicast and unicast (DA) addresses – Option to pass all multicast addressed frames – Promiscuous mode support to pass all frames without any filtering for network monitoring – Passes all incoming packets (as per filter) with a status report. – VLAN Filtering – L3 and L4 Filtering • Multi Queues Support up to 8 TX and 8 RX queues • Native DMA with simple independent channels Transmit and Receive engines – 8 RX channels, FIFO size 8 KB for receive channel – 8 TX channels, FIFO size 8 KB for transmit channel – Dynamic Mapping enables routing of the specific DMA channel by receive filter each packet – DMA implements dual buffer (ring) or linked list (chained) descriptor chaining • Advanced IEEE 1588-2002 & 2008 ethernet frame time stamping support – Timer module implemented – IEEE1588 Time base information, with reference clock of 125 MHz (same sources as GMII) – IEEE1588 external snapshot (Two signals) – PTP timestamp offload function – One-step timestamp • Programmable CRC generation and checking • TCP/IP offload / ARP offload features • Support for RMON statistics • Station Management Block, MDIO interface • Ethernet Energy Efficiency compliant with IEEE 802.3az-2010 – Support for wake up on LAN on magic packet and packet filtering – Support Energy Efficiency feature (LPI Mode) – Wake-up capability
Event link (input)	• PTP Timer capture
Module-stop function	• Module-stop state can be set to reduce power consumption.

Figure 28.1 is a block diagram of the Ethernet interface.

Gray modules and registers are described in section 27, Ethernet Subsystem, section 29, Ethernet Switch (ETHSW), and section 30, EtherCAT Slave Controller (ESC). See the related sections regarding the other registers and modules which are needed to operate the Ethernet MAC.

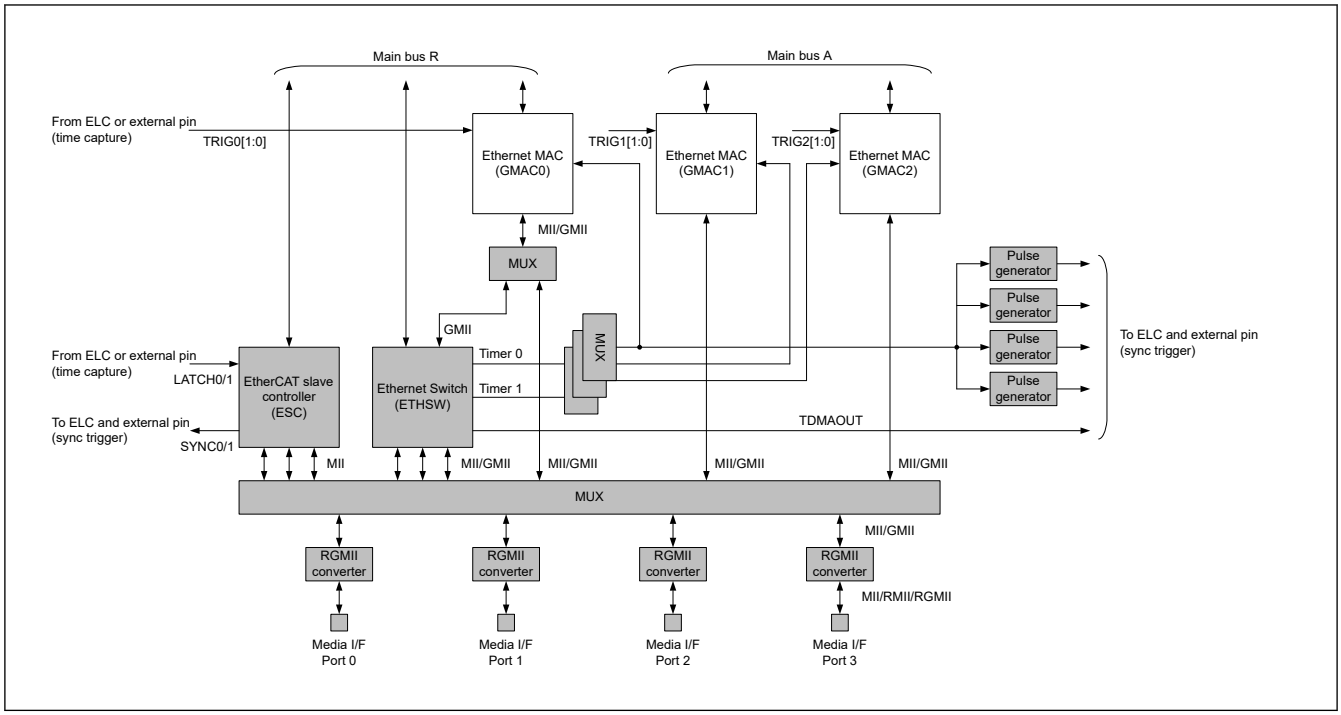

Figure 28.1 Block diagram of the Ethernet interface

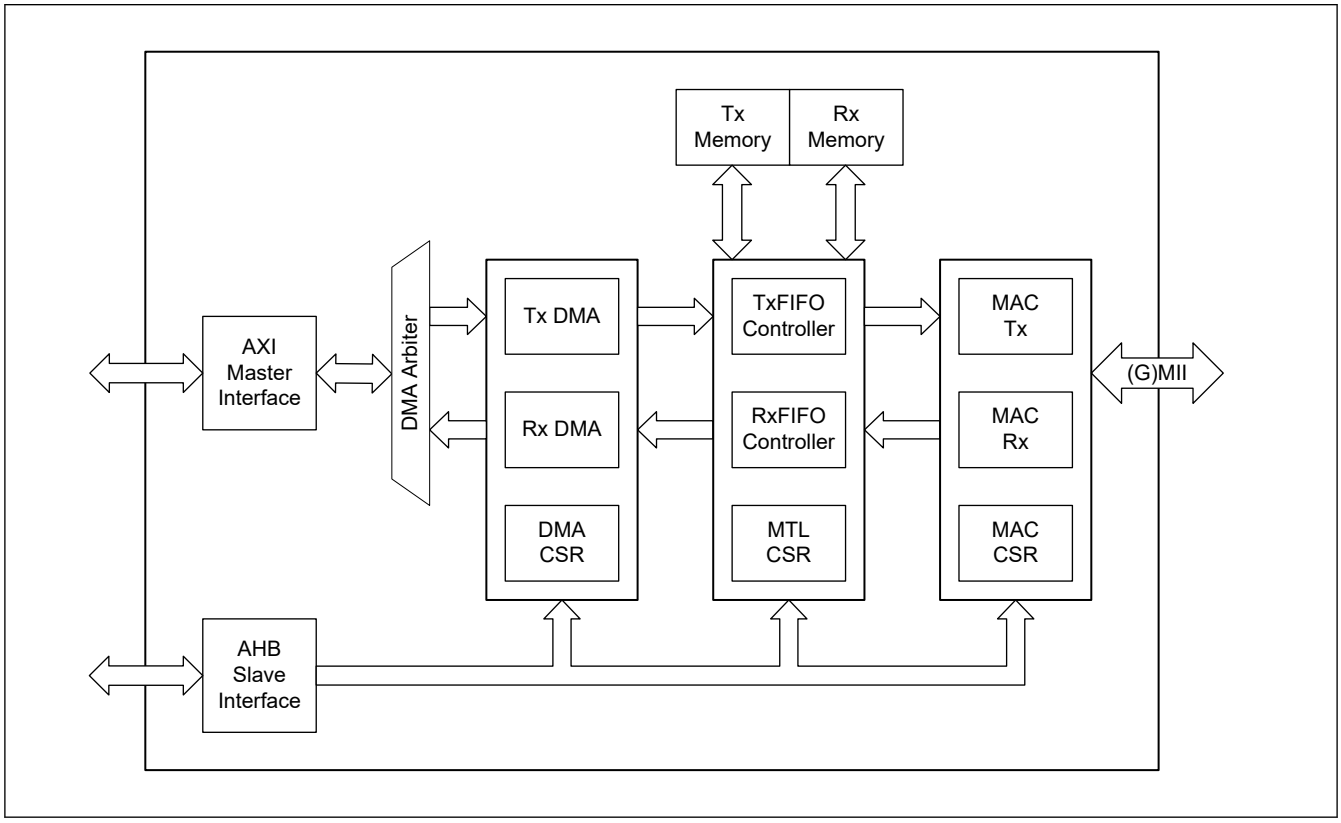

Figure 28.2 Block diagram of GMAC

Table 28.2 Input/output pins of GMAC (1 of 2)

Pin name	I/O	Function
GMACn_PTPTRG0	Input	PTP timer trigger external input 0
GMACn_PTPTRG1	Input	PTP timer trigger external input 1

Table 28.2 Input/output pins of GMAC (2 of 2)

Pin name	I/O	Function
GMACn_MDC	Output	Management data clock output pin
GMACn_MDIO	I/O	Management data I/O pin

Note: n = 0 to 2

28.2 Register Map

Table 28.3 GMAC register map (1 of 11)

Address	Register Symbol	Register Name	Write Protection
0x8011_0400	GMACTRGSEL	GMAC PTP Trigger Select register	PRCMD
0x8010_0000 (m = 0) 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_Configuration	MAC Configuration Register	—
0x8010_0004 (m = 0) 0x9200_0004 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_Ext_Configuration	MAC Extended Configuration Register	—
0x8010_0008 (m = 0) 0x9200_0008 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_Packet_Filter	MAC Packet Filter register	—
0x8010_000C (m = 0) 0x9200_000C + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_Watchdog_Timeout	Watchdog Timeout register	—
0x8010_0010 + 0x04 × n (m = 0) 0x9200_0010 + 0x04 × n + 0x1_0000 × (m - 1 + 0x04 × n) (m = 1, 2)	MAC_HASH_TABLE_REGn	Hash Table Register n (n = 0 to 7)	—
0x8010_0050 (m = 0) 0x9200_0050 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_VLAN_Tag_Ctrl	VLAN Tag Control Register	—
0x8010_0054 (m = 0) 0x9200_0054 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_VLAN_Tag_Data	VLAN Tag Data Register	—
0x8010_0058 (m = 0) 0x9200_0058 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_VLAN_Hash_Table	VLAN Hash Table Register	—
0x8010_0070 (m = 0) 0x9200_0070 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_Q0_Tx_Flow_Ctrl	Flow Control register	—
0x8010_0090 (m = 0) 0x9200_0090 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_Rx_Flow_Ctrl	Receive Flow Control register	—
0x8010_0094 (m = 0) 0x9200_0094 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_RxQ_Ctrl4	Receive Queue Control 4 register	—
0x8010_00A0 (m = 0) 0x9200_00A0 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_RxQ_Ctrl0	Receive Queue Control 0 register	—
0x8010_00A4 (m = 0) 0x9200_00A4 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_RxQ_Ctrl1	Receive Queue Control 1 register	—
0x8010_00A8 (m = 0) 0x9200_00A8 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_RxQ_Ctrl2	Receive Queue Control 2 register	—
0x8010_00AC (m = 0) 0x9200_00AC + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_RxQ_Ctrl3	Receive Queue Control 3 register	—
0x8010_00B0 (m = 0) 0x9200_00B0 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_Interrupt_Status	MAC Interrupt Status Register	—
0x8010_00B4 (m = 0) 0x9200_00B4 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_Interrupt_Enable	MAC Interrupt Enable Register	—
0x8010_00B8 (m = 0) 0x9200_00B8 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_Rx_Tx_Status	Receive and Transmit Status Register	—
0x8010_00C0 (m = 0) 0x9200_00C0 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_PMT_Control_Status	PMT Control and Status Register	—
0x8010_00C4 (m = 0) 0x9200_00C4 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_RWK_Packet_Filter	Remote Wakeup Filter Register	—

Table 28.3 GMAC register map (2 of 11)

Address	Register Symbol	Register Name	Write Protection
0x8010_00D0 (m = 0) 0x9200_00D0 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_LPI_Control_Status	LPI Control and Status Register	—
0x8010_00D4 (m = 0) 0x9200_00D4 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_LPI_Timers_Control	LPI Timers Control Register	—
0x8010_00D8 (m = 0) 0x9200_00D8 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_LPI_Entry_Timer	LPI entry timer Register	—
0x8010_00DC (m = 0) 0x9200_00DC + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_1US_Tic_Counter	LP1 1us Tick Counter Register	—
0x8010_0110 (m = 0) 0x9200_0110 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_Version	Version Register	—
0x8010_0114 (m = 0) 0x9200_0114 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_Debug	MAC Debug Register	—
0x8010_011C (m = 0) 0x9200_011C + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_HW_Feature0	MAC Hardware Feature 0 Register	—
0x8010_0120 (m = 0) 0x9200_0120 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_HW_Feature1	MAC Hardware Feature 1 Register	—
0x8010_0124 (m = 0) 0x9200_0124 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_HW_Feature2	MAC Hardware Feature 2 Register	—
0x8010_0128 (m = 0) 0x9200_0128 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_HW_Feature3	MAC Hardware Feature 3 Register	—
0x8010_0200 (m = 0) 0x9200_0200 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_MDIO_Address	MDIO Address Register	—
0x8010_0204 (m = 0) 0x9200_0204 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_MDIO_Data	MDIO Data Register	—
0x8010_0210 (m = 0) 0x9200_0210 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_ARP_Address	ARP Address Register	—
0x8010_0230 (m = 0) 0x9200_0230 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_CSR_SW_Ctrl	CSR Software Control Register	—
0x8010_0234 (m = 0) 0x9200_0234 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_FPE_CTRL_STS	Frame Preemption Control and Status Register	—
0x8010_0238 (m = 0) 0x9200_0238 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_Ext_Cfg1	Split Mode Control Register	—
0x8010_0300 (m = 0) 0x9200_0300 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_ADDRESS0_HIGH	MAC Address 0 High register	—
0x8010_0304 (m = 0) 0x9200_0304 + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_ADDRESS0_LOW	MAC Address 0 Low register	—
0x8010_0300 + 0x08 × n (m = 0) 0x9200_0300 + 0x08 × n + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_ADDRESSn_HIGH	MAC Address n High register (n = 1 to 31)	—
0x8010_0304 + 0x08 × n (m = 0) 0x9200_0304 + 0x08 × n + 0x1_0000 × (m - 1) (m = 1, 2)	MAC_ADDRESSn_LOW	MAC Address n Low register (n = 1 to 31)	—
0x8010_0700 (m = 0) 0x9200_0700 + 0x1_0000 × (m - 1) (m = 1, 2)	MMC_Control	MMC Control Register	—
0x8010_0704 (m = 0) 0x9200_0704 + 0x1_0000 × (m - 1) (m = 1, 2)	MMC_Rx_Interrupt	MMC Receive Interrupt Register	—
0x8010_0708 (m = 0) 0x9200_0708 + 0x1_0000 × (m - 1) (m = 1, 2)	MMC_Tx_Interrupt	MMC Transmit Interrupt Register	—
0x8010_070C (m = 0) 0x9200_070C + 0x1_0000 × (m - 1) (m = 1, 2)	MMC_Rx_Interrupt_Mask	MMC Receive Interrupt Mask Register	—

Table 28.3 GMAC register map (3 of 11)

Address	Register Symbol	Register Name	Write Protection
0x8010_0710 (m = 0) 0x9200_0710 + 0x1_0000 × (m - 1) (m = 1, 2)	MMC_Tx_Interrupt_Mask	MMC Transmit Interrupt Mask Register	—
0x8010_0714 (m = 0) 0x9200_0714 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Octet_Count_Good_Bad	Transmit Octet Count for Good and Bad 64 Byte Packets	—
0x8010_0718 (m = 0) 0x9200_0718 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Packet_Count_Good_Bad	Transmit Packet Count for Good and Bad Packets	—
0x8010_071C (m = 0) 0x9200_071C + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Broadcast_Packets_Good	Transmit Packet Count for Good Broadcast Packets	—
0x8010_0720 (m = 0) 0x9200_0720 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Multicast_Packets_Good	Transmit Packet Count for Good Multicast Packets	—
0x8010_0724 (m = 0) 0x9200_0724 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_64Octets_Packets_Good_Bad	Transmit Octet Count for Good and Bad 64 Byte Packets	—
0x8010_0728 (m = 0) 0x9200_0728 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_65To127Octets_Packets_Good_Bad	Transmit Octet Count for Good and Bad 65 to 127 Bytes Packets	—
0x8010_072C (m = 0) 0x9200_072C + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_128To255Octets_Packets_Good_Bad	Transmit Octet Count for Good and Bad 128 to 255 Bytes Packets	—
0x8010_0730 (m = 0) 0x9200_0730 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_256To511Octets_Packets_Good_Bad	Transmit Octet Count for Good and Bad 256 to 511 Bytes Packets	—
0x8010_0734 (m = 0) 0x9200_0734 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_512To1023Octets_Packets_Good_Bad	Transmit Octet Count for Good and Bad 512 to 1023 Bytes Packets	—
0x8010_0738 (m = 0) 0x9200_0738 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_1024ToMaxOctets_Packets_Good_Bad	Transmit Octet Count for Good and Bad 1024 to Maxsize Bytes Packets	—
0x8010_073C (m = 0) 0x9200_073C + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Unicast_Packets_Good_Bad	Transmit Packet Count for Good and Bad Unicast Packets	—
0x8010_0740 (m = 0) 0x9200_0740 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Multicast_Packets_Good_Bad	Transmit Packet Count for Good and Bad Multicast Packets	—
0x8010_0744 (m = 0) 0x9200_0744 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Broadcast_Packets_Good_Bad	Transmit Packet Count for Good and Bad Broadcast Packets	—
0x8010_0748 (m = 0) 0x9200_0748 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Underflow_Error_Packets	Transmit Packet Count for Underflow Error Packets	—
0x8010_074C (m = 0) 0x9200_074C + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Single_Collision_Good_Packets	Transmit Packet Count for Packets Transmitted after Single Collision	—
0x8010_0750 (m = 0) 0x9200_0750 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Multiple_Collision_Good_Packets	Transmit Packet Count for Packets Transmitted after Multiple Collision	—
0x8010_0754 (m = 0) 0x9200_0754 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Deferred_Packets	Transmit Packet Count for Deferred Packets	—
0x8010_0758 (m = 0) 0x9200_0758 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Late_Collision_Packets	Transmit Packet Count for Late Collision Error Packets	—
0x8010_075C (m = 0) 0x9200_075C + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Excessive_Collision_Packets	Transmit Packet Count for Excessive Collision Error Packets	—
0x8010_0760 (m = 0) 0x9200_0760 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Carrier_Error_Packets	Transmit Packet Count for Carrier Sense Error Packets	—
0x8010_0764 (m = 0) 0x9200_0764 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Octet_Count_Good	Transmit Octet Count for Good Packets	—
0x8010_0768 (m = 0) 0x9200_0768 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Packet_Count_Good	Transmit Packet Count for Good Packets	—
0x8010_076C (m = 0) 0x9200_076C + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Excessive_Deferral_Error	Transmit Packet Count for Excessive Deferral Error Packets	—
0x8010_0770 (m = 0) 0x9200_0770 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_Pause_Packets	Transmit Packet Count for Good PAUSE Packets	—

Table 28.3 GMAC register map (4 of 11)

Address	Register Symbol	Register Name	Write Protection
0x8010_0774 (m = 0) 0x9200_0774 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_VLAN_Packets_Good	Transmit Packet Count for Good VLAN Packets	—
0x8010_0778 (m = 0) 0x9200_0778 + 0x1_0000 × (m - 1) (m = 1, 2)	Tx_OSize_Packets_Good	Transmit Packet Count for Good Oversize Packets	—
0x8010_0780 (m = 0) 0x9200_0780 + 0x1_0000 × (m - 1) (m = 1, 2)	Rx_Packets_Count_Good_Bad	Receive Packet Count for Good and Bad Packets	—

28.3 Register Descriptions

28.3.1 GMACTRGSEL : GMAC PTP Trigger Select register

Base address: GMACC = 0x8011_0400

Offset address: 0x0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	G2TRGSEL1	G2TRGSEL0	G1TRGSEL1	G1TRGSEL0	G0TRGSEL1	G0TRGSEL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	G0TRGSEL0	Select PTP Timestamp Trigger 0 for GMAC0 0: Select GMAC0_PTPTRG0 trigger from ELC 1: Select external GMAC0_PTPTRG0 trigger input pin	R/W

Bit	Symbol	Function	R/W
1	G0TRGSEL1	Select PTP Timestamp Trigger 1 for GMAC0 0: Select GMAC0_PTPTRG1 trigger from ELC 1: Select external GMAC0_PTPTRG1 trigger input pin	R/W
2	G1TRGSEL0	Select PTP Timestamp Trigger 0 for GMAC1 0: Select GMAC1_PTPTRG0 trigger from ELC 1: Select external GMAC1_PTPTRG0 trigger input pin	R/W
3	G1TRGSEL1	Select PTP Timestamp Trigger 1 for GMAC1 0: Select GMAC1_PTPTRG1 trigger from ELC 1: Select external GMAC1_PTPTRG1 trigger input pin	R/W
4	G2TRGSEL0	Select PTP Timestamp Trigger 0 for GMAC2 0: Select GMAC2_PTPTRG0 trigger from ELC 1: Select external GMAC2_PTPTRG0 trigger input pin	R/W
5	G2TRGSEL1	Select PTP Timestamp Trigger 1 for GMAC2 0: Select GMAC2_PTPTRG1 trigger from ELC 1: Select external GMAC2_PTPTRG1 trigger input pin	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written when protection is unlocked by a specific sequence using the Ethernet Protect Register (PRCMD). For the protection unlock procedure, see section 27.3.1. PRCMD : Ethernet Protect Register. The special sequence is not necessary when reading the value of this register.

The GMACTRGSEL register is used to select GMAC PTP Timestamp Trigger.

28.3.2 MAC_Configuration : MAC Configuration Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ARPEN	—	—	—	IPC	IPG[2:0]			GPSLCE	S2KP	CST	ACS	WD	BE	JD	JE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PS	FES	DM	LM	ECRSFD	DO	DCRS	DR	—	BL[1:0]		DC	PRELEN[1:0]		TE	RE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RE	Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII or MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII or MII interface. 0: Receiver is disabled 1: Receiver is enabled	R/W
1	TE	Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII or MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets. 0: Transmitter is disabled 1: Transmitter is enabled	R/W

Bit	Symbol	Function	R/W
3:2	PRELEN[1:0]	Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 0 0: 7 bytes of preamble 0 1: 5 bytes of preamble 1 0: 3 bytes of preamble 1 1: Reserved	R/W
4	DC	Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. 0: Deferral check function is disabled 1: Deferral check function is enabled	R/W
6:5	BL[1:0]	Back-Off Limit The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range $0 \leq r < 2^k$. This bit is applicable only in the half-duplex mode. 0 0: k = min(n, 10) 0 1: k = min(n, 8) 1 0: k = min(n, 4) 1 1: k = min(n, 1)	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	DR	Disable Retry When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. 0: Enable Retry 1: Disable Retry	R/W
9	DCRS	Disable Carrier Sense During Transmission When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. 0: Enable Carrier Sense During Transmission 1: Disable Carrier Sense During Transmission	R/W
10	DO	Disable Receive Own When this bit is set, the MAC disables the reception of packets when the TXEN is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode. 0: Enable Receive Own 1: Disable Receive Own	R/W

Bit	Symbol	Function	R/W
11	ECRSFD	Enable Carrier Sense Before Transmission in Full-Duplex Mode When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal. 0: ECRSFD is disabled 1: ECRSFD is enabled	R/W
12	LM	Loopback Mode When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Rx clock input RX_CLK is required for the loopback to work properly. This is because the Tx clock is not internally looped back. 0: Loopback is disabled 1: Loopback is enabled	R/W
13	DM	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. 0: Half-duplex mode 1: Full-duplex mode	R/W
14	FES	Speed This bit selects the speed mode. 0: 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0 1: 100 Mbps when PS bit is 1	R/W
15	PS	Port Select This bit selects the Ethernet line speed. This bit, along with Bit 14, selects the exact line speed. 0: For 1000 Mbps operations 1: For 10 or 100 Mbps operations	R/W
16	JE	Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status. 0: Jumbo packet is disabled 1: Jumbo packet is enabled	R/W
17	JD	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet. 0: Jabber is enabled 1: Jabber is disabled	R/W
18	BE	Packet Burst Enable When this bit is set, the MAC allows packet bursting during transmission in the GMII half-duplex mode. 0: Packet Burst is disabled 1: Packet Burst is enabled	R/W
19	WD	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes. 0: Watchdog is enabled 1: Watchdog is disabled	R/W
20	ACS	Automatic Pad or CRC Stripping[*1] 0: Automatic Pad or CRC Stripping is disabled. MAC passes all incoming packets to the application, without any modification. 1: Automatic Pad or CRC Stripping is enabled. MAC strips the pad or the FCS field of the incoming Ethernet Length packets. For the Ethernet Type packets, MAC transfers the packets to the application without stripping the Pad or FCS field.	R/W

Bit	Symbol	Function	R/W
21	CST	CRC stripping for Type packets[*1] 0: CRC stripping for Type packets is disabled 1: CRC stripping for Type packets is enabled. MAC strips and drops the last four bytes (FCS) of all Ether type packets, as indicated by the Length/Type field of the packet, before forwarding the packet to the application.	R/W
22	S2KP	IEEE 802.3as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, see the Table, Giant Packet Status based on S2KP and JE Bits.[*2] 0: Support up to 2K packet is disabled 1: Support up to 2K packet is Enabled	R/W
23	GPSLCE	Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status. 0: Giant Packet Size Limit Control is disabled 1: Giant Packet Size Limit Control is enabled	R/W
26:24	IPG[2:0]	Inter-Packet Gap These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of back pressure activation, the MAC does not consider the minimum IPG. This function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_Ext_Configuration register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register. 0 0 0: 96 bit times IPG 0 0 1: 88 bit times IPG 0 1 0: 80 bit times IPG 0 1 1: 72 bit times IPG 1 0 0: 64 bit times IPG 1 0 1: 56 bit times IPG 1 1 0: 48 bit times IPG 1 1 1: 40 bit times IPG	R/W
27	IPC	Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit. 0: IP header/payload checksum checking is disabled 1: IP header/payload checksum checking is enabled	R/W
30:28	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
31	ARPEN	ARP Offload Enable When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It forwards the ARP packet to the application and also indicate the events in the Rx Status. When this bit is reset, the MAC receiver does not recognize any ARP packet and indicates them as Type frame in the Rx Status. This bit is available only when the Enable IPv4 ARP Offload is selected. 0: ARP Offload is disabled 1: ARP Offload is enabled	R/W

Note 1. For more details about impact of CST and ACS bit settings on the packet length, see "Packet Length based on the CST and ACS Bits" table in the Architecture chapter.
Note 2. When the JE bit is set, setting this bit has no effect on the giant packet status.

The MAC_Configuration register establishes the operating mode of the MAC.

28.3.3 MAC_Ext_Configuration : MAC Extended Configuration Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	APDIM	EIPG[4:0]					EIPGEN	—	HDSMS[2:0]			PDC	USP	SPEN	DCRCC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	GPSL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	GPSL[13:0]	Giant Packet Size Limit If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_Configuration register.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
16	DCRCC	Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets. 0: CRC Checking is enabled 1: CRC Checking is disabled	R/W
17	SPEN	Slow Protocol Detection Enable 0: Slow Protocol Detection is disabled. MAC forwards all the error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets. 1: Slow Protocol Detection is enabled. MAC processes the Slow Protocol packets (Ether Type = 0x8809) and provides the Slow Protocol Sub-Type and Code fields in the Rx status.	R/W

Bit	Symbol	Function	R/W
18	USP	Unicast Slow Protocol Packet Detect When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_ADDRESS0_High and MAC_ADDRESS0_Low registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2015, Section 5. 0: Unicast Slow Protocol Packet Detection is disabled 1: Unicast Slow Protocol Packet Detection is enabled	R/W
19	PDC	Packet Duplication Control 0: Packet Duplication Control is disabled. MAC interprets the DSC field of the MAC_ADDRESSn_High_register as a binary value. 1: Packet Duplication Control is enabled. MAC interprets the DCS field of the MAC_ADDRESSn_High register as a one-hot value; each bit of the DCS field corresponds to a Rx DMA channel.	R/W
22:20	HDSMS[2:0]	Maximum Size for Splitting the Header Data These bits indicate the maximum header size allowed for splitting the header data in the received packet. 0 0 0: Maximum Size for Splitting the Header Data is 64 bytes 0 0 1: Maximum Size for Splitting the Header Data is 128 bytes 0 1 0: Maximum Size for Splitting the Header Data is 256 bytes 0 1 1: Maximum Size for Splitting the Header Data is 512 bytes 1 0 0: Maximum Size for Splitting the Header Data is 1024 bytes Others: Reserved	R/W
23	—	This bit is read as 0. The write value should be 0.	R/W
24	EIPGEN	Extended Inter-Packet Gap Enable*1 0: Extended Inter-Packet Gap is disabled. MAC ignores EIPG field. MAC uses the IPG field of the MAC_Configuration register as the minimum IPG less than or equal to 96-bit times, in steps of 8-bit times. 1: Extended Inter-Packet Gap is enabled. MAC uses the EIPG field for the extended inter-packet gap. For more details of how the MAC uses the EIPG field, see the description of the EIPG field.	R/W
29:25	EIPG[4:0]	Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit of this register is 1. The 5 bits of this field are the most significant bits; IPG field of the MAC_Configuration register are the least significant 3 bits. Together, these 8 bits represent the value of the minimum IPG greater than 96-bit times, in steps of 8-bit times. {EIPG, IPG} 0x00: 104 bit times 0x01: 112 bit times 0x02: 120 bit times ⋮ 0xFF: 2144 bit times	R/W
30	APDIM	ARP Packet Drop if IP Address Mismatch When this bit is set, Packet for which Target Protocol Address does not match IPv4 address is dropped in the MTL layer. When this bit is reset, when target Protocol Address does not match, packet is forwarded to MTL. 0: mux select to drop the arp packet if target protocol address mismatches IPv4 address disabled 1: mux select to drop the arp packet if target protocol address mismatches IPv4 address enabled	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

Note 1. Use this feature only when operating in full-duplex mode. If you enable this feature in half-duplex mode, you might see undesirable effects on back-pressure function and frame transmission.

The MAC_Ext_Configuration Register establishes the operating mode of the MAC.

28.3.4 MAC_Packet_Filter : MAC Packet Filter register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RA	—	—	—	—	—	—	—	—	—	DNTU	IPFE	—	—	—	VTFE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	HPF	SAF	SAIF	PCF[1:0]		DBF	PM	DAIF	HMC	HUC	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PR	Promiscuous Mode 0: Promiscuous Mode is disabled. MAC transfers to the application only the packets that pass destination or source address filtering. 1: Promiscuous Mode is enabled. MAC transfers all incoming packets to the application regardless of the destination or source address filtering status. MAC clears the SA or DA Filter Fail status bits of the MAC Rx status word. For more details about MAC Rx status word, see "Receive Status Word at the MAC Interface" table in the Architecture chapter.	R/W
1	HUC	Hash Unicast 0: Hash Unicast is disabled. MAC performs a perfect filtering of destination address for unicast packets, that is, it compares the DA field with the values you programmed in the MAC_ADDRESSn_High and MAC_ADDRESSn_Low registers. 1: Hash Unicast is enabled. MAC performs the destination address filtering of unicast packets according to the hash table.	R/W
2	HMC	Hash Multicast 0: Hash Multicast is disabled. MAC performs perfect filtering of destination address for multicast packets, that is, it compares the DA field of the packet with the values programmed in the MAC_ADDRESSn_High and MAC_ADDRESSn_Low registers. 1: Hash Multicast is enabled. MAC performs the destination address filtering of the received multicast packets according to the hash table.	R/W
3	DAIF	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed. 0: DA Inverse Filtering is disabled 1: DA Inverse Filtering is enabled	R/W
4	PM	Pass All Multicast When this bit is set, it indicates that all the received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit. 0: Pass All Multicast is disabled 1: Pass All Multicast is enabled	R/W
5	DBF	Disable Broadcast Packets When this bit is set, the AFM module blocks all the incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets. 0: Enable Broadcast Packets 1: Disable Broadcast Packets	R/W

Bit	Symbol	Function	R/W
7:6	PCF[1:0]	Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 0 0: MAC filters all control packets from reaching the application 0 1: MAC forwards all control packets except Pause packets to the application even if they fail the Address filter 1 0: MAC forwards all control packets to the application even if they fail the Address filter 1 1: MAC forwards the control packets that pass the Address filter	R/W
8	SAIF	SA Inverse Filtering When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter. 0: SA Inverse Filtering is disabled 1: SA Inverse Filtering is enabled	R/W
9	SAF	Source Address Filter Enable*1 0: SA Filtering is disabled. MAC forwards the received packet to the application. Also, MAC updates the result of SA address comparison in the SA Filter Fail, bit [48] of the MAC Rx status word. For more details about MAC Rx status word, see "Receive Status Word at the MAC Interface" table in the Architecture chapter. 1: SA Filtering is enabled. MAC compares the SA field of the received packets with the values you programmed in the MAC_ADDRESSn_High and MAC_ADDRESSn_Low registers. If the comparison fails, the MAC drops the packet.	R/W
10	HPF	Hash or Perfect Filter When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit. When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter. 0: Hash or Perfect Filter is disabled 1: Hash or Perfect Filter is enabled	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
16	VTFE	VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag. 0: LAN Tag Filter is disabled 1: VLAN Tag Filter is enabled	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	IPFE	Layer 3 and Layer 4 Filter Enable When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields. 0: Layer 3 and Layer 4 Filters are disabled 1: Layer 3 and Layer 4 Filters are enabled	R/W
21	DNTU	Drop Non-TCP/UDP over IP Packets When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets. 0: Forward Non-TCP/UDP over IP Packets 1: Drop Non-TCP/UDP over IP Packets	R/W
30:22	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
31	RA	Receive All 0: Receive All is disabled. The MAC receiver transfers only the packets that pass the SA or DA address filter, to the application. 1: Receive All is enabled. The MAC receiver transfers all the received packets to the application regardless of the address filter status. MAC updates the SA or DA filtering status in the corresponding bit of the MAC filter status word. For more details, see the "MAC Filter Status Word Format" table in the Architecture chapter.	R/W

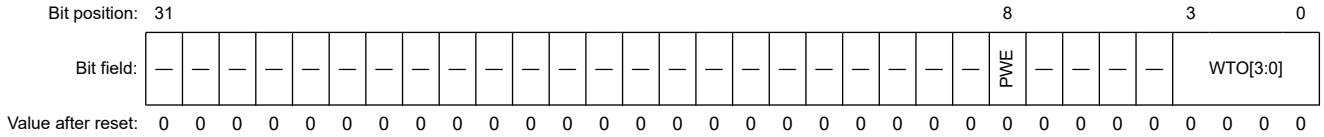
Note 1. According to the IEEE specification, Bit 47 of the SA is reserved. However, in GMAC, the MAC compares all 48 bits. The application must consider this while programming the MAC address registers for SA.

The MAC_Packet_Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

28.3.5 MAC_Watchdog_Timeout : Watchdog Timeout register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x000C



Bit	Symbol	Function	R/W
3:0	WTO[3:0]	Watchdog Timeout When the PWE bit is set and the WD bit of the MAC_Configuration register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet.*1 0x0: 2 KB 0x1: 3 KB 0x2: 4 KB 0x3: 5 KB 0x4: 6 KB 0x5: 7 KB 0x6: 8 KB 0x7: 9 KB 0x8: 10 KB 0x9: 11 KB 0xA: 12 KB 0xB: 13 KB 0xC: 14 KB 0xD: 15 KB 0xE: 16383 Bytes 0xF: Reserved	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	PWE	Programmable Watchdog Enable When this bit is set and the WD bit of the MAC_Configuration register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_Configuration register. 0: Programmable Watchdog is disabled 1: Programmable Watchdog is enabled	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped.

The MAC_Watchdog_Timeout register controls the watchdog timeout for received packets.

28.3.6 MAC_HASH_TABLE_REGn : Hash Table Register n (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0010 + 0x04 × n

Bit position:	31																												0
Bit field:	HT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	HT[31:0]	MAC Hash Table n-th 32 Bits This field contains the n-the 32 Bits [(n+1)*32-1 : n*32] of the Hash table.	R/W

The Hash Table Register 0 contains the first 32 bits of the hash table, when the width of the hash table is 256 bits.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 10111111b (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 8 bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits [31:24] of the Hash Table Register n registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

28.3.7 MAC_VLAN_Tag_Ctrl : VLAN Tag Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0050

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	EIVLRXS	—	EIVLS[1:0]		ERIVLT	EDVLP	VTHM	EVLRXS	—	EVLS[1:0]		DOVLTC	ERSVLM	ESVL	VTIM	ETV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	OFS[3:0]				CT	OB
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OB	Operation Busy ● Software writes 1 in this bit to initiate an indirect read or write access to the MAC_VLAN_Tag register. ● MAC writes 0 in this bit when it completes the indirect read or write access to the MAC_VLAN_Tag register. MAC can initiate the next indirect register access when this bit has a value 0. ● During a write operation, MAC writes 0 in this bit after it completes writing the data into the MAC_VLAN_Tag register. ● During a read operation, the application must read the data from the MAC_VLAN_Tag_Data register only after MAC writes 0 in this bit. 0: Operation Busy is disabled 1: Operation Busy is enabled	R/W
1	CT	Command Type This bit indicates if the current register access is a read or a write. 0: Write operation. Indicates a write operation. 1: Read operation. Indicates a read operation.	R/W
5:2	OFS[3:0]	Offset This field holds the address offset (i) of the MAC_VLAN_Tag_Filter i Register (i = 0 to 15) which the application is trying to access.	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W
16	ETV	Enable 12-Bit VLAN Tag Comparison for VLAN Hash Filtering 0: 12-Bit VLAN Tag Comparison is disabled. All 16 bits of the 15th and 16th bytes of the received VLAN packet are used for VLAN hash filtering. 1: 12-Bit VLAN Tag Comparison is enabled. A 12-bit VLAN identifier is used for VLAN Hash filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag in the received VLAN-tagged packet are used for hash-based VLAN filtering.	R/W
17	VTIM	VLAN Tag Inverse Match Enable 0: VLAN Tag Inverse Match is disabled. Enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched. 1: VLAN Tag Inverse Match is enabled. Enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched.	R/W
18	ESVL	Enable S-VLAN 0: S-VLAN is disabled. 1: S-VLAN is enabled. MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets.	R/W
19	ERSVLM	Enable Receive S-VLAN Match for VLAN Hash Filtering The ERIVLT bit determines the VLAN tag position considered for VLAN Hash filtering or matching. 0: Receive S-VLAN Match is disabled. MAC receiver enables VLAN Hash filtering or matching for C-VLAN (Type = 0x8100) packets. 1: Receive S-VLAN Match is enabled. MAC receiver enables VLAN Hash filtering or matching for S-VLAN (Type = 0x88A8) packets.	R/W
20	DOVLTC	Disable VLAN Type Check for VLAN Hash Filtering 0: VLAN Type Check is enabled. MAC VLAN Hash Filter filters or matches the VLAN Tag specified by the ERIVLT bit only when VLAN Tag type is similar to the one specified by the ERSVLM bit. 1: VLAN Type Check is disabled. MAC VLAN Hash Filter does not check whether the VLAN Tag specified by the ERIVLT bit is of type S-VLAN or C-VLAN.	R/W

Bit	Symbol	Function	R/W
22:21	EVLS[1:0]	Enable VLAN Tag Stripping on Receive This field indicates the stripping operation on the outer VLAN Tag in received packet. 0 0: Do not strip 0 1: Strip if VLAN filter passes 1 0: Strip if VLAN filter fails 1 0: Always strip	R/W
23	—	This bit is read as 0. The write value should be 0.	R/W
24	EVLRXS	Enable VLAN Tag in Rx status 0: VLAN Tag in Rx status is disabled. MAC does not provide the outer VLAN Tag in Rx status. 1: VLAN Tag in Rx status is enabled. MAC provides the outer VLAN Tag in the Rx status.	R/W
25	VTHM	VLAN Tag Hash Table Match Enable*1 0: VLAN Tag Hash Table Match is disabled. MAC does not perform the VLAN Hash Match operation. 1: VLAN Tag Hash Table Match is enabled. MAC uses the most significant four bits of CRC of VLAN Tag to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the MAC_VLAN_Hash_Table register, corresponding to the index, indicates that the packet matched the VLAN hash table. ● When ETV = 1, MAC uses the CRC of the 12-bit VLAN Identifier (VID) for comparison. ● When ETV = 0, MAC uses the CRC of the 16-bit VLAN Identifier (VID) for comparison.	R/W
26	EDVLP	Enable Double VLAN Processing 0: Double VLAN Processing is disabled. MAC enables processing of up to one VLAN Tag on Tx and Rx (if present). 1: Double VLAN Processing is enabled. MAC enables processing of up to two VLAN Tags on Tx and Rx (if present).	R/W
27	ERIVLT	Enable Inner VLAN Tag Comparison When this bit, VTHM bit and the EDVLP field are set, the MAC receiver enables VLAN Hash filtering operation on the inner VLAN Tag (if present). When this bit is reset and VTHM bit is set, the MAC receiver enables VLAN Hash filtering operation on the outer VLAN Tag (if present). The ERSVLM bit and DOVLTC bit determines which VLAN type is enabled for filtering. 0: VLAN tag is disabled 1: VLAN tag is enabled	R/W
29:28	EIVLS[1:0]	Enable Inner VLAN Tag Stripping on Receive This field indicates the stripping operation on inner VLAN Tag in received packet. 0 0: Do not strip 0 1: Strip if VLAN filter passes 1 0: Strip if VLAN filter fails 1 1: Always strip	R/W
30	—	This bit is read as 0. The write value should be 0.	R/W
31	EIVLRXS	Enable Inner VLAN Tag in Rx Status 0: Inner VLAN Tag in Rx status is disabled. MAC does not provide the inner VLAN Tag in Rx status. 1: Inner VLAN Tag in Rx status is enabled. MAC provides the inner VLAN Tag in the Rx status.	R/W

Note 1. For more details, see section 28.6.3.2. VLAN Tag Hash Filtering.

This register is the redefined format of the MAC VLAN Tag Register. It is used for indirect addressing. It contains the address offset, command type and Busy Bit for CSR access of the Per VLAN Tag registers.

28.3.8 MAC_VLAN_Tag_Data : VLAN Tag Data Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0054

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	DMACHN[2:0]			DMAC HEN	—	—	—	RIVLT	ERSV LM	DOVL TC	ETV	VEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	VID[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	VID[15:0]	VLAN Tag ID This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.	R/W
16	VEN	VLAN Tag Enable This bit is used to enable or disable the VLAN Tag. 0: VLAN Tag is disabled. MAC does not compare the VLAN Tag of received packet with the VLAN Tag ID, irrespective of the programming of the other fields. 1: VLAN Tag is enabled. MAC compares the VLAN Tag of the received packet with the VLAN Tag ID.	R/W
17	ETV	12-Bit or 16-Bit VLAN Comparison This bit is valid only when you enable the VLAN Tag by programming the VEN field of the corresponding MAC_VLAN_Tag_Filter i register. 0: 16 bit VLAN comparison. 1: 12 bit VLAN comparison. MAC uses a 12-bit VLAN tag for the comparison and filtering instead of the 16-bit VLAN tag. MAC compares the bits [11:0] of the VLAN tag with the corresponding field in the received VLAN-tagged packet.	R/W
18	DOVLTC	Disable VLAN Type Comparison This bit is valid only when you enable the VLAN Tag by programming the VEN field of the MAC_VLAN_Tag_Filter i register. 0: VLAN type comparison is enabled. MAC considers the VLAN Tag type during the comparison. The VLAN Tag type, S-VLAN or C-VLAN, used by the MAC for comparison is determined by the value you program in the ERSVLM field of the MAC_VLAN_Tag_Ctrl register. 1: VLAN type comparison is disabled. MAC does not check the type of the VLAN Tag during the VLAN tag comparison. MAC performs either inner or outer VLAN Tag comparison based on the value you program in the ERIVLT field of the MAC_VLAN_Tag_Filter i register.	R/W
19	ERSVLM	Enable S-VLAN Match for received Frames This bit is valid only when you enable the VLAN Tag by programming the VEN field of the MAC_VLAN_Tag_Filter i register. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. 0: Receive S-VLAN Match is disabled 1: Receive S-VLAN Match is enabled	R/W

Bit	Symbol	Function	R/W
20	RIVLT	Enable Inner VLAN Tag Comparison This bit is valid only when Double VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). 0: Inner VLAN tag comparison is disabled 1: Inner VLAN tag comparison is enabled	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
24	DMACHEN	DMA Channel Number Enable 0: DMA Channel Number is disabled. 1: DMA Channel Number is enabled. Enables the DMA channel number that you program in the DMACHN field.	R/W
27:25	DMACHN[2:0]	DMA Channel Number The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field need not be programmed.	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

This register holds the read or write data for the indirect access of the MAC_VLAN_Tag_Filter i (i = 0 to 15) registers.

- For the read operation, this register contains valid read data only after the MAC writes 0 to the OB bit of the MAC_VLAN_Tag_Ctrl register.
- For the write operation, Software must ensure valid data in this register before writing 1 to the OB bit of the MAC_VLAN_Tag_Ctrl register.

28.3.9 MAC_VLAN_Hash_Table : VLAN Hash Table Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0058

Bit position:	31															15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VLHT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	VLHT[15:0]	VLAN Hash Table This field contains the 16-bit VLAN Hash Table.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

When VTHM bit of the MAC_VLAN_Tag register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag Register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated hash value are used to index the contents of the VLAN Hash table. For example, hash value of 1000b selects Bit 8 of the VLAN Hash table.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).
- Perform bitwise reversal for the value obtained in step 1.
- Take the upper four bits from the value obtained in step 2.

If the VLAN hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits [15:8] of this register are written.

- If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

28.3.10 MAC_Q0_Tx_Flow_Ctrl : Flow Control register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	DZPQ	PLT[2:0]			—	—	TFE	FCB_ BPA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FCB_BPA	Flow Control Busy or Back pressure Activate*1 This bit initiates a Pause packet in the full-duplex mode and activates the back pressure function in the half-duplex mode if the TFE bit is set. **Full-Duplex Mode:** In the full-duplex mode, this bit should be read as 0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 0. You should not write to this register until this bit is cleared. **Half-Duplex Mode:** When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the back pressure. During back pressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. 0: Flow Control Busy or Back pressure Activate is disabled 1: Flow Control Busy or Back pressure Activate is enabled	R/W
1	TFE	Transmit Flow Control Enable **Full-Duplex Mode:** In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. **Half-Duplex Mode:** In the half-duplex mode, when this bit is set, the MAC enables the back pressure operation. When this bit is reset, the back pressure feature is disabled. 0: Transmit Flow Control is disabled 1: Transmit Flow Control is enabled	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
6:4	PLT[2:0]	Pause Low Threshold This field configures the threshold of the Pause timer for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits [31:16]. For example, if PT = 0x100 (256 slot times), and PLT = 001b, a second Pause packet is automatically transmitted if the trigger is asserted at 228 (256 - 28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times. 0 0 0: Pause Time minus 4 Slot Times (PT - 4 slot times) 0 0 1: Pause Time minus 28 Slot Times (PT - 28 slot times) 0 1 0: Pause Time minus 36 Slot Times (PT - 36 slot times) 0 1 1: Pause Time minus 144 Slot Times (PT - 144 slot times) 1 0 0: Pause Time minus 256 Slot Times (PT - 256 slot times) 1 0 1: Pause Time minus 512 Slot Times (PT - 512 slot times) Others: Reserved	R/W
7	DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion from the FIFO layer. When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled. 0: Zero-Quanta Pause packet generation is enabled 1: Zero-Quanta Pause packet generation is disabled	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W
31:16	PT[15:0]	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the (G)MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.	R/W

Note 1. Access restrictions apply.

- MAC initiates the pause packet or activates the back pressure, when application writes 1.
- MAC writes 0 after the operation is complete.
- MAC ignores when application writes 0.

The MAC_Q0_Tx_Flow_Ctrl register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

When the PFCE bit in the MAC_Rx_Flow_Ctrl register is enabled, this register controls the generation of Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_RxQ_Ctrl2 register.

28.3.11 MAC_Rx_Flow_Ctrl : Receive Flow Control register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0090

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	UP	RFE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFE	Receive Flow Control Enable When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time. 0: Receive Flow Control is disabled 1: Receive Flow Control is enabled	R/W
1	UP	Unicast Pause Packet Detect A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_ADDRESS0_High and MAC_ADDRESS0_Low. When this bit is reset, the MAC only detects Pause packets with unique multicast address.*1 0: Unicast Pause Packet Detect disabled 1: Unicast Pause Packet Detect enabled	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011.

The MAC_Rx_Flow_Ctrl register controls the pausing of MAC Transmit based on the received Pause packet.

28.3.12 MAC_RxQ_Ctrl4 : Receive Queue Control 4 register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0094

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	VFFQ[2:0]			VFFQE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	MFFQ[2:0]			MFFQE	—	—	—	—	UFFQ[2:0]			UFFQE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	UFFQE	Unicast Address Filter Fail Packets Queuing Enable When this bit is set, the Unicast packets which fail the Destination or Source address filter is routed to the Rx Queue Number programmed in the UFFQ. When this bit is reset, the Unicast packets which fail the Destination or Source address filter is routed based on other routing options. This bit is valid only when the RA bit of the MAC_Packet_Filter register is set. 0: Unicast Address Filter Fail Packets Queuing is disabled 1: Unicast Address Filter Fail Packets Queuing is enabled	R/W
3:1	UFFQ[2:0]	Unicast Address Filter Fail Packets Queue This field holds the Rx queue number to which the Unicast packets failing the Destination or Source Address filter are routed to. This field is valid only when the UFFQE bit is set.	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
8	MFFQE	Multicast Address Filter Fail Packets Queuing Enable When this bit is set, the Multicast packets which fail the Destination or Source address filter is routed to the Rx Queue Number programmed in the MFFQ. When this bit is reset, the Multicast packets which fail the Destination or Source address filter is routed based on other routing options. This bit is valid only when the RA bit of the MAC_Packet_Filter register is set. 0: Multicast Address Filter Fail Packets Queuing is disabled 1: Multicast Address Filter Fail Packets Queuing is enabled	R/W
11:9	MFFQ[2:0]	Multicast Address Filter Fail Packets Queue This field holds the Rx queue number to which the Multicast packets failing the Destination or Source Address filter are routed to. This field is valid only when the MFFQE bit is set.	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
16	VFFQE	VLAN Tag Filter Fail Packets Queuing Enable When this bit is set, the tagged packets which fail the Destination or Source address filter or fail the VLAN tag filter, are routed to the Rx Queue Number programmed in the VFFQ. When this bit is reset, the tagged packets which fail the Destination or Source address filter or fail the VLAN tag filter are routed based on other routing options. This bit is valid only when the RA bit of the MAC_Packet_Filter register is set. 0: VLAN tag Filter Fail Packets Queuing is disabled 1: VLAN tag Filter Fail Packets Queuing is enabled	R/W
19:17	VFFQ[2:0]	VLAN Tag Filter Fail Packets Queue This field holds the Rx queue number to which the tagged packets failing the Destination or Source Address filter (and UFFQE/MFFQE not enabled) or failing the VLAN tag filter must be routed to. This field is valid only when the VFFQE bit is set.	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

The MAC_RxQ_Ctrl4 register controls the routing of unicast and multicast packets that fail the Destination or Source address filter to the Rx queues.

28.3.13 MAC_RxQ_Ctrl0 : Receive Queue Control 0 register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00A0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15:14	RXQ7EN[1:0]	Receive Queue 7 Enable This field is similar to the RXQ0EN[1:0] field. 0 0: Queue not enabled 0 1: Queue enabled for AV 1 0: Queue enabled for DCB/Generic 1 1: Reserved	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The MAC_RxQ_Ctrl0 register controls the queue management in the MAC Receiver.

Note: All the queues are disabled by default. Enable the Rx queue by programming the corresponding field in this register.

28.3.14 MAC_RxQ_Ctrl1 : Receive Queue Control 1 register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00A4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	TBRQE	OMCBCQ	—	FPRQ[2:0]			TPQC[1:0]		TACPQE	MCBCQEN	—	MCBCQ[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	UPQ[2:0]			—	—	—	—	—	PTPQ[2:0]			—	AVCPQ[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	AVCPQ[2:0]	AV Untagged Control Packets Queue This field specifies the Receive queue on which the received AV tagged and untagged control packets are routed. The AV tagged (when TACPQE bit is set) and untagged control packets are routed to Receive queue specified by this field. 0 0 0: Receive Queue 0 0 0 1: Receive Queue 1 0 1 0: Receive Queue 2 0 1 1: Receive Queue 3 1 0 0: Receive Queue 4 1 0 1: Receive Queue 5 1 1 0: Receive Queue 6 1 1 1: Receive Queue 7	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
6:4	PTPQ[2:0]	PTP Packets Queue This field specifies the Rx queue on which the PTP packets sent over the Ethernet payload (not over IPv4 or IPv6) are routed. When the AV8021ASMEN bit of MAC_Timestamp_Control register is set, only untagged PTP over Ethernet packets are routed on an Rx Queue. If the bit is not set, then based on programming of TPQC field, both tagged and untagged PTPoE packets can be routed to this Rx Queue. 0 0 0: Receive Queue 0 0 0 1: Receive Queue 1 0 1 0: Receive Queue 2 0 1 1: Receive Queue 3 1 0 0: Receive Queue 4 1 0 1: Receive Queue 5 1 1 0: Receive Queue 6 1 1 1: Receive Queue 7	R/W
11:7	—	These bits are read as 0. The write value should be 0.	R/W
14:12	UPQ[2:0]	Untagged Packet Queue This field indicates the Rx Queue to which Untagged Packets are to be routed. Any Rx Queue enabled for Generic/DCB/AV traffic can be used to route the Untagged Packets. 0 0 0: Receive Queue 0 0 0 1: Receive Queue 1 0 1 0: Receive Queue 2 0 1 1: Receive Queue 3 1 0 0: Receive Queue 4 1 0 1: Receive Queue 5 1 1 0: Receive Queue 6 1 1 1: Receive Queue 7	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
18:16	MCBCQ[2:0]	Multicast and Broadcast Queue This field specifies the Rx Queue onto which Multicast or Broadcast Packets are routed. Any Rx Queue enabled for Generic/DCB/AV traffic can be used to route the Multicast or Broadcast Packets. 0 0 0: Receive Queue 0 0 0 1: Receive Queue 1 0 1 0: Receive Queue 2 0 1 1: Receive Queue 3 1 0 0: Receive Queue 4 1 0 1: Receive Queue 5 1 1 0: Receive Queue 6 1 1 1: Receive Queue 7	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W
20	MCBCQEN	Multicast and Broadcast Queue Enable This bit specifies that Multicast or Broadcast packets routing to the Rx Queue is enabled and the Multicast or Broadcast packets must be routed to Rx Queue specified in MCBCQ field. 0: Multicast and Broadcast Queue is disabled 1: Multicast and Broadcast Queue is enabled	R/W

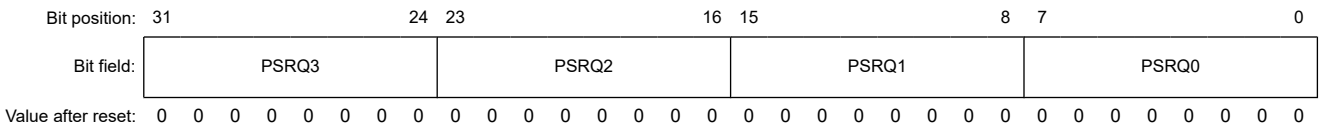
Bit	Symbol	Function	R/W
21	TACPQE	Tagged AV Control Packets Queuing Enable When set, the MAC routes the received Tagged AV Control packets to the Rx queue specified by AVCPQ field. When reset, the MAC routes the received Tagged AV Control packets based on the tag priority matching the PSRQ fields in MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. 0: Tagged AV Control Packets Queuing is disabled 1: Tagged AV Control Packets Queuing is enabled	R/W
23:22	TPQC[1:0]	Tagged PTP over Ethernet Packets Queuing Control This field controls the routing of the VLAN Tagged PTPoE packets. The following programmable options are allowed. 0 0: VLAN Tagged PTPoE packets are routed as generic VLAN Tagged packet (based on PSRQ for only non-AV enabled Rx Queues) 0 1: VLAN Tagged PTPoE packets are routed to Rx Queue specified by PTPQ field (That Rx Queue can be enabled for AV or non-AV traffic) 1 0: VLAN Tagged PTPoE packets are routed to only AV enabled Rx Queues based on PSRQ 1 1: Reserved	R/W
26:24	FPRQ[2:0]	Frame Preemption Residue Queue This field holds the Rx queue number to which the residual preemption frames must be forwarded. Preemption frames that are tagged and pass the SA/DA/VLAN filtering are routed based on PSRQ and all other frames are treated as residual frames and is routed to the queue number mentioned in this field. The Queue-0 is used as a default queue for express frames, so this field cannot be programmed to a value 0.	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W
28	OMCBCQ	Over-riding MC-BC queue priority select 0: Overriding MCBCQ priority disabled. Received Multicast/Broadcast packet is routed to MCBCQ. 1: Overriding MCBCQ priority enabled. Priority of MCBCQ is reduced and the received packet is first routed to PTPQ, AVCPQ, DCBCPQ depending on packet type.	R/W
29	TBRQE	Type Field Based Rx Queuing Enable When this bit is set, it enables Type Field based Rx Queuing where the Type field of received packet is compared with programmed TYP field in MAC_TMRQ_REGSn and if a match occurs the packet is routed to the corresponding TMRQ field.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

The MAC_RxQ_Ctrl1 register controls the routing of multicast, broadcast, AV, DCB, and untagged packets to the Rx queues.

28.3.15 MAC_RxQ_Ctrl2 : Receive Queue Control 2 register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00A8



Bit	Symbol	Function	R/W
7:0	PSRQ0	Priorities Selected in the Receive Queue 0 This field decides the priorities assigned to Rx Queue 0. All packets with priorities that match the values set in this field are routed to Rx Queue 0. For example, if PSRQ0[5] is set, packets with USP field equal to 5 are routed to Rx Queue 0. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.	R/W

Bit	Symbol	Function	R/W
15:8	PSRQ1	Priorities Selected in the Receive Queue 1 This field decides the priorities assigned to Rx Queue 1. All packets with priorities that match the values set in this field are routed to Rx Queue 1. For example, if PSRQ1[4] is set, packets with USP field equal to 4 are routed to Rx Queue 1. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.	R/W
23:16	PSRQ2	Priorities Selected in the Receive Queue 2 This field decides the priorities assigned to Rx Queue 2. All packets with priorities that match the values set in this field are routed to Rx Queue 2. For example, if PSRQ2[1, 0] are set, packets with USP field equal to 1 or 0 are routed to Rx Queue 2. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.	R/W
31:24	PSRQ3	Priorities Selected in the Receive Queue 3 This field decides the priorities assigned to Rx Queue 3. Packets whose priorities match the values set in this field are routed to Rx Queue 3. For example, if PSRQ3[6, 3] have value 1, the packets whose USP field of the VLAN Tag has value 3 or 6 are routed to Rx Queue 3. Application must ensure that values in the PSRQ fields of all the Rx queues within a set that you enable generically or for AV or DCB features, are mutually exclusive. This is because multiple Rx queues cannot have the same priority within a set.	R/W

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 3.

28.3.16 MAC_RxQ_Ctrl3 : Receive Queue Control 3 register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00AC

Bit position:	31							24	23							16	15							8	7							0
Bit field:	PSRQ7								PSRQ6								PSRQ5								PSRQ4							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PSRQ4	Priorities Selected in the Receive Queue 4 This field decides the priorities assigned to Rx Queue 4. All packets with priorities that match the values set in this field are routed to Rx Queue 4. For example, if PSRQ4[7:4] is set, packets with USP field equal to 7, 6, 5, or 4 are routed to Rx Queue 4. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.	R/W
15:8	PSRQ5	Priorities Selected in the Receive Queue 5 This field decides the priorities assigned to Rx Queue 5. All packets with priorities that match the values set in this field are routed to Rx Queue 5. For example, if PSRQ5[6] is set, packets with USP field equal to 6 are routed to Rx Queue 5. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.	R/W
23:16	PSRQ6	Priorities Selected in the Receive Queue 6 This field decides the priorities assigned to Rx Queue 6. All packets with priorities that match the values set in this field are routed to Rx Queue 6. For example, if PSRQ6[5] are set, packets with USP field equal to 5 are routed to Rx Queue 6. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.	R/W
31:24	PSRQ7	Priorities Selected in the Receive Queue 7 This field decides the priorities assigned to Rx Queue 7. All packets with priorities that match the values set in this field are routed to Rx Queue 7. For example, if PSRQ7[7, 4] are set, packets with USP field equal to 7 or 4 are routed to Rx Queue 7. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.	R/W

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 4 to 7.

28.3.17 MAC_Interrupt_Status : MAC Interrupt Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00B0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	MFRIS	MFTIS	MDIOIS	FPEIS	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	RXSTSIS	TXSTSIS	TSIS	MMCRXIPIS	MMCTXIS	MMCRXIS	MMCIS	—	—	LPIIS	PMTIS	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0.	R
4	PMTIS	PMT Interrupt Status This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in MAC_PMT_Control_Status register). This bit is cleared when corresponding interrupt source bit are cleared because of a Read operation to the MAC_PMT_Control_Status register (or corresponding interrupt source bit of MAC_PMT_Control_Status register is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set). 0: PMT Interrupt status not active 1: PMT Interrupt status active	R
5	LPIIS	LPI Interrupt Status When the Energy Efficient Ethernet feature is enabled, this bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the corresponding interrupt source bit of MAC_LPI_Control_Status register is read (or corresponding interrupt source bit of MAC_LPI_Control_Status register is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set). 0: LPI Interrupt status not active 1: LPI Interrupt status active	R
7:6	—	These bits are read as 0.	R
8	MMCIS	MMC Interrupt Status This bit is set high when Bit 11, Bit 10, or Bit 9 is set high. This bit is cleared only when all these bits are low. 0: MMC Interrupt status not active 1: MMC Interrupt status active	R
9	MMCRXIS	MMC Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. 0: MMC Receive Interrupt status not active 1: MMC Receive Interrupt status active	R
10	MMCTXIS	MMC Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. 0: MMC Transmit Interrupt status not active 1: MMC Transmit Interrupt status active	R
11	MMCRXIPIS	MMC Receive Checksum Offload Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. 0: MMC Receive Checksum Offload Interrupt status not active 1: MMC Receive Checksum Offload Interrupt status active	R

Bit	Symbol	Function	R/W
12	TSIS	Timestamp Interrupt Status If you select Enable Timestamp feature, this bit is 1, when any of the following conditions is true: An overflow in the MAC_System_Time_Seconds register. If you select Auxiliary Snapshot feature, this bit is 1. ● When the auxiliary snapshot trigger is asserted. ● When you enable drop transmit status in MTL, this bit is 1 when the MAC updates the captured transmit timestamp in the MAC_Tx_Timestamp_Status_Nanoseconds and MAC_Tx_Timestamp_Status_Seconds registers. ● When you select Enable PTP Offload feature, this bit is 1, when the MAC updates the captured transmit timestamp in the MAC_Tx_Timestamp_Status_Nanoseconds and MAC_Tx_Timestamp_Status_Seconds registers, for the PTO generated Delay Request and Pdelay request packets. MAC writes 0 to this bit when ● Application reads the corresponding interrupt source bit in the MAC_Timestamp_Status register. ● Application writes 1 to the corresponding interrupt source bit in the MAC_Timestamp_Status register, when RCWE = 1 in the MAC_CSR_SW_Ctrl register. 0: Timestamp Interrupt status not active 1: Timestamp Interrupt status active	R
13	TXSTSIS	Transmit Status Interrupt This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the MAC_Rx_Tx_Status register: ● Excessive Collision (EXCOL) ● Late Collision (LCOL) ● Excessive Deferral (EXDEF) ● Loss of Carrier (LCARR) ● No Carrier (NCARR) ● Jabber Timeout (TJT) This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register. 0: Transmit Interrupt status not active 1: Transmit Interrupt status active	R
14	RXSTSIS	Receive Status Interrupt This bit indicates the status of received packets. This bit is set when the RWT bit is set in the MAC_Rx_Tx_Status register. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register. 0: Receive Interrupt status not active 1: Receive Interrupt status active	R
16:15	—	These bits are read as 0.	R
17	FPEIS	Frame Preemption Interrupt Status This bit indicates an interrupt event during the operation of Frame Preemption (Bits [19:16] of MAC_FPE_CTRL_STS register is set). To reset this bit, the application must clear the event in MAC_FPE_CTRL_STS that has caused the Interrupt. 0: Frame Preemption Interrupt status not active 1: Frame Preemption Interrupt status active	R
18	MDIOIS	MDIO Interrupt Status This bit indicates an interrupt event after the completion of MDIO operation. Following access restrictions apply. ● Clears on read ● Clears on write 1, when RCWE = 1 in the MAC_CSR_SW_Ctrl register ● Self-set to 1 on internal event 0: MDIO Interrupt status not active. 1: MDIO Interrupt status active.	R
19	MFTIS	MMC FPE Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. 0: MMC FPE Transmit Interrupt status not active 1: MMC FPE Transmit Interrupt status active	R

Bit	Symbol	Function	R/W
20	MFRIS	MMC FPE Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. 0: MMC FPE Receive Interrupt status not active. 1: MMC FPE Receive Interrupt status active	R
31:21	—	These bits are read as 0.	R

The MAC_Interrupt_Status register contains the status of interrupts.

28.3.18 MAC_Interrupt_Enable : MAC Interrupt Enable Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00B4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	MDIOIE	FPEIE	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	RXSTSIE	TXSTSIE	TSIE	—	—	—	—	—	—	LPIIE	PMTIE	PHYIE	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
3	PHYIE	PHY Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of PHYIS bit in MAC_Interrupt_Status register. 0: PHY Interrupt is disabled 1: PHY Interrupt is enabled	R/W
4	PMTIE	PMT Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of PMTIS bit in MAC_Interrupt_Status register. 0: PMT Interrupt is disabled 1: PMT Interrupt is enabled	R/W
5	LPIIE	LPI Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of LPIIS bit in MAC_Interrupt_Status register. 0: LPI Interrupt is disabled 1: LPI Interrupt is enabled	R/W
11:6	—	These bits are read as 0. The write value should be 0.	R/W
12	TSIE	Timestamp Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of TSIS bit in MAC_Interrupt_Status register. 0: Timestamp Interrupt is disabled 1: Timestamp Interrupt is enabled	R/W
13	TXSTSIE	Transmit Status Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of TXSTSIS bit in the MAC_Interrupt_Status register. 0: Timestamp Status Interrupt is disabled 1: Timestamp Status Interrupt is enabled	R/W
14	RXSTSIE	Receive Status Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of RXSTSIS bit in the MAC_Interrupt_Status register. 0: Receive Status Interrupt is disabled 1: Receive Status Interrupt is enabled	R/W

Bit	Symbol	Function	R/W
16:15	—	These bits are read as 0. The write value should be 0.	R/W
17	FPEIE	Frame Preemption Interrupt Enable When this bit is set, it enables the assertion of the interrupt when FPEIS field is set in the MAC_Interrupt_Status register. 0: Frame Preemption Interrupt is disabled 1: Frame Preemption Interrupt is enabled	R/W
18	MDIOIE	MDIO Interrupt Enable When this bit is set, it enables the assertion of the interrupt when MDIOIS field is set in the MAC_Interrupt_Status register. 0: MDIO Interrupt is disabled 1: MDIO Interrupt is enabled	R/W
31:19	—	These bits are read as 0. The write value should be 0.	R/W

The MAC_Interrupt_Enable register contains the masks for generating the interrupts.

28.3.19 MAC_Rx_Tx_Status : Receive and Transmit Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00B8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	RWT	—	—	EXCOL	LCOL	EXDEF	LCARR	NCARR	TJT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TJT	Transmit Jabber Timeout*1 This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_Configuration register. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the MAC_Configuration register. 0: No Transmit Jabber Timeout 1: Transmit Jabber Timeout occurred	R
1	NCARR	No Carrier*1 When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. 0: Carrier is present 1: No carrier	R
2	LCARR	Loss of Carrier*1 When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the CRS signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. 0: Carrier is present 1: Loss of carrier	R
3	EXDEF	Excessive Deferral*1 When the DTXSTS bit is set in the MTL_Operation_Mode register and the DC bit is set in the MAC_Configuration register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000 Mbps mode or when Jumbo packet is enabled). 0: No Excessive deferral 1: Excessive deferral	R

Bit	Symbol	Function	R/W
4	LCOL	Late Collision*1 When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode; 512 bytes including Preamble and Carrier Extension in GMII mode). This bit is not valid if the Underflow error occurs. 0: No collision 1: Late collision is sensed	R
5	EXCOL	Excessive Collisions*1 When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after the first collision and the packet transmission is aborted. 0: No collision 1: Excessive collision is sensed	R
7:6	—	These bits are read as 0.	R
8	RWT	Receive Watchdog Timeout*1 This bit is set when a packet with length greater than 2,048 bytes is received (10,240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_Configuration register. This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the MAC_Configuration register. 0: No receive watchdog timeout 1: Receive watchdog timed out	R
31:9	—	These bits are read as 0.	R

Note 1. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

The MAC_Rx_Tx_Status register contains the Receive and Transmit Error status.

28.3.20 MAC_PMT_Control_Status : PMT Control and Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RWKFILTRST	—	—	RWKPTR[4:0]					—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	RWKPFE	GLBLUCAST	—	—	RWKPRCVD	MGKPRCVD	—	—	RWKPKTEN	MGKPKTEN	PWRDWN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PWRDWN	Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high.*1 *3 0: Power down is disabled 1: Power down is enabled	R/W

Bit	Symbol	Function	R/W
1	MGKPKTEN	Magic Packet Enable When this bit is set, a power management event is generated when the MAC receives a magic packet. 0: Magic Packet is disabled 1: Magic Packet is enabled	R/W
2	RWKPKTEN	Remote Wake-Up Packet Enable When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet. 0: Remote wake-up packet is disabled 1: Remote wake-up packet is enabled	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	MGKPRCVD	Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read.*4 0: No Magic packet is received 1: Magic packet is received	R
6	RWKPRCVD	Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read.*4 0: No Remote wake-up packet is received 1: Remote wake-up packet is received	R
8:7	—	These bits are read as 0. The write value should be 0.	R/W
9	GLBLUCAST	Global Unicast When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet. 0: Global unicast is disabled 1: Global unicast is enabled	R/W
10	RWKPFE	Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high.*2 *3 0: Remote Wake-up Packet Forwarding is disabled 1: Remote Wake-up Packet Forwarding is enabled	R/W
23:11	—	These bits are read as 0. The write value should be 0.	R/W
28:24	RWKPTR[4:0]	Remote Wake-up FIFO Pointer This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to maximum for the selected number of Remote Wake-up Packet Filters, the contents of the Remote Wake-up Packet Filter Register are transferred to the RX_CLK domain when a Write occurs to that register.	R
30:29	—	These bits are read as 0. The write value should be 0.	R/W
31	RWKFILTRST	Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 000b. It is automatically cleared after 1 clock cycle.*3 0: Remote Wake-Up Packet Filter Register Pointer is not Reset 1: Remote Wake-Up Packet Filter Register Pointer is Reset	R/W

Note 1. You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the software cannot clear this bit.
Note 2. If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application.
Note 3. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
Note 4. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

The MAC_PMT_Control_Status Register

28.3.21 MAC_RWK_Packet_Filter : Remote Wakeup Filter Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00C4

Bit position:	31																												0
Bit field:	WKUPFRMFTR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	WKUPFRMFTR[31:0]	RWK Packet Filter This field contains the various controls of RWK Packet filter.	R/W

MAC_RWK_Packet_Filter register is used to program CRC, offset, and byte mask of the pattern embedded in remote wakeup packet and the filter operation commands in a filter lookup table. See
section 28.13.1.2. Description of Remote Wakeup Packet Mode
in detail.

28.3.22 MAC_LPI_Control_Status : LPI Control and Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00D0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	LPIATE	LPITXA	—	PLS	LPIEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	RLPIST	TLPIST	—	—	—	—	RLPIEX	RLPIEN	TLPIEX	TLPIEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TLPIEN	Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). 0: Transmit LPI entry not detected 1: Transmit LPI entry detected	R
1	TLPIEX	Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). 0: Transmit LPI exit not detected 1: Transmit LPI exit detected	R
2	RLPIEN	Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set).*1 0: Receive LPI entry not detected 1: Receive LPI entry detected	R

Bit	Symbol	Function	R/W
3	RLPIEX	Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set).*1 0: Receive LPI exit not detected 1: Receive LPI exit detected	R
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	TLPIST	Transmit LPI State When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface. 0: Transmit LPI state not detected 1: Transmit LPI state detected	R
9	RLPIST	Receive LPI State When this bit is set, it indicates that the MAC is receiving the LPI pattern on the GMII or MII interface. 0: Receive LPI state not detected 1: Receive LPI state detected	R
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	LPIEN	LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. 0: LPI state is disabled 1: LPI state is enabled	R/W
17	PLS	PHY Link Status This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down. 0: Link is down 1: Link is okay (UP)	R/W
18	—	This bit is read as 0. The write value should be 0.	R/W
19	LPITXA	LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the IP) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of MTL_TxQ0_Operation_Mode register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. 0: LPI Tx Automate is disabled 1: LPI Tx Automate is enabled	R/W
20	LPIATE	LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPIATE, LPITXA and LPIEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the MAC_LPI_Entry_Timer register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPIATE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions. 0: LPI Timer is disabled 1: LPI Timer is enabled	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. This bit might not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.

The MAC_LPI_Control_Status register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

28.3.23 MAC_LPI_Timers_Control : LPI Timers Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00D4

Bit position:	31						25									16	15														0
Bit field:	—	—	—	—	—	—	LST[9:0]										TWT[15:0]															
Value after reset:	0	0	0	0	0	0	1	1	1	1	1	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TWT[15:0]	LPI TW Timer This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.	R/W
25:16	LST[9:0]	LPI LS Timer This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

The MAC_LPI_Timers_Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

28.3.24 MAC_LPI_Entry_Timer : LPI entry timer Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00D8

Bit position:	31											19																3			0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	LPIET[16:0]																—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

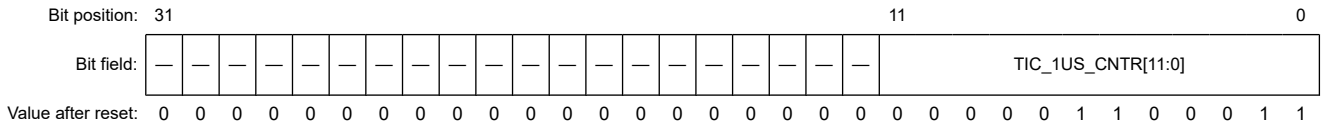
Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
19:3	LPIET[16:0]	LPI Entry Timer This field specifies the time in microseconds the MAC waits to enter LPI mode, after it has transmitted all the frames. This field is valid and used only when LPITE and LPITXA are set to 1. Bits [2:0] are read-only so that the granularity of this timer is in steps of 8 micro-seconds.	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

This register controls the Tx LPI entry timer. This counter is enabled only when bit [20] (LPITE) bit of MAC_LPI_Control_Status is set to 1.

28.3.25 MAC_1US_Tic_Counter : LP1 1us Tick Counter Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x00DC



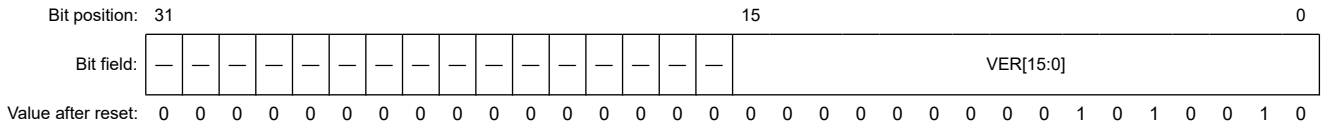
Bit	Symbol	Function	R/W
11:0	TIC_1US_CNTR[11:0]	1US TIC Counter The application must program this counter so that the number of clock cycles of CSR clock is 1 µs. (Subtract 1 from the value before programming). For example if the CSR clock is 100 MHz then this field needs to be programmed to value 100 - 1 = 99 (which is 0x63). This is required to generate the 1 US events that are used to update some of the EEE related counters.	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

This register controls the generation of the Reference time (1 microsecond tic) for all the LPI timers. This timer has to be programmed by the software initially.

28.3.26 MAC_Version : Version Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0110



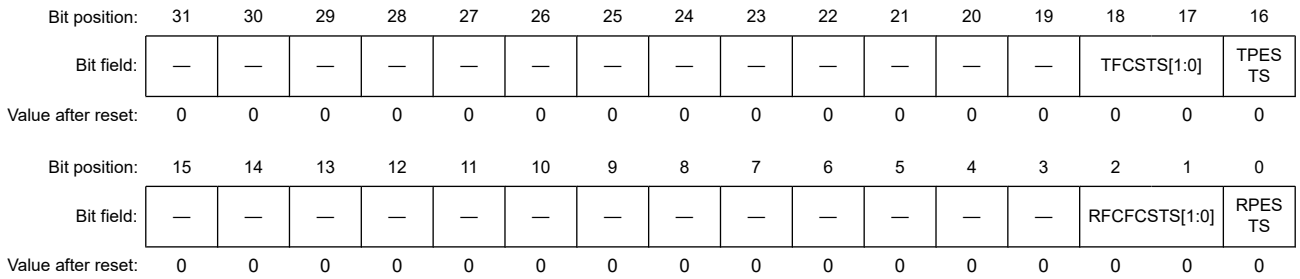
Bit	Symbol	Function	R/W
15:0	VER[15:0]	Version	R
31:16	—	These bits are read as 0.	R

The MAC_Version register identifies the version of the GMAC.

28.3.27 MAC_Debug : MAC Debug Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0114



Bit	Symbol	Function	R/W
0	RPESTS	MAC GMII or MII Receive Protocol Engine Status When this bit is set, it indicates that the MAC GMII or MII receive protocol engine is actively receiving data, and it is not in the Idle state. 0: MAC GMII or MII Receive Protocol Engine Status not detected 1: MAC GMII or MII Receive Protocol Engine Status detected	R
2:1	RFCFCSTS[1:0]	MAC Receive Packet Controller FIFO Status When this bit is set, this field indicates the active state of the small FIFO Read and Write controllers of the MAC Receive Packet Controller module.	R
15:3	—	These bits are read as 0.	R
16	TPESTS	MAC GMII or MII Transmit Protocol Engine Status When this bit is set, it indicates that the MAC GMII or MII transmit protocol engine is actively transmitting data, and it is not in the Idle state. 0: MAC GMII or MII Transmit Protocol Engine Status not detected 1: MAC GMII or MII Transmit Protocol Engine Status detected	R
18:17	TFCSTS[1:0]	MAC Transmit Packet Controller Status This field indicates the state of the MAC Transmit Packet Controller module. 0 0: Idle state 0 1: Waiting for one of the following: Status of the previous packet OR IPG or back off period to be over 1 0: Generating and transmitting a Pause control packet (in full-duplex mode) 1 1: Transferring input packet for transmission	R
31:19	—	These bits are read as 0.	R

The MAC_Debug register provides the debug status of various MAC blocks.

28.3.28 MAC_HW_Feature0 : MAC Hardware Feature 0 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x011C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	TSTSSEL[1:0]		—	—	ADDMACADRSEL[4:0]					—	RXCOESEL
Value after reset:	0	0	0	0	0	1	0	0	0	1	1	1	1	1	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	TXCOESEL	EEESEL	TSSEL	—	—	ARPOFFSEL	MMCSEL	MGKSEL	RWKSEL	SMASEL	VLHASH	—	HDSEL	GMIISEL	MIISEL
Value after reset:	0	1	1	1	0	0	1	1	1	1	1	1	0	1	1	1

Bit	Symbol	Function	R/W
0	MIISEL	10 or 100 Mbps Support This bit is set to 1 when 10/100 Mbps is selected as the Mode of Operation. 0: No 10 or 100 Mbps support 1: 10 or 100 Mbps support	R
1	GMIISEL	1000 Mbps Support This bit is set to 1 when 1000 Mbps is selected as the Mode of Operation. 0: No 1000 Mbps support 1: 1000 Mbps support	R
2	HDSEL	Half-duplex Support This bit is set to 1 when the half-duplex mode is selected. 0: No Half-duplex support 1: Half-duplex support	R
3	—	This bit is read as 0.	R

Bit	Symbol	Function	R/W
4	VLHASH	VLAN Hash Filter Selected This bit is set to 1 when the Enable VLAN Hash Table Based Filtering option is selected. 0: VLAN Hash Filter not selected 1: VLAN Hash Filter selected	R
5	SMASEL	SMA (MDIO) Interface This bit is set to 1 when the Enable Station Management (MDIO Interface) option is selected. 0: SMA (MDIO) Interface not selected 1: SMA (MDIO) Interface selected	R
6	RWKSEL	PMT Remote Wake-up Packet Enable This bit is set to 1 when the Enable Remote Wake-Up Packet Detection option is selected. 0: PMT Remote Wake-up Packet Enable option is not selected 1: PMT Remote Wake-up Packet Enable option is selected	R
7	MGKSEL	PMT Magic Packet Enable This bit is set to 1 when the Enable Magic Packet Detection option is selected. 0: PMT Magic Packet Enable option is not selected 1: PMT Magic Packet Enable option is selected	R
8	MMCSEL	RMON Module Enable This bit is set to 1 when the Enable MAC Management Counters (MMC) option is selected. 0: RMON Module Enable option is not selected 1: RMON Module Enable option is selected	R
9	ARPOFFSEL	ARP Offload Enabled This bit is set to 1 when the Enable IPv4 ARP Offload option is selected. 0: ARP Offload Enable option is not selected 1: ARP Offload Enable option is selected	R
11:10	—	These bits are read as 0.	R
12	TSSEL	IEEE 1588-2008 Timestamp Enabled This bit is set to 1 when the Enable IEEE 1588 Timestamp Support option is selected. 0: IEEE 1588-2008 Timestamp Enable option is not selected 1: IEEE 1588-2008 Timestamp Enable option is selected	R
13	EEESEL	Energy Efficient Ethernet Enabled This bit is set to 1 when the Enable Energy Efficient Ethernet (EEE) option is selected. 0: Energy Efficient Ethernet Enable option is not selected 1: Energy Efficient Ethernet Enable option is selected	R
14	TXCOESEL	Transmit Checksum Offload Enabled This bit is set to 1 when the Enable Transmit TCP/IP Checksum Insertion option is selected. 0: Transmit Checksum Offload Enable option is not selected 1: Transmit Checksum Offload Enable option is selected	R
15	—	This bit is read as 0.	R
16	RXCOESEL	Receive Checksum Offload Enabled This bit is set to 1 when the Enable Receive TCP/IP Checksum Check option is selected. 0: Receive Checksum Offload Enable option is not selected 1: Receive Checksum Offload Enable option is selected	R
17	—	This bit is read as 0.	R
22:18	ADDMACADRSEL[4:0]	MAC Addresses 1-31 Selected This bit is set to 1 when the non-zero value is selected for Enable Additional 1-31 MAC Address Registers option.	R
24:23	—	These bits are read as 0.	R
26:25	TSSTSSEL[1:0]	Timestamp System Time Source This bit indicates the source of the Timestamp system time: This bit is set to 1 when the Enable IEEE 1588 Timestamp Support option is selected. 0 0: Internal 0 1: External 1 0: Both 1 1: Reserved	R
31:27	—	These bits are read as 0.	R

This register indicates the presence of first set of the optional features or functions of the GMAC. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

28.3.29 MAC_HW_Feature1 : MAC Hardware Feature 1 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0120

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	L3L4FNUM[3:0]				—	HASHTBLSZ[1:0]		POUOST	—	—	AVSEL	—	—	SPHEN	—
Value after reset:	0	1	0	0	0	0	1	1	1	0	0	1	0	0	1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDR64[1:0]		—	PTOEN	OSTEN	TXFIFOSIZE[4:0]					—	RXFIFOSIZE[4:0]				
Value after reset:	0	0	0	1	1	0	0	1	1	0	0	0	0	1	1	0

Bit	Symbol	Function	R/W
4:0	RXFIFOSIZE[4:0]	MTL Receive FIFO Size This field contains the configured value of MTL Rx FIFO in bytes. 0x6: 8192 bytes	R
5	—	This bit is read as 0.	R
10:6	TXFIFOSIZE[4:0]	MTL Transmit FIFO Size This field contains the configured value of MTL Tx FIFO in bytes. 0x6: 8192 bytes	R
11	OSTEN	One-Step Timestamping Enable This bit is set to 1 when the Enable One-Step Timestamp Feature is selected. 0: One-Step Timestamping feature is not selected 1: One-Step Timestamping feature is selected	R
12	PTOEN	PTP Offload Enable This bit is set to 1 when the Enable PTP Timestamp Offload Feature is selected. 0: PTP Offload feature is not selected 1: PTP Offload feature is selected	R
13	—	This bit is read as 0.	R
15:14	ADDR64[1:0]	Address Width This field indicates the configured address width: 0 0: 32 0 1: 40 1 0: 48 1 1: Reserved	R
16	—	This bit is read as 0.	R
17	SPHEN	Split Header Feature Enable This bit is set to 1 when the Enable Split Header Structure option is selected. 0: Split Header Feature is not selected 1: Split Header Feature is selected	R
19:18	—	These bits are read as 0.	R
20	AVSEL	AV Feature Enable This bit is set to 1 when the Enable Audio Video Bridging option is selected. 0: AV Feature is not selected 1: AV Feature is selected	R
22:21	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
23	POUOST	One Step for PTP over UDP/IP Feature Enable This bit is set to 1 when the Enable One step timestamp for PTP over UDP/IP feature is selected. 0: One Step for PTP over UDP/IP Feature is not selected 1: One Step for PTP over UDP/IP Feature is selected	R
25:24	HASHTBLSZ[1:0]	Hash Table Size This field indicates the size of the hash table: 0 0: No hash table 0 1: 64 1 0: 128 1 1: 256	R
26	—	This bit is read as 0.	R
30:27	L3L4FNUM[3:0]	Total number of L3 or L4 Filters This field indicates the total number of L3 or L4 filters: 0x0: No L3 or L4 Filters 0x1: 1 L3 or L4 Filter 0x2: 2 L3 or L4 Filters 0x3: 3 L3 or L4 Filters 0x4: 4 L3 or L4 Filters 0x5: 5 L3 or L4 Filters 0x6: 6 L3 or L4 Filters 0x7: 7 L3 or L4 Filters 0x8: 8 L3 or L4 Filters Others: Reserved	R
31	—	This bit is read as 0.	R

This register indicates the presence of second set of the optional features or functions of the GMAC. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

28.3.30 MAC_HW_Feature2 : MAC Hardware Feature 2 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0124

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	AUXSNAPNUM[2:0]			—	—	—	—	—	—	TXCHCNT[3:0]				—	—
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	1	1	1	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RXCHCNT[3:0]				—	—	TXQCNT[3:0]				—	—	RXQCNT[3:0]			
Value after reset:	0	1	1	1	0	0	0	1	1	1	0	0	0	1	1	1

Bit	Symbol	Function	R/W
3:0	RXQCNT[3:0]	Number of MTL Receive Queues This field indicates the number of MTL Receive queues: 0x0: 1 MTL Rx Queue 0x1: 2 MTL Rx Queues 0x2: 3 MTL Rx Queues 0x3: 4 MTL Rx Queues 0x4: 5 MTL Rx Queues 0x5: 6 MTL Rx Queues 0x6: 7 MTL Rx Queues 0x7: 8 MTL Rx Queues Others: Reserved	R
5:4	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
9:6	TXQCNT[3:0]	Number of MTL Transmit Queues This field indicates the number of MTL Transmit queues: 0x0: 1 MTL Tx Queue 0x1: 2 MTL Tx Queues 0x2: 3 MTL Tx Queues 0x3: 4 MTL Tx Queues 0x4: 5 MTL Tx Queues 0x5: 6 MTL Tx Queues 0x6: 7 MTL Tx Queues 0x7: 8 MTL Tx Queues Others: Reserved	R
11:10	—	These bits are read as 0.	R
15:12	RXCHCNT[3:0]	Number of DMA Receive Channels This field indicates the number of DMA Receive channels: 0x0: 1 MTL Rx Channel 0x1: 2 MTL Rx Channels 0x2: 3 MTL Rx Channels 0x3: 4 MTL Rx Channels 0x4: 5 MTL Rx Channels 0x5: 6 MTL Rx Channels 0x6: 7 MTL Rx Channels 0x7: 8 MTL Rx Channels Others: Reserved	R
17:16	—	These bits are read as 0.	R
21:18	TXCHCNT[3:0]	Number of DMA Transmit Channels This field indicates the number of DMA Transmit channels: 0x0: 1 MTL Tx Channel 0x1: 2 MTL Tx Channels 0x2: 3 MTL Tx Channels 0x3: 4 MTL Tx Channels 0x4: 5 MTL Tx Channels 0x5: 6 MTL Tx Channels 0x6: 7 MTL Tx Channels 0x7: 8 MTL Tx Channels Others: Reserved	R
27:22	—	These bits are read as 0.	R
30:28	AUXSNAPNUM[2:0]	Number of Auxiliary Snapshot Inputs This field indicates the number of auxiliary snapshot inputs: 0 0 0: No auxiliary input 0 0 1: 1 auxiliary input 0 1 0: 2 auxiliary input 0 1 1: 3 auxiliary input 1 0 0: 4 auxiliary input Others: Reserved	R
31	—	This bit is read as 0.	R

This register indicates the presence of third set of the optional features or functions of the GMAC. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

28.3.31 MAC_HW_Feature3 : MAC Hardware Feature 3 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0128

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	TBSSEL	FPESEL	—	—	—	—	ESTWID[1:0]		ESTDEP[2:0]			ESTSEL
Value after reset:	0	0	0	0	1	1	0	0	0	0	1	1	0	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PDUPSEL	—	—	—	DVLAN	—	—	NRVF[2:0]		
Value after reset:	0	0	0	0	0	0	1	0	0	0	1	0	0	0	1	1

Bit	Symbol	Function	R/W
2:0	NRVF[2:0]	Number of Extended VLAN Tag Filters Enabled This field indicates the Number of Extended VLAN Tag Filters selected: 0 0 0: No Extended Rx VLAN Filters 0 0 1: 4 Extended Rx VLAN Filters 0 1 0: 8 Extended Rx VLAN Filters 0 1 1: 16 Extended Rx VLAN Filters 1 0 0: 24 Extended Rx VLAN Filters 1 0 1: 32 Extended Rx VLAN Filters Others: Reserved	R
4:3	—	These bits are read as 0.	R
5	DVLAN	Double VLAN Tag Processing Selected This bit is set to 1 when the Enable Double VLAN Processing Feature is selected. 0: Double VLAN option is not selected 1: Double VLAN option is selected	R
8:6	—	These bits are read as 0.	R
9	PDUPSEL	Broadcast/Multicast Packet Duplication This bit is set to 1 when the Broadcast/Multicast Packet Duplication feature is selected. 0: Broadcast/Multicast Packet Duplication feature is not selected 1: Broadcast/Multicast Packet Duplication feature is selected	R
15:10	—	These bits are read as 0.	R
16	ESTSEL	Enhancements to Scheduled Traffic Enable This bit is set to 1 when the Enable Enhancements to Scheduling Traffic feature is selected. 0: Enable Enhancements to Scheduling Traffic feature is not selected 1: Enable Enhancements to Scheduling Traffic feature is selected	R
19:17	ESTDEP[2:0]	Depth of the Gate Control List Indicates the depth of Gate Control list in bytes. 0 0 0: No Depth configured 0 0 1: 64 0 1 0: 128 0 1 1: 256 1 0 0: 512 1 0 1: 1024 Others: Reserved	R
21:20	ESTWID[1:0]	Width of the Time Interval field in the Gate Control List This field indicates the width of the Configured Time Interval Field. 0 0: Width not configured 0 1: 16 1 0: 20 1 1: 24	R
25:22	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
26	FPESEL	Frame Preemption Enable This bit is set to 1 when the Enable Frame preemption feature is selected. 0: Frame Preemption Enable feature is not selected 1: Frame Preemption Enable feature is selected	R
27	TBSSEL	Time Based Scheduling Enable This bit is set to 1 when the Time Based Scheduling feature is selected. 0: Time Based Scheduling Enable feature is not selected 1: Time Based Scheduling Enable feature is selected	R
31:28	—	These bits are read as 0.	R

This register indicates the presence of fourth set the optional features or functions of the GMAC. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

28.3.32 MAC_MDIO_Address : MDIO Address Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0200

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	PSE	BTB	PA[4:0]					RDA[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	NTC[2:0]			CR[3:0]				—	—	—	SKAP	GOC[1:0]		C45E	GB
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	GB	GMII Busy*1 The application writes 1 to this bit to instruct the SMA to initiate a read or write access to the MDIO slave. The MAC writes 0 to this bit after the MDIO frame transfer is complete. Therefore, the application must modify the fields of the MAC_MDIO_Address and MAC_MDIO_Data registers only when the value in this bit is 0. For write operation, application must follow these steps: ● Write the 16-bit data in the GDI field of the MAC_MDIO_Data register. ● Update the RA field of the MAC_MDIO_Data register with the register address of the PHY. **Note:** RA field is valid only when C45E field is 1. ● Write 1 to this bit. For read operation, application must follow these steps: ● Update the RA field of the MAC_MDIO_Data register with the register address of the PHY. **Note:** RA field is valid only when C45E field is 1. ● Write 1 to this bit. ● Wait until MAC writes 0 to this bit. When MAC writes 0 to this bit, it implies that the data read from the PHY is available in the GD field of the MAC_MDIO_Data register and the read transfer is complete. 0: GMII Busy is disabled 1: GMII Busy is enabled	R/W
1	C45E	Clause 45 PHY Enable 0: Clause 45 PHY is disabled. Clause 22 capable PHY is connected to MDIO. 1: Clause 45 PHY is enabled. Clause 45 capable PHY is connected to MDIO.	R/W

Bit	Symbol	Function	R/W
3:2	GOC[1:0]	GMII Operation Command This is the lower bit of the operation command to the PHY or RevMII. When in SMA mode (MDIO master) this bit along with GOC_1 determines the operation to be performed to the PHY. When only RevMII is selected in configuration this bit is read-only and tied to 1. 0 0: Reserved 0 1: Write 1 0: Post Read Increment Address for Clause 45 PHY 1 1: Read When Clause 22 PHY is enabled, only Write and Read commands are valid.	R/W
4	SKAP	Skip Address Packet 0: Skip Address Packet is disabled. 1: Skip Address Packet is enabled. SMA does not send the address packets before read, write, or post-read increment address packets.*2	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
11:8	CR[3:0]	CSR Clock Range*3 The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency (100 MHz for unit 0, 200 MHz for unit 1, 2). The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 0xA, the resultant MDC clock is of 12.5 MHz which is beyond the range specified in IEEE 802.3. Note that supported max frequency is 12.5 MHz in this LSI. 0x0: CSR clock/42 0x1: CSR clock/62 0x2: CSR clock/16 0x3: CSR clock/26 0x4: CSR clock/102 0x5: CSR clock/124 0x6: CSR clock/204 0x7: CSR clock/324 0x8: CSR clock/4 0x9: CSR clock/6 0xA: CSR clock/8 0xB: CSR clock/10 0xC: CSR clock/12 0xD: CSR clock/14 0xE: CSR clock/16 0xF: CSR clock/18	R/W
14:12	NTC[2:0]	Number of Trailing Clocks This field controls the number of trailing clock cycles generated on the MDC signal, after the end of MDIO frame transfer. The valid values are 000b to 111b. When you program a value of 011b in this field, MAC generates three clock cycles on the MDC line after the end of MDIO frame transfer.	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
20:16	RDA[4:0]	Register or Device Address*4 ● For clause 45 PHY: Specifies the selected MDIO device. ● For clause 45 PHY: Specifies the selected MDIO device. 0x00: B10T1S PLCA control 0x01: B10T1S PLCA node control 0x02: B10T1S PLCA status 0x03: B10T1S PLCA timer 0x0B: B10T1S PCS control 0x0C: B10T1S PCS status 0x0D: B10T1S PCS diagnostic 1 0x0E: B10T1S PCS diagnostic 2 0x14: B10T1S PMA/PMD extended ability 0x15: B10T1S PMA/PMD control 0x16: B10T1S PMA control 0x17: B10T1S PMA status 0x18: B10T1S test mode control Others: Reserved	R/W
25:21	PA[4:0]	Physical Layer Address Specifies the address of the PHY device, out of the 32 possible PHY devices.*4	R/W
26	BTB	Back-to-Back Transactions*5 0: Back to Back transactions disabled. MAC considers the read or write command to be complete, that is, MAC clears the GB field, only after generating the trailing clocks. This mode ensures that the NTC is always generated after each frame. 1: Back to Back transactions enabled. If NTC > 0, at the end of the frame transfer, MAC acknowledges the completion of a read or write command before transferring the trailing clocks. So, application can initiate the next command and MAC can execute it immediately without waiting for the transmission of the trailing clocks of the previous frame.	R/W
27	PSE	Preamble Suppression Enable 0: Preamble Suppression disabled. The SMA does not suppress the preamble. So, the MDIO frame has 32-bit preamble as defined in the IEEE specifications. 1: Preamble Suppression enabled. The SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit.	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

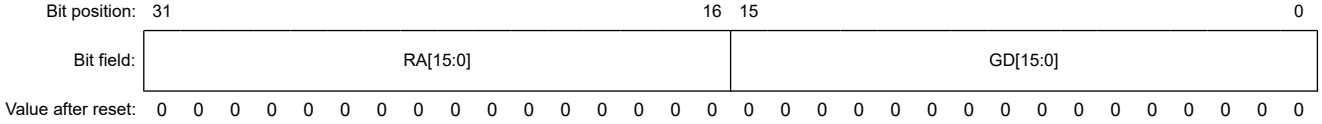
Note 1. Even if the addressed PHY is not present, there is no change in the functionality of this bit.
Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
Note 2. This bit is valid only when C45E is set.
Note 3. These bits are not used when you select Reverse MII interface. These bits are read-only when you select Reverse MII as the single PHY interface.
Note 4. The value you program in the C45E field determines if the PHY device is clause 45 capable or clause 22 capable.
Note 5. Program this field with a value 1, only when NTC > 0.

The MAC_MDIO_Address register controls the management cycles to external PHY through a management interface.

28.3.33 MAC_MDIO_Data : MDIO Data Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0204



Bit	Symbol	Function	R/W
15:0	GD[15:0]	GMII Data This field contains the 16-bit data value read from the PHY or RevMII after a Management Read operation or the 16-bit data value to be written to the PHY or RevMII before a Management Write operation.	R/W
31:16	RA[15:0]	Register Address This field is valid only when C45E is set. It contains the Register Address in the PHY to which the MDIO frame is intended for.	R/W

The MAC_MDIO_Data register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_Address. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

28.3.34 MAC_ARP_Address : ARP Address Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0210

Bit position:	31																													0
Bit field:	ARPPA[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ARPPA[31:0]	ARP Protocol Address This field contains the IPv4 Destination Address of the MAC. This address is used for perfect match with the Protocol Address of Target field in the received ARP packet. This field is available only when the Enable IPv4 ARP Offload option is selected.	R/W

The MAC_ARP_Address register contains the IPv4 Destination Address of the MAC.

28.3.35 MAC_CSR_SW_Ctrl : CSR Software Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0230

Bit position:	31																						8							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SEEN	—	—	—	—	—	—	RCWE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RCWE	Register Clear on Write 1 Enable When this bit is set, the access mode of some register fields changes to Clear on Write 1, the application needs to set that respective bit to 1 to clear it. When this bit is reset, the access mode of these register fields remain as Clear on Read. 0: Register Clear on Write 1 is disabled 1: Register Clear on Write 1 is enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	SEEN	Slave Error Response Enable When this bit is set, the MAC responds with Slave Error for accesses to reserved registers in CSR space. When this bit is reset, the MAC responds with Okay response to any register accessed from CSR space. 0: Slave Error Response is disabled 1: Slave Error Response is enabled	R/W

Bit	Symbol	Function	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

This register contains software programmable controls for changing the CSR access response and status bits clearing.

28.3.36 MAC_FPE_CTRL_STS : Frame Preemption Control and Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0234

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	TRSP	TVER	RRSP	RVER
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	S1_SET_0	SRSP	SVER	EFPE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EFPE	Enable Tx Frame Preemption When set Frame Preemption Tx functionality is enabled. 0: Tx Frame Preemption is disabled 1: Tx Frame Preemption is enabled	R/W
1	SVER	Send Verify mPacket*1 When set indicates hardware to send a verify mPacket. Reset by hardware after sending the Verify mPacket. 0: Send Verify mPacket is disabled 1: Send Verify mPacket is enabled	R/W
2	SRSP	Send Respond mPacket*1 When set indicates hardware to send a Respond mPacket. Reset by hardware after sending the Respond mPacket. 0: Send Respond mPacket is disabled 1: Send Respond mPacket is enabled	R/W
3	S1_SET_0	Synopsys Reserved, Must be set to "0". This field is reserved for Synopsys Internal use, and must always be set to "0" unless instructed by Synopsys. Setting to "1" might cause unexpected behavior in the IP.	R/W
15:4	—	These bits are read as 0. The write value should be 0.	R/W
16	RVER	Received Verify Frame*2 Set when a Verify mPacket is received. An interrupt can be generated for this event if FPEIE bit of MAC_Interrupt_Enable is set. 0: Not received Verify Frame 1: Received Verify Frame	R/W
17	RRSP	Received Respond Frame*2 Set when a Respond mPacket is received. An interrupt can be generated for this event if FPEIE bit of MAC_Interrupt_Enable is set. 0: Not received Respond Frame 1: Received Respond Frame	R/W
18	TVER	Transmitted Verify Frame*2 Set when a Verify mPacket is transmitted (triggered by setting SVER field). An interrupt can be generated for this event if FPEIE bit of MAC_Interrupt_Enable is set. 0: Not transmitted Verify Frame 1: Transmitted Verify Frame	R/W

Bit	Symbol	Function	R/W
19	TRSP	Transmitted Respond Frame*2 Set when a Respond mPacket is transmitted (triggered by setting SRSP field). An interrupt can be generated for this event if FPEIE bit of MAC_Interrupt_Enable is set. 0: Not transmitted Respond Frame 1: Transmitted Respond Frame	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
Note 2. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

This register controls the operation of Frame Preemption.

28.3.37 MAC_Ext_Cfg1 : Split Mode Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0238

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	SAVE	—	SAVO[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SPLM[1:0]		—	SPLOFST[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

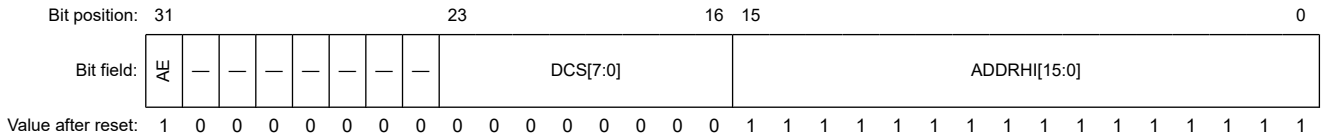
Bit	Symbol	Function	R/W
6:0	SPLOFST[6:0]	Split Offset These bits indicate the value of offset from the beginning of Length/Type field at which header split should take place when the appropriate SPLM[1:0] is selected. The reset value of this field is 2 bytes indicating a split at L2 header. Value is in terms of bytes.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
9:8	SPLM[1:0]	Split Mode These bits indicate the mode of splitting the incoming Rx packets. They are: 0 0: Split at L3/L4 header 0 1: Split at L2 header with an offset. Always Split at SPLOFST[6:0] bytes from the beginning of Length/Type field of the Frame 1 0: Combination mode: Split similar to SPLM[1:0] = 00b for IP packets that are untagged or tagged and VLAN stripped 1 1: Reserved	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
22:16	SAVO[6:0]	Split AV Offset When SAVE bit is set to 1, and the received packet is an AV Type packet, these bits indicate the value of the offset from the beginning of Length/Type field at which header should be split, when appropriate SPLM[1:0] is selected. The reset value of this field is 2 bytes, indicating a split at L2 header. Value is in terms of bytes.	R/W
23	—	This bit is read as 0. The write value should be 0.	R/W
24	SAVE	Split AV Enable • When this bit is set to 1, and the received packet is an AV Type packet, the header is split at SAVO[6:0] bytes from the beginning of Length/Type field of the packet, for L2 Split. • When this bit is set to 0, header is split at SPLOFST[6:0] bytes from the beginning of Length/Type field of the frame, for L2 Split.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

This register contains Split mode control field and offset field for Split Header feature.

28.3.38 MAC_ADDRESS0_HIGH : MAC Address 0 High register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0300



Bit	Symbol	Function	R/W
15:0	ADDRHI[15:0]	MAC Address0 [47:32] This field contains the upper 16 bits [47:32] of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.	R/W
23:16	DCS[7:0]	DMA Channel Select This field indicates the Rx DMA channel number or DMA channel numbers to which the MAC routes the received packet. When the MAC receives a packet with multicast or broadcast destination address, MAC routes the packet to multiple Rx DMA channels. The PDC field of the MAC_Ext_Configuration register determines if the MAC interprets the value of this field as a binary number or a one-hot encoded number.	R/W
30:24	—	These bits are read as 0. The write value should be 0.	R/W
31	AE	Address Enable This bit must be always set to 1.	R

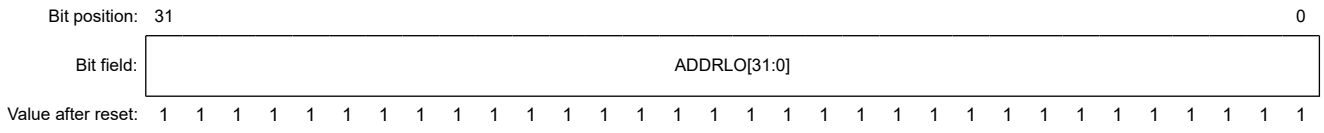
The MAC_ADDRESS0_HIGH register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits [31:24] of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

28.3.39 MAC_ADDRESS0_LOW : MAC Address 0 Low register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0304



Bit	Symbol	Function	R/W
31:0	ADDRLO[31:0]	MAC Address0 [31:0] This field contains the lower 32 bits of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.	R/W

The MAC_ADDRESS0_LOW register holds the lower 32 bits of the 6-byte first MAC address of the station.

28.3.40 MAC_ADDRESSn_HIGH : MAC Address n High register (n = 1 to 31)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0308 + 0x08 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	AE	SA	MBC[5:0]						DCS[7:0]								ADDRHI[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	ADDRHI[15:0]	MAC Address1 [47:32] This field contains the upper 16 bits [47:32] of the second 6-byte MAC address.	R/W
23:16	DCS[7:0]	DMA Channel Select If the PDC bit of MAC_Ext_Configuration register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC_ADDRESSn content is routed. If the PDC bit of MAC_Ext_Configuration register is set: This field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC_ADDRESSn content is routed.	R/W
29:24	MBC[5:0]	Mask Byte Control These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows: Bit 29: MAC_ADDRESSn_High[15:8] Bit 28: MAC_ADDRESSn_High[7:0] Bit 27: MAC_ADDRESSn_Low[31:24] ⋮ Bit 24: MAC_ADDRESSn_Low[7:0] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.	R/W
30	SA	Source Address When this bit is set, the MAC Address1 [47:0] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address1 [47:0] is used to compare with the DA fields of the received packet. 0: Compare with Destination Address 1: Compare with Source Address	R/W
31	AE	Address Enable When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering. 0: Address is ignored 1: Address is enabled	R/W

The MAC_ADDRESSn_HIGH register holds the upper 16 bits of the second 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits [31:24] of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

28.3.41 MAC_ADDRESSn_LOW : MAC Address n Low register (n = 1 to 31)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x030C + 0x08 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDRLO[31:0]																															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
31:0	ADDRLO[31:0]	MAC Address1 [31:0] This field contains the lower 32 bits of second 6-byte MAC address. The content of this field is undefined until loaded by the application after the initialization process.	R/W

The MAC_ADDRESSn_LOW register holds the lower 32 bits of the second 6-byte MAC address of the station.

28.3.42 MMC_Control : MMC Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0700

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	UCDBC	—	—	CNTPRSTLVL	CNTPRST	CNTFREEZ	RSTONRD	CNTSTOPRO	CNTRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CNTRST	Counters Reset*1 When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. 0: Counters are not reset 1: All counters are reset	R/W
1	CNTSTOPRO	Counter Stop Rollover When this bit is set, the counter does not roll over to zero after reaching the maximum value. 0: Counter Stop Rollover is disabled 1: Counter Stop Rollover is enabled	R/W
2	RSTONRD	Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits [7:0]) is read. 0: Reset on Read is disabled 1: Reset on Read is enabled	R/W
3	CNTFREEZ	MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. 0: MMC Counter Freeze is disabled 1: MMC Counter Freeze is enabled	R/W
4	CNTPRST	Counters Preset*1 When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. 0: Counters Preset is disabled 1: Counters Preset is enabled	R/W

Bit	Symbol	Function	R/W
5	CNTPRSTLVL	Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2 KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2 KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. 0: Full-Half Preset is disabled 1: Full-Half Preset is enabled	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	UCDBC	Update MMC Counters for Dropped Broadcast Packets*2 When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets. 0: Update MMC Counters for Dropped Broadcast Packets is disabled 1: Update MMC Counters for Dropped Broadcast Packets is enabled	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restrictions apply.

- Initiates the counter reset when application writes 1.
- MAC writes 0 after the counter reset is complete.
- MAC ignores when application writes 0.

Note 2. The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.

This register establishes the operating mode of MMC.

28.3.43 MMC_Rx_Interrupt : MMC Receive Interrupt Register

Base address: GMAC0 = 0x8010_0000

14	RX256T511OCTGBPIS	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status*1 This bit is set when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status not detected 1: MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status detected	R
15	RX512T1023OCTGBPIS	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status*1 This bit is set when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status not detected 1: MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status detected	R
16	RX1024TMAXOCTGBPIS	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status*1 This bit is set when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status not detected 1: MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status detected	R
17	RXUCGPIS	MMC Receive Unicast Good Packet Counter Interrupt Status*1 This bit is set when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value. 0: MMC Receive Unicast Good Packet Counter Interrupt Status not detected 1: MMC Receive Unicast Good Packet Counter Interrupt Status detected	R
18	RXLENERPIS	MMC Receive Length Error Packet Counter Interrupt Status*1 This bit is set when the rxlengtherror counter reaches half of the maximum value or the maximum value. 0: MMC Receive Length Error Packet Counter Interrupt Status not detected 1: MMC Receive Length Error Packet Counter Interrupt Status detected	R
19	RXORANGEPIS	MMC Receive Out Of Range Error Packet Counter Interrupt Status.*1 This bit is set when the rxoutofrangetype counter reaches half of the maximum value or the maximum value. 0: MMC Receive Out Of Range Error Packet Counter Interrupt Status not detected 1: MMC Receive Out Of Range Error Packet Counter Interrupt Status detected	R
20	RXPAUSPIS	MMC Receive Pause Packet Counter Interrupt Status*1 This bit is set when the rxpausepackets counter reaches half of the maximum value or the maximum value. 0: MMC Receive Pause Packet Counter Interrupt Status not detected 1: MMC Receive Pause Packet Counter Interrupt Status detected	R
21	RXFOVPIS	MMC Receive FIFO Overflow Packet Counter Interrupt Status*1 This bit is set when the rxfifooverflow counter reaches half of the maximum value or the maximum value. 0: MMC Receive FIFO Overflow Packet Counter Interrupt Status not detected 1: MMC Receive FIFO Overflow Packet Counter Interrupt Status detected	R
22	RXVLANGBPIS	MMC Receive VLAN Good Bad Packet Counter Interrupt Status*1 This bit is set when the rxvlanpackets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Receive VLAN Good Bad Packet Counter Interrupt Status not detected 1: MMC Receive VLAN Good Bad Packet Counter Interrupt Status detected	R

Bit	Symbol	Function	R/W
23	RXWDOGPIS	MMC Receive Watchdog Error Packet Counter Interrupt Status*1 This bit is set when the rxwatchdog error counter reaches half of the maximum value or the maximum value. 0: MMC Receive Watchdog Error Packet Counter Interrupt Status not detected 1: MMC Receive Watchdog Error Packet Counter Interrupt Status detected	R
24	RXRCVERRPIS	MMC Receive Error Packet Counter Interrupt Status*1 This bit is set when the rxrcverror counter reaches half of the maximum value or the maximum value. 0: MMC Receive Error Packet Counter Interrupt Status not detected 1: MMC Receive Error Packet Counter Interrupt Status detected	R
25	RXCTRLPIS	MMC Receive Control Packet Counter Interrupt Status*1 This bit is set when the rxctrlpackets_g counter reaches half of the maximum value or the maximum value. 0: MMC Receive Control Packet Counter Interrupt Status not detected 1: MMC Receive Control Packet Counter Interrupt Status detected	R
26	RXLPIUSCIS	MMC Receive LPI microsecond counter interrupt status*1 This bit is set when the Rx_LPI_USEC_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Receive LPI microsecond Counter Interrupt Status not detected 1: MMC Receive LPI microsecond Counter Interrupt Status detected	R
27	RXLPITRCIS	MMC Receive LPI transition counter interrupt status*1 This bit is set when the Rx_LPI_Tran_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Receive LPI transition Counter Interrupt Status not detected 1: MMC Receive LPI transition Counter Interrupt Status detected	R
31:28	—	These bits are read as 0.	R

Note 1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

This register maintains the interrupts generated from all Receive statistics counters.

The MMC_Rx_Interrupt register maintains the interrupts that are generated when the following occur:

- Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter)
- Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter)

When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits [7:0]) of the respective counter must be read to clear the interrupt bit.

Note: R_SS_RC means that this register bit is set internally, and it is cleared when the Counter register is read.

28.3.44 MMC_Tx_Interrupt : MMC Transmit Interrupt Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

22	TXEXDEFPIS	MMC Transmit Excessive Deferral Packet Counter Interrupt Status*1 This bit is set when the txexcessdef counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Excessive Deferral Packet Counter Interrupt Status not detected 1: MMC Transmit Excessive Deferral Packet Counter Interrupt Status detected	R
23	TXPAUSPIS	MMC Transmit Pause Packet Counter Interrupt Status*1 This bit is set when the txpausepacketserror counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Pause Packet Counter Interrupt Status not detected 1: MMC Transmit Pause Packet Counter Interrupt Status detected	R
24	TXVLANGPIS	MMC Transmit VLAN Good Packet Counter Interrupt Status*1 This bit is set when the txvlanpackets_g counter reaches half of the maximum value or the maximum value. 0: MMC Transmit VLAN Good Packet Counter Interrupt Status not detected 1: MMC Transmit VLAN Good Packet Counter Interrupt Status detected	R
25	TXOSIZEGPIS	MMC Transmit Oversize Good Packet Counter Interrupt Status*1 This bit is set when the txoversize_g counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Oversize Good Packet Counter Interrupt Status not detected 1: MMC Transmit Oversize Good Packet Counter Interrupt Status detected	R
26	TXLPIUSCIS	MMC Transmit LPI microsecond counter interrupt status*1 This bit is set when the Tx_LPI_USEC_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Transmit LPI microsecond Counter Interrupt Status not detected 1: MMC Transmit LPI microsecond Counter Interrupt Status detected	R
27	TXLPITRCIS	MMC Transmit LPI transition counter interrupt status*1 This bit is set when the Tx_LPI_Tran_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Transmit LPI transition Counter Interrupt Status not detected 1: MMC Transmit LPI transition Counter Interrupt Status detected	R
31:28	—	These bits are read as 0.	R

Note 1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

This register maintains the interrupts generated from all Transmit statistics counters.

The MMC_Tx_Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values(0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The MMC_Tx_Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (Bits [7:0]) of the respective counter must be read to clear the interrupt bit.

28.3.45 MMC_Rx_Interrupt_Mask : MMC Receive Interrupt Mask Register

Base address: GMAC0 = 0x8010_0000

13	RX128T255OCTGBPIM	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Mask is enabled	R/W
14	RX256T511OCTGBPIM	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Mask is enabled	R/W
15	RX512T1023OCTGBPIM	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask is enabled	R/W
16	RX1024TMAXOCTGBPIM	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask. Setting this bit masks the interrupt when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask is enabled	R/W
17	RXUCGPIM	MMC Receive Unicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value. 0: MMC Receive Unicast Good Packet Counter Interrupt Mask is disabled 1: MMC Receive Unicast Good Packet Counter Interrupt Mask is enabled	R/W

Bit	Symbol	Function	R/W
18	RXLENERPIM	MMC Receive Length Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxlengtherror counter reaches half of the maximum value or the maximum value. 0: MMC Receive Length Error Packet Counter Interrupt Mask is disabled 1: MMC Receive Length Error Packet Counter Interrupt Mask is enabled	R/W
19	RXORANGEPIM	MMC Receive Out Of Range Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoutofrangetype counter reaches half of the maximum value or the maximum value. 0: MMC Receive Out Of Range Error Packet Counter Interrupt Mask is disabled 1: MMC Receive Out Of Range Error Packet Counter Interrupt Mask is enabled	R/W
20	RXPAUSPIM	MMC Receive Pause Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxpausepackets counter reaches half of the maximum value or the maximum value. 0: MMC Receive Pause Packet Counter Interrupt Mask is disabled 1: MMC Receive Pause Packet Counter Interrupt Mask is enabled	R/W
21	RXFOVPIM	MMC Receive FIFO Overflow Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxfifooverflow counter reaches half of the maximum value or the maximum value. 0: MMC Receive FIFO Overflow Packet Counter Interrupt Mask is disabled 1: MMC Receive FIFO Overflow Packet Counter Interrupt Mask is enabled	R/W
22	RXVLANGBPIM	MMC Receive VLAN Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxvlanpackets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Receive VLAN Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Receive VLAN Good Bad Packet Counter Interrupt Mask is enabled	R/W
23	RXWDOGPIM	MMC Receive Watchdog Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxwatchdog counter reaches half of the maximum value or the maximum value. 0: MMC Receive Watchdog Error Packet Counter Interrupt Mask is disabled 1: MMC Receive Watchdog Error Packet Counter Interrupt Mask is enabled	R/W
24	RXRCVERRPIM	MMC Receive Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxrcverror counter reaches half of the maximum value or the maximum value. 0: MMC Receive Error Packet Counter Interrupt Mask is disabled 1: MMC Receive Error Packet Counter Interrupt Mask is enabled	R/W
25	RXCTRLPIM	MMC Receive Control Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxctrlpackets_g counter reaches half of the maximum value or the maximum value. 0: MMC Receive Control Packet Counter Interrupt Mask is disabled 1: MMC Receive Control Packet Counter Interrupt Mask is enabled	R/W
26	RXLPIUSCIM	MMC Receive LPI microsecond counter interrupt Mask Setting this bit masks the interrupt when the Rx_LPI_USEC_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Receive LPI microsecond counter interrupt Mask is disabled 1: MMC Receive LPI microsecond counter interrupt Mask is enabled	R/W
27	RXLPITRCIM	MMC Receive LPI transition counter interrupt Mask Setting this bit masks the interrupt when the Rx_LPI_Tran_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Receive LPI transition counter interrupt Mask is disabled 1: MMC Receive LPI transition counter interrupt Mask is enabled	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

This register maintains the masks for interrupts generated from all Receive statistics counters.

The MMC_Rx_Interrupt_Mask register maintains the masks for the interrupts generated when receive statistic counters reach half of their maximum value or the maximum values.

28.3.46 MMC_Tx_Interrupt_Mask : MMC Transmit Interrupt Mask Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0710

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit field:	TXMCOLGPIM	TXSCOLGPIM	TXUFLOWERPIM	TXBCGBPIM	TXMCGBPIM	TXUCGBPIM	TX1024TMAXOCTGBPIM	TX512T1023OCTGBPIM	TX256T511OCTGBPIM	TX128T255OCTGBPIM	TX65T127OCTGBPIM	TX64OCTGBPIM	TXMCGPIM	TXBCGPIM	TXGBPKTIM	TXGBOCTIM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TXGBOCTIM	MMC Transmit Good Bad Octet Counter Interrupt Mask Setting this bit masks the interrupt when the txoctetcount_gb counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Good Bad Octet Counter Interrupt Mask is disabled 1: MMC Transmit Good Bad Octet Counter Interrupt Mask is enabled	R/W
1	TXGBPKTIM	MMC Transmit Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txpacketcount_gb counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Transmit Good Bad Packet Counter Interrupt Mask is enabled	R/W
2	TXBCGPIM	MMC Transmit Broadcast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txbroadcastpackets_g counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Broadcast Good Packet Counter Interrupt Mask is disabled 1: MMC Transmit Broadcast Good Packet Counter Interrupt Mask is enabled	R/W
3	TXMCGPIM	MMC Transmit Multicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticastpackets_g counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Multicast Good Packet Counter Interrupt Mask is disabled 1: MMC Transmit Multicast Good Packet Counter Interrupt Mask is enabled	R/W
4	TX64OCTGBPIM	MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx64octets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Mask is enabled	R/W
5	TX65T127OCTGBPIM	MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx65to127octets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Mask is enabled	R/W
6	TX128T255OCTGBPIM	MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx128to255octets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Mask is enabled	R/W

Bit	Symbol	Function	R/W
7	TX256T511OCTGBPIM	MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx256to511octets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Mask is enabled	R/W
8	TX512T1023OCTGBPIM	MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx512to1023octets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask is enabled	R/W
9	TX1024TMAXOCTGBPIM	MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask is enabled	R/W
10	TXUCGBPIM	MMC Transmit Unicast Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txunicastpackets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Unicast Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Transmit Unicast Good Bad Packet Counter Interrupt Mask is enabled	R/W
11	TXMCGBPIM	MMC Transmit Multicast Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticastpackets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Multicast Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Transmit Multicast Good Bad Packet Counter Interrupt Mask is enabled	R/W
12	TXBCGBPIM	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txbroadcastpackets_gb counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Broadcast Good Bad Packet Counter Interrupt Mask is disabled 1: MMC Transmit Broadcast Good Bad Packet Counter Interrupt Mask is enabled	R/W
13	TXUFLOWERPIM	MMC Transmit Underflow Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txunderflowerror counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Underflow Error Packet Counter Interrupt Mask is disabled 1: MMC Transmit Underflow Error Packet Counter Interrupt Mask is enabled	R/W
14	TXSCOLGPIM	MMC Transmit Single Collision Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txsinglecol_g counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Single Collision Good Packet Counter Interrupt Mask is disabled 1: MMC Transmit Single Collision Good Packet Counter Interrupt Mask is enabled	R/W
15	TXMCOLGPIM	MMC Transmit Multiple Collision Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticol_g counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Multiple Collision Good Packet Counter Interrupt Mask is disabled 1: MMC Transmit Multiple Collision Good Packet Counter Interrupt Mask is enabled	R/W
16	TXDEFPIM	MMC Transmit Deferred Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txdeferred counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Deferred Packet Counter Interrupt Mask is disabled 1: MMC Transmit Deferred Packet Counter Interrupt Mask is enabled	R/W
17	TXLATCOLPIM	MMC Transmit Late Collision Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txlatecol counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Late Collision Packet Counter Interrupt Mask is disabled 1: MMC Transmit Late Collision Packet Counter Interrupt Mask is enabled	R/W

Bit	Symbol	Function	R/W
18	TXEXCOLPIM	MMC Transmit Excessive Collision Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txexcesscol counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Excessive Collision Packet Counter Interrupt Mask is disabled 1: MMC Transmit Excessive Collision Packet Counter Interrupt Mask is enabled	R/W
19	TXCARERPIM	MMC Transmit Carrier Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txcarriererror counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Carrier Error Packet Counter Interrupt Mask is disabled 1: MMC Transmit Carrier Error Packet Counter Interrupt Mask is enabled	R/W
20	TXGOCTIM	MMC Transmit Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the txoctetcount_g counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Good Octet Counter Interrupt Mask is disabled 1: MMC Transmit Good Octet Counter Interrupt Mask is enabled	R/W
21	TXGPKTIM	MMC Transmit Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txpacketcount_g counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Good Packet Counter Interrupt Mask is disabled 1: MMC Transmit Good Packet Counter Interrupt Mask is enabled	R/W
22	TXEXDEFPIM	MMC Transmit Excessive Deferral Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txexcessdef counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Excessive Deferral Packet Counter Interrupt Mask is disabled 1: MMC Transmit Excessive Deferral Packet Counter Interrupt Mask is enabled	R/W
23	TXPAUSPIM	MMC Transmit Pause Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txpausepackets counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Pause Packet Counter Interrupt Mask is disabled 1: MMC Transmit Pause Packet Counter Interrupt Mask is enabled	R/W
24	TXVLANGPIM	MMC Transmit VLAN Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txvlanpackets_g counter reaches half of the maximum value or the maximum value. 0: MMC Transmit VLAN Good Packet Counter Interrupt Mask is disabled 1: MMC Transmit VLAN Good Packet Counter Interrupt Mask is enabled	R/W
25	TXOSIZEGPIM	MMC Transmit Oversize Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txoversize_g counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Oversize Good Packet Counter Interrupt Mask is disabled 1: MMC Transmit Oversize Good Packet Counter Interrupt Mask is enabled	R/W
26	TXLPIUSCIM	MMC Transmit LPI microsecond counter interrupt Mask Setting this bit masks the interrupt when the Tx_LPI_USEC_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Transmit LPI microsecond counter interrupt Mask is disabled 1: MMC Transmit LPI microsecond counter interrupt Mask is enabled	R/W
27	TXLPITRCIM	MMC Transmit LPI transition counter interrupt Mask Setting this bit masks the interrupt when the Tx_LPI_Tran_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Transmit LPI transition counter interrupt Mask is disabled 1: MMC Transmit LPI transition counter interrupt Mask is enabled	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

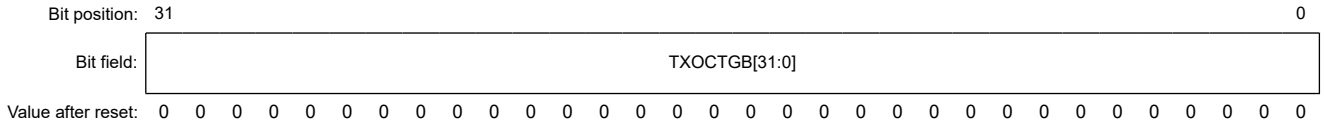
This register maintains the masks for interrupts generated from all Transmit statistics counters.

The MMC_Tx_Interrupt_Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.

28.3.47 Tx_Octet_Count_Good_Bad : Transmit Octet Count for Good and Bad 64 Byte Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0714



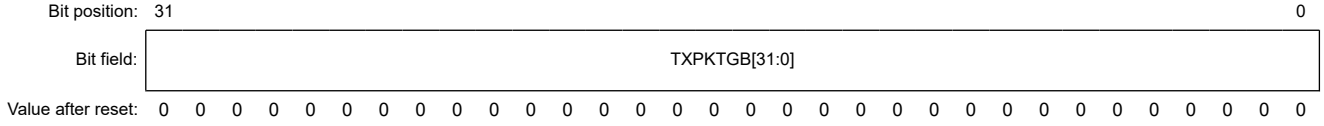
Bit	Symbol	Function	R/W
31:0	TXOCTGB[31:0]	Tx Octet Count Good Bad This field indicates the number of bytes transmitted, exclusive of preamble and retried bytes, in good and bad packets.	R

This register provides the number of bytes transmitted by the GMAC, exclusive of preamble and retried bytes, in good and bad packets.

28.3.48 Tx_Packet_Count_Good_Bad : Transmit Packet Count for Good and Bad Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0718



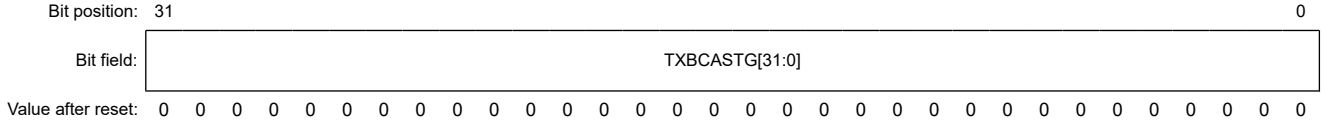
Bit	Symbol	Function	R/W
31:0	TXPKTGB[31:0]	Tx Packet Count Good Bad This field indicates the number of good and bad packets transmitted, exclusive of retried packets.	R

This register provides the number of good and bad packets transmitted by GMAC, exclusive of retried packets.

28.3.49 Tx_Broadcast_Packets_Good : Transmit Packet Count for Good Broadcast Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x071C



Bit	Symbol	Function	R/W
31:0	TXBCASTG[31:0]	Tx Broadcast Packets Good This field indicates the number of good broadcast packets transmitted.	R

This register provides the number of good broadcast packets transmitted by GMAC.

28.3.50 Tx_Multicast_Packets_Good : Transmit Packet Count for Good Multicast Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0720

Bit position:	31																												0
Bit field:	TXMCASTG[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TXMCASTG[31:0]	Tx Multicast Packets Good This field indicates the number of good multicast packets transmitted.	R

This register provides the number of good multicast packets transmitted by GMAC.

28.3.51 Tx_64Octets_Packets_Good_Bad : Transmit Octet Count for Good and Bad 64 Byte Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0724

Bit position:	31																												0
Bit field:	TX64OCTGB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TX64OCTGB[31:0]	Tx 64Octets Packets Good_Bad This field indicates the number of good and bad packets transmitted with length 64 bytes, exclusive of preamble and retried packets.	R

This register provides the number of good and bad packets transmitted by GMAC with length 64 bytes, exclusive of preamble and retried packets.

28.3.52 Tx_65To127Octets_Packets_Good_Bad : Transmit Octet Count for Good and Bad 65 to 127 Bytes Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0728

Bit position:	31																												0
Bit field:	TX65_127OCTGB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TX65_127OCTGB[31:0]	Tx 65To127Octets Packets Good Bad This field indicates the number of good and bad packets transmitted with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried packets.	R

This register provides the number of good and bad packets transmitted by GMAC with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried packets.

28.3.53 Tx_128To255Octets_Packets_Good_Bad : Transmit Octet Count for Good and Bad 128 to 255 Bytes Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x072C

Bit position:	31																												0
Bit field:	TX128_255OCTGB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TX128_255OCTGB[31:0]	Tx 128To255Octets Packets Good Bad This field indicates the number of good and bad packets transmitted with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried packets.	R

This register provides the number of good and bad packets transmitted by GMAC with length between 128 to 255 (inclusive) bytes, exclusive of preamble and retried packets.

28.3.54 Tx_256To511Octets_Packets_Good_Bad : Transmit Octet Count for Good and Bad 256 to 511 Bytes Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0730

Bit position:	31																												0
Bit field:	TX256_511OCTGB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TX256_511OCTGB[31:0]	Tx 256To511Octets Packets Good Bad This field indicates the number of good and bad packets transmitted with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried packets.	R

This register provides the number of good and bad packets transmitted by GMAC with length between 256 to 511 (inclusive) bytes, exclusive of preamble and retried packets.

28.3.55 Tx_512To1023Octets_Packets_Good_Bad : Transmit Octet Count for Good and Bad 512 to 1023 Bytes Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0734

Bit position:	31																												0
Bit field:	TX512_1023OCTGB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

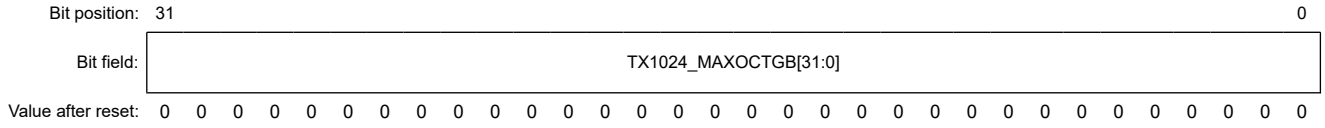
Bit	Symbol	Function	R/W
31:0	TX512_1023OCTGB[31:0]	Tx 512To1023Octets Packets Good Bad This field indicates the number of good and bad packets transmitted with length between 512 and 1023 (inclusive) bytes, exclusive of preamble and retried packets.	R

This register provides the number of good and bad packets transmitted by GMAC with length 512 to 1023 (inclusive) bytes, exclusive of preamble and retried packets.

28.3.56 Tx_1024ToMaxOctets_Packets_Good_Bad : Transmit Octet Count for Good and Bad 1024 to Maxsize Bytes Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0738



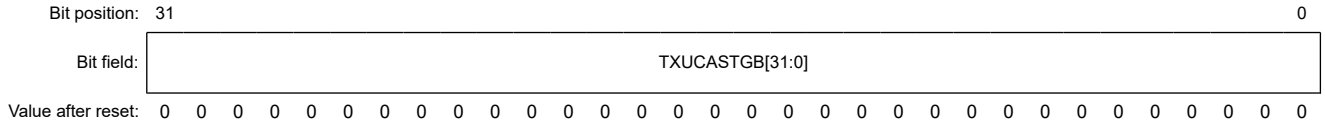
Bit	Symbol	Function	R/W
31:0	TX1024_MAXOCTGB[31:0]	Tx 1024ToMaxOctets Packets Good Bad This field indicates the number of good and bad packets transmitted with length between 1024 and maxsize (inclusive) bytes, exclusive of preamble and retried packets.	R

This register provides the number of good and bad packets transmitted by GMAC with length 1024 to maxsize (inclusive) bytes, exclusive of preamble and retried packets.

28.3.57 Tx_Unicast_Packets_Good_Bad : Transmit Packet Count for Good and Bad Unicast Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x073C



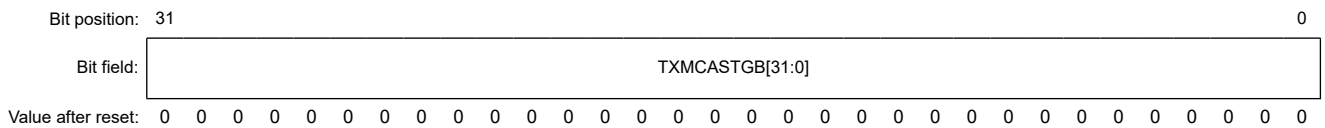
Bit	Symbol	Function	R/W
31:0	TXUCASTGB[31:0]	Tx Unicast Packets Good Bad This field indicates the number of good and bad unicast packets transmitted.	R

This register provides the number of good and bad unicast packets transmitted by GMAC.

28.3.58 Tx_Multicast_Packets_Good_Bad : Transmit Packet Count for Good and Bad Multicast Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0740



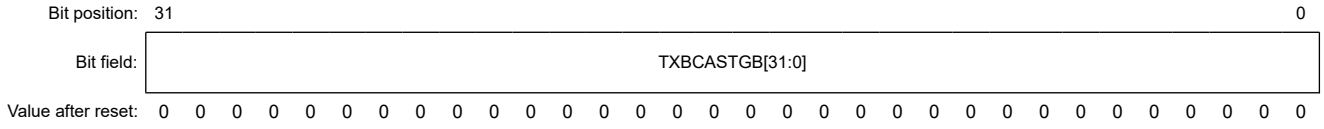
Bit	Symbol	Function	R/W
31:0	TXMCASTGB[31:0]	Tx Multicast Packets Good Bad This field indicates the number of good and bad multicast packets transmitted.	R

This register provides the number of good and bad multicast packets transmitted by GMAC.

28.3.59 Tx_Broadcast_Packets_Good_Bad : Transmit Packet Count for Good and Bad Broadcast Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0744



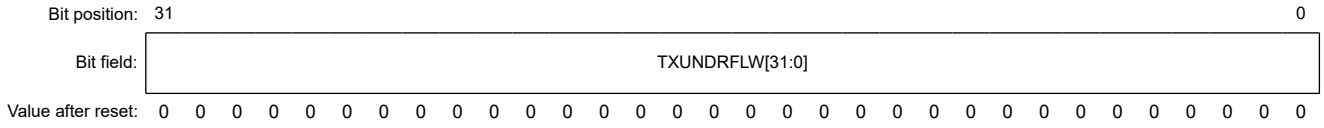
Bit	Symbol	Function	R/W
31:0	TXBCASTGB[31:0]	Tx Broadcast Packets Good Bad This field indicates the number of good and bad broadcast packets transmitted.	R

This register provides the number of good and bad broadcast packets transmitted by GMAC.

28.3.60 Tx_Underflow_Error_Packets : Transmit Packet Count for Underflow Error Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0748



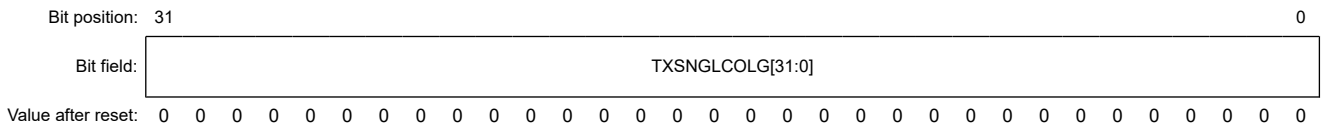
Bit	Symbol	Function	R/W
31:0	TXUNDRFLW[31:0]	Tx Underflow Error Packets This field indicates the number of packets aborted because of packets underflow error.	R

This register provides the number of packets aborted by GMAC because of packets underflow error.

28.3.61 Tx_Single_Collision_Good_Packets : Transmit Packet Count for Packets Transmitted after Single Collision

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x074C



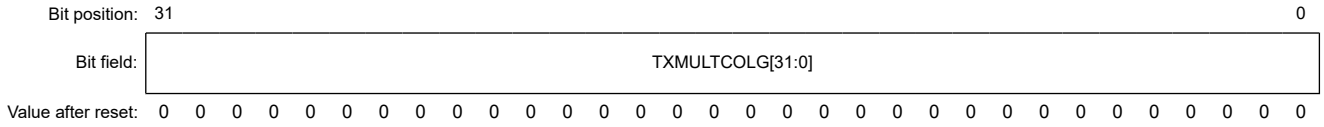
Bit	Symbol	Function	R/W
31:0	TXSNGLCOLG[31:0]	Tx Single Collision Good Packets This field indicates the number of successfully transmitted packets after a single collision in the half-duplex mode.	R

This register provides the number of successfully transmitted packets by GMAC after a single collision in the half-duplex mode.

28.3.62 Tx_Multiple_Collision_Good_Packets : Transmit Packet Count for Packets Transmitted after Multiple Collision

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0750



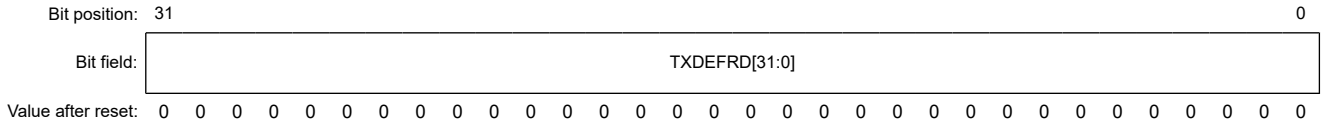
Bit	Symbol	Function	R/W
31:0	TXMULTCOLG[31:0]	Tx Multiple Collision Good Packets This field indicates the number of successfully transmitted packets after multiple collisions in the half-duplex mode.	R

This register provides the number of successfully transmitted packets by GMAC after multiple collisions in the half-duplex mode.

28.3.63 Tx_Deferred_Packets : Transmit Packet Count for Deferred Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0754



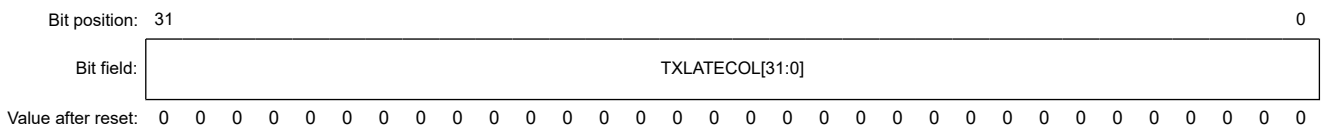
Bit	Symbol	Function	R/W
31:0	TXDEFRD[31:0]	Tx Deferred Packets This field indicates the number of successfully transmitted after a deferral in the half-duplex mode.	R

This register provides the number of successfully transmitted by GMAC after a deferral in the half-duplex mode.

28.3.64 Tx_Late_Collision_Packets : Transmit Packet Count for Late Collision Error Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0758



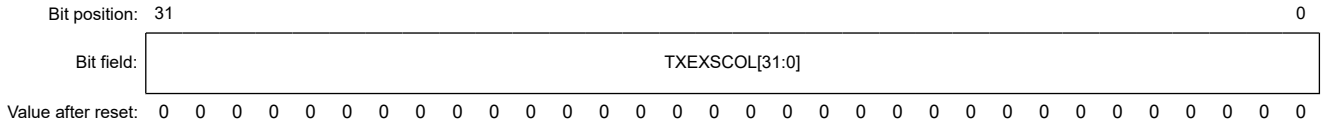
Bit	Symbol	Function	R/W
31:0	TXLATECOL[31:0]	Tx Late Collision Packets This field indicates the number of packets aborted because of late collision error.	R

This register provides the number of packets aborted by GMAC because of late collision error.

28.3.65 Tx_Excessive_Collision_Packets : Transmit Packet Count for Excessive Collision Error Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x075C



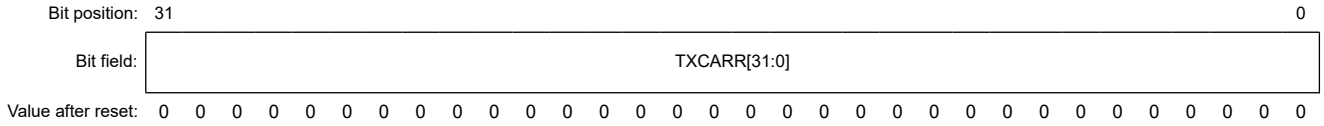
Bit	Symbol	Function	R/W
31:0	TXEXSCOL[31:0]	Tx Excessive Collision Packets This field indicates the number of packets aborted because of excessive (16) collision errors.	R

This register provides the number of packets aborted by GMAC because of excessive (16) collision errors.

28.3.66 Tx_Carrier_Error_Packets : Transmit Packet Count for Carrier Sense Error Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0760



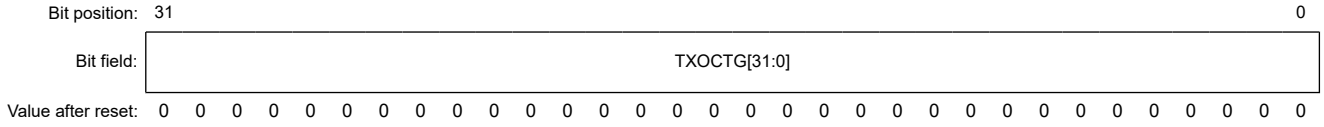
Bit	Symbol	Function	R/W
31:0	TXCARR[31:0]	Tx Carrier Error Packets This field indicates the number of packets aborted because of carrier sense error (no carrier or loss of carrier).	R

This register provides the number of packets aborted by GMAC because of carrier sense error (no carrier or loss of carrier).

28.3.67 Tx_Octet_Count_Good : Transmit Octet Count for Good Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0764



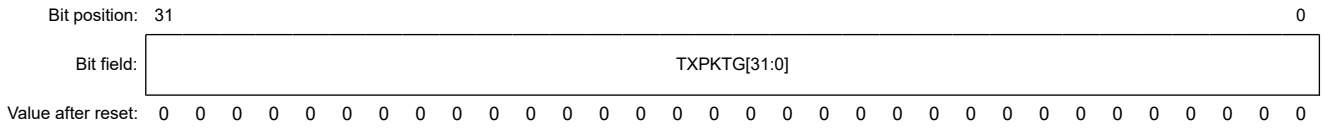
Bit	Symbol	Function	R/W
31:0	TXOCTG[31:0]	Tx Octet Count Good This field indicates the number of bytes transmitted, exclusive of preamble, only in good packets.	R

This register provides the number of bytes transmitted by GMAC, exclusive of preamble, only in good packets.

28.3.68 Tx_Packet_Count_Good : Transmit Packet Count for Good Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0768



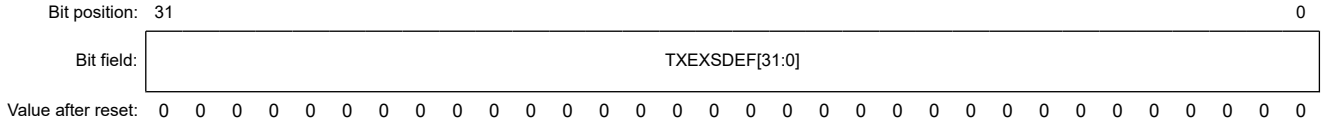
Bit	Symbol	Function	R/W
31:0	TXPKTG[31:0]	Tx Packet Count Good This field indicates the number of good packets transmitted.	R

This register provides the number of good packets transmitted by GMAC.

28.3.69 Tx_Excessive_Deferral_Error : Transmit Packet Count for Excessive Deferral Error Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x076C



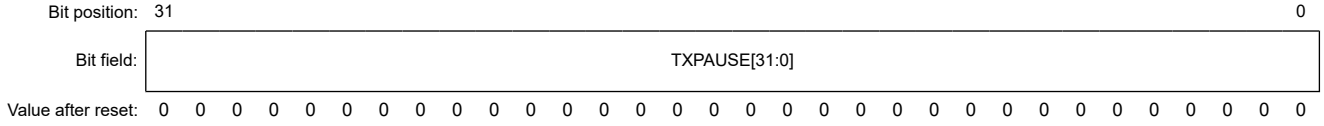
Bit	Symbol	Function	R/W
31:0	TXEXSDEF[31:0]	Tx Excessive Deferral Error This field indicates the number of packets aborted because of excessive deferral error (deferred for more than two max-sized packet times).	R

This register provides the number of packets aborted by GMAC because of excessive deferral error (deferred for more than two max-sized packet times).

28.3.70 Tx_Pause_Packets : Transmit Packet Count for Good PAUSE Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0770



Bit	Symbol	Function	R/W
31:0	TXPAUSE[31:0]	Tx Pause Packets This field indicates the number of good Pause packets transmitted.	R

This register provides the number of good Pause packets transmitted by GMAC.

28.3.71 Tx_VLAN_Packets_Good : Transmit Packet Count for Good VLAN Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0774

Bit position:	31																												0
Bit field:	TXVLANG[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TXVLANG[31:0]	Tx VLAN Packets Good This field provides the number of good VLAN packets transmitted.	R

This register provides the number of good VLAN packets transmitted by GMAC.

28.3.72 Tx_OSize_Packets_Good : Transmit Packet Count for Good Oversize Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0778

Bit position:	31																												0
Bit field:	TXOSIZG[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TXOSIZG[31:0]	Tx OSize Packets Good This field indicates the number of packets transmitted without errors and with length greater than the maxsize (1,518 or 1,522 bytes for VLAN tagged packets; 2000 bytes if enabled in S2KP bit of the MAC_Configuration register).	R

This register provides the number of packets transmitted by GMAC without errors and with length greater than the maxsize (1,518 or 1,522 bytes for VLAN tagged packets; 2000 bytes if enabled in S2KP bit of the MAC_Configuration register).

28.3.73 Rx_Packets_Count_Good_Bad : Receive Packet Count for Good and Bad Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0780

Bit position:	31																												0
Bit field:	RXPKTGB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXPKTGB[31:0]	Rx Packets Count Good Bad This field indicates the number of good and bad packets received.	R

This register provides the number of good and bad packets received by GMAC.

28.3.74 Rx_Octet_Count_Good_Bad : Receive Octet Count for Good and Bad Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0784

Bit position:	31																												0
Bit field:	RXOCTGB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXOCTGB[31:0]	Rx Octet Count Good Bad This field indicates the number of bytes received, exclusive of preamble, in good and bad packets.	R

This register provides the number of bytes received by GMAC, exclusive of preamble, in good and bad packets.

28.3.75 Rx_Octet_Count_Good : Receive Octet Count for Good Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0788

Bit position:	31																												0
Bit field:	RXOCTG[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXOCTG[31:0]	Rx Octet Count Good This field indicates the number of bytes received, exclusive of preamble, only in good packets.	R

This register provides the number of bytes received by GMAC, exclusive of preamble, only in good packets.

28.3.76 Rx_Broadcast_Packets_Good : Receive Packet Count for Good Broadcast Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x078C

Bit position:	31																												0
Bit field:	RXBCASTG[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXBCASTG[31:0]	Rx Broadcast Packets Good This field indicates the number of good broadcast packets received.	R

This register provides the number of good broadcast packets received by GMAC.

28.3.77 Rx_Multicast_Packets_Good : Receive Packet Count for Good Multicast Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0790

Bit position:	31																												0
Bit field:	RXMCASTG[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXMCASTG[31:0]	Rx Multicast Packets Good This field indicates the number of good multicast packets received.	R

This register provides the number of good multicast packets received by GMAC.

28.3.78 Rx_CRC_Error_Packets : Receive Packet Count for CRC Error Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0794

Bit position:	31																												0
Bit field:	RXCRCERR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXCRCERR[31:0]	Rx CRC Error Packets This field indicates the number of packets received with CRC error.	R

This register provides the number of packets received by GMAC with CRC error.

28.3.79 Rx_Alignment_Error_Packets : Receive Packet Count for Alignment Error Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0798

Bit position:	31																												0
Bit field:	RXALGNERR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXALGNERR[31:0]	Rx Alignment Error Packets This field indicates the number of packets received with alignment (dribble) error. It is valid only in 10/100 mode.	R

This register provides the number of packets received by GMAC with alignment (dribble) error. It is valid only in 10/100 mode.

28.3.80 Rx_Runt_Error_Packets : Receive Packet Count for Runt Error Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x079C

Bit position:	31																												0
Bit field:	RXRUNTERR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXRUNTERR[31:0]	Rx Runt Error Packets This field indicates the number of packets received with runt (length less than 64 bytes and CRC error) error.	R

This register provides the number of packets received by GMAC with runt (length less than 64 bytes and CRC error) error.

28.3.81 Rx_Jabber_Error_Packets : Receive Packet Count for Jabber Error Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07A0

Bit position:	31																												0
Bit field:	RXJABERR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXJABERR[31:0]	Rx Jabber Error Packets This field indicates the number of giant packets received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Packet mode is enabled, packets of length greater than 9,018 bytes (9,022 bytes for VLAN tagged) are considered as giant packets.	R

This register provides the number of giant packets received by GMAC with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Packet mode is enabled, packets of length greater than 9,018 bytes (9,022 bytes for VLAN tagged) are considered as giant packets.

28.3.82 Rx_Undersize_Packets_Good : Receive Packet Count for Undersize Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07A4

Bit position:	31																												0
Bit field:	RXUNDERSZG[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXUNDERSZG[31:0]	Rx Undersize Packets Good This field indicates the number of packets received with length less than 64 bytes, without any errors.	R

This register provides the number of packets received by GMAC with length less than 64 bytes, without any errors.

28.3.83 Rx_Oversize_Packets_Good : Receive Packet Count for Oversize Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07A8

Bit position:	31																												0
Bit field:	RXOVERSZG[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXOVERSZG[31:0]	Rx Oversize Packets Good This field indicates the number of packets received without errors, with length greater than the maxsize (1,518 bytes or 1,522 bytes for VLAN tagged packets; 2000 bytes if enabled in the S2KP bit of the MAC_Configuration register).	R

This register provides the number of packets received by GMAC without errors, with length greater than the maxsize (1,518 bytes or 1,522 bytes for VLAN tagged packets; 2000 bytes if enabled in the S2KP bit of the MAC_Configuration register).

28.3.84 Rx_64Octets_Packets_Good_Bad : Receive Packet Count for Good and Bad 64 Byte Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07AC

Bit position:	31																												0
Bit field:	RX64OCTGB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RX64OCTGB[31:0]	Rx 64 Octets Packets Good Bad This field indicates the number of good and bad packets received with length 64 bytes, exclusive of the preamble.	R

This register provides the number of good and bad packets received by GMAC with length 64 bytes, exclusive of the preamble.

28.3.85 Rx_65To127Octets_Packets_Good_Bad : Receive Packet Count for Good and Bad 65 to 127 Bytes Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07B0

Bit position:	31																												0
Bit field:	RX65_127OCTGB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

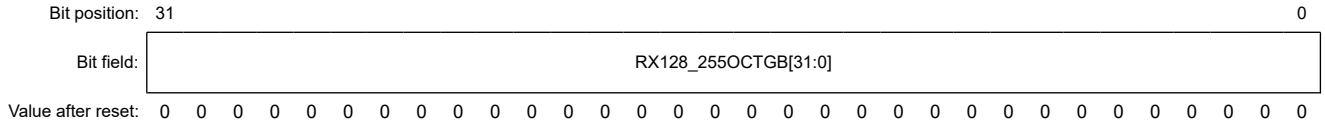
Bit	Symbol	Function	R/W
31:0	RX65_127OCTGB[31:0]	Rx 65-127 Octets Packets Good Bad This field indicates the number of good and bad packets received with length between 65 and 127 (inclusive) bytes, exclusive of the preamble.	R

This register provides the number of good and bad packets received by GMAC with length between 65 and 127 (inclusive) bytes, exclusive of the preamble.

28.3.86 Rx_128To255Octets_Packets_Good_Bad : Receive Packet Count for Good and Bad 128 to 255 Bytes Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07B4



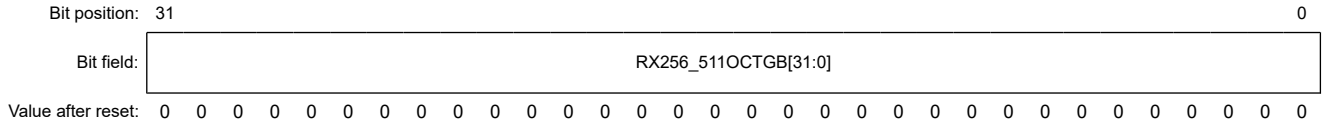
Bit	Symbol	Function	R/W
31:0	RX128_255OCTGB[31:0]	Rx 128-255 Octets Packets Good Bad This field indicates the number of good and bad packets received with length between 128 and 255 (inclusive) bytes, exclusive of the preamble.	R

This register provides the number of good and bad packets received by GMAC with length between 128 and 255 (inclusive) bytes, exclusive of the preamble.

28.3.87 Rx_256To511Octets_Packets_Good_Bad : Receive Packet Count for Good and Bad 256 to 511 Bytes Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07B8



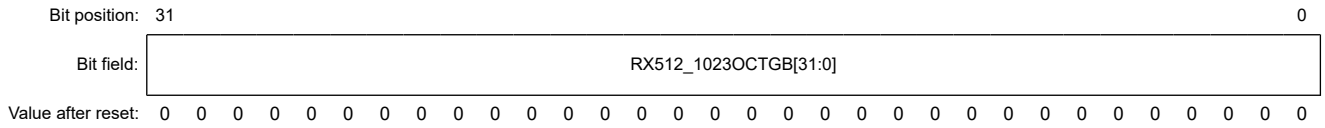
Bit	Symbol	Function	R/W
31:0	RX256_511OCTGB[31:0]	Rx 256-511 Octets Packets Good Bad This field indicates the number of good and bad packets received with length between 256 and 511 (inclusive) bytes, exclusive of the preamble.	R

This register provides the number of good and bad packets received by GMAC with length between 256 and 511 (inclusive) bytes, exclusive of the preamble.

28.3.88 Rx_512To1023Octets_Packets_Good_Bad : Receive Packet Count for Good and Bad 512 to 1,023 Bytes Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07BC



Bit	Symbol	Function	R/W
31:0	RX512_1023OCTGB[31:0]	RX 512-1023 Octets Packets Good Bad This field indicates the number of good and bad packets received with length between 512 and 1023 (inclusive) bytes, exclusive of the preamble.	R

This register provides the number of good and bad packets received by GMAC with length between 512 and 1023 (inclusive) bytes, exclusive of the preamble.

28.3.89 Rx_1024ToMaxOctets_Packets_Good_Bad : Receive Packet Count for Good and Bad 1,024 to Maxsize Bytes Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07C0

Bit position:	31																												0
Bit field:	RX1024_MAXOCTGB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RX1024_MAXOCTGB[31:0]	Rx 1024-Max Octets Good Bad This field indicates the number of good and bad packets received with length between 1024 and maxsize (inclusive) bytes, exclusive of the preamble.	R

This register provides the number of good and bad packets received by GMAC with length between 1024 and maxsize (inclusive) bytes, exclusive of the preamble.

28.3.90 Rx_Unicast_Packets_Good : Receive Packet Count for Good Unicast Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07C4

Bit position:	31																												0
Bit field:	RXUCASTG[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXUCASTG[31:0]	Rx Unicast Packets Good This field indicates the number of good unicast packets received.	R

This register provides the number of good unicast packets received by GMAC.

28.3.91 Rx_Length_Error_Packets : Receive Packet Count for Length Error Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07C8

Bit position:	31																												0
Bit field:	RXLENERR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

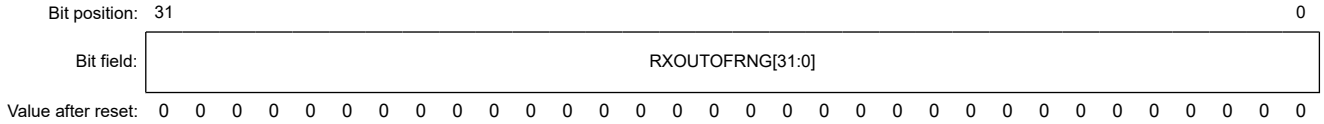
Bit	Symbol	Function	R/W
31:0	RXLENERR[31:0]	Rx Length Error Packets This field indicates the number of packets received with length error (Length Type field not equal to packet size), for all packets with valid length field.	R

This register provides the number of packets received by GMAC with length error (Length Type field not equal to packet size), for all packets with valid length field.

28.3.92 Rx_Out_Of_Range_Type_Packets : Receive Packet Count for Out of Range Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07CC



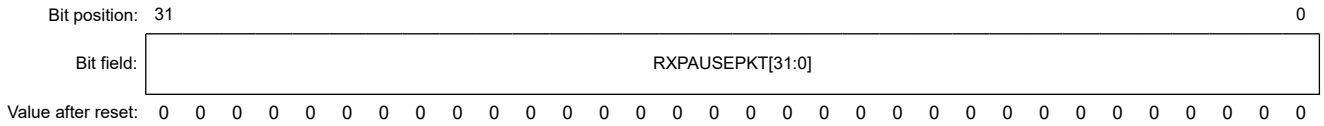
Bit	Symbol	Function	R/W
31:0	RXOUTOFRNG[31:0]	Rx Out of Range Type Packet This field indicates the number of packets received with length field not equal to the valid packet size (greater than 1,500 but less than 1,536).	R

This register provides the number of packets received by GMAC with length field not equal to the valid packet size (greater than 1,500 but less than 1,536).

28.3.93 Rx_Pause_Packets : Receive Packet Count for PAUSE Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07D0



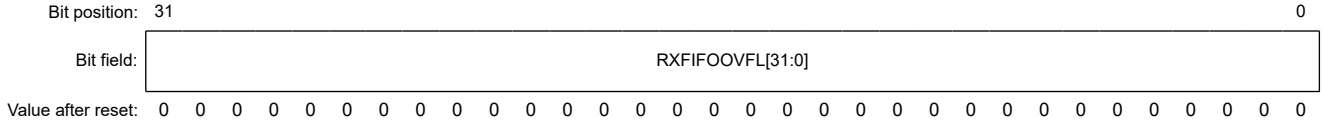
Bit	Symbol	Function	R/W
31:0	RXPAUSEPKT[31:0]	Rx Pause Packets This field indicates the number of good and valid Pause packets received.	R

This register provides the number of good and valid Pause packets received by GMAC.

28.3.94 Rx_FIFO_Overflow_Packets : Receive Packet Count for FIFO Overflow Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07D4



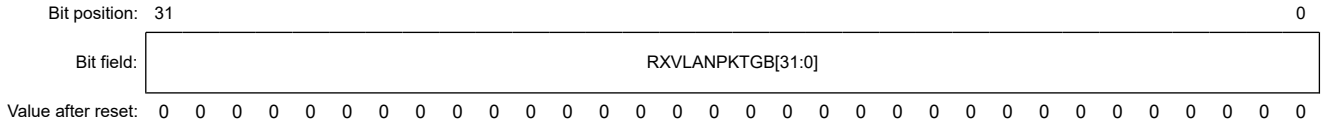
Bit	Symbol	Function	R/W
31:0	RXFIFOOVFL[31:0]	Rx FIFO Overflow Packets This field indicates the number of missed received packets because of FIFO overflow.	R

This register provides the number of missed received packets because of FIFO overflow in GMAC.

28.3.95 Rx_VLAN_Packets_Good_Bad : Receive Packet Count for Good and Bad VLAN Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07D8



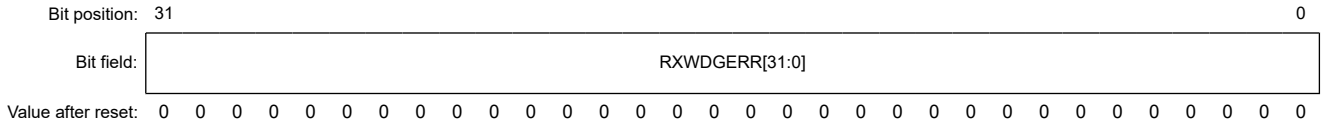
Bit	Symbol	Function	R/W
31:0	RXVLANPKTGB[31:0]	Rx VLAN Packets Good Bad This field indicates the number of good and bad VLAN packets received.	R

This register provides the number of good and bad VLAN packets received by GMAC.

28.3.96 Rx_Watchdog_Error_Packets : Receive Packet Count for Watchdog Error Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07DC



Bit	Symbol	Function	R/W
31:0	RXWDGERR[31:0]	Rx Watchdog Error Packets This field indicates the number of packets received with error because of watchdog timeout error (packets with a data load larger than 2,048 bytes (when JE and WD bits are reset in MAC_Configuration register), 10,240 bytes (when JE bit is set and WD bit is reset in MAC_Configuration register), 16,384 bytes (when WD bit is set in MAC_Configuration register) or the value programmed in the MAC_Watchdog_Timeout register).	R

This register provides the number of packets received by GMAC with error because of watchdog timeout error (packets with a data load larger than 2,048 bytes (when JE and WD bits are reset in MAC_Configuration register), 10,240 bytes (when JE bit is set and WD bit is reset in MAC_Configuration register), 16,384 bytes (when WD bit is set in MAC_Configuration register) or the value programmed in the MAC_Watchdog_Timeout register).

28.3.97 Rx_Receive_Error_Packets : Receive Packet Count for Receive Error Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07E0

Bit position:	31																												0
Bit field:	RXRCVERR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXRCVERR[31:0]	Rx Receive Error Packets This field indicates the number of packets received with Receive error or Packet Extension error on the GMII or MII interface.	R

This register provides the number of packets received by GMAC with Receive error or Packet Extension error on the GMII or MII interface.

28.3.98 Rx_Control_Packets_Good : Receive Packet Count for Good Control Packets

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07E4

Bit position:	31																												0
Bit field:	RXCTRLG[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXCTRLG[31:0]	Rx Control Packets Good This field indicates the number of good control packets received.	R

This register provides the number of good control packets received by GMAC.

28.3.99 Tx_LPI_USEC_Cntr : Tx LPI Microseconds Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07EC

Bit position:	31																												0
Bit field:	TXLPIUSC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TXLPIUSC[31:0]	Tx LPI Microseconds Counter This field indicates the number of microseconds Tx LPI is asserted. For every Tx LPI Entry and Exit, the Timer value can have an error of ±1 microsecond.	R

This register provides the number of microseconds Tx LPI is asserted by GMAC.

28.3.100 Tx_LPI_Tran_Cntr : Tx LPI Transition Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07F0

Bit position:	31																												0
Bit field:	TXLPITRC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TXLPITRC[31:0]	Tx LPI Transition counter This field indicates the number of times Tx LPI Entry has occurred. Even if Tx LPI Entry occurs in Automate Mode (because of LPITXA bit set in the LPI Control and Status register), the counter increments.	R

This register provides the number of times GMAC has entered Tx LPI.

28.3.101 Rx_LPI_USEC_Cntr : Rx LPI Microseconds Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07F4

Bit position:	31																												0
Bit field:	RXLPIUSC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXLPIUSC[31:0]	Rx LPI Microseconds Counter This field indicates the number of microseconds Rx LPI is asserted. For every Rx LPI Entry and Exit, the Timer value can have an error of ±1 microsecond.	R

This register provides the number of microseconds Rx LPI is sampled by GMAC.

28.3.102 Rx_LPI_Tran_Cntr : Rx LPI Transition Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x07F8

Bit position:	31																												0
Bit field:	RXLPITRC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXLPITRC[31:0]	Rx LPI Transition counter This field indicates the number of times Rx LPI Entry has occurred.	R

This register provides the number of times GMAC has entered Rx LPI.

28.3.103 MMC_IPC_Rx_Interrupt_Mask : MMC Receive Checksum Off load Interrupt Mask Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0800

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	RXICMPEROIM	RXICMPGOIM	RXTCPEROIM	RXTCPGOIM	RXUDPEROIM	RXUDPGOIM	RXIPV6NOPAYOIM	RXIPV6HEROIM	RXIPV6GOIM	RXIPV4UDSBLOIM	RXIPV4FRAGOIM	RXIPV4NOPAYOIM	RXIPV4HEROIM	RXIPV4GOIM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	RXICMPERPIM	RXICMPGPIM	RXTCPERPIM	RXTCPGPIM	RXUDPERPIM	RXUDPGPIM	RXIPV6NOPAYPIM	RXIPV6HERPIM	RXIPV6GPIM	RXIPV4UDSBLPIM	RXIPV4FRAGPIM	RXIPV4NOPAYPIM	RXIPV4HERPIM	RXIPV4GPIM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RXIPV4GPIM	MMC Receive IPV4 Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_gd_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV4 Good Packet Counter Interrupt Mask is disabled 1: MMC Receive IPV4 Good Packet Counter Interrupt Mask is enabled	R/W
1	RXIPV4HERPIM	MMC Receive IPV4 Header Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_hdrerr_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV4 Header Error Packet Counter Interrupt Mask is disabled 1: MMC Receive IPV4 Header Error Packet Counter Interrupt Mask is enabled	R/W
2	RXIPV4NOPAYPIM	MMC Receive IPV4 No Payload Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_nopay_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV4 No Payload Packet Counter Interrupt Mask is disabled 1: MMC Receive IPV4 No Payload Packet Counter Interrupt Mask is enabled	R/W
3	RXIPV4FRAGPIM	MMC Receive IPV4 Fragmented Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_frag_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV4 Fragmented Packet Counter Interrupt Mask is disabled 1: MMC Receive IPV4 Fragmented Packet Counter Interrupt Mask is enabled	R/W
4	RXIPV4UDSBLPIM	MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_udsbl_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Mask is disabled 1: MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Mask is enabled	R/W
5	RXIPV6GPIM	MMC Receive IPV6 Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_gd_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV6 Good Packet Counter Interrupt Mask is disabled 1: MMC Receive IPV6 Good Packet Counter Interrupt Mask is enabled	R/W
6	RXIPV6HERPIM	MMC Receive IPV6 Header Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_hdrerr_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV6 Header Error Packet Counter Interrupt Mask is disabled 1: MMC Receive IPV6 Header Error Packet Counter Interrupt Mask is enabled	R/W

Bit	Symbol	Function	R/W
7	RXIPV6NOPAYPIM	MMC Receive IPV6 No Payload Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_nopay_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV6 No Payload Packet Counter Interrupt Mask is disabled 1: MMC Receive IPV6 No Payload Packet Counter Interrupt Mask is enabled	R/W
8	RXUDPGPIM	MMC Receive UDP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_gd_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive UDP Good Packet Counter Interrupt Mask is disabled 1: MMC Receive UDP Good Packet Counter Interrupt Mask is enabled	R/W
9	RXUDPERPIM	MMC Receive UDP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_err_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive UDP Error Packet Counter Interrupt Mask is disabled 1: MMC Receive UDP Error Packet Counter Interrupt Mask is enabled	R/W
10	RXTCPGPIM	MMC Receive TCP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_gd_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive TCP Good Packet Counter Interrupt Mask is disabled 1: MMC Receive TCP Good Packet Counter Interrupt Mask is enabled	R/W
11	RXTCPERPIM	MMC Receive TCP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_err_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive TCP Error Packet Counter Interrupt Mask is disabled 1: MMC Receive TCP Error Packet Counter Interrupt Mask is enabled	R/W
12	RXICMPGPIM	MMC Receive ICMP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_gd_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive ICMP Good Packet Counter Interrupt Mask is disabled 1: MMC Receive ICMP Good Packet Counter Interrupt Mask is enabled	R/W
13	RXICMPERPIM	MMC Receive ICMP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_err_pkts counter reaches half of the maximum value or the maximum value. 0: MMC Receive ICMP Error Packet Counter Interrupt Mask is disabled 1: MMC Receive ICMP Error Packet Counter Interrupt Mask is enabled	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
16	RXIPV4GOIM	MMC Receive IPV4 Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_gd_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV4 Good Octet Counter Interrupt Mask is disabled 1: MMC Receive IPV4 Good Octet Counter Interrupt Mask is enabled	R/W
17	RXIPV4HEROIM	MMC Receive IPV4 Header Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_hdrerr_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV4 Header Error Octet Counter Interrupt Mask is disabled 1: MMC Receive IPV4 Header Error Octet Counter Interrupt Mask is enabled	R/W
18	RXIPV4NOPAYOIM	MMC Receive IPV4 No Payload Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_nopay_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV4 No Payload Octet Counter Interrupt Mask is disabled 1: MMC Receive IPV4 No Payload Octet Counter Interrupt Mask is enabled	R/W
19	RXIPV4FRAGOIM	MMC Receive IPV4 Fragmented Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_frag_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV4 Fragmented Octet Counter Interrupt Mask is disabled 1: MMC Receive IPV4 Fragmented Octet Counter Interrupt Mask is enabled	R/W

Bit	Symbol	Function	R/W
20	RXIPV4UDSBLOIM	MMC Receive IPV4 UDP Checksum Disabled Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_udsbl_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV4 UDP Checksum Disabled Octet Counter Interrupt Mask is disabled 1: MMC Receive IPV4 UDP Checksum Disabled Octet Counter Interrupt Mask is enabled	R/W
21	RXIPV6GOIM	MMC Receive IPV6 Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_gd_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV6 Good Octet Counter Interrupt Mask is disabled 1: MMC Receive IPV6 Good Octet Counter Interrupt Mask is enabled	R/W
22	RXIPV6HEROIM	MMC Receive IPV6 Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_hdrerr_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV6 Good Octet Counter Interrupt Mask is disabled 1: MMC Receive IPV6 Good Octet Counter Interrupt Mask is enabled	R/W
23	RXIPV6NOPAYOIM	MMC Receive IPV6 Header Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_nopay_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV6 Header Error Octet Counter Interrupt Mask is disabled 1: MMC Receive IPV6 Header Error Octet Counter Interrupt Mask is enabled	R/W
24	RXUDPGOIM	MMC Receive IPV6 No Payload Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_gd_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV6 No Payload Octet Counter Interrupt Mask is disabled 1: MMC Receive IPV6 No Payload Octet Counter Interrupt Mask is enabled	R/W
25	RXUDPEROIM	MMC Receive UDP Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_err_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive UDP Good Octet Counter Interrupt Mask is disabled 1: MMC Receive UDP Good Octet Counter Interrupt Mask is enabled	R/W
26	RXTCPGOIM	MMC Receive TCP Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_gd_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive TCP Good Octet Counter Interrupt Mask is disabled 1: MMC Receive TCP Good Octet Counter Interrupt Mask is enabled	R/W
27	RXTCPEROIM	MMC Receive TCP Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_err_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive TCP Error Octet Counter Interrupt Mask is disabled 1: MMC Receive TCP Error Octet Counter Interrupt Mask is enabled	R/W
28	RXICMPGOIM	MMC Receive ICMP Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_gd_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive ICMP Good Octet Counter Interrupt Mask is disabled 1: MMC Receive ICMP Good Octet Counter Interrupt Mask is enabled	R/W
29	RXICMPEROIM	MMC Receive ICMP Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_err_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive ICMP Error Octet Counter Interrupt Mask is disabled 1: MMC Receive ICMP Error Octet Counter Interrupt Mask is enabled	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

This register maintains the mask for the interrupt generated from the receive IPC statistic counters.

The MMC_IPC_Rx_Interrupt_Mask register maintains the masks for the interrupts generated when the receive IPC (Checksum Off load) statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32 bits wide.

28.3.104 MMC_IPC_Rx_Interrupt : MMC Receive Checksum Off load Interrupt Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0808

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

23	RXIPV6NOPAYOIS	MMC Receive IPV6 No Payload Octet Counter Interrupt Status*1 This bit is set when the rxipv6_nopay_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive IPV6 No Payload Octet Counter Interrupt Status not detected 1: MMC Receive IPV6 No Payload Octet Counter Interrupt Status detected	R
24	RXUDPGOIS	MMC Receive UDP Good Octet Counter Interrupt Status*1 This bit is set when the rxudp_gd_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive UDP Good Octet Counter Interrupt Status not detected 1: MMC Receive UDP Good Octet Counter Interrupt Status detected	R
25	RXUDPEROIS	MMC Receive UDP Error Octet Counter Interrupt Status*1 This bit is set when the rxudp_err_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive UDP Error Octet Counter Interrupt Status not detected 1: MMC Receive UDP Error Octet Counter Interrupt Status detected	R
26	RXTCPGOIS	MMC Receive TCP Good Octet Counter Interrupt Status*1 This bit is set when the rxtcp_gd_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive TCP Good Octet Counter Interrupt Status not detected 1: MMC Receive TCP Good Octet Counter Interrupt Status detected	R
27	RXTCPEROIS	MMC Receive TCP Error Octet Counter Interrupt Status*1 This bit is set when the rxtcp_err_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive TCP Error Octet Counter Interrupt Status not detected 1: MMC Receive TCP Error Octet Counter Interrupt Status detected	R
28	RXICMPGOIS	MMC Receive ICMP Good Octet Counter Interrupt Status*1 This bit is set when the rxicmp_gd_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive ICMP Good Octet Counter Interrupt Status not detected 1: MMC Receive ICMP Good Octet Counter Interrupt Status detected	R
29	RXICMPEROIS	MMC Receive ICMP Error Octet Counter Interrupt Status*1 This bit is set when the rxicmp_err_octets counter reaches half of the maximum value or the maximum value. 0: MMC Receive ICMP Error Octet Counter Interrupt Status not detected 1: MMC Receive ICMP Error Octet Counter Interrupt Status detected	R
31:30	—	These bits are read as 0.	R

Note 1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

This register maintains the interrupt that the receive IPC statistic counters generate.

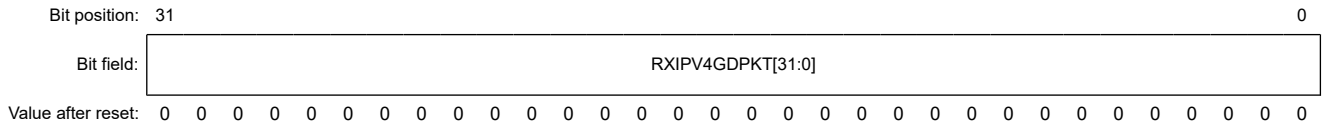
The MMC_IPC_Rx_Interrupt register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The MMC_IPC_Rx_Interrupt register is 32 bit wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (Bits [7:0]) must be read to clear the interrupt bit.

28.3.105 RxIPv4_Good_Packets : RxIPv4 Good Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0810



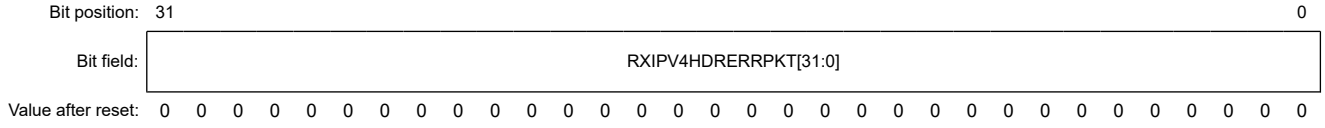
Bit	Symbol	Function	R/W
31:0	RXIPV4GDPKT[31:0]	RxIPv4 Good Packets This field indicates the number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload.	R

This register provides the number of good IPv4 datagrams received by GMAC with the TCP, UDP, or ICMP payload.

28.3.106 RxIPv4_Header_Error_Packets : RxIPv4 Header Error Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0814



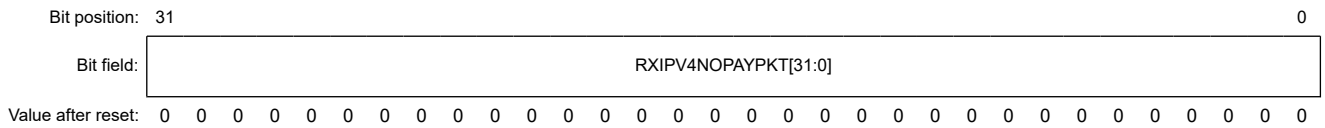
Bit	Symbol	Function	R/W
31:0	RXIPV4HDRERRPKT[31:0]	RxIPv4 Header Error Packets This field indicates the number of IPv4 datagrams received with header (checksum, length, or version mismatch) errors.	R

This register provides the number of IPv4 datagrams received by GMAC with header (checksum, length, or version mismatch) errors.

28.3.107 RxIPv4_No_Payload_Packets : RxIPv4 Payload Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0818



Bit	Symbol	Function	R/W
31:0	RXIPV4NOPAYPKT[31:0]	RxIPv4 Payload Packets This field indicates the number of IPv4 datagram packets received that did not have a TCP, UDP, or ICMP payload.	R

This register provides the number of IPv4 datagram packets received by GMAC that did not have a TCP, UDP, or ICMP payload.

28.3.108 RxIPv4_Fragmented_Packets : RxIPv4 Fragmented Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x081C

Bit position:	31																												0
Bit field:	RXIPV4FRAGPKT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXIPV4FRAGPKT[31:0]	RxIPv4 Fragmented Packets This field indicates the number of good IPv4 datagrams received with fragmentation.	R

This register provides the number of good IPv4 datagrams received by GMAC with fragmentation.

28.3.109 RxIPv4_UDP_Checksum_Disabled_Packets : RxIPv4 UDP Checksum Disabled Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0820

Bit position:	31																												0
Bit field:	RXIPV4UDSBLPKT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXIPV4UDSBLPKT[31:0]	RxIPv4 UDP Checksum Disabled Packets This field indicates the number of good IPv4 datagrams received that had a UDP payload with checksum disabled.	R

This register provides the number of good IPv4 datagrams received by GMAC that had a UDP payload with checksum disabled.

28.3.110 RxIPv6_Good_Packets : RxIPv6 Good Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0824

Bit position:	31																												0
Bit field:	RXIPV6GDPKT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

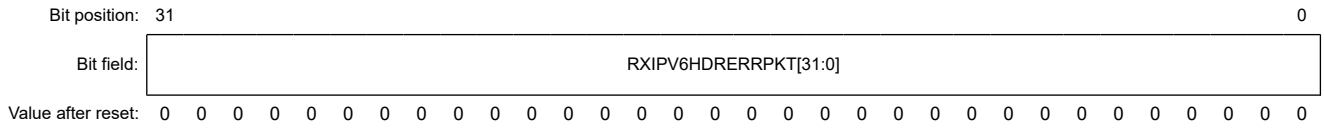
Bit	Symbol	Function	R/W
31:0	RXIPV6GDPKT[31:0]	RxIPv6 Good Packets This field indicates the number of good IPv6 datagrams received with the TCP, UDP, or ICMP payload.	R

This register provides the number of good IPv6 datagrams received by GMAC with the TCP, UDP, or ICMP payload.

28.3.111 RxIPv6_Header_Error_Packets : RxIPv6 Header Error Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0828



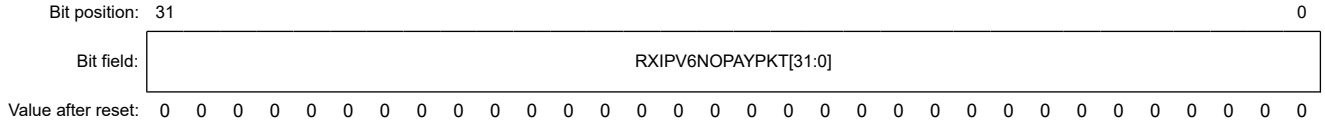
Bit	Symbol	Function	R/W
31:0	RXIPV6HDRERRPKT[31:0]	RxIPv6 Header Error Packets This field indicates the number of IPv6 datagrams received with header (length or version mismatch) errors.	R

This register provides the number of IPv6 datagrams received by GMAC with header (length or version mismatch) errors.

28.3.112 RxIPv6_No_Payload_Packets : RxIPv6 No Payload Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x082C



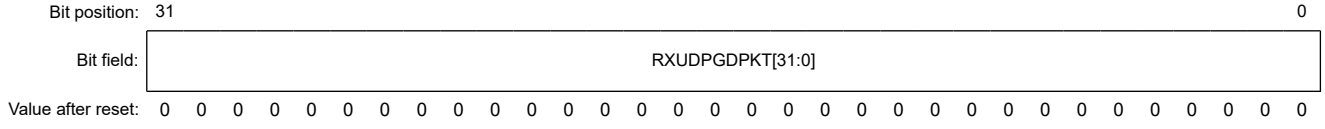
Bit	Symbol	Function	R/W
31:0	RXIPV6NOPAYPKT[31:0]	RxIPv6 Payload Packets This field indicates the number of IPv6 datagram packets received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.	R

This register provides the number of IPv6 datagram packets received by GMAC that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

28.3.113 RxUDP_Good_Packets : RxUDP Good Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0830



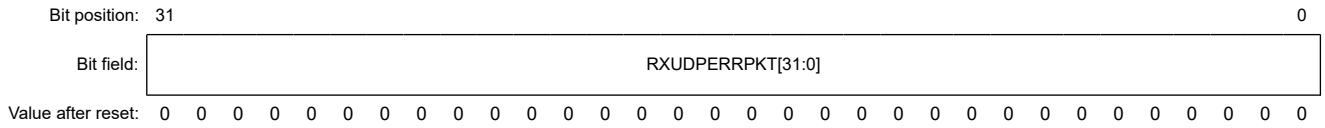
Bit	Symbol	Function	R/W
31:0	RXUDPGDPKT[31:0]	RxUDP Good Packets This field indicates the number of good IP datagrams received with a good UDP payload. This counter is not updated when the RxIPv4_UDP_Checksum_Disabled_Packets counter is incremented.	R

This register provides the number of good IP datagrams received by GMAC with a good UDP payload. This counter is not updated when the RxIPv4_UDP_Checksum_Disabled_Packets counter is incremented.

28.3.114 RxUDP_Error_Packets : RxUDP Error Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0834



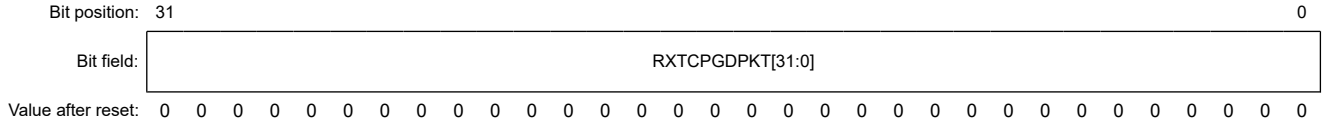
Bit	Symbol	Function	R/W
31:0	RXUDPERRPKT[31:0]	RxUDP Error Packets This field indicates the number of good IP datagrams received whose UDP payload has a checksum error.	R

This register provides the number of good IP datagrams received by GMAC whose UDP payload has a checksum error.

28.3.115 RxTCP_Good_Packets : RxTCP Good Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0838



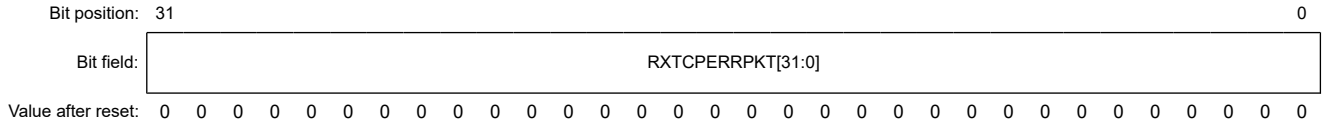
Bit	Symbol	Function	R/W
31:0	RXTCPGDPKT[31:0]	RxTCP Good Packets This field indicates the number of good IP datagrams received with a good TCP payload.	R

This register provides the number of good IP datagrams received by GMAC with a good TCP payload.

28.3.116 RxTCP_Error_Packets : RxTCP Error Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x083C



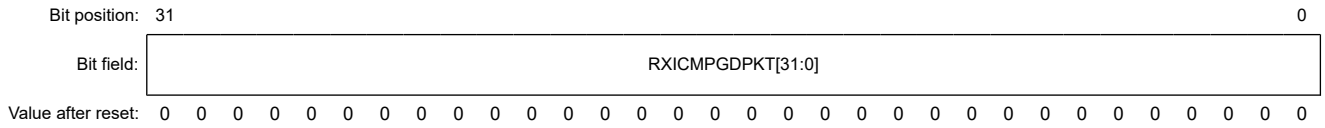
Bit	Symbol	Function	R/W
31:0	RXTCPERRPKT[31:0]	RxTCP Error Packets This field indicates the number of good IP datagrams received whose TCP payload has a checksum error.	R

This register provides the number of good IP datagrams received by GMAC whose TCP payload has a checksum error.

28.3.117 RxICMP_Good_Packets : RxICMP Good Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0840



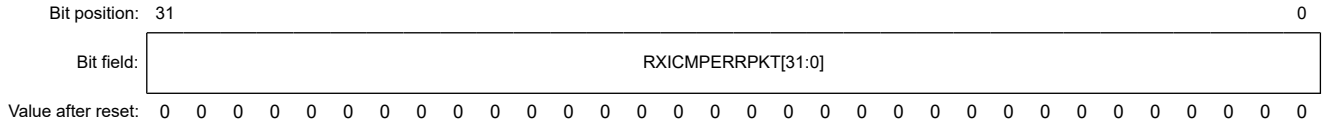
Bit	Symbol	Function	R/W
31:0	RXICMPGDPKT[31:0]	RxICMP Good Packets This field indicates the number of good IP datagrams received with a good ICMP payload.	R

This register provides the number of good IP datagrams received by GMAC with a good ICMP payload.

28.3.118 RxICMP_Error_Packets : RxICMP Error Packets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0844



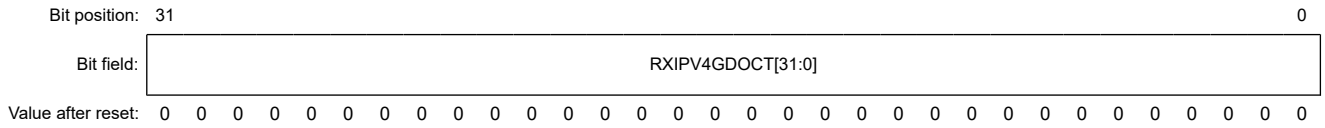
Bit	Symbol	Function	R/W
31:0	RXICMPERRPKT[31:0]	RxICMP Error Packets This field indicates the number of good IP datagrams received whose ICMP payload has a checksum error.	R

This register provides the number of good IP datagrams received by GMAC whose ICMP payload has a checksum error.

28.3.119 RxIPv4_Good_Octets : RxIPv4 Good Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0850



Bit	Symbol	Function	R/W
31:0	RXIPV4GDOCT[31:0]	RxIPv4 Good Octets This field indicates the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)	R

This register provides the number of bytes received by GMAC in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

28.3.120 RxIPv4_Header_Error_Octets : RxIPv4 Header Error Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0854

Bit position:	31																												0
Bit field:	RXIPV4HDRERROCT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXIPV4HDRERROCT[31:0]	RxIPv4 Header Error Octets This field indicates the number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)	R

This register provides the number of bytes received by GMAC in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

28.3.121 RxIPv4_No_Payload_Octets : RxIPv4 No Payload Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0858

Bit position:	31																												0
Bit field:	RXIPV4NOPAYOCT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXIPV4NOPAYOCT[31:0]	RxIPv4 Payload Octet This field indicates the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)	R

This register provides the number of bytes received by GMAC in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

28.3.122 RxIPv4_Fragmented_Octets : RxIPv4 Fragmented Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x085C

Bit position:	31																												0
Bit field:	RXIPV4FRAGOCT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXIPV4FRAGOCT[31:0]	RxIPv4 Fragmented Octets This field indicates the number of bytes received in fragmented IPv4 datagrams. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)	R

This register provides the number of bytes received by GMAC in fragmented IPv4 datagrams. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

28.3.123 RxIPv4_UDP_Checksum_Disable_Octets : RxIPv4 UDP Checksum Disable Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0860

Bit position:	31																												0
Bit field:	RXIPV4UDSBLOCT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXIPV4UDSBLOCT[31:0]	RxIPv4 UDP Checksum Disable Octets This field indicates the number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)	R

This register provides the number of bytes received by GMAC in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

28.3.124 RxIPv6_Good_Octets : RxIPv6 Good Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0864

Bit position:	31																												0
Bit field:	RXIPV6GDOCT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXIPV6GDOCT[31:0]	RxIPv6 Good Octets This field indicates the number of bytes received in good IPv6 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)	R

This register provides the number of bytes received by GMAC in good IPv6 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

28.3.125 RxIPv6_Header_Error_Octets : RxIPv6 Header Error Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0868

Bit position:	31																												0
Bit field:	RXIPV6HDRERROCT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXIPV6HDRERROCT[31:0]	RxIPv6 Header Error Octets This field indicates the number of bytes received in IPv6 datagrams with header errors (length, version mismatch). The value in the Length field of IPv6 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)	R

This register provides the number of bytes received by GMAC in IPv6 datagrams with header errors (length, version mismatch). The value in the Length field of IPv6 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

28.3.126 RxIPv6_No_Payload_Octets : RxIPv6 No Payload Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x086C

Bit position:	31																												0
Bit field:	RXIPV6NOPAYOCT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXIPV6NOPAYOCT[31:0]	RxIPv6 Payload Octets This field indicates the number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv6 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)	R

This register provides the number of bytes received by GMAC in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv6 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

28.3.127 RxUDP_Good_Octets : RxUDP Good Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0870

Bit position:	31																												0
Bit field:	RXUDPGDOCT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

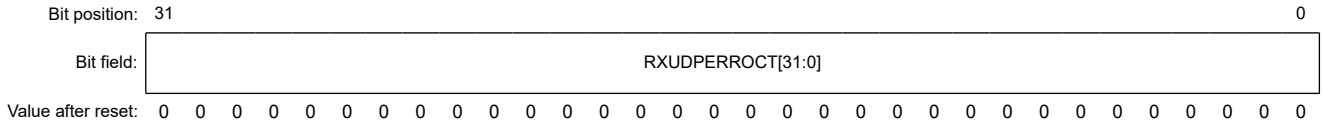
Bit	Symbol	Function	R/W
31:0	RXUDPGDOCT[31:0]	RxUDP Good Octets This field indicates the number of bytes received in a good UDP segment. This counter does not count IP header bytes.	R

This register provides the number of bytes received by GMAC in a good UDP segment. This counter does not count IP header bytes.

28.3.128 RxUDP_Error_Octets : RxUDP Error Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0874



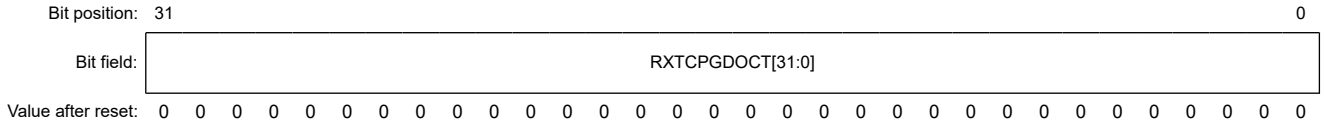
Bit	Symbol	Function	R/W
31:0	RXUDPERROCT[31:0]	RxUDP Error Octets This field indicates the number of bytes received in a UDP segment that had checksum errors. This counter does not count IP header bytes.	R

This register provides the number of bytes received by GMAC in a UDP segment that had checksum errors. This counter does not count IP header bytes.

28.3.129 RxTCP_Good_Octets : RxTCP Good Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0878



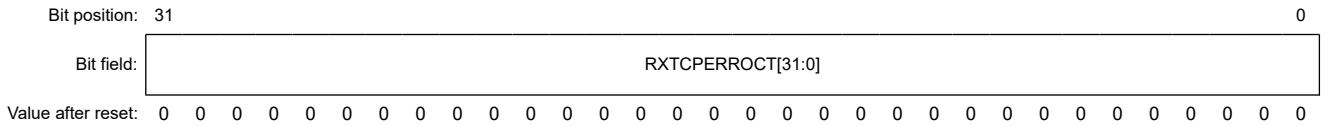
Bit	Symbol	Function	R/W
31:0	RXTCPGDOCT[31:0]	RxTCP Good Octets This field indicates the number of bytes received in a good TCP segment. This counter does not count IP header bytes.	R

This register provides the number of bytes received by GMAC in a good TCP segment. This counter does not count IP header bytes.

28.3.130 RxTCP_Error_Octets : RxTCP Error Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x087C



Bit	Symbol	Function	R/W
31:0	RXTCPERROCT[31:0]	RxTCP Error Octets This field indicates the number of bytes received in a TCP segment that had checksum errors. This counter does not count IP header bytes.	R

This register provides the number of bytes received by GMAC in a TCP segment that had checksum errors. This counter does not count IP header bytes.

28.3.131 RxICMP_Good_Octets : RxICMP Good Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0880

Bit position:	31																												0
Bit field:	RXICMPGDOCT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXICMPGDOCT[31:0]	RxICMP Good Octets This field indicates the number of bytes received in a good ICMP segment. This counter does not count IP header bytes.	R

This register provides the number of bytes received by GMAC in a good ICMP segment. This counter does not count IP header bytes.

28.3.132 RxICMP_Error_Octets : RxICMP Error Octets Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0884

Bit position:	31																												0
Bit field:	RXICMPERROCT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXICMPERROCT[31:0]	RxICMP Error Octets This field indicates the number of bytes received in a ICMP segment that had checksum errors. This counter does not count IP header bytes.	R

This register provides the number of bytes received by GMAC in a ICMP segment that had checksum errors. This counter does not count IP header bytes.

28.3.133 MMC_FPE_Tx_Interrupt : MMC FPE Transmit Interrupt Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x08A0

Bit	Symbol	Function	R/W
0	FCIS	MMC Tx FPE Fragment Counter Interrupt status*1 This bit is set when the Tx_FPE_Fragment_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Tx FPE Fragment Counter Interrupt status not detected 1: MMC Tx FPE Fragment Counter Interrupt status detected	R
1	HRCIS	MMC Tx Hold Request Counter Interrupt Status*1 This bit is set when the Tx_Hold_Req_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Tx Hold Request Counter Interrupt Status not detected 1: MMC Tx Hold Request Counter Interrupt Status detected	R
31:2	—	These bits are read as 0.	R

Note 1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

This register maintains the interrupts generated from all FPE related Transmit statistics counters. The MMC_FPE_Tx_Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC_FPE_Tx_Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits [7:0]) of the respective counter must be read to clear the interrupt bit.

28.3.134 MMC_FPE_Tx_Interrupt_Mask : MMC FPE Transmit Interrupt Mask Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x08A4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	HRCIM	FCIM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FCIM	MMC Transmit Fragment Counter Interrupt Mask Setting this bit masks the interrupt when the Tx_FPE_Fragment_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Fragment Counter Interrupt Mask is disabled 1: MMC Transmit Fragment Counter Interrupt Mask is enabled	R/W
1	HRCIM	MMC Transmit Hold Request Counter Interrupt Mask Setting this bit masks the interrupt when the Tx_Hold_Req_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Transmit Hold Request Counter Interrupt Mask is disabled 1: MMC Transmit Hold Request Counter Interrupt Mask is enabled	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

This register maintains the masks for interrupts generated from all FPE related Transmit statistics counters. The MMC_FPE_Tx_Interrupt_Mask register maintains the masks for the interrupts generated when FPE related receive statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.

28.3.135 MMC_Tx_FPE_Fragment_Cntr : Tx FPE Fragment Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x08A8

Bit position:	31																												0
Bit field:	TXFFC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TXFFC[31:0]	Tx FPE Fragment counter This field indicates the number of additional mPackets that has been transmitted due to preemption.	R

This register provides the number of additional mPackets transmitted due to preemption.

28.3.136 MMC_Tx_Hold_Req_Cntr : Tx Hold Request Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x08AC

Bit position:	31																												0
Bit field:	TXHRC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TXHRC[31:0]	Tx Hold Request Counter This field indicates count of number of a hold request is given to MAC.	R

This register provides the count of number of times a hold request is given to MAC.

28.3.137 MMC_FPE_Rx_Interrupt : MMC FPE Receive Interrupt Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x08C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	FCIS	PAOCIS	PSECIS	PAECIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PAECIS	MMC Rx Packet Assembly Error Counter Interrupt Status[*1] This bit is set when the Rx_Packet_Assemble_Err_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Rx Packet Assembly Error Counter Interrupt Status not detected 1: MMC Rx Packet Assembly Error Counter Interrupt Status detected	R

Bit	Symbol	Function	R/W
1	PSECIS	MMC Rx Packet SMD Error Counter Interrupt Status*1 This bit is set when the Rx_Packet_SMD_Err_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Rx Packet SMD Error Counter Interrupt Status not detected 1: MMC Rx Packet SMD Error Counter Interrupt Status detected	R
2	PAOCIS	MMC Rx Packet Assembly OK Counter Interrupt Status*1 This bit is set when the Rx_Packet_Assemble_Ok_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Rx Packet Assembly OK Counter Interrupt Status not detected 1: MMC Rx Packet Assembly OK Counter Interrupt Status detected	R
3	FCIS	MMC Rx FPE Fragment Counter Interrupt Status*1 This bit is set when the Rx_FPE_Fragment_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Rx FPE Fragment Counter Interrupt Status not detected 1: MMC Rx FPE Fragment Counter Interrupt Status detected	R
31:4	—	These bits are read as 0.	R

Note 1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

This register maintains the interrupts generated from all FPE related Receive statistics counters. The MMC_FPE_Rx_Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC_FPE_Rx_Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits [7:0]) of the respective counter must be read to clear the interrupt bit.

28.3.138 MMC_FPE_Rx_Interrupt_Mask : MMC FPE Receive Interrupt Mask Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x08C4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	FCIM	PAOCIM	PSECIM	PAECIM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PAECIM	MMC Rx Packet Assembly Error Counter Interrupt Mask Setting this bit masks the interrupt when the Rx_Packet_Assemble_Err_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Rx Packet Assembly Error Counter Interrupt Mask is disabled 1: MMC Rx Packet Assembly Error Counter Interrupt Mask is enabled	R/W
1	PSECIM	MMC Rx Packet SMD Error Counter Interrupt Mask Setting this bit masks the interrupt when the Rx_Packet_SMD_Err_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Rx Packet SMD Error Counter Interrupt Mask is disabled 1: MMC Rx Packet SMD Error Counter Interrupt Mask is enabled	R/W
2	PAOCIM	MMC Rx Packet Assembly OK Counter Interrupt Mask Setting this bit masks the interrupt when the Rx_Packet_Assemble_Ok_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Rx Packet Assembly OK Counter Interrupt Mask is disabled 1: MMC Rx Packet Assembly OK Counter Interrupt Mask is enabled	R/W

Bit	Symbol	Function	R/W
3	FCIM	MMC Rx FPE Fragment Counter Interrupt Mask Setting this bit masks the interrupt when the Tx_FPE_Fragment_Cntr counter reaches half of the maximum value or the maximum value. 0: MMC Rx FPE Fragment Counter Interrupt Mask is disabled 1: MMC Rx FPE Fragment Counter Interrupt Mask is enabled	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

This register maintains the masks for interrupts generated from all FPE related Receive statistics counters. The MMC_FPE_Rx_Interrupt_Mask register maintains the masks for the interrupts generated when FPE related receive statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.

28.3.139 MMC_Rx_Packet_Assembly_Err_Cntr : Rx Packet Assembly Error Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x08C8

Bit position:	31																												0
Bit field:	PAEC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PAEC[31:0]	Rx Packet Assembly Error Counter This field indicates the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.	R

This register provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.

28.3.140 MMC_Rx_Packet_SMD_Err_Cntr : Rx Packet SMD Error Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x08CC

Bit position:	31																												0
Bit field:	PSEC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PSEC[31:0]	Rx Packet SMD Error Counter This field indicates the number of MAC frames rejected due to unknown SMD value and MAC frame fragments rejected due to arriving with an SMD-C when there was no preceding preempted frame.	R

This register provides the number of received MAC frames rejected due to unknown SMD value and MAC frame fragments rejected due to arriving with an SMD-C when there was no preceding preempted frame.

28.3.141 MMC_Rx_Packet_Assembly_OK_Cntr : Rx Packet Assembly OK Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x08D0

Bit position:	31																												0
Bit field:	PAOC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PAOC[31:0]	Rx Packet Assembly OK Counter This field indicates the number of MAC frames that were successfully reassembled and delivered to MAC.	R

This register provides the number of MAC frames that were successfully reassembled and delivered to MAC.

28.3.142 MMC_Rx_FPE_Fragment_Cntr : Rx FPE Fragment Counter

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x08D4

Bit position:	31																												0
Bit field:	FFC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FFC[31:0]	Rx FPE Fragment Counter This field indicates the number of additional mPackets received due to preemption.	R

This register provides the number of additional mPackets received due to preemption.

28.3.143 MAC_L3_L4_CONTROLn : MAC Layer 3 and Layer 4 Control Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0900 + 0x30 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	DMCH EN0	—	DMCHN0[2:0]			—	—	L4DPI M0	L4DP M0	L4SPI M0	L4SP M0	—	L4PEN 0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	L3HDBM0[4:0]					L3HSBM0[4:0]					L3DAI M0	L3DA M0	L3SAI M0	L3SA M0	—	L3PEN 0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	L3PEN0	Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. 0: Layer 3 Protocol is disabled 1: Layer 3 Protocol is enabled	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	L3SAM0	Layer 3 IP SA Match Enable*1 When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching. 0: Layer 3 IP SA Match is disabled 1: Layer 3 IP SA Match is enabled	R/W
3	L3SAIM0	Layer 3 IP SA Inverse Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when the L3SAM0 bit is set. 0: Layer 3 IP SA Inverse Match is disabled 1: Layer 3 IP SA Inverse Match is enabled	R/W
4	L3DAM0	Layer 3 IP DA Match Enable*2 When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching. 0: Layer 3 IP DA Match is disabled 1: Layer 3 IP DA Match is enabled	R/W
5	L3DAIM0	Layer 3 IP DA Inverse Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when the L3DAM0 bit is set high. 0: Layer 3 IP DA Inverse Match is disabled 1: Layer 3 IP DA Inverse Match is enabled	R/W
10:6	L3HSBM0[4:0]	Layer 3 IP SA Higher Bits Match **IPv4 Packets:** 0x00: No bits are masked 0x01: LSb [0] is masked 0x02: Two LSbs [1:0] are masked ⋮ 0x1F: All bits except MSb are masked **IPv6 Packets:** This field contains Bits [4:0] of L3HSBM0. These bits indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high. See description of the L3HDBM0 field.	R/W
15:11	L3HDBM0[4:0]	Layer 3 IP DA Higher Bits Match*3 **IPv4 Packets:** 0x00: No bits are masked 0x01: LSb [0] is masked 0x02: Two LSbs [1:0] are masked ⋮ 0x1F: All bits except MSb are masked **IPv6 Packets:** Bits [12:11] of this field correspond to Bits [6:5] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits: 0x00: No bits are masked 0x01: LSb [0] is masked 0x02: Two LSbs [1:0] are masked ⋮ 0x7F: All bits except MSb are masked	R/W

Bit	Symbol	Function	R/W
16	L4PEN0	Layer 4 Protocol Enable When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching. The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set. 0: Layer 4 Protocol is disabled 1: Layer 4 Protocol is enabled	R/W
17	—	This bit is read as 0. The write value should be 0.	R/W
18	L4SPM0	Layer 4 Source Port Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching. 0: Layer 4 Source Port Match is disabled 1: Layer 4 Source Port Match is enabled	R/W
19	L4SPIM0	Layer 4 Source Port Inverse Match Enable*4 When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching. 0: Layer 4 Source Port Inverse Match is disabled 1: Layer 4 Source Port Inverse Match is enabled	R/W
20	L4DPM0	Layer 4 Destination Port Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching. 0: Layer 4 Destination Port Match is disabled 1: Layer 4 Destination Port Match is enabled	R/W
21	L4DPIM0	Layer 4 Destination Port Inverse Match Enable*5 When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching. 0: Layer 4 Destination Port Inverse Match is disabled 1: Layer 4 Destination Port Inverse Match is enabled	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
26:24	DMCHN0[2:0]	DMA Channel Number When DMCHEN is set high, this field selects the DMA Channel number to which the packet passed by this filter is routed.	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W
28	DMCHEN0	DMA Channel Select Enable When set, this bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. The DMA channel is indicated by the DMCHN bits. When this bit is reset, the DMA channel is not decided by this filter. 0: DMA Channel Select is disabled 1: DMA Channel Select is enabled	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.
Note 2. When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.
Note 3. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.
Note 4. This bit is valid and applicable only when the L4SPM0 bit is set high.
Note 5. This bit is valid and applicable only when the L4DPM0 bit is set high.

The MAC_L3_L4_CONTROLn register controls the operations of filter 0 of Layer 3 and Layer 4.

28.3.144 MAC_LAYER4_ADDRESSn : MAC Layer 4 Address n Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0904 + 0x30 × n

Bit position:	31															16	15													0
Bit field:	L4DP0[15:0]																L4SP0[15:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	L4SP0[15:0]	Layer 4 Source Port Number Field When the L4PEN0 bit is reset and the L4SPM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4SPM0 bits are set in MAC_L3_L4_Control0 register, this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.	R/W
31:16	L4DP0[15:0]	Layer 4 Destination Port Number Field When the L4PEN0 bit is reset and the L4DPM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4DPM0 bits are set in MAC_L3_L4_Control0 register, this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.	R/W

The MAC_LAYER4_ADDRESSn, MAC_L3_L4_CONTROLn, MAC_LAYER3_ADDR0_REGn, MAC_LAYER3_ADDR1_REGn, MAC_LAYER3_ADDR2_REGn, and MAC_LAYER3_ADDR3_REGn registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the IP.

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the IP. When you select this option, the synchronization is triggered only when Bits [31:24] of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

28.3.145 MAC_LAYER3_ADDR0_REGn : MAC Layer 3 Address 0 Register n (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0910 + 0x30 × n

Bit position:	31																													0
Bit field:	L3A00[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

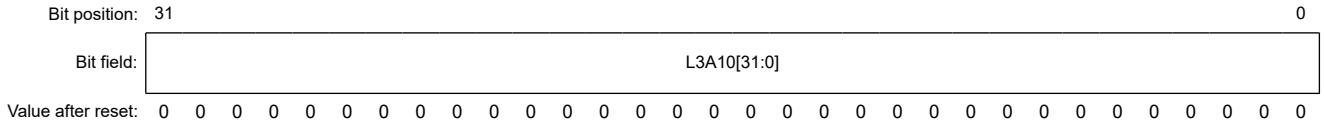
Bit	Symbol	Function	R/W
31:0	L3A00[31:0]	Layer 3 Address 0 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits [31:0] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits [31:0] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset and the L3SAM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the IP Source Address field in the IPv4 packets.	R/W

For IPv4 packets, the Layer 3 Address 0 Register 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits [31:0] of the 128-bit IP Source Address or Destination Address field.

28.3.146 MAC_LAYER3_ADDR1_REGn : MAC Layer 3 Address 1 Register n (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0914 + 0x30 × n



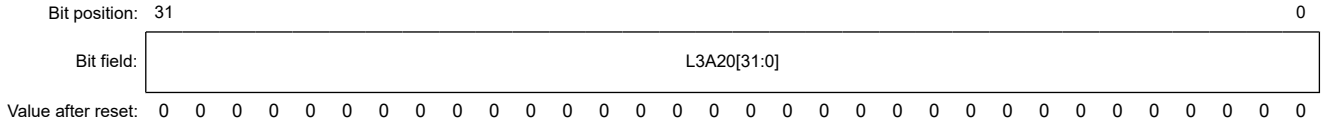
Bit	Symbol	Function	R/W
31:0	L3A10[31:0]	Layer 3 Address 1 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits [63:32] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits [63:32] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset and the L3SAM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the IP Destination Address field in the IPv4 packets.	R/W

For IPv4 packets, the Layer 3 Address 1 Register 0 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits [63:32] of the 128-bit IP Source Address or Destination Address field.

28.3.147 MAC_LAYER3_ADDR2_REGn : MAC Layer 3 Address 2 Register n (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0918 + 0x30 × n



Bit	Symbol	Function	R/W
31:0	L3A20[31:0]	Layer 3 Address 2 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits [95:64] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits [95:64] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset in the MAC_L3_L4_Control0 register, this field is not used.	R/W

The Layer 3 Address 2 Register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits [95:64] of 128-bit IP Source Address or Destination Address field.

28.3.148 MAC_LAYER3_ADDR3_REGn : MAC Layer 3 Address 3 Register n (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x091C + 0x30 × n

Bit position:	31																												0
Bit field:	L3A30[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	L3A30[31:0]	Layer 3 Address 3 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits [127:96] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits [127:96] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset in the MAC_L3_L4_Control0 register, this field is not used.	R/W

The Layer 3 Address 3 Register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits [127:96] of 128-bit IP Source Address or Destination Address field.

28.3.149 MAC_Indir_Access_Ctrl : MAC Indirect Access Control and Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0A70

Bit position:	31											19		16	15				8		5			1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	MSEL[3:0]			AOFF[7:0]						AUTO			COM	OB
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OB	Operation Busy This bit is set along with a read or write command for initiating the indirect access to MAC_<MSEL>_<AOFF> register. This bit is reset when the read or write command to MAC_<MSEL>_<AOFF> register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into MAC_<MSEL>_<AOFF> register. During a read operation, the data should be read from MAC_Indir_Access_Data register only after this bit is reset.	R/W
1	COM	Command type This bit indicates the register access type. 0: Write operation. Indicates a write operation. 1: Read operation. Indicates a read operation.	R/W
4:2	—	These bits are read as 0. The write value should be 0.	R/W
5	AUTO	Auto increment 0: AOFF is not incremented automatically. Software should program the correct Address Offset for each access. 1: AOFF is incremented by 1. Software should ensure not to cause a wrap condition. Byte wise read/write is not supported when auto increment is enabled.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	AOFF[7:0]	Address Offset This field is used in indirect access of MAC_<MSEL>_<AOFF>. This field must be set along with initiation of read/write to MAC_<MSEL>_<AOFF> and should not be changed until the OB is reset. 0x00: Reg0 (Indirect register 0) 0x01: Reg1 (Indirect register 1) ⋮ 0x07: Reg7 (Indirect register 7) Others: Reserved	R/W
19:16	MSEL[3:0]	Mode Select This field is used in indirect access of MAC_<MSEL>_<AOFF>. This field must be set along with initiation of read/write to MAC_<MSEL>_<AOFF> and should not be changed until the OB is reset. 0x0: TMRQ (Type based RXQ mapping) Others: Reserved	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

This register provides the Indirect Access control and status for MAC_<MSEl>_<AOFF> registers.

28.3.150 MAC_Indir_Access_Data : MAC Indirect Access Data Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0A74

Bit position:	31																													0
Bit field:	DATA[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DATA[31:0]	This field contains data to read/write for Indirect address access associated with MAC_Indir_Access_Ctrl register.	R/W

This register holds the read/write data for Indirect Access of MAC_<MSEL>_<AOFF> registers.

28.3.151 MAC_Timestamp_Control : Timestamp Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	AV8021ASMEN	—	—	—	TXTSTSM	—	—	—	—	CSC	TSENMACADDR	SNAPTYPSEL[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSMSTRENA	TSEVNTENA	TSIPV4ENA	TSIPV6ENA	TSIPENA	TSVER2ENA	TSCTRLSSR	TSENALL	—	—	—	TSTRIG	—	—	—	TSENA
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TSENA	Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set. 0: Timestamp is disabled 1: Timestamp is enabled	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	TSTRIG	Enable Timestamp Interrupt Trigger*1 When this bit is set, the timestamp interrupt is generated when the System Time becomes greater than the value written in the Target Time register. This bit is reset after the Timestamp Trigger Interrupt is generated. 0: Timestamp Interrupt Trigger is not enabled 1: Timestamp Interrupt Trigger is enabled	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	TSENALL	Enable Timestamp for All Packets When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC. 0: Timestamp for All Packets disabled 1: Timestamp for All Packets enabled	R/W
9	TSCTRLSSR	Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit. 0: Timestamp Digital or Binary Rollover Control is disabled 1: Timestamp Digital or Binary Rollover Control is enabled	R/W
10	TSVER2ENA	Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'. 0: PTP Packet Processing for Version 2 Format is disabled 1: PTP Packet Processing for Version 2 Format is enabled	R/W
11	TSIPENA	Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets. 0: Processing of PTP over Ethernet Packets is disabled 1: Processing of PTP over Ethernet Packets is enabled	R/W
12	TSIPV6ENA	Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets. 0: Processing of PTP Packets Sent over IPv6-UDP is disabled 1: Processing of PTP Packets Sent over IPv6-UDP is enabled	R/W
13	TSIPV4ENA	Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default. 0: Processing of PTP Packets Sent over IPv4-UDP is disabled 1: Processing of PTP Packets Sent over IPv4-UDP is enabled	R/W
14	TSEVNTENA	Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see Timestamp Snapshot Dependency on Register Bits Table. 0: Timestamp Snapshot for Event Messages is disabled 1: Timestamp Snapshot for Event Messages is enabled	R/W

Bit	Symbol	Function	R/W
15	TSMSTRENA	Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. 0: Snapshot for Messages Relevant to Master is disabled 1: Snapshot for Messages Relevant to Master is enabled	R/W
17:16	SNAPTYPSEL[1:0]	Select PTP packets for Taking Snapshots These bits, along with Bits 15 and 14, decide the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Timestamp Snapshot Dependency on Register Bits Table.	R/W
18	TSENMACADDR	Enable MAC Address for PTP Packet Filtering When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated, when PTP is directly sent over Ethernet. For normal time stamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching. For PTP offload, only MAC address register 0 is considered for unicast destination address matching. 0: MAC Address for PTP Packet Filtering is disabled 1: MAC Address for PTP Packet Filtering is enabled	R/W
19	CSC	Enable checksum correction during OST for PTP over UDP/IPv4 packets When this bit is set, the last two bytes of PTP message sent over UDP/IPv4 is updated to keep the UDP checksum correct, for changes made to origin timestamp and/or correction field as part of one step timestamp operation. The application forms the packet with these two dummy bytes. When reset, no updates are done to keep the UDP checksum correct. The application forms the packet with UDP checksum set to 0. 0: Checksum correction during OST for PTP over UDP/IPv4 packets is disabled 1: Checksum correction during OST for PTP over UDP/IPv4 packets is enabled	R/W
23:20	—	These bits are read as 0. The write value should be 0.	R/W
24	TXTSSTSM	Transmit Timestamp Status Mode When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_Tx_Timestamp_Status_Nanoseconds register. When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_Tx_Timestamp_Status_Nanoseconds register. 0: Transmit Timestamp Status Mode is disabled 1: Transmit Timestamp Status Mode is enabled	R/W
27:25	—	These bits are read as 0. The write value should be 0.	R/W
28	AV8021ASMEN	AV 802.1AS Mode Enable When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS mode of operation. When PTP offload feature is enabled, for the purpose of PTP offload, the transport specific field in the PTP header is generated and checked based on the value of this bit. 0: AV 802.1AS Mode is disabled 1: AV 802.1AS Mode is enabled	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

28.3.152 MAC_System_Time_Seconds : Timestamp Seconds Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B08

Bit position:	31																												0
Bit field:	TSS[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TSS[31:0]	Timestamp Second The value in this field indicates the current value in seconds of the System Time maintained by the MAC.	R

The MAC_System_Time_Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from PTP clock to CSR clock).

28.3.153 MAC_System_Time_Nanoseconds : Timestamp Nanoseconds Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B0C

Bit position:	31	30																											0
Bit field:	—	TSSS[30:0]																											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
30:0	TSSS[30:0]	Timestamp Sub Seconds The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When Bit 9 is set in MAC_Timestamp_Control, each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.	R
31	—	This bit is read as 0.	R

The MAC_System_Time_Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.

28.3.154 MAC_Timestamp_Status : Timestamp Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	ATSNS[4:0]					ATSSTM	—	—	—	—	—	—	ATSSTN[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TXTSSIS	—	—	—	—	—	—	—	—	—	—	—	—	AUXTSTRIG	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0.	R
2	AUXTSTRIG	Auxiliary Timestamp Trigger Snapshot*1 This bit is set high when the auxiliary snapshot is written to the FIFO. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected. 0: Auxiliary Timestamp Trigger Snapshot status not detected 1: Auxiliary Timestamp Trigger Snapshot status detected	R
14:3	—	These bits are read as 0.	R
15	TXTSSIS	Tx Timestamp Status Interrupt Status This bit is set when the captured transmit timestamp is updated in the MAC_Tx_Timestamp_Status_Nanoseconds and MAC_Tx_Timestamp_Status_Seconds registers When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the MAC_Tx_Timestamp_Status_Nanoseconds and MAC_Tx_Timestamp_Status_Seconds registers, for PTO generated Delay Request and Pdelay request packets. This bit is cleared when the MAC_Tx_Timestamp_Status_Seconds register is read (or write to MAC_Tx_Timestamp_Status_Seconds register when RCWE bit of MAC_CSR_SW_Ctrl register is set). 0: Tx Timestamp Status Interrupt status not detected 1: Tx Timestamp Status Interrupt status detected	R
17:16	ATSSTN[1:0]	Auxiliary Timestamp Snapshot Trigger Identifier*2 These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of Auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list: Bit 16: Auxiliary trigger 0 Bit 17: Auxiliary trigger 1	R
23:18	—	These bits are read as 0.	R
24	ATSSTM	Auxiliary Timestamp Snapshot Trigger Missed This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO. 0: Auxiliary Timestamp Snapshot Trigger Missed status not detected 1: Auxiliary Timestamp Snapshot Trigger Missed status detected	R
29:25	ATSNS[4:0]	Number of Auxiliary Timestamp Snapshots This field indicates the number of Snapshots available in the FIFO. A value equal to the selected depth of FIFO 4 indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 0x00) when the Auxiliary snapshot FIFO clear bit is set.	R
31:30	—	These bits are read as 0.	R

Note 1. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
Note 2. The software can read this register to find the triggers that are set when the timestamp is taken.

This register indicates the status of the Timestamp. All bits except Bits [27:25] gets cleared when the application reads this register.

28.3.155 MAC_Tx_Timestamp_Status_Nanoseconds : Transmit Timestamp Status Nanoseconds Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B30

Bit position:	31	30																												0
Bit field:	TXTSSMIS	TXTSSLO[30:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
30:0	TXTSSLO[30:0]	Transmit Timestamp Status Low This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.	R
31	TXTSSMIS	Transmit Timestamp Status Missed*1 *2 0: Transmit Timestamp Status Missed status not detected 1: Transmit Timestamp Status Missed status detected	R

Note 1. Access restriction applies. Clears on read. Self-set to 1 on internal event.
Note 2. When this bit is set, it indicates one of the following:

- The timestamp of the current packet is ignored if TXTSSTSM bit of the MAC_Timestamp_Control register is reset.
- The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the MAC_Timestamp_Control register is set.

This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled.

The MAC_Tx_Timestamp_Status_Nanoseconds register, along with MAC_Tx_Timestamp_Status_Seconds, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_Tx_Timestamp_Status_Nanoseconds is read. This means when bits [31:24] are read; If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_Timestamp_Control register. The status bit TXTSSIS bit [15] in MAC_Timestamp_Status register is set when the MAC transmitter captures the timestamp.

28.3.156 MAC_Tx_Timestamp_Status_Seconds : Transmit Timestamp Status Seconds Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B34

Bit position:	31																														0
Bit field:	TXTSSHI[31:0]																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TXTSSHI[31:0]	Transmit Timestamp Status High This field contains the 32 bits of the Seconds field of Transmit packet's captured timestamp.	R

The register contains the 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

28.3.157 MAC_Auxiliary_Control : Auxiliary Timestamp Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B40

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	ATSEN1	ATSEN0	—	—	—	ATSFC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ATSFC	Auxiliary Snapshot FIFO Clear*1 When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO. 0: Auxiliary Snapshot FIFO Clear is disabled 1: Auxiliary Snapshot FIFO Clear is enabled	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	ATSEN0	Auxiliary Snapshot 0 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on GMAC_PTPTRG0 input is enabled. When this bit is reset, the events on this input are ignored. 0: Auxiliary Snapshot 0 is disabled 1: Auxiliary Snapshot 0 is enabled	R/W
5	ATSEN1	Auxiliary Snapshot 1 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 1. When this bit is set, the auxiliary snapshot of the event on GMAC_PTPTRG1 input is enabled. When this bit is reset, the events on this input are ignored. 0: Auxiliary Snapshot 1 is disabled 1: Auxiliary Snapshot 1 is enabled	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

The MAC_Auxiliary_Control register controls the Auxiliary Timestamp snapshot.

28.3.158 MAC_Auxiliary_Timestamp_Nanoseconds : Auxiliary Timestamp Nanoseconds Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B48

Bit position:	31	30																												0
Bit field:	—	AUXTSLO[30:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
30:0	AUXTSLO[30:0]	Auxiliary Timestamp Contains the lower 31 bits (nanoseconds field) of the auxiliary timestamp.	R
31	—	This bit is read as 0.	R

The MAC_Auxiliary_Timestamp_Nanoseconds register, along with MAC_Auxiliary_Timestamp_Seconds, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4.

You can store multiple snapshots in this FIFO. Bits [29:25] in MAC_Timestamp_Status indicate the fill-level of the FIFO. The top of the FIFO is removed only when the last byte of MAC_Auxiliary_Timestamp_Seconds register is read. This means when Bits [31:24] are read.

28.3.159 MAC_Auxiliary_Timestamp_Seconds : Auxiliary Timestamp Seconds Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B4C

Bit position:	31																													0
Bit field:	AUXTSHI[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	AUXTSHI[31:0]	Auxiliary Timestamp Contains the 32 bits of the Seconds field of the auxiliary timestamp.	R

The MAC_Auxiliary_Timestamp_Seconds register contains the 32 bits of the Seconds field of the auxiliary timestamp register.

28.3.160 MAC_Timestamp_Ingress_Asym_Corr : Timestamp Ingress Asymmetry Correction Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B50

Bit position:	31																												0
Bit field:	OSTIAC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	OSTIAC[31:0]	One-Step Timestamp Ingress Asymmetry Correction This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programmed value should be in units of nanoseconds and multiplied by 2^{16}. For example, 2.5 ns is represented as 0x00028000. The value can also be negative, which is represented in 2's complement form with bit 31 representing the sign bit.	R/W

The MAC_Timestamp_Ingress_Asym_Corr register contains the Ingress Asymmetry Correction value to be used while updating correction field in PDelay_Resp PTP messages.

28.3.161 MAC_Timestamp_Egress_Asym_Corr : Timestamp Egress Asymmetry Correction Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B54

Bit position:	31																												0
Bit field:	OSTEAC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

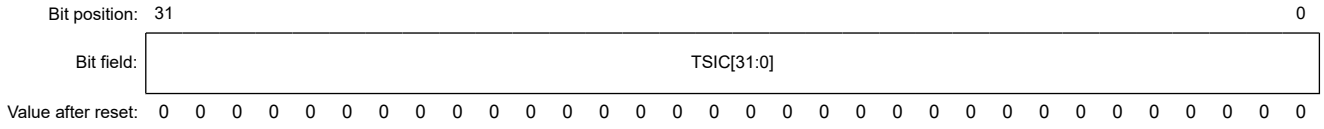
Bit	Symbol	Function	R/W
31:0	OSTEAC[31:0]	One-Step Timestamp Egress Asymmetry Correction This field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^{16}. For example, if the required correction is +2.5 ns, the programmed value must be 0xFFFD_8000, which is the 2's complement of 0x0002_8000 (2.5 × 216). Similarly, if the required correction is -3.3 ns, the programmed value is 0x0003_4CCC (3.3 × 216).	R/W

The MAC_Timestamp_Egress_Asym_Corr register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

28.3.162 MAC_Timestamp_Ingress_Corr_Nanosecond : Timestamp Ingress Correction Nanosecond Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B58



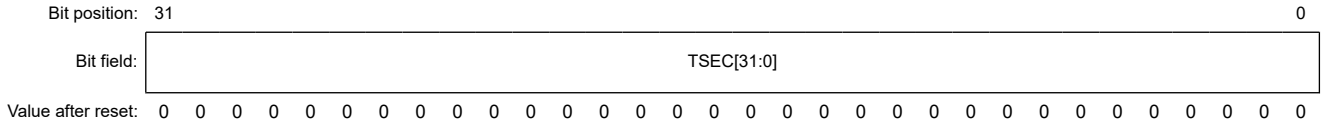
Bit	Symbol	Function	R/W
31:0	TSIC[31:0]	Timestamp Ingress Correction This field contains the ingress path correction value as defined by the Ingress Correction expression.	R/W

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.

28.3.163 MAC_Timestamp_Egress_Corr_Nanosecond : Timestamp Egress Correction Nanosecond Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B5C



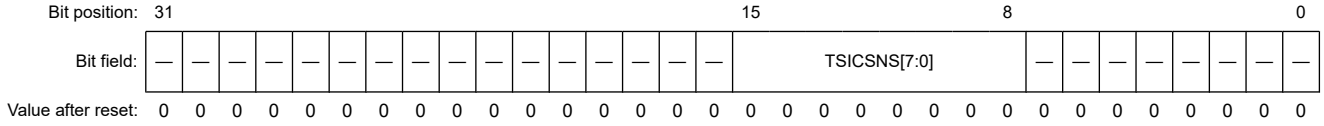
Bit	Symbol	Function	R/W
31:0	TSEC[31:0]	Timestamp Egress Correction This field contains the nanoseconds part of the egress path correction value as defined by the Egress Correction expression.	R/W

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the egress path.

28.3.164 MAC_Timestamp_Ingress_Corr_Subnanosec : Timestamp Ingress Correction Subnanosecond Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B60



Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
15:8	TSICSNS[7:0]	Timestamp Ingress Correction, sub-nanoseconds This field contains the sub-nanoseconds part of the ingress path correction value as defined by the "Ingress Correction" expression.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

This register contains the sub-nanosecond part of the correction value to be used with the captured timestamp value, for ingress direction.

28.3.165 MAC_Timestamp_Egress_Corr_Subnanosec : Timestamp Egress Correction Subnanosecond Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B64

Bit position:	31																15								8							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSECSNS[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
15:8	TSECSNS[7:0]	Timestamp Egress Correction, sub-nanoseconds This field contains the sub-nanoseconds part of the egress path correction value as defined by the "Egress Correction" expression.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

This register contains the sub-nanosecond part of the correction value to be used with the captured timestamp value, for egress direction.

28.3.166 MAC_Timestamp_Ingress_Latency : Timestamp Ingress Latency Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B68

Bit position:	31				27											16	15							8							0
Bit field:	—	—	—	—	ITLNS[11:0]												ITLSNS[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0.	R
15:8	ITLSNS[7:0]	Ingress Timestamp Latency, in nanoseconds This register holds the average latency in nanoseconds between the input ports RXD of MAC and the actual point (GMII/MII) where the ingress timestamp is taken. Ingress correction value is computed as described in the section, "Ingress Correction".	R
27:16	ITLNS[11:0]	Ingress Timestamp Latency, in sub-nanoseconds This register holds the average latency in sub-nanoseconds between the input ports RXD of MAC and the actual point (GMII/MII) where the ingress timestamp is taken. Ingress correction value is computed as described in the section, "Ingress Correction".	R
31:28	—	These bits are read as 0.	R

This register holds the Ingress MAC latency.

28.3.167 MAC_Timestamp_Egress_Latency : Timestamp Egress Latency Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0B6C

Bit position:	31				27											16	15								8							0
Bit field:	—	—	—	—	ETLNS[11:0]												ETLSNS[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0.	R
15:8	ETLSNS[7:0]	Egress Timestamp Latency, in sub-nanoseconds This register holds the average latency in sub-nanoseconds between the actual point (GMII/MII) where the egress timestamp is taken and the output ports TXD of the MAC. Ingress correction value is computed as described in the section "Ingress Correction".	R
27:16	ETLNS[11:0]	Egress Timestamp Latency, in nanoseconds This register holds the average latency in nanoseconds between the actual point (GMII/MII) where the egress timestamp is taken and the output ports TXD of the MAC. Ingress correction value is computed as described in the section, "Ingress Correction".	R
31:28	—	These bits are read as 0.	R

This register holds the Egress MAC latency.

28.3.168 MAC_PTO_Control : PTP Offload Engine Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0BC0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DN[7:0]								PDRDIS	DRRDIS	APDREQTRIG	ASYNCTRIG	—	APDREQEN	ASYNCEN	PTOEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PTOEN	PTP Offload Enable When this bit is set, the PTP Offload feature is enabled. 0: PTP Offload feature is disabled 1: PTP Offload feature is enabled	R/W
1	ASYNCEN	Automatic PTP SYNC message Enable When this bit is set, PTP SYNC message is generated periodically based on interval programmed or trigger from application, when the MAC is programmed to be in Clock Master mode. 0: Automatic PTP SYNC message is disabled 1: Automatic PTP SYNC message is enabled	R/W
2	APDREQEN	Automatic PTP Pdelay_Req message Enable When this bit is set, PTP Pdelay_Req message is generated periodically based on interval programmed or trigger from application, when the MAC is programmed to be in Peer-to-Peer Transparent mode. 0: Automatic PTP Pdelay_Req message is disabled 1: Automatic PTP Pdelay_Req message is enabled	R/W

Bit	Symbol	Function	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	ASYNCTRIG	Automatic PTP SYNC message Trigger*1 When this bit is set, one PTP SYNC message is transmitted. This bit is automatically cleared after the PTP SYNC message is transmitted. The application should set the ASYNCEN bit for this operation. 0: Automatic PTP SYNC message Trigger is disabled 1: Automatic PTP SYNC message Trigger is enabled	R/W
5	APDREQTRIG	Automatic PTP Pdelay_Req message Trigger*1 When this bit is set, one PTP Pdelay_Req message is transmitted. This bit is automatically cleared after the PTP Pdelay_Req message is transmitted. The application should set the APDREQEN bit for this operation. 0: Automatic PTP Pdelay_Req message Trigger is disabled 1: Automatic PTP Pdelay_Req message Trigger is enabled	R/W
6	DRRDIS	Disable PTO Delay Request/Response response generation When this bit is set, the Delay Request and Delay response is not generated for received SYNC and Delay request packet respectively, as required by the programmed mode. 0: PTO Delay Request/Response response generation is enabled 1: PTO Delay Request/Response response generation is disabled	R/W
7	PDRDIS	Disable Peer Delay Response response generation*2 When this bit is set, the Peer Delay Response (Pdelay_Resp) response is not be generated for received Peer Delay Request (Pdelay_Req) request packet, as required by the programmed mode. 0: Peer Delay Response response generation is enabled 1: Peer Delay Response response generation is disabled	R/W
15:8	DN[7:0]	Domain Number This field indicates the domain Number in which the PTP node is operating.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

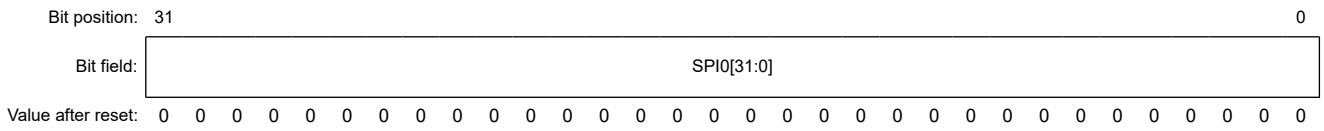
Note 1. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
Note 2. Setting this bit to 1 affects the normal PTP Offload operation and the time synchronization. So, this bit must be set only if there is problem with Pdelay_Resp generation in hardware and/or Pdelay_Resp generation is handled by software.

This register controls the PTP Offload Engine operation. This register is available only when the Enable PTP Timestamp Offload feature is selected.

28.3.169 MAC_Source_Port_Identity0 : PTP Source Port Identity 0 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0BC4



Bit	Symbol	Function	R/W
31:0	SPI0[31:0]	Source Port Identity 0 This field indicates bits [31:0] of sourcePortIdentity of PTP node.	R/W

This register contains Bits [31:0] of the 80-bit Source Port Identity of the PTP node. This register is available only when the Enable PTP Timestamp Offload feature is selected.

28.3.170 MAC_Source_Port_Identity1 : PTP Source Port Identity 1 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0BC8

Bit position:	31																												0
Bit field:	SPI1[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SPI1[31:0]	Source Port Identity 1 This field indicates bits [63:32] of sourcePortIdentity of PTP node.	R/W

This register contains Bits [63:32] of the 80-bit Source Port Identity of the PTP node. This register is available only when the Enable PTP Timestamp Offload feature is selected.

28.3.171 MAC_Source_Port_Identity2 : PTP Source Port Identity 2 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0BCC

Bit position:	31															15													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPI2[15:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SPI2[15:0]	Source Port Identity 2 This field indicates bits [79:64] of sourcePortIdentity of PTP node.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

This register contains Bits [79:64] of the 80-bit Source Port Identity of the PTP node. This register is available only when the Enable PTP Timestamp Offload feature is selected.

28.3.172 MAC_Log_Message_Interval : PTP Log Message Interval Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0BD0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	LMPDRI[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	DRSYNCR[2:0]			LSI[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	LSI[7:0]	Log Sync Interval This field indicates the periodicity of the automatically generated SYNC message when the PTP node is Master. Allowed values are -15 to 15. Negative value must be represented in 2's-complement form. For example, if the required value is -1, the value programmed must be 0xFF.	R/W
10:8	DRSYNCR[2:0]	Delay_Req to SYNC Ratio*1 *2 The master sends this information (logMinDelayReqInterval) in the DelayResp PTP messages to the slave. The GMAC Receiver processes this value from the received DelayResp messages and updates this field accordingly. In the Slave mode, the host must not write/update this register unless it has to override the received value. In Master mode, the sum of this field and logSyncInterval (LSI) field is provided in the logMinDelayReqInterval field of the generated multicast Delay_Resp PTP message. 0 0 0: DelayReq generated for every received SYNC 0 0 1: DelayReq generated every alternate reception of SYNC 0 1 0: For every 4 SYNC messages 0 1 1: For every 8 SYNC messages 1 0 0: For every 16 SYNC messages 1 0 1: For every 32 SYNC messages Others: Reserved	R/W
23:11	—	These bits are read as 0. The write value should be 0.	R/W
31:24	LMPDRI[7:0]	Log Min Pdelay_Req Interval This field indicates logMinPdelayReqInterval of PTP node. This is used to schedule the periodic Pdelay request packet transmission. Allowed values are -15 to 15. Negative value must be represented in 2's-complement form. For example, if the required value is -1, the value programmed must be 0xFF.	R/W

Note 1. In Slave mode, it is used for controlling frequency of Delay_Req messages transmitted.
Note 2. Access restriction applies. Updated based on the event. Setting 1 sets. Setting 0 clears.

This register contains the periodic intervals for automatic PTP packet generation. This register is available only when the Enable PTP Timestamp Offload feature is selected.

28.3.173 MTL_Operation_Mode : MTL Operation Mode Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CNTCLR	CNTPRST	—	SCHALG[1:0]		—	—	RAA	DTXSTS	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	DTXSTS	Drop Transmit Status 0: Drop Transmit Status is disabled. Tx packet status received from the MAC is forwarded to the application 1: Drop Transmit Status is enabled. Tx packet status received from the MAC is dropped in the MTL	R/W
2	RAA	Receive Arbitration Algorithm This field is used to select the arbitration algorithm for the Rx side. 0: Strict priority (SP). Queue 0 has the lowest priority and the last queue has the highest priority. 1: Weighted Strict Priority (WSP).	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
6:5	SCHALG[1:0]	Tx Scheduling Algorithm This field indicates the algorithm for Tx scheduling: 0 0: WRR algorithm 0 1: WFQ algorithm when DCB feature is selected. Otherwise, Reserved. 1 0: DWRR algorithm when DCB feature is selected. Otherwise, Reserved. 1 1: Strict priority algorithm	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	CNTPRST	Counters Preset*1 When this bit is set, ● MTL_TxQ[0-7]_UNDERFLOW register is initialized/preset to 0x7F0. ● Missed Packet and Overflow Packet counters in MTL_RxQ[0-7]_MISSED_PACKET_OVERFLOW_CNT register is initialized/preset to 0x7F0. 0: Counters Preset is disabled 1: Counters Preset is enabled	R/W
9	CNTCLR	Counters Reset*1 When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. If this bit is set along with CNT_PRESET bit, CNT_PRESET has precedence. 0: Counters are not reset 1: All counters are reset	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restrictions apply.

- MAC initiates the counters preset when application writes 1.
- MAC writes 0 after the counters preset is complete.
- MAC ignores when application writes 0.

The MTL_Operation_Mode register establishes the Transmit and Receive operating modes and commands.

28.3.174 MTL_Interrupt_Status : MTL Interrupt Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	ESTIS	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	Q7IS	Q6IS	Q5IS	Q4IS	Q3IS	Q2IS	Q1IS	Q0IS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	Q0IS	Queue 0 Interrupt status This bit indicates that there is an interrupt from Queue 0. To reset this bit, the application must read Queue 0 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source. 0: Queue 0 Interrupt status not detected 1: Queue 0 Interrupt status detected	R
1	Q1IS	Queue 1 Interrupt status This bit indicates that there is an interrupt from Queue 1. To reset this bit, the application must read the MTL_Q1_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0: Queue 1 Interrupt status not detected 1: Queue 1 Interrupt status detected	R

Bit	Symbol	Function	R/W
2	Q2IS	Queue 2 Interrupt status This bit indicates that there is an interrupt from Queue 2. To reset this bit, the application must read the MTL_Q2_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0: Queue 2 Interrupt status not detected 1: Queue 2 Interrupt status detected	R
3	Q3IS	Queue 3 Interrupt status This bit indicates that there is an interrupt from Queue 3. To reset this bit, the application must read the MTL_Q3_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0: Queue 3 Interrupt status not detected 1: Queue 3 Interrupt status detected	R
4	Q4IS	Queue 4 Interrupt status This bit indicates that there is an interrupt from Queue 4. To reset this bit, the application must read the MTL_Q4_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0: Queue 4 Interrupt status not detected 1: Queue 4 Interrupt status detected	R
5	Q5IS	Queue 5 Interrupt status This bit indicates that there is an interrupt from Queue 5. To reset this bit, the application must read the MTL_Q5_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0: Queue 5 Interrupt status not detected 1: Queue 5 Interrupt status detected	R
6	Q6IS	Queue 6 Interrupt status This bit indicates that there is an interrupt from Queue 6. To reset this bit, the application must read the MTL_Q6_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0: Queue 6 Interrupt status not detected 1: Queue 6 Interrupt status detected	R
7	Q7IS	Queue 7 Interrupt status This bit indicates that there is an interrupt from Queue 7. To reset this bit, the application must read the MTL_Q7_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0: Queue 7 Interrupt status not detected 1: Queue 7 Interrupt status detected	R
17:8	—	These bits are read as 0.	R
18	ESTIS	EST (TAS- 802.1Qbv) Interrupt Status This bit indicates an interrupt event during the operation of 802.1Qbv. To reset this bit, the application must clear the error/event that has caused the Interrupt. 0: EST (TAS- 802.1Qbv) Interrupt status not detected 1: EST (TAS- 802.1Qbv) Interrupt status detected	R
31:19	—	These bits are read as 0.	R

The software driver (application) reads this register during interrupt service routine or polling to determine the interrupt status of MTL queues and the MAC.

28.3.175 MTL_RxQ_DMA_Map0 : Receive Queue and DMA Channel Mapping 0 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C30

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	Q3DD MACH	—	Q3MDMACH[2:0]			—	—	—	Q2DD MACH	—	Q2MDMACH[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	Q1DD MACH	—	Q1MDMACH[2:0]			—	—	—	Q0DD MACH	—	Q0MDMACH[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	Q0MDMACH[2:0]	Queue 0 Mapped to DMA Channel This field is valid when the Q0DDMACH field is reset. The width of this field depends on the number of RX DMA channels and not all the values might be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000b and 001b are valid, the other bits are reserved. This field controls the routing of the packet received in Queue 0 to the DMA channel: 0 0 0: DMA Channel 0 0 0 1: DMA Channel 1 0 1 0: DMA Channel 2 0 1 1: DMA Channel 3 1 0 0: DMA Channel 4 1 0 1: DMA Channel 5 1 1 0: DMA Channel 6 1 1 1: DMA Channel 7	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	Q0DDMACH	Queue 0 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 0 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 0 are routed to the DMA Channel programmed in the Q0MDMACH field. 0: Queue 0 disabled for DA-based DMA Channel Selection 1: Queue 0 enabled for DA-based DMA Channel Selection	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
10:8	Q1MDMACH[2:0]	Queue 1 Mapped to DMA Channel This field is valid when the Q1DDMACH field is reset. The width of this field depends on the number of RX DMA channels and not all the values might be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000b and 001b are valid, the other bits are reserved. This field controls the routing of the received packet in Queue 1 to the DMA channel: 0 0 0: DMA Channel 0 0 0 1: DMA Channel 1 0 1 0: DMA Channel 2 0 1 1: DMA Channel 3 1 0 0: DMA Channel 4 1 0 1: DMA Channel 5 1 1 0: DMA Channel 6 1 1 1: DMA Channel 7	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
12	Q1DDMACH	Queue 1 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 1 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 1 are routed to the DMA Channel programmed in the Q1MDMACH field (Bits [10:8]). 0: Queue 1 disabled for DA-based DMA Channel Selection 1: Queue 1 enabled for DA-based DMA Channel Selection	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
18:16	Q2MDMACH[2:0]	Queue 2 Mapped to DMA Channel This field is valid when the Q2DDMACH field is reset. This field controls the routing of the received packet in Queue 2 to the DMA channel: 0 0 0: DMA Channel 0 0 0 1: DMA Channel 1 0 1 0: DMA Channel 2 0 1 1: DMA Channel 3 1 0 0: DMA Channel 4 1 0 1: DMA Channel 5 1 1 0: DMA Channel 6 1 1 1: DMA Channel 7	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W
20	Q2DDMACH	Queue 2 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 2 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 2 are routed to the DMA Channel programmed in the Q2MDMACH field (Bits [18:16]). 0: Queue 2 disabled for DA-based DMA Channel Selection 1: Queue 2 enabled for DA-based DMA Channel Selection	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
26:24	Q3MDMACH[2:0]	Queue 3 Mapped to DMA Channel This field is valid when the Q3DDMACH field is reset.*1 This field controls the routing of the received packet in Queue 3 to the DMA channel: 0 0 0: DMA Channel 0 0 0 1: DMA Channel 1 0 1 0: DMA Channel 2 0 1 1: DMA Channel 3 1 0 0: DMA Channel 4 1 0 1: DMA Channel 5 1 1 0: DMA Channel 6 1 1 1: DMA Channel 7	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W
28	Q3DDMACH	Queue 3 Enabled for Dynamic (per packet) DMA Channel Selection When set, this bit indicates that the packets received in Queue 3 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 3 are routed to the DMA Channel programmed in the Q3MDMACH field (Bits [26:24]). 0: Queue 3 disabled for DA-based DMA Channel Selection 1: Queue 3 enabled for DA-based DMA Channel Selection	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The width of this field depends on the number of RX DMA channels and not all the values might be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000b and 001b are valid, the others are reserved.

28.3.176 MTL_RxQ_DMA_Map1 : Receive Queue and DMA Channel Mapping 1 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C34

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	Q7DD MACH	—	Q7MDMACH[2:0]			—	—	—	Q6DD MACH	—	Q6MDMACH[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	Q5DD MACH	—	Q5MDMACH[2:0]			—	—	—	Q4DD MACH	—	Q4MDMACH[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

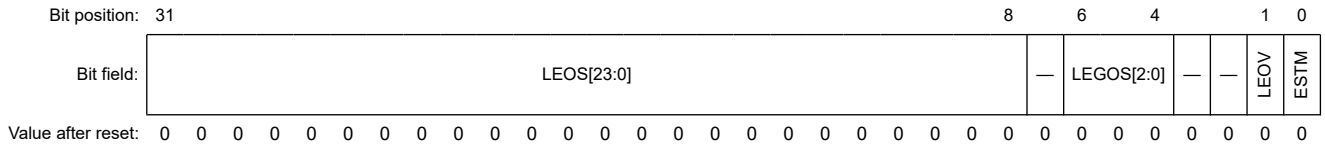
Bit	Symbol	Function	R/W
2:0	Q4MDMACH[2:0]	Queue 4 Mapped to DMA Channel This field is valid when the Q4DDMACH field is reset. The width of this field depends on the number of RX DMA channels and not all the values might be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000b and 001b are valid, the other bits are reserved. This field controls the routing of the packet received in Queue 4 to the DMA channel: 0 0 0: DMA Channel 0 0 0 1: DMA Channel 1 0 1 0: DMA Channel 2 0 1 1: DMA Channel 3 1 0 0: DMA Channel 4 1 0 1: DMA Channel 5 1 1 0: DMA Channel 6 1 1 1: DMA Channel 7	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	Q4DDMACH	Queue 4 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 4 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 4 are routed to the DMA Channel programmed in the Q4MDMACH field. 0: Queue 4 disabled for DA-based DMA Channel Selection 1: Queue 4 enabled for DA-based DMA Channel Selection	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
10:8	Q5MDMACH[2:0]	Queue 5 Mapped to DMA Channel This field is valid when the Q5DDMACH field is reset. The width of this field depends on the number of RX DMA channels and not all the values might be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000b and 001b are valid, the other bits are reserved. This field controls the routing of the packets received in Queue 5 to the DMA channel: 0 0 0: DMA Channel 0 0 0 1: DMA Channel 1 0 1 0: DMA Channel 2 0 1 1: DMA Channel 3 1 0 0: DMA Channel 4 1 0 1: DMA Channel 5 1 1 0: DMA Channel 6 1 1 1: DMA Channel 7	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
12	Q5DDMACH	Queue 5 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 5 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 5 are routed to the DMA Channel programmed in the Q5MDMACH field. 0: Queue 5 disabled for DA-based DMA Channel Selection 1: Queue 5 enabled for DA-based DMA Channel Selection	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
18:16	Q6MDMACH[2:0]	Queue 6 Mapped to DMA Channel This field is valid when the Q6DDMACH field is reset. The width of this field depends on the number of RX DMA channels and not all the values might be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000b and 001b are valid, the other bits are reserved. This field controls the routing of the packet received in Queue 6 to the DMA channel: 0 0 0: DMA Channel 0 0 0 1: DMA Channel 1 0 1 0: DMA Channel 2 0 1 1: DMA Channel 3 1 0 0: DMA Channel 4 1 0 1: DMA Channel 5 1 1 0: DMA Channel 6 1 1 1: DMA Channel 7	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W
20	Q6DDMACH	Queue 6 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 6 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 6 are routed to the DMA Channel programmed in the Q6MDMACH field. 0: Queue 6 disabled for DA-based DMA Channel Selection 1: Queue 6 enabled for DA-based DMA Channel Selection	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
26:24	Q7MDMACH[2:0]	Queue 7 Mapped to DMA Channel This field is valid when the Q7DDMACH field is reset. The width of this field depends on the number of RX DMA channels and not all the values might be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000b and 001b are valid, the other bits are reserved. This field controls the routing of the packet received in Queue 7 to the DMA channel: 0 0 0: DMA Channel 0 0 0 1: DMA Channel 1 0 1 0: DMA Channel 2 0 1 1: DMA Channel 3 1 0 0: DMA Channel 4 1 0 1: DMA Channel 5 1 1 0: DMA Channel 6 1 1 1: DMA Channel 7	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W
28	Q7DDMACH	Queue 7 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 7 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 7 are routed to the DMA Channel programmed in the Q7MDMACH field. 0: Queue 7 disabled for DA-based DMA Channel Selection 1: Queue 7 enabled for DA-based DMA Channel Selection	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

28.3.177 MTL_TBS_CTRL : Time Based Scheduling Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C40



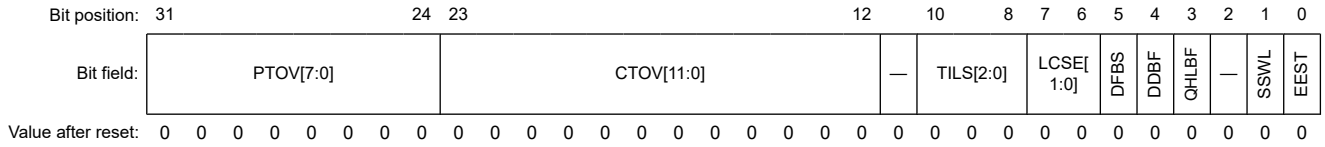
Bit	Symbol	Function	R/W
0	ESTM	EST offset Mode When this bit is set, the Launch Time value used in Time Based Scheduling is interpreted as an EST offset value and is added to the Base Time Register (BTR) of the current list. When reset, the Launch Time value is used as an absolute value that should be compared with the System time [39:8]. 0: EST offset Mode is disabled 1: EST offset Mode is enabled	R/W
1	LEOV	Launch Expiry Offset Valid When set indicates the LEOS field is valid. When not set, indicates the Launch Expiry Offset is not valid and the MTL must not check for Launch expiry time. 0: LEOS field is invalid 1: LEOS field is valid	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
6:4	LEGOS[2:0]	Launch Expiry GSN Offset The number GSN slots that has to be added to the Launch GSN to compute the Launch Expiry time. Value valid only when LEOV is set.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
31:8	LEOS[23:0]	Launch Expiry Offset The value in units of 256 nanoseconds that has to be added to the Launch time to compute the Launch Expiry time. Value valid only when LEOV is set. Max value: 999,999,999 ns, additionally should be smaller than CTR - 1 value when ESTM mode is set since this value is a modulo CTR value.	R/W

This register controls the operation of Time Based Scheduling.

28.3.178 MTL_EST_Control : EST Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C50



Bit	Symbol	Function	R/W
0	EEST	Enable EST When reset, the gate control list processing is halted and all gates are assumed to be in Open state. Should be set for the hardware to start processing the gate control lists. During the toggle from 0 to 1, the gate control list processing starts only after the SSWL bit it set. 0: EST is disabled 1: EST is enabled	R/W

Bit	Symbol	Function	R/W
1	SSWL	Switch to S/W owned list*1 When set indicates that the software has programmed that list that it currently owns (SWOL) and the IP must switch to the new list based on the new BTR. IP clears this bit when the switch to the SWOL happens to indicate the completion of the switch or when a BTR error (BTRE in Status register) is set. When BTRE is set, this bit is cleared but SWOL is not updated as the switch was not successful. 0: Switch to S/W owned list is disabled 1: Switch to S/W owned list is enabled	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	QHLBF	Quick Assertion of HLBF Error When set, Time Window for Head-of-Line blocking due to Frame Size Error is 1 to 2 loop count of GCL list. On reset, Time Window for Head-of-Line blocking due to Frame Size Error is 2 to 3 loop counts of GCL list. 0: Disable Quick assertion of HLBF Error 1: Quick Assertion of HLBF Error	R/W
4	DDBF	Do not Drop frames during Frame Size Error When set, frames are not be dropped during Head-of-Line blocking due to Frame Size Error (HLBF field of EST_Status register). 0: Drop frames during Frame Size Error 1: Do not Drop frames during Frame Size Error	R/W
5	DFBS	Drop Frames causing Scheduling Error When set frames reported to cause HOL Blocking due to not getting scheduled (HLBS field of EST_Status register) after 4, 8, 16, 32 (based on LCSE field of this register) GCL iterations are dropped. 0: Do not Drop Frames causing Scheduling Error 1: Drop Frames causing Scheduling Error	R/W
7:6	LCSE[1:0]	Loop Count to report Scheduling Error Programmable number of GCL list iterations before reporting an HLBS error defined in EST_Status register. 0 0: 4 iterations 0 1: 8 iterations 1 0: 16 iterations 1 1: 32 iterations	R/W
10:8	TILS[2:0]	Time Interval Left Shift Amount This field provides the left shift amount for the programmed Time Interval values used in the Gate Control Lists. 0 0 0: No left shift needed (equal to x1 ns) 0 0 1: Left shift TI by 1 bit (equal to x2 ns) 0 1 0: Left shift TI by 2 bits (equal to x4 ns) ⋮ 1 0 0: Left shift TI by 7 bits (equal to x128 ns) Others: Reserved	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
23:12	CTOV[11:0]	Current Time Offset Value Provides a 12 bit time offset value in nanosecond that is added to the current time to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays and so on. This offset helps to ensure that the impact of gate controls is visible on the line exactly at the pre-determined schedule (or as close to the schedule as possible).	R/W
31:24	PTOV[7:0]	PTP Time Offset Value The value of PTP Clock period multiplied by 6 in nanoseconds. This value is needed to avoid transmission overruns at the beginning of the installation of a new GCL.	R/W

Note 1. Access restrictions apply.

- MAC initiates switching to software owned list, when application writes 1.
- MAC writes 0 after switching to software owned list is complete.
- MAC ignores when application writes 0.

This register controls the operation of Enhancements to Scheduled Transmission (IEEE802.1Qbv).

28.3.179 MTL_EST_Ext_Control : EST Extended Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C54

Bit position:	31																								5	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OVHD[5:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	OVHD[5:0]	Overhead Bytes Value This field indicates the fixed overhead for every packet to account for EST Scheduler Delay, IPG or EIPG, and Preamble bytes.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

This register indicates the number of Overhead bytes for EST related scheduling.

28.3.180 MTL_EST_Status : EST Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C58

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CGSN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BTRL[7:0]								SWOL	—	—	CGCE	HLBS	HLBF	BTRE	SWLC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SWLC	Switch to S/W owned list Complete[*1] When "1" indicates the hardware has successfully switched to the SWOL, and the SWOL bit has been updated to that effect. Cleared when the SSWL of EST_Control register transitions from 0 to 1, or on a software write. 0: Switch to S/W owned list Complete not detected 1: Switch to S/W owned list Complete detected	R/W
1	BTRE	BTR Error[*1] When "1" indicates a programming error in the BTR of SWOL where the programmed value is less than current time. If the BTRL = "0xFF", SWOL is not updated and software should reprogram the BTR to a value greater than current time and then set SSWL to reinitiate the switch to SWOL. Else if the value of BTRL < "0xFF", SWOL is updated and this field indicates the number of iterations (of + CycleTime) taken by hardware to update the BTR to a value greater than Current Time. 0: BTR Error not detected 1: BTR Error detected	R/W

Bit	Symbol	Function	R/W
2	HLBF	Head-Of-Line Blocking due to Frame Size Set when HOL Blocking is noticed on one or more Queues as a result of none of the Time Intervals of gate open in the GCL being greater than or equal to the duration needed for frame size (or frame fragment size when preemption is enabled) transmission. The one hot encoded Queue numbers that are experiencing HLBF are indicated in the MTL_EST_Frm_Size_Error register. Additionally, the first Queue number that experienced HLBF along with the frame size is captured in MTL_EST_Frm_Size_Capture register. Bit cleared when MTL_EST_Frame_Size_ Error register is all zeros. 0: Head-Of-Line Blocking due to Frame Size not detected 1: Head-Of-Line Blocking due to Frame Size detected	R
3	HLBS	Head-Of-Line Blocking due to Scheduling Set when the frame is not able to win arbitration and get scheduled even after 4 iterations of the GCL. Indicates to software a potential programming error. The one hot encoded values of the Queue Numbers that are not able to make progress are indicated in the MTL_EST_Sch_Error register. Bit cleared when MTL_EST_Sch_Error register is all zeros. 0: Head-Of-Line Blocking due to Scheduling not detected 1: Head-Of-Line Blocking due to Scheduling detected	R
4	CGCE	Constant Gate Control Error*1 This error occurs when the list length (LLR) is 1 and the Cycle Time (CTR) is less than or equal to the programmed Time Interval (TI) value after the optional Left Shifting. This implies, Gates are either always Closed or always Open based on the Gate Control values; the same effect can be achieved by other simpler (non TSN) programming mechanisms. Since the implementation does not support such a programming an error is reported. 0: Constant Gate Control Error not detected 1: Constant Gate Control Error detected	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	SWOL	S/W owned list When "0" indicates Gate control list number "0" is owned by software and when "1" indicates the Gate Control list "1" is owned by the software. Any reads/writes by the software (using indirect access through GCL_Control) is directed to the list indicated by this value by default. The inverse of this value is treated as HWOL. R/W operations performed by hardware are directed to the list pointed by HWOL by default. 0: Gate control list number "0" is owned by software 1: Gate control list number "1" is owned by software	R
15:8	BTRL[7:0]	BTR Error Loop Count Provides the minimum count (N) for which the equation Current Time ≤ New BTR + (N × New Cycle Time) becomes true. N = "0xFF" indicates the iterations exceeded the value of 128 and the hardware was not able to update New BTR to be equal to or greater than Current Time. Software intervention is needed to update the New BTR. Value cleared when BTRE field of this register is cleared.	R
19:16	CGSN[3:0]	Current GCL Slot Number Indicates the slot number of the GCL list. Slot number is a modulo 16 count of the GCL List loops executed so far. Even if a new GCL list is installed, the count is incremental.	R
31:20	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

This register provides Status related to Enhancements to Scheduled Transmission (IEEE802.1Qbv).

28.3.181 MTL_EST_Sch_Error : EST Scheduing Error Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C60

Bit position:	31																								7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SEQN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SEQN[7:0]	Schedule Error Queue Number*1 The One Hot Encoded Queue Numbers that have experienced error/timeout described in HLBS field of status register.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

This register provides the One Hot encoded Queue Numbers that are having the Scheduling related error (timeout).

28.3.182 MTL_EST_Frm_Size_Error : EST Frame Size Error Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C64

Bit position:	31																						7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FEQN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	FEQN[7:0]	Frame Size Error Queue Number*1 The One Hot Encoded Queue Numbers that have experienced error described in HLBF field of status register.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

This register provides the One Hot encoded Queue Numbers that are having the Frame Size related error.

28.3.183 MTL_EST_Frm_Size_Capture : EST Frame Size Error Capture Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C68

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	HBFQ[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	HBFS[14:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
14:0	HBFS[14:0]	Frame Size of HLBF Captures the Frame Size of the dropped frame related to queue number indicated in HBFQ field of this register. Contents of this register should be considered invalid, if this field is zero. Cleared when MTL_EST_Frm_Size_Error register is all zeros.	R
15	—	This bit is read as 0.	R

Bit	Symbol	Function	R/W
18:16	HBFQ[2:0]	Queue Number of HLBF Captures the binary value of the of the first Queue (number) experiencing HLBF error (see HLBF field of status register). Value once written is not altered by any subsequent queue errors of similar nature. Once cleared the queue number of the next occurring HLBF error is captured. Width is based on the number of Tx Queues configured; remaining bits are Read-Only. Cleared when MTL_EST_Frm_Size_Error register is all zeros.	R
31:19	—	These bits are read as 0.	R

This register captures the Frame Size and Queue Number of the first occurrence of the Frame Size related error. Up on clearing it captures the data of immediate next occurrence of a similar error.

28.3.184 MTL_EST_Intr_Enable : EST Interrupt Enable Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C70

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	CGCE	IEHS	IEHF	IEBE	IECC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IECC	Interrupt Enable for Switch List When set, generates interrupt when the configuration change is successful and the hardware has switched to the new list. When reset this event does not generate an interrupt. 0: Interrupt for Switch List is disabled 1: Interrupt for Switch List is enabled	R/W
1	IEBE	Interrupt Enable for BTR Error When set, generates interrupt when the BTR Error occurs and is indicated in the status. When reset this event does not generate an interrupt. 0: Interrupt for BTR Error is disabled 1: Interrupt for BTR Error is enabled	R/W
2	IEHF	Interrupt Enable for HLBF When set, generates interrupt when the Head-of-Line Blocking due to Frame Size error occurs and is indicated in the status. When reset this event does not generate an interrupt. 0: Interrupt for HLBF is disabled 1: Interrupt for HLBF is enabled	R/W
3	IEHS	Interrupt Enable for HLBS When set, generates interrupt when the Head-of-Line Blocking due to Scheduling issue and is indicated in the status. When reset this event does not generate an interrupt. 0: Interrupt for HLBS is disabled 1: Interrupt for HLBS is enabled	R/W
4	CGCE	Interrupt Enable for CGCE When set, generates interrupt when the Constant Gate Control Error occurs and is indicated in the status. When reset this event does not generate an interrupt. 0: Interrupt for CGCE is disabled 1: Interrupt for CGCE is enabled	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

This register implements the Interrupt Enable bits for the various events that generate an interrupt. Bit positions have a 1 to 1 correlation with the status bit positions in MTL_ETS_Status register.

28.3.185 MTL_EST_GCL_Control : EST GCL Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C80

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDR[7:0]								—	—	DBGB	DBGM	—	GCRR	R1W0	SRWO
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRWO	Start Read or Write Operation*1 ● 1: Indicates the start or progress of a read or write operation. ● MAC writes 0: Indicates that the read or write operation is complete or an error has occurred. ● Reads: Data can be read from MTL_EST_GCL_Data register when this field is 0. ● Writes: You must program the MTL_EST_GCL_Data register with the data before setting this bit. 0: Start Read/Write Op disabled 1: Start Read/Write Op enabled	R/W
1	R1W0	Read '1', Write '0': 0: Write Operation 1: Read Operation	R/W
2	GCRR	Gate Control Related Registers When set to "1" indicates the R/W access is for the GCL related registers (BTR, CTR, TER, LLR) whose address is provided by GCRA. When "0" indicates R/W should be directed to GCL from the address provided by GCLA. 0: Gate Control Related Registers are disabled 1: Gate Control Related Registers are enabled	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	DBGM	Debug Mode When set to "1" indicates R/W in debug mode where the memory bank (for GCL and Time related registers) is explicitly provided by DBGB value, when set to "0" SWOL bit is used to determine which bank to use. 0: Debug Mode is disabled 1: Debug Mode is enabled	R/W
5	DBGB	Debug Mode Bank Select When set to "0" indicates R/W in debug mode should be directed to Bank 0 (GCL0 and corresponding Time related registers). When set to "1" indicates R/W in debug mode should be directed to Bank 1 (GCL1 and corresponding Time related registers). This value is used when DBGM is set and overrides by value of SWOL which is normally used. 0: R/W in debug mode should be directed to Bank 0 1: R/W in debug mode should be directed to Bank 1	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	ADDR[7:0]	Gate Control List Address: (GCLA when GCRR is "0"). Provides the address (row number) of the Gate Control List at which the R/W operation has to be performed. By default the Gate Control List pointed by SWOL of MTL_EST_Status is selected for R/W, however if the DBGM bit of this register is set, a debug mode access is given to R/W from DBGB. Gate Control List Related Registers Address: (GCRA when GCRR is "1"). By default the GCL related register set pointed by SWOL of MTL_EST_Status is selected for R/W, however if the DBGM bit of this register is set, a debug mode access is given to R/W from DBGB. Lower 3 bits are only used in this mode, higher order bits are treated as do not cares. 0x00: BTR Low (31:0) 0x01: BTR High (63:31) 0x02: CTR Low (31:0) 0x03: CTR High (39:32) 0x04: TER (31:0) 0x05: LLR (8:0) Others: Reserved	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restrictions apply.

- MAC initiates the read or write operation when application writes 1.
- MAC writes 0 after the read or write operation is complete.
- MAC ignores when application writes 0.

This register provides the control information for reading/writing to the Gate Control lists.

28.3.186 MTL_EST_GCL_Data : EST GCL Data Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C84

Bit position:	31																													0
Bit field:	GCD[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	GCD[31:0]	Gate Control Data The data corresponding to the address selected in the GCL_Control register. Used for both Read and Write operations.	R/W

This register holds the read data or write data in case of reads and writes, respectively.

28.3.187 MTL_FPE_CTRL_STS : FPE Control and Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C90

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	HRS	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PEC[7:0]								—	—	—	—	—	—	AFSZ[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

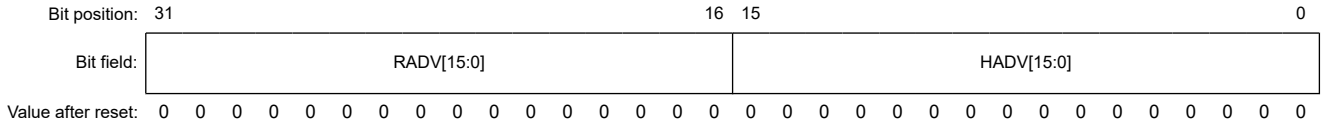
Bit	Symbol	Function	R/W
1:0	AFSZ[1:0]	Additional Fragment Size Used to indicate, in units of 64 bytes, the minimum number of bytes over 64 bytes required in non-final fragments of preempted frames. The minimum non-final fragment size is (AFSZ + 1) × 64 bytes.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
15:8	PEC[7:0]	Preemption Classification When set indicates the corresponding Queue must be classified as preemptable, when '0' Queue is classified as express. When both EST (Qbv) and Preemption are enabled, Queue-0 is always assumed to be preemptable. When EST (Qbv) is enabled Queues categorized as preemptable here are always assumed to be in "Open" state in the Gate Control List.	R/W
27:16	—	These bits are read as 0. The write value should be 0.	R/W
28	HRS	Hold/Release Status 0: Indicates a Set-and-Release-MAC operation was last executed and the pMAC is in Release State 1: Indicates a Set-and-Hold-MAC operation was last executed and the pMAC is in Hold State	R
31:29	—	These bits are read as 0. The write value should be 0.	R/W

This register controls the operation of, and provides status for Frame Preemption (IEEE802.1Qbu/802.3br).

28.3.188 MTL_FPE_Advance : FPE Advance Time Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0C94



Bit	Symbol	Function	R/W
15:0	HADV[15:0]	Hold Advance The maximum time in nanoseconds that can elapse between issuing a HOLD to the MAC and the MAC ceasing to transmit any preemptable frame that is in the process of transmission or any preemptable frames that are queued for transmission.	R/W
31:16	RADV[15:0]	Release Advance The maximum time in nanoseconds that can elapse between issuing a RELEASE to the MAC and the MAC being ready to resume transmission of preemptable frames, in the absence of there being any express frames available for transmission.	R/W

This register holds the Hold and Release Advance time.

28.3.189 MTL_TXQ0_OPERATION_MODE : Queue 0 Transmit Operation Mode Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	TQS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	TTC[2:0]			TXQEN[1:0]		TSF	FTQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FTQ	Flush Transmit Queue*1 When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission.*2 0: Flush Transmit Queue is disabled 1: Flush Transmit Queue is enabled	R/W
1	TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits [6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0: Transmit Store and Forward is disabled 1: Transmit Store and Forward is enabled	R/W
3:2	TXQEN[1:0]	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. 0 0: Not enabled 0 1: Enable in AV mode 1 0: Enabled 1 1: Reserved	R/W
6:4	TTC[2:0]	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 0 0 0: 32 0 0 1: 64 0 1 0: 96 0 1 1: 128 1 0 0: 192 1 0 1: 256 1 1 0: 384 1 1 1: 512	R/W
15:7	—	These bits are read as 0. The write value should be 0.	R/W
20:16	TQS[4:0]	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program TQS [4:0] = 0x0F to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (TQS + 1) × 256 bytes.	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restrictions apply.

- MAC initiates the Tx queue flush when application writes 1.

- MAC writes 0 after the Tx queue flush is complete.
- MAC ignores when application writes 0.

Note 2. The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock TX_CLK should be active.

Note 3. All the queues are disabled by default. Enable the Tx queue by programming this field.

The MTL_TXQ0_OPERATION_MODE register establishes the Transmit queue operating modes and commands.

28.3.190 MTL_TXQ0_UNDERFLOW : Queue 0 Underflow Counter Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	UFCNTOVF	UFFRMCNT[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	UFFRMCNT[10:0]	Underflow Packet Counter*1 This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read.	R
11	UFCNTOVF	Overflow Bit for Underflow Packet Counter*1 This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. 0: Overflow not detected for Underflow Packet Counter 1: Overflow detected for Underflow Packet Counter	R
31:12	—	These bits are read as 0.	R

Note 1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

The MTL_TXQ0_UNDERFLOW register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.

28.3.191 MTL_TXQ0_DEBUG : Queue 0 Transmit Debug Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	STXSTSF[2:0]			—	PTXQ[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TXSTSFSTS	TXQSTS	TWCSTS	TRCSTS[1:0]		TXQPAUSED
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: ● Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled. ● Reception of 802.3x Pause packet when PFC is disabled. 0: Transmit Queue in Pause status is not detected 1: Transmit Queue in Pause status is detected	R
2:1	TRCSTS[1:0]	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 0 0: Idle state 0 1: Read state (transferring data to the MAC transmitter) 1 0: Waiting for pending Tx Status from the MAC transmitter 1 1: Flushing the Tx queue because of the Packet Abort request from the MAC	R
3	TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. 0: MTL Tx Queue Write Controller status is not detected 1: MTL Tx Queue Write Controller status is detected	R
4	TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. 0: MTL Tx Queue Not Empty status is not detected 1: MTL Tx Queue Not Empty status is detected	R
5	TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. 0: MTL Tx Status FIFO Full status is not detected 1: MTL Tx Status FIFO Full status is detected	R
15:6	—	These bits are read as 0.	R
18:16	PTXQ[2:0]	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.	R
19	—	This bit is read as 0.	R
22:20	STXSTSF[2:0]	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.	R
31:23	—	These bits are read as 0.	R

The MTL_TXQ0_DEBUG register gives the debug status of various blocks related to the Transmit queue.

28.3.192 MTL_TXQ0_ETS_STATUS : Queue 0 ETS Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D14

Bit position:	31								23																						0
Bit field:	—	—	—	—	—	—	—	—	ABS[23:0]																						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	ABS[23:0]	Average Bits per Slot This field contains the average transmitted bits per slot. When the DCB operation is enabled for Queue 0, this field is computed over every 10 million bit times slot (10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.	R
31:24	—	These bits are read as 0.	R

The MTL_TXQ0_ETS_STATUS register provides the average traffic transmitted in Queue 0.

28.3.193 MTL_TXQ0_QUANTUM_WEIGHT : Queue 0 Quantum or Weights Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D18

Bit position:	31											20																			0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	ISCQW[20:0]																			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
20:0	ISCQW[20:0]	Quantum or Weights When the DCB operation is enabled with DWRR algorithm for Queue 0 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. When DCB operation is enabled with WFQ algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits [20:14] must be written to zero. The higher the programmed weights lesser the bandwidth allocated for the particular Transmit Queue. This is because the weights are used to compute the packet finish time (weights × packet_size). Lesser the finish time, higher the probability of the packet getting scheduled first and using more bandwidth. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero.	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

The MTL_TXQ0_QUANTUM_WEIGHT register contains the quantum value for Deficit Weighted Round Robin (DWRR), weights for the Weighted Round Robin (WRR), and Weighted Fair Queuing (WFQ) for Queue 0.

28.3.194 MTL_Q0_INTERRUPT_CONTROL_STATUS : Queue 0 Interrupt Control and Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D2C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	RXOIE	—	—	—	—	—	—	—	RXOVFIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ABPSIE	TXUIE	—	—	—	—	—	—	ABPSIS	TXUNFIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TXUNFIS	Transmit Queue Underflow Interrupt Status*1 This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. 0: Transmit Queue Underflow Interrupt Status not detected 1: Transmit Queue Underflow Interrupt Status detected	R/W
1	ABPSIS	Average Bits Per Slot Interrupt Status*1 When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. 0: Average Bits Per Slot Interrupt Status not detected 1: Average Bits Per Slot Interrupt Status detected	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. 0: Transmit Queue Underflow Interrupt Status is disabled 1: Transmit Queue Underflow Interrupt Status is enabled	R/W
9	ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the GMAC_SBD interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event. 0: Average Bits Per Slot Interrupt is disabled 1: Average Bits Per Slot Interrupt is enabled	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	RXOVFIS	Receive Queue Overflow Interrupt Status*1 This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. 0: Receive Queue Overflow Interrupt Status not detected 1: Receive Queue Overflow Interrupt Status detected	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
24	RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled. 0: Receive Queue Overflow Interrupt is disabled 1: Receive Queue Overflow Interrupt is enabled	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

This register contains the interrupt enable and status bits for the queue 0 interrupts.

28.3.195 MTL_RXQ0_OPERATION_MODE : Queue 0 Receive Operation Mode Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D30

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	RQS[4:0]					—	—	RFD[3:2]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RFD[1:0]		—	—	RFA[3:0]				EHFC	DIS_TCP_EF	RSF	FEP	FUP	—	RTC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RTC[1:0]	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 0 0: 64 0 1: 32 1 0: 96 1 1: 128	R/W
2	—	These bits are read as 0. The write value should be 0.	R/W
3	FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01b. 0: Forward Undersized Good Packets is disabled 1: Forward Undersized Good Packets is enabled	R/W
4	FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA. 0: Forward Error Packets is disabled 1: Forward Error Packets is enabled	R/W
5	RSF	Receive Queue Store and Forward When this bit is set, the GMAC reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0: Receive Queue Store and Forward is disabled 1: Receive Queue Store and Forward is enabled	R/W
6	DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0: Dropping of TCP/IP Checksum Error Packets is enabled 1: Dropping of TCP/IP Checksum Error Packets is disabled	R/W
7	EHFC	Enable Hardware Flow Control When this bit is set, the flow control operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0: Hardware Flow Control is disabled 1: Hardware Flow Control is enabled	R/W
11:8	RFA[3:0]	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.	R/W
13:12	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
17:14	RFD[3:0]	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation:*1 *2 0x0: Full minus 1 KB, that is, FULL 1 KB 0x1: Full minus 1.5 KB, that is, FULL 1.5 KB 0x2: Full minus 2 KB, that is, FULL 2 KB 0x3: Full minus 2.5 KB, that is, FULL 2.5 KB ⋮ 0xE: Full minus 8 KB, that is, FULL 8 KB 0xF: Full minus 8.5 KB, that is, FULL 8.5 KB	R/W
19:18	—	These bits are read as 0. The write value should be 0.	R/W
24:20	RQS[4:0]	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program RQS [4:0] = 0x0F to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS + 1) × 256 bytes.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The de-assertion is effective only after flow control is asserted.
Note 2. The value must be programmed in such a way to make sure that the threshold is a positive number.
When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB.
For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register.

The MTL_RXQ0_OPERATION_MODE register establishes the Receive queue operating modes and command.

28.3.196 MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT : Queue 0 Missed Packet and Overflow Counter Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D34

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	MISCNTOVF	MISPKTCNT[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	OVFCNTOVF	OVFPKTCNT[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	OVFPKTCNT[10:0]	Overflow Packet Counter*1 This field indicates the number of packets discarded by the GMAC because of Receive queue overflow. This counter is incremented each time the GMAC discards an incoming packet because of overflow. This counter is reset when this register is read.	R
11	OVFCNTOVF	Overflow Counter Overflow Bit*1 When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. 0: Overflow Counter overflow not detected 1: Overflow Counter overflow detected	R
15:12	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
26:16	MISPKTCNT[10:0]	Missed Packet Counter*1 This field indicates the number of packets missed by the GMAC because the application asserted flush for this queue. This counter is reset when this register is read. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability.	R
27	MISCNTOVF	Missed Packet Counter Overflow Bit*1 When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. 0: Missed Packet Counter overflow not detected 1: Missed Packet Counter overflow detected	R
31:28	—	These bits are read as 0.	R

Note 1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

The MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

28.3.197 MTL_RXQ0_DEBUG : Queue 0 Receive Debug Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D38

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	PRXQ[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	RXQSTS[1:0]		—	RRCSTS[1:0]		RWCSTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RWCSTS	MTL Rx Queue Write Controller Active Status When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue. 0: MTL Rx Queue Write Controller Active Status not detected 1: MTL Rx Queue Write Controller Active Status detected	R
2:1	RRCSTS[1:0]	MTL Rx Queue Read Controller State This field gives the state of the Rx queue Read controller: 0 0: Idle state 0 1: Reading packet data 1 0: Reading packet status (or timestamp) 1 1: Flushing the packet data and status	R
3	—	This bit is read as 0.	R
5:4	RXQSTS[1:0]	MTL Rx Queue Fill-Level Status This field gives the status of the fill-level of the Rx Queue: 0 0: Rx Queue empty 0 1: Rx Queue fill-level below flow-control deactivate threshold 1 0: Rx Queue fill-level above flow-control activate threshold 1 1: Rx Queue full	R
15:6	—	These bits are read as 0.	R
29:16	PRXQ[13:0]	Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256 KB / 16 B = 16 K Packets, that is, Max_Queue_Size/ Min_Packet_Size.	R
31:30	—	These bits are read as 0.	R

The MTL_RXQ0_DEBUG register gives the debug status of various blocks related to the Receive queue.

28.3.198 MTL_RXQ0_CONTROL : Queue 0 Receive Control Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D3C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	RXQ_FRM_ARBIT	RXQ_WEGT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	RXQ_WEGT[2:0]	Receive Queue Weight*1 This field indicates the weight assigned to the Rx Queue 0. This field needs to be programmed with one value less than the required weight, that is, reset value of 0 indicates weight of 1, value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.	R/W
3	RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the GMAC drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the GMAC drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: ● PBL amount of data or ● Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the GMAC drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0: Receive Queue Packet Arbitration is disabled 1: Receive Queue Packet Arbitration is enabled	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA = SP to RAA = WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the MTL_RXQ0_CONTROL registers must be programmed before the MTL_Operation_Mode register.

The MTL_RXQ0_CONTROL register controls the receive arbitration and passing of received packets to the application.

28.3.199 MTL_TXQn_OPERATION_MODE : Queue n Transmit Operation Mode Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D40 + 0x40 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	TQS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	TTC[2:0]			TXQEN[1:0]		TSF	FTQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FTQ	Flush Transmit Queue*1 When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TXQ1_OPERATION_MODE register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **Note**: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock TX_CLK should be active. 0: Flush Transmit Queue is disabled 1: Flush Transmit Queue is enabled	R/W
1	TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits [6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0: Transmit Store and Forward is disabled 1: Transmit Store and Forward is enabled	R/W
3:2	TXQEN[1:0]	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. All the queues are disabled by default. Enable the Tx queue by programming this field. 0 0: Not enabled 0 1: Enable in AV mode 1 0: Enabled 1 1: Reserved	R/W
6:4	TTC[2:0]	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 0 0 0: 32 0 0 1: 64 0 1 0: 96 0 1 1: 128 1 0 0: 192 1 0 1: 256 1 1 0: 384 1 1 1: 512	R/W
15:7	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
20:16	TQS[4:0]	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program TQS [4:0] = 0x0F to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (TQS + 1) × 256 bytes.	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restrictions apply.

- MAC initiates the Tx queue flush when application writes 1.
- MAC writes 0 after the Tx queue flush is complete.
- MAC ignores when application writes 0.

The MTL_TXQn_OPERATION_MODE register establishes the Transmit queue operating modes and commands.

28.3.200 MTL_TXQn_UNDERFLOW : Queue n Underflow Counter Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D44 + 0x40 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	UFCNTOVF	UFFRMCNT[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	UFFRMCNT[10:0]	Underflow Packet Counter*1 This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read.	R
11	UFCNTOVF	Overflow Bit for Underflow Packet Counter*1 This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. 0: Overflow not detected for Underflow Packet Counter 1: Overflow detected for Underflow Packet Counter	R
31:12	—	These bits are read as 0.	R

Note 1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

The MTL_TXQn_UNDERFLOW register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.

28.3.201 MTL_TXQn_DEBUG : Queue n Transmit Debug Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D48 + 0x40 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	STXSTSF[2:0]			—	PTXQ[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TXSTSFSTS	TXQSTS	TWCSTS	TRCSTS[1:0]		TXQPAUSED
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: ● Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled. ● Reception of 802.3x Pause packet when PFC is disabled. 0: Transmit Queue in Pause status is not detected 1: Transmit Queue in Pause status is detected	R
2:1	TRCSTS[1:0]	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 0 0: Idle state 0 1: Read state (transferring data to the MAC transmitter) 1 0: Waiting for pending Tx Status from the MAC transmitter 1 1: Flushing the Tx queue because of the Packet Abort request from the MAC	R
3	TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. 0: MTL Tx Queue Write Controller status is not detected 1: MTL Tx Queue Write Controller status is detected	R
4	TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. 0: MTL Tx Queue Not Empty status is not detected 1: MTL Tx Queue Not Empty status is detected	R
5	TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. 0: MTL Tx Status FIFO Full status is not detected 1: MTL Tx Status FIFO Full status is detected	R
15:6	—	These bits are read as 0.	R
18:16	PTXQ[2:0]	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.	R
19	—	This bit is read as 0.	R
22:20	STXSTSF[2:0]	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.	R
31:23	—	These bits are read as 0.	R

The MTL_TXQn_DEBUG register gives the debug status of various blocks related to the Transmit queue.

28.3.202 MTL_TXQn_ETS_CONTROL : Queue n ETS Control Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D50 + 0x40 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	SLC[2:0]			CC	AVALG	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0. The write value should be 0.	R/W
2	AVALG	AV Algorithm When Queue 1 is programmed for AV, this field configures the scheduling algorithm for this queue: This bit when set, indicates credit based shaper algorithm (CBS) is selected for Queue 1 traffic. When reset, strict priority is selected. 0: CBS Algorithm is disabled 1: CBS Algorithm is enabled	R/W
3	CC	Credit Control When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in Channel 1. The credit accumulates even when there is no packet waiting in Channel 1 and another channel is transmitting. When this bit is reset, the accumulated credit parameter in the credit-based shaper algorithm logic is set to zero when there is positive credit and no packet to transmit in Channel 1. When there is no packet waiting in Channel 1 and other channel is transmitting, no credit is accumulated. 0: Credit Control is disabled 1: Credit Control is enabled	R/W
6:4	SLC[2:0]	Slot Count If the credit-based shaper algorithm is enabled, the software can program the number of slots over which the average transmitted bits per slot, provided in the MTL_TXQn_ETS_STATUS register, need to be computed for Queue. The encoding is as follows: 0 0 0: 1 slot 0 0 1: 2 slots 0 1 0: 4 slots 0 1 1: 8 slots 1 0 0: 16 slots Others: Reserved	R/W
31:7	—	These bits are read as 0. The write value should be 0.	R/W

The MTL_TXQn_ETS_CONTROL register controls the enhanced transmission selection operation.

28.3.203 MTL_TXQn_ETS_STATUS : Queue n ETS Status Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D54 + 0x40 × (n - 1)

Bit position:	31								23																						0
Bit field:	—	—	—	—	—	—	—	—	ABS[23:0]																							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	ABS[23:0]	Average Bits per Slot This field contains the average transmitted bits per slot. If AV operation is enabled, this field is computed over number of slots, programmed in the SLC field of MTL_TXQn_ETS_CONTROL register. The maximum value of this field is 0x6_4000 in 100 Mbps, 0x3E_8000 in 1000 Mbps. When the DCB operation is enabled for Queue, this field is computed over every 10 million bit times slot (10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.	R
31:24	—	These bits are read as 0.	R

The MTL_TXQn_ETS_STATUS register provides the average traffic transmitted in Queue 1.

28.3.204 MTL_TXQn_QUANTUM_WEIGHT : Queue n Quantum or Weights Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D58 + 0x40 × (n - 1)

Bit position:	31											20																			0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	ISCQW[20:0]																			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
20:0	ISCQW[20:0]	idleSlopeCredit, Quantum, or Weights*1 *2 *3 **idleSlopeCredit** When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000 Mbps mode and 0x1000 in 100 Mbps mode. Bits [20:14] must be written to zero. **Quantum** When the DCB operation is enabled with DWRR algorithm for Queue 1 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. **Weights** When DCB operation is enabled with WFQ algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits [20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero.	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. This field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is MTL_Operation_Mode register.

Note 2. For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula:
(previous_finish_time of particular Transmit Queue + (weights × packet_size))

Note 3. The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

The MTL_TXQn_QUANTUM_WEIGHT register provides the average traffic transmitted in Queue 1.

28.3.205 MTL_TXQn_SENDSLOPECREDIT : Queue n CBS SendSlope Credit Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D5C + 0x40 × (n - 1)

Bit position:	31														13														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SSC[13:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	SSC[13:0]	sendSlopeCredit Value When AV operation is enabled, this field contains the sendSlopeCredit value required for credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns, 8 ns for 100 Mbps, 1000 Mbps, respectively) when the credit is decreasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000 Mbps mode and 0x1000 in 100 Mbps mode. This field should be programmed with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when Channel 1 is selected for transmission.	R/W
31:14	—	These bits are read as 0. The write value should be 0.	R/W

The MTL_TXQn_SENDSLOPECREDIT register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

28.3.206 MTL_TXQn_HICREDIT : Queue n CBS Hi Credit Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D60 + 0x40 × (n - 1)

Bit position:	31			28																									0
Bit field:	—	—	—	HC[28:0]																									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
28:0	HC[28:0]	hiCredit Value When the AV feature is enabled, this field contains the hiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16,384 bytes or 131,072 bits). The value to be specified is 131,072 × 1,024 = 134,217,728 or 0x0800_0000.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

The MTL_TXQn_HICREDIT register contains the hiCredit value required for the credit-based shaper algorithm for the Queue.

28.3.207 MTL_TXQn_LOCREDIT : Queue n CBS Lo Credit Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D64 + 0x40 × (n - 1)

Bit position:	31			28																										0
Bit field:	—	—	—	LC[28:0]																										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
28:0	LC[28:0]	loCredit Value When AV operation is enabled, this field contains the loCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value to be programmed is corresponds to twice the maxFrameSize transmitted from this queue. If the maxFrameSize is 8192 bytes, then (8192 × 2) × 8 × 1024 = 134,217,728 or 0x0800_0000. Because it is a negative value, the programmed value is 2's complement of the value, that is, 0x1800_0000.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

The MTL_TXQn_LOCREDIT register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

28.3.208 MTL_Qn_INTERRUPT_CONTROL_STATUS : Queue n Interrupt Control and Status Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D6C + 0x40 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	RXOIE	—	—	—	—	—	—	—	RXOVFIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ABPSIE	TXUIE	—	—	—	—	—	—	ABPSIS	TXUNFIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TXUNFIS	Transmit Queue Underflow Interrupt Status*1 This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. 0: Transmit Queue Underflow Interrupt Status not detected 1: Transmit Queue Underflow Interrupt Status detected	R/W
1	ABPSIS	Average Bits Per Slot Interrupt Status*1 When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. 0: Average Bits Per Slot Interrupt Status not detected 1: Average Bits Per Slot Interrupt Status detected	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
8	TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. 0: Transmit Queue Underflow Interrupt Status is disabled 1: Transmit Queue Underflow Interrupt Status is enabled	R/W
9	ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the GMAC_SBD interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event. 0: Average Bits Per Slot Interrupt is disabled 1: Average Bits Per Slot Interrupt is enabled	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	RXOVFIS	Receive Queue Overflow Interrupt Status*1 This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. 0: Receive Queue Overflow Interrupt Status not detected 1: Receive Queue Overflow Interrupt Status detected	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
24	RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled. 0: Receive Queue Overflow Interrupt is disabled 1: Receive Queue Overflow Interrupt is enabled	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

This register contains the interrupt enable and status bits for the queue 1 interrupts.

28.3.209 MTL_RXQn_OPERATION_MODE : Queue n Receive Operation Mode Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D70 + 0x40 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	RQS[4:0]					—	—	RFD[3:2]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RFD[1:0]		—	—	RFA[3:0]				EHFC	DIS_TCP_EF	RSF	FEP	FUP	—	RTC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RTC[1:0]	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 0 0: 64 0 1: 32 1 0: 96 1 1: 128	R/W

Bit	Symbol	Function	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01b. 0: Forward Undersized Good Packets is disabled 1: Forward Undersized Good Packets is enabled	R/W
4	FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA. 0: Forward Error Packets is disabled 1: Forward Error Packets is enabled	R/W
5	RSF	Receive Queue Store and Forward When this bit is set, the GMAC reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0: Receive Queue Store and Forward is disabled 1: Receive Queue Store and Forward is enabled	R/W
6	DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0: Dropping of TCP/IP Checksum Error Packets is enabled 1: Dropping of TCP/IP Checksum Error Packets is disabled	R/W
7	EHFC	Enable Hardware Flow Control When this bit is set, the flow control operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0: Hardware Flow Control is disabled 1: Hardware Flow Control is enabled	R/W
11:8	RFA[3:0]	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.	R/W
13:12	—	These bits are read as 0. The write value should be 0.	R/W
17:14	RFD[3:0]	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes)*1 *2 These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: 0x0: Full minus 1 KB, that is, FULL 1 KB 0x1: Full minus 1.5 KB, that is, FULL 1.5 KB 0x2: Full minus 2 KB, that is, FULL 2 KB 0x3: Full minus 2.5 KB, that is, FULL 2.5 KB ⋮ 0xE: Full minus 8 KB, that is, FULL 8 KB 0xF: Full minus 8.5 KB, that is, FULL 8.5 KB	R/W
19:18	—	These bits are read as 0. The write value should be 0.	R/W
24:20	RQS[4:0]	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program RQS [4:0] = 0x0F to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS + 1) × 256 bytes.	R/W

Bit	Symbol	Function	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The de-assertion is effective only after flow control is asserted.
Note 2. The value must be programmed in such a way to make sure that the threshold is a positive number.
When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB.
For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register.

The MTL_RXQn_OPERATION_MODE register establishes the Receive queue operating modes and command.

28.3.210 MTL_RXQn_MISSED_PACKET_OVERFLOW_CNT : Queue n Missed Packet and Overflow Counter Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D74 + 0x40 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	MISCNTOVF	MISPKTCNT[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	OVFCNTOVF	OVFPKTCNT[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	OVFPKTCNT[10:0]	Overflow Packet Counter*1 This field indicates the number of packets discarded by the GMAC because of Receive queue overflow. This counter is incremented each time the GMAC discards an incoming packet because of overflow. This counter is reset when this register is read with.	R
11	OVFCNTOVF	Overflow Counter Overflow Bit*1 When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. 0: Overflow Counter overflow not detected 1: Overflow Counter overflow detected	R
15:12	—	These bits are read as 0.	R
26:16	MISPKTCNT[10:0]	Missed Packet Counter*1 This field indicates the number of packets missed by the GMAC because the application asserted flush for this queue. This counter is reset when this register is read with. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability.	R
27	MISCNTOVF	Missed Packet Counter Overflow Bit*1 When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. 0: Missed Packet Counter overflow not detected 1: Missed Packet Counter overflow detected	R
31:28	—	These bits are read as 0.	R

Note 1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

The MTL_RXQn_MISSED_PACKET_OVERFLOW_CNT register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

28.3.211 MTL_RXQn_DEBUG : Queue n Receive Debug Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D78 + 0x40 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	PRXQ[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	RXQSTS[1:0]		—	RRCSTS[1:0]		RWCSTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RWCSTS	MTL Rx Queue Write Controller Active Status When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue. 0: MTL Rx Queue Write Controller Active Status not detected 1: MTL Rx Queue Write Controller Active Status detected	R
2:1	RRCSTS[1:0]	MTL Rx Queue Read Controller State This field gives the state of the Rx queue Read controller: 0 0: Idle state 0 1: Reading packet data 1 0: Reading packet status (or timestamp) 1 1: Flushing the packet data and status	R
3	—	This bit is read as 0.	R
5:4	RXQSTS[1:0]	MTL Rx Queue Fill-Level Status This field gives the status of the fill-level of the Rx Queue: 0 0: Rx Queue empty 0 1: Rx Queue fill-level below flow-control deactivate threshold 1 0: Rx Queue fill-level above flow-control activate threshold 1 1: Rx Queue full	R
15:6	—	These bits are read as 0.	R
29:16	PRXQ[13:0]	Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256 KB / 16 B = 16 K Packets, that is, Max_Queue_Size/ Min_Packet_Size.	R
31:30	—	These bits are read as 0.	R

The MTL_RXQn_DEBUG register gives the debug status of various blocks related to the Receive queue.

28.3.212 MTL_RXQn_CONTROL : Queue n Receive Control Register (n = 1 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x0D7C + 0x40 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	RXQ_FRM_ARBIT	RXQ_WEGT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	RXQ_WEGT[2:0]	Receive Queue Weight*1 This field indicates the weight assigned to the Rx Queue 0. This field needs to be programmed with one value less than the required weight, that is, reset value of 0 indicates weight of 1, value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.	R/W
3	RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the GMAC drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the GMAC drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: ● PBL amount of data or ● Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the GMAC drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0: Receive Queue Packet Arbitration is disabled 1: Receive Queue Packet Arbitration is enabled	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA = SP to RAA = WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the MTL_RXQn_CONTROL registers must be programmed before the MTL_Operation_Mode register.

The MTL_RXQn_CONTROL register controls the receive arbitration and passing of received packets to the application.

28.3.213 DMA_Mode : Bus Mode Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INTM[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	TXPR	—	—	DSPW	—	—	—	TAA[2:0]			—	SWR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SWR	Software Reset*1 After writing 1 to this bit, wait for at the least 4 CSR clock cycles, before reading this bit. **Note**: The reset operation is complete only when GMAC has de-asserted all resets in all active clock domains. Therefore, it is essential that all PHY input clocks of the selected PHY interface are present for the completion of the software reset. The time required to complete the software reset operation depends on the frequency of the slowest active clock. 0: Software Reset is disabled. 1: Software Reset is enabled. Indicates that MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all GMAC clock domains. Before reprogramming any GMAC register, read a value of zero in this bit.	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
4:2	TAA[2:0]	Transmit Arbitration Algorithm This field is used to select the arbitration policy for the Transmit side when you select multiple Tx DMAs. 0 0 0: Fixed priority (Channel 0 has the lowest priority and the last channel has the highest priority) 0 0 1: Weighted Strict Priority (WSP) 0 1 0: Weighted Round-Robin (WRR) Others: Reserved	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	DSPW	Descriptor Posted Write 0: Descriptor Posted Write is disabled. Indicates that the descriptor writes are non-posted. 1: Descriptor Posted Write is enabled. Indicates that descriptor writes are non-posted only when IOC = 1 (Interrupt on completion) in the last descriptor. Otherwise, the descriptor writes are always posted.	R/W
10:9	—	These bits are read as 0. The write value should be 0.	R/W
11	TXPR	Transmit Priority 0: Transmit Priority is disabled. 1: Transmit Priority is enabled. Indicates that the Tx DMA has priority over the Rx DMA during arbitration for the system-side bus. When you enable descriptor cache feature, descriptor reads from DCACHE memory.	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
17:16	INTM[1:0]	Interrupt Mode This field defines the interrupt mode of GMAC. The behavior of the following outputs change depending on the following settings: ● GMAC_TXINTn (Transmit Per Channel Interrupt) ● GMAC_RXINTn (Receive Per Channel Interrupt) ● GMAC_SBD (Common Interrupt) It also changes the behavior of the RI/TI bits in the DMA_CH0_STATUS. 0 0: GMAC_TXINTn/GMAC_RXINTn are pulse signals for each TX/RX packet transfer completion events (irrespective of whether corresponding interrupts are enabled) for which IOC bits are enabled in descriptor. GMAC_SBD is also asserted when corresponding interrupts are enabled and cleared only when software clears the corresponding RI/TI status bits. 0 1: GMAC_TXINTn/GMAC_RXINTn are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. The GMAC_SBD is not asserted for these TX/RX packet transfer completion events. 1 0: GMAC_TXINTn/GMAC_RXINTn are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. However, the signal is asserted again if the same event occurred again before it was cleared. The GMAC_SBD is not asserted for these TX/RX packet transfer completion events. 1 1: Reserved	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restrictions apply.

- Initiates the software reset when application writes 1.
- MAC writes 0 after the software reset is complete.
- MAC ignores when application writes 0.

The DMA_Mode register establishes the bus operating modes for the DMA.

28.3.214 DMA_SysBus_Mode : System Bus Mode Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	EN_LPI	LPI_XIT_PKT	—	—	WR_OSR_LMT[3:0]				—	—	—	—	RD_OSR_LMT[3:0]			
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	ONEKBBE	AAL	—	AALE	—	—	—	—	—	—	BLEN16	BLEN8	BLEN4	FB
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FB	Fixed Burst Length 0: Fixed Burst Length is disabled. The AXI master initiates burst transfers that are equal to or less than the maximum allowed burst length programmed in TxPBL/RxPBL. 1: Fixed Burst Length is enabled. The AXI master initiates burst transfers of specified lengths: ● Burst transfers of fixed burst lengths as indicated by the BLEN16, BLEN8, or BLEN4 field ● Burst transfers of length 1	R/W
1	BLEN4	AXI Burst Length 4*1 When this bit is set to 1 or the FB bit is set to 1, the AXI master can select a burst length of 4 on the AXI interface. 0: No effect 1: AXI Burst Length 4	R/W
2	BLEN8	AXI Burst Length 8*1 When this bit is set to 1 or the FB bit is set to 1, the AXI master can select a burst length of 8 on the AXI interface. 0: No effect 1: AXI Burst Length 8	R/W
3	BLEN16	AXI Burst Length 16*1 When this bit is set to 1 or the FB bit is set to 1, the AXI master can select a burst length of 16 on the AXI interface. 0: No effect 1: AXI Burst Length 16	R/W
9:4	—	These bits are read as 0. The write value should be 0.	R/W
10	AALE	Automatic AXI LPI enable 0: Automatic AXI LPI is disabled. 1: Automatic AXI LPI is enabled. Enables the AXI master to enter into LPI state when there is no activity in the GMAC for certain number of system clock cycles. You can program the number of clock cycles in the LPIEI field of AXI_LPI_Entry_Interval register.	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
12	AAL	Address-Aligned Beats 0: Address-Aligned Beats is disabled. The AXI master performs burst transfers on Read and Write channels without aligning to address boundaries. 1: Address-Aligned Beats is enabled. The AXI master performs address-aligned burst transfers on Read and Write channels.	R/W
13	ONEKBBE	1 KB Boundary Crossing Enable for the AXI Master 0: 1 KB Boundary Crossing for the AXI Master Beats is disabled. The burst transfers performed by the AXI master do not cross 4 KB boundary. 1: 1 KB Boundary Crossing for the AXI Master Beats is enabled. The burst transfers performed by the AXI master do not cross 1 KB boundary.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
19:16	RD_OSR_LMT[3:0]	AXI Maximum Read Outstanding Request Limit This value limits the maximum outstanding request on the AXI read interface. Maximum outstanding requests = RD_OSR_LMT + 1	R/W
23:20	—	These bits are read as 0. The write value should be 0.	R/W
27:24	WR_OSR_LMT[3:0]	AXI Maximum Write Outstanding Request Limit This value limits the maximum outstanding request on the AXI write interface. Maximum outstanding requests = WR_OSR_LMT + 1	R/W
29:28	—	These bits are read as 0. The write value should be 0.	R/W
30	LPI_XIT_PKT	Unlock on Magic Packet or Remote Wake-Up Packet 0: Unlock on Magic Packet or Remote Wake-Up Packet is disabled. Enables the AXI master to come out of the LPI mode when any packet is received. 1: Unlock on Magic Packet or Remote Wake-Up Packet is enabled. Enables the AXI master to come out of the LPI mode only when the magic packet or remote wake-up packet is received.	R/W
31	EN_LPI	Enable Low Power Interface (LPI) 0: Low Power Interface (LPI) is disabled. Disables the LPI mode. Denies the LPI request from the AXI system clock controller. 1: Low Power Interface (LPI) is enabled. Enables the LPI mode and accepts the LPI request from the AXI system clock controller.	R/W

Note 1. When the FB bit is set to 0, setting this bit has no effect.

This register controls the behavior of the AHB or AXI master. It mainly controls burst splitting and the number of outstanding requests.

28.3.215 DMA_Interrupt_Status : DMA Interrupt Status Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MACIS	MTLIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	DC7IS	DC6IS	DC5IS	DC4IS	DC3IS	DC2IS	DC1IS	DC0IS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DC0IS	DMA Channel 0 Interrupt Status This bit indicates an interrupt event in DMA Channel 0. To reset this bit to 0, the software must read the corresponding register in DMA Channel 0 to get the exact cause of the interrupt and clear its source. 0: DMA Channel 0 Interrupt Status not detected 1: DMA Channel 0 Interrupt Status detected	R
1	DC1IS	DMA Channel 1 Interrupt Status This bit indicates an interrupt event in DMA Channel 1. To reset this bit to 0, the software must read the corresponding register in DMA Channel 1 to get the exact cause of the interrupt and clear its source. 0: DMA Channel 1 Interrupt Status not detected 1: DMA Channel 1 Interrupt Status detected	R
2	DC2IS	DMA Channel 2 Interrupt Status This bit indicates an interrupt event in DMA Channel 2. To reset this bit to 0, the software must read the corresponding register in DMA Channel 2 to get the exact cause of the interrupt and clear its source. 0: DMA Channel 2 Interrupt Status not detected 1: DMA Channel 2 Interrupt Status detected	R
3	DC3IS	DMA Channel 3 Interrupt Status This bit indicates an interrupt event in DMA Channel 3. To reset this bit to 0, the software must read the corresponding register in DMA Channel 3 to get the exact cause of the interrupt and clear its source. 0: DMA Channel 3 Interrupt Status not detected 1: DMA Channel 3 Interrupt Status detected	R
4	DC4IS	DMA Channel 4 Interrupt Status This bit indicates an interrupt event in DMA Channel 4. To reset this bit to 0, the software must read the corresponding register in DMA Channel 4 to get the exact cause of the interrupt and clear its source. 0: DMA Channel 4 Interrupt Status not detected 1: DMA Channel 4 Interrupt Status detected	R
5	DC5IS	DMA Channel 5 Interrupt Status This bit indicates an interrupt event in DMA Channel 5. To reset this bit to 0, the application must read the corresponding register in DMA Channel 5, get the exact cause of the interrupt and clear the source of the interrupt. 0: DMA Channel 5 Interrupt Status not detected 1: DMA Channel 5 Interrupt Status detected	R
6	DC6IS	DMA Channel 6 Interrupt Status This bit indicates an interrupt event in DMA Channel 6. To reset this bit to 0, the application must read the corresponding register in DMA Channel 6, get the exact cause of the interrupt and clear the source of the interrupt. 0: DMA Channel 6 Interrupt Status not detected 1: DMA Channel 6 Interrupt Status detected	R
7	DC7IS	DMA Channel 7 Interrupt Status This bit indicates an interrupt event in DMA Channel 7. To reset this bit to 0, the application must read the corresponding register in DMA Channel 7, get the exact cause of the interrupt and clear the source of the interrupt. 0: DMA Channel 7 Interrupt Status not detected 1: DMA Channel 7 Interrupt Status detected	R
15:8	—	These bits are read as 0.	R
16	MTLIS	MTL Interrupt Status This bit indicates an interrupt event in the MTL. To reset this bit to 0, the application must read the corresponding register in the MTL, get the exact cause of the interrupt and clear the source of the interrupt. 0: MTL Interrupt Status not detected 1: MTL Interrupt Status detected	R
17	MACIS	MAC Interrupt Status This bit indicates an interrupt event in the MAC. To reset this bit to 0, the application must read the corresponding register in the MAC, get the exact cause of the interrupt and clear the source of the interrupt. 0: MAC Interrupt Status not detected 1: MAC Interrupt Status detected	R

Bit	Symbol	Function	R/W
31:18	—	These bits are read as 0.	R

The application reads this DMA_Interrupt_Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

28.3.216 DMA_Debug_Status0 : DMA Debug Status 0 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x100C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TPS2[3:0]				RPS2[3:0]				TPS1[3:0]				RPS1[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TPS0[3:0]				RPS0[3:0]				—	—	—	—	—	—	AXRH STS	AXWH STS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AXWHSTS	AXI Master Write Channel When high, this bit indicates that the write channel of the AXI master is active, and it is transferring data. 0: AXI Master Write Channel or AHB Master Status not detected 1: AXI Master Write Channel or AHB Master Status detected	R
1	AXRHSTS	AXI Master Read Channel Status 0: AXI Master Read Channel Status not detected. 1: AXI Master Read Channel Status detected. Indicates that the read channel of the AXI master is active, and it is transferring the data.	R
7:2	—	These bits are read as 0.	R
11:8	RPS0[3:0]	DMA Channel 0 Receive Process State This field indicates the Rx DMA FSM state for Channel 0. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Receive Command issued) 0x1: Running (Fetching Rx Transfer Descriptor) 0x2: Reserved for future use 0x3: Running (Waiting for Rx packet) 0x4: Suspended (Rx Descriptor Unavailable) 0x5: Running (Closing the Rx Descriptor) 0x6: Timestamp write state 0x7: Running (Transferring the received packet data from the Rx buffer to the system memory)	R
15:12	TPS0[3:0]	DMA Channel 0 Transmit Process State This field indicates the Tx DMA FSM state for Channel 0. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Transmit Command issued) 0x1: Running (Fetching Tx Transfer Descriptor) 0x2: Running (Waiting for status) 0x3: Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO)) 0x4: Timestamp write state 0x5: Reserved for future use 0x6: Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow) 0x7: Running (Closing Tx Descriptor)	R

Bit	Symbol	Function	R/W
19:16	RPS1[3:0]	DMA Channel 1 Receive Process State This field indicates the Rx DMA FSM state for Channel 1. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Receive Command issued) 0x1: Running (Fetching Rx Transfer Descriptor) 0x2: Reserved for future use 0x3: Running (Waiting for Rx packet) 0x4: Suspended (Rx Descriptor Unavailable) 0x5: Running (Closing the Rx Descriptor) 0x6: Timestamp write state 0x7: Running (Transferring the received packet data from the Rx buffer to the system memory)	R
23:20	TPS1[3:0]	DMA Channel 1 Transmit Process State This field indicates the Tx DMA FSM state for Channel 1. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Transmit Command issued) 0x1: Running (Fetching Tx Transfer Descriptor) 0x2: Running (Waiting for status) 0x3: Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO)) 0x4: Timestamp write state 0x5: Reserved for future use 0x6: Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow) 0x7: Running (Closing Tx Descriptor)	R
27:24	RPS2[3:0]	DMA Channel 2 Receive Process State This field indicates the Rx DMA FSM state for Channel 2. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Receive Command issued) 0x1: Running (Fetching Rx Transfer Descriptor) 0x2: Reserved for future use 0x3: Running (Waiting for Rx packet) 0x4: Suspended (Rx Descriptor Unavailable) 0x5: Running (Closing the Rx Descriptor) 0x6: Timestamp write state 0x7: Running (Transferring the received packet data from the Rx buffer to the system memory)	R
31:28	TPS2[3:0]	DMA Channel 2 Transmit Process State This field indicates the Tx DMA FSM state for Channel 2. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Transmit Command issued) 0x1: Running (Fetching Tx Transfer Descriptor) 0x2: Running (Waiting for status) 0x3: Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO)) 0x4: Timestamp write state 0x5: Reserved for future use 0x6: Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow) 0x7: Running (Closing Tx Descriptor)	R

The DMA_Debug_Status0 register gives the Receive and Transmit process status for DMA Channel 0 to Channel 2 for debugging purpose.

28.3.217 DMA_Debug_Status1 : DMA Debug Status 1 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1010

Bit position:	31 28	27 24	23 20	19 16	15 12	11 8	7 4	3 0
Bit field:	TPS6[3:0]	RPS6[3:0]	TPS5[3:0]	RPS5[3:0]	TPS4[3:0]	RPS4[3:0]	TPS3[3:0]	RPS3[3:0]
Value after reset:	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0

Bit	Symbol	Function	R/W
3:0	RPS3[3:0]	DMA Channel 3 Receive Process State This field indicates the Rx DMA FSM state for Channel 3. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Receive Command issued) 0x1: Running (Fetching Rx Transfer Descriptor) 0x2: Reserved for future use 0x3: Running (Waiting for Rx packet) 0x4: Suspended (Rx Descriptor Unavailable) 0x5: Running (Closing the Rx Descriptor) 0x6: Timestamp write state 0x7: Running (Transferring the received packet data from the Rx buffer to the system memory)	R
7:4	TPS3[3:0]	DMA Channel 3 Transmit Process State This field indicates the Tx DMA FSM state for Channel 3. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Transmit Command issued) 0x1: Running (Fetching Tx Transfer Descriptor) 0x2: Running (Waiting for status) 0x3: Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO)) 0x4: Timestamp write state 0x5: Reserved for future use 0x6: Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow) 0x7: Running (Closing Tx Descriptor)	R
11:8	RPS4[3:0]	DMA Channel 4 Receive Process State This field indicates the Rx DMA FSM state for Channel 4. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Receive Command issued) 0x1: Running (Fetching Rx Transfer Descriptor) 0x2: Reserved for future use 0x3: Running (Waiting for Rx packet) 0x4: Suspended (Rx Descriptor Unavailable) 0x5: Running (Closing the Rx Descriptor) 0x6: Timestamp write state 0x7: Running (Transferring the received packet data from the Rx buffer to the system memory)	R
15:12	TPS4[3:0]	DMA Channel 4 Transmit Process State This field indicates the Tx DMA FSM state for Channel 4. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Transmit Command issued) 0x1: Running (Fetching Tx Transfer Descriptor) 0x2: Running (Waiting for status) 0x3: Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO)) 0x4: Timestamp write state 0x5: Reserved for future use 0x6: Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow) 0x7: Running (Closing Tx Descriptor)	R
19:16	RPS5[3:0]	DMA Channel 5 Receive Process State This field indicates the Rx DMA FSM state for Channel 5. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Receive Command issued) 0x1: Running (Fetching Rx Transfer Descriptor) 0x2: Reserved for future use 0x3: Running (Waiting for Rx packet) 0x4: Suspended (Rx Descriptor Unavailable) 0x5: Running (Closing the Rx Descriptor) 0x6: Timestamp write state 0x7: Running (Transferring the received packet data from the Rx buffer to the system memory)	R

Bit	Symbol	Function	R/W
23:20	TPS5[3:0]	DMA Channel 5 Transmit Process State This field indicates the Tx DMA FSM state for Channel 5. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Transmit Command issued) 0x1: Running (Fetching Tx Transfer Descriptor) 0x2: Running (Waiting for status) 0x3: Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO)) 0x4: Timestamp write state 0x5: Reserved for future use 0x6: Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow) 0x7: Running (Closing Tx Descriptor)	R
27:24	RPS6[3:0]	DMA Channel 6 Receive Process State This field indicates the Rx DMA FSM state for Channel 6. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Receive Command issued) 0x1: Running (Fetching Rx Transfer Descriptor) 0x2: Reserved for future use 0x3: Running (Waiting for Rx packet) 0x4: Suspended (Rx Descriptor Unavailable) 0x5: Running (Closing the Rx Descriptor) 0x6: Timestamp write state 0x7: Running (Transferring the received packet data from the Rx buffer to the system memory)	R
31:28	TPS6[3:0]	DMA Channel 6 Transmit Process State This field indicates the Tx DMA FSM state for Channel 6. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Transmit Command issued) 0x1: Running (Fetching Tx Transfer Descriptor) 0x2: Running (Waiting for status) 0x3: Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO)) 0x4: Timestamp write state 0x5: Reserved for future use 0x6: Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow) 0x7: Running (Closing Tx Descriptor)	R

The DMA_Debug_Status1 register gives the Receive and Transmit process status for DMA Channel 3 to Channel 6.

28.3.218 DMA_Debug_Status2 : DMA Debug Status 2 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TPS7[3:0]				RPS7[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	RPS7[3:0]	DMA Channel 7 Receive Process State This field indicates the Rx DMA FSM state for Channel 7. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Receive Command issued) 0x1: Running (Fetching Rx Transfer Descriptor) 0x2: Reserved for future use 0x3: Running (Waiting for Rx packet) 0x4: Suspended (Rx Descriptor Unavailable) 0x5: Running (Closing the Rx Descriptor) 0x6: Timestamp write state 0x7: Running (Transferring the received packet data from the Rx buffer to the system memory)	R
7:4	TPS7[3:0]	DMA Channel 7 Transmit Process State This field indicates the Tx DMA FSM state for Channel 7. The MSB of this field always returns 0. This field does not generate an interrupt. 0x0: Stopped (Reset or Stop Transmit Command issued) 0x1: Running (Fetching Tx Transfer Descriptor) 0x2: Running (Waiting for status) 0x3: Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO)) 0x4: Timestamp write state 0x5: Reserved for future use 0x6: Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow) 0x7: Running (Closing Tx Descriptor)	R
31:8	—	These bits are read as 0.	R

The DMA_Debug_Status2 register gives the Receive and Transmit process status for DMA Channel 7.

28.3.219 AXI_LPI_Entry_Interval : AXI LPI Entry Interval Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1040

Bit position:	31																											3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LPIEI[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	LPIEI[3:0]	LPI Entry Interval Contains the number of system clock cycles, multiplied by 64, to wait for an activity in the GMAC to enter into the AXI low power state. 0 indicates 64 clock cycles.	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

This register is used to control the AXI LPI entry interval.

28.3.220 DMA_TBS_CTRL0 : DMA TBS Attributes Control 0 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1050

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	FTOS[23:8]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FTOS[7:0]								—	FGOS[2:0]			—	—	—	FTOV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FTOV	Fetch Time Offset Valid When set indicates the FTOS field is valid. When not set, indicates the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions. 0: Fetch Time Offset is invalid 1: Fetch Time Offset is valid	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
6:4	FGOS[2:0]	Fetch GSN Offset The number GSN slots that must be deducted from the Launch GSN to compute the Fetch GSN. Value valid only when FTOV is set.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
31:8	FTOS[23:0]	Fetch Time Offset The value in units of 256 ns, that has to be deducted from the Launch time to compute the Fetch Time. Max value: 999,999,999 ns, additionally should be smaller than CTR - 1 value when ESTM mode is set since this value is a modulo CTR value.	R/W

This register is used to control the TBS attributes.

28.3.221 DMA_TBS_CTRL1 : DMA TBS Attributes Control 1 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1054

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	FTOS[23:8]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FTOS[7:0]								—	FGOS[2:0]			—	—	—	FTOV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FTOV	Fetch Time Offset Valid When set indicates the FTOS field is valid. When not set, indicates the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions. 0: Fetch Time Offset is invalid 1: Fetch Time Offset is valid	R/W

Bit	Symbol	Function	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
6:4	FGOS[2:0]	Fetch GSN Offset The number GSN slots that must be deducted from the Launch GSN to compute the Fetch GSN. Value valid only when FTOV is set.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
31:8	FTOS[23:0]	Fetch Time Offset The value in units of 256 nanoseconds, that has to be deducted from the Launch time to compute the Fetch Time. Max value: 999,999,999 ns, additionally should be smaller than CTR - 1 value when ESTM mode is set since this value is a modulo CTR value.	R/W

This register is used to control the TBS attributes.

28.3.222 DMA_TBS_CTRL2 : DMA TBS Attributes Control 2 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1058

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	FTOS[23:8]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FTOS[7:0]								—	FGOS[2:0]			—	—	—	FTOV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FTOV	Fetch Time Offset Valid When set indicates the FTOS field is valid. When not set, indicates the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions. 0: Fetch Time Offset is invalid 1: Fetch Time Offset is valid	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
6:4	FGOS[2:0]	Fetch GSN Offset The number GSN slots that must be deducted from the Launch GSN to compute the Fetch GSN. Value valid only when FTOV is set.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
31:8	FTOS[23:0]	Fetch Time Offset The value in units of 256 nanoseconds, that has to be deducted from the Launch time to compute the Fetch Time. Max value: 999,999,999 ns, additionally should be smaller than CTR - 1 value when ESTM mode is set since this value is a modulo CTR value.	R/W

This register is used to control the TBS attributes.

28.3.223 DMA_TBS_CTRL3 : DMA TBS Attributes Control 3 Register

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x105C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	FTOS[23:8]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FTOS[7:0]								—	FGOS[2:0]			—	—	—	FTOV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FTOV	Fetch Time Offset Valid When set indicates the FTOS field is valid. When not set, indicates the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions. 0: Fetch Time Offset is invalid 1: Fetch Time Offset is valid	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
6:4	FGOS[2:0]	Fetch GSN Offset The number GSN slots that must be deducted from the Launch GSN to compute the Fetch GSN. Value valid only when FTOV is set.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
31:8	FTOS[23:0]	Fetch Time Offset The value in units of 256 nanoseconds, that has to be deducted from the Launch time to compute the Fetch Time. Max value: 999,999,999 ns, additionally should be smaller than CTR - 1 value when ESTM mode is set since this value is a modulo CTR value.	R/W

This register is used to control the TBS attributes.

28.3.224 DMA_CHn_CONTROL : DMA Channel n Control Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1100 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	SPH	—	—	—	DSL[2:0]			—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
17:0	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
20:18	DSL[2:0]	Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
24	SPH	Split Headers The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload. This bit is available only when you select Enable Split Header Structure feature. 0: Split Headers feature is disabled. 1: Split Headers feature is enabled. DMA splits the header and payload in the receive path. The DMA writes the header to the Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

The DMA_CHn_CONTROL register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting.

28.3.225 DMA_CHn_TX_CONTROL : DMA Channel n Transmit Control Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1104 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	TFSEL[1:0]		EDSE	—	—	—	—	—	—	TxPBL[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	IPBL	—	—	—	—	—	—	—	—	—	—	OSF	TCW[2:0]			ST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ST	Start or Stop Transmission Command The DMA tries to acquire descriptor from either of the following positions: ● The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TXDESC_LIST_ADDRESS register. ● The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_STATUS register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TXDESC_LIST_ADDRESS register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0: Stop Transmission Command. 1: Start Transmission Command. Transmission is placed in the running state. The DMA checks the Tx list at the current position for a packet to be transmitted.	R/W

Bit	Symbol	Function	R/W
3:1	TCW[2:0]	Transmit Channel Weight This field indicates the weight assigned to the corresponding Tx channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels.	R/W
4	OSF	Operate on Second Packet 0: Operate on Second Packet disabled. 1: Operate on Second Packet enabled. Instructs the DMA to process the second packet of the Tx data even before the status for the first packet is obtained.	R/W
14:5	—	These bits are read as 0. The write value should be 0.	R/W
15	IPBL	Ignore PBL Requirement*1 0: Ignore PBL Requirement is disabled. 1: Ignore PBL Requirement is enabled. DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL might use handshaking to slow the DMA.	R/W
21:16	TxPBL[5:0]	Transmit Programmable Burst Length*2 These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, or 16. Any other value results in undefined behavior.	R/W
27:22	—	These bits are read as 0. The write value should be 0.	R/W
28	EDSE	Enhanced Descriptor Enable 0: Enhanced Descriptor is disabled. The corresponding channel uses the descriptors that are 16 Bytes. 1: Enhanced Descriptor is enabled. The corresponding channel uses Enhanced Descriptors that are 32 Bytes for both Normal and Context Descriptors.	R/W
30:29	TFSEL[1:0]	TBS Fetch Select Select bits for one of the four DMA_TBS_CTRL register fields (FTOS, FGSN, FTOV) for the channel. 0 0: DMA_TBS_CTRL0 0 1: DMA_TBS_CTRL1 1 0: DMA_TBS_CTRL2 1 1: DMA_TBS_CTRL3	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

Note 1. Do not use this mode when you enable multiple Transmit DMA channels. Because, it might block other Transmit and Receive DMA Channels from accessing the Read Data Channel of the AXI bus until space is available in Transmit Queue for current transfer.

Note 2. The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TXQn_OPERATION_MODE register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, the total locations in Tx Queue of size 512 bytes is 32, TxPBL needs to be programmed to less than or equal to 16.

The DMA_CHn_TX_CONTROL register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

28.3.226 DMA_CHn_RX_CONTROL : DMA Channel n Receive Control Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1108 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RPF	—	—	—	—	—	—	—	—	—	RxPBL[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	RBSZ_13_y[9:0]										RBSZ_x_0[3:0]				SR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SR	Start or Stop Receive The DMA tries to acquire descriptor from either of the following positions: ● The current position in the list: This is the address set by the DMA_CH0_RXDESC_LIST_ADDRESS register. ● The position at which the Rx process was previously stopped: If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_STATUS register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. 0: Stop Receive. Rx DMA operation stops after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 1: Start Receive. DMA attempts to acquire the descriptor from the Receive list and processes the incoming packets.	R/W
4:1	RBSZ_x_0[3:0]	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width.	R
14:5	RBSZ_13_y[9:0]	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16 Kbytes. The buffer size is applicable to payload buffers when split headers are enabled. **Note**: The buffer size must be a multiple of 16 depending on the data bus widths. This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
21:16	RxPBL[5:0]	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, or 16. Any other value results in undefined behavior. **Note**: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of MTL_RXQn_OPERATION_MODE register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, the total locations in Rx Queue of size 512 bytes is 32, so RxPBL needs to be programmed to less than or equal to 16.	R/W
30:22	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
31	RPF	Rx Packet Flush **Note**: The stopping of packet flow from a Rx DMA Channel to the application by setting RPF works only when there is one-to-one mapping of Rx Queue to Rx DMA channels. In Dynamic mapping mode, setting RPF bit in any DMA_CHn_RX_CONTROL register might flush packets from unintended Rx Queues which are destined to the stopped Rx DMA Channel. 0: Rx Packet Flush is disabled. GMAC does not flush the packet in the Rx Queue destined to this Rx DMA Channel when it is in STOP state. This might cause head-of-line blocking in the corresponding Rx Queue. 1: Rx Packet Flush is enabled. GMAC automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this Rx DMA was stopped, are flushed out. The packets that are received by the MAC after the Rx DMA is re-started are routed to the Rx DMA. The flushing is done on the Read side of the Rx Queue.	R/W

The DMA_CHn_RX_CONTROL register controls the Rx features such as PBL, buffer size, and extended status.

28.3.227 DMA_CHn_TXDESC_LIST_ADDRESS : DMA Channel n Tx Descriptor List Address Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1114 + 0x80 × n

Bit position:	31																												0
Bit field:	TDESLA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TDESLA[31:0]	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (3:0) and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).	R/W

The DMA_CHn_TXDESC_LIST_ADDRESS register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Lword-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

28.3.228 DMA_CHn_RXDESC_LIST_ADDRESS : DMA Channel n Rx Descriptor List Address Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x111C + 0x80 × n

Bit position:	31																												0
Bit field:	RDESLA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RDESLA[31:0]	Start of Receive List This field contains the base address of the first descriptor in the Rx Descriptor list. The DMA ignores the LSB bits (3:0) and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).	R/W

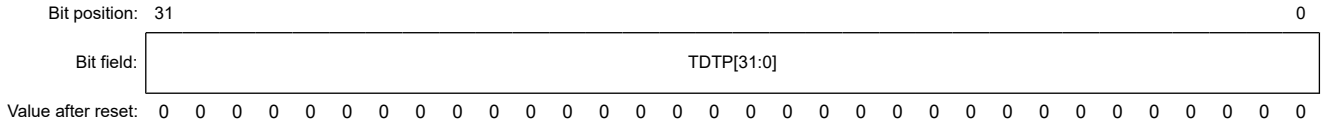
The DMA_CHn_RXDESC_LIST_ADDRESS register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Lword-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given.

You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_RX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

28.3.229 DMA_CHn_TXDESC_TAIL_POINTER : DMA Channel n Tx Descriptor Tail Pointer Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1120 + 0x80 × n



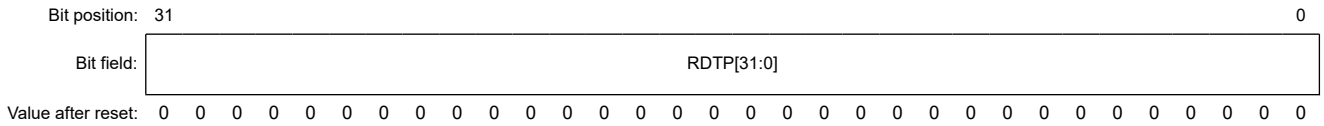
Bit	Symbol	Function	R/W
31:0	TDTP[31:0]	Transmit Descriptor Tail Pointer This field contains the tail pointer for the Tx descriptor ring. The software writes the tail pointer to add more descriptors to the Tx channel. The hardware tries to transmit all packets referenced by the descriptors between the head and the tail pointer registers. LSB (3:0) is ignored.	R/W

The DMA_CHn_TXDESC_TAIL_POINTER register points to an offset from the base and indicates the location of the last valid descriptor.

28.3.230 DMA_CHn_RXDESC_TAIL_POINTER : DMA Channel n Rx Descriptor Tail Pointer Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1128 + 0x80 × n



Bit	Symbol	Function	R/W
31:0	RDTP[31:0]	Receive Descriptor Tail Pointer This field contains the tail pointer for the Rx descriptor ring. The software writes the tail pointer to add more descriptors to the Rx channel. The hardware tries to write all received packets to the descriptors referenced between the head and the tail pointer registers. LSB (3:0) is ignored.	R/W

The DMA_CHn_RXDESC_TAIL_POINTER register points to an offset from the base and indicates the location of the last valid descriptor.

28.3.231 DMA_CHn_TXDESC_RING_LENGTH : DMA Channel n Tx Descriptor Ring Length Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x112C + 0x80 × n

Bit position:	31																					9								0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TDRL[9:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	TDRL[9:0]	Transmit Descriptor Ring Length This field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. Synopsys recommends a minimum ring descriptor length of 4. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

The DMA_CHn_TXDESC_RING_LENGTH register contains the length of the Transmit descriptor ring.

28.3.232 DMA_CHn_RX_CONTROL2 : DMA Channel n Receive Control 2 Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1130 + 0x80 × n

Bit position:	31								23							18						9								0
Bit field:	—	—	—	—	—	—	—	—	ARBS[5:0]							—	—	—	—	—	—	—	—	RDRL[9:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	RDRL[9:0]	Receive Descriptor Ring Length This register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.	R/W
17:10	—	These bits are read as 0. The write value should be 0.	R/W
23:18	ARBS[5:0]	Alternate Receive Buffer Size Indicates size in bytes for Buffer 1 when ARBS is programmed to a non-zero value (when split header feature is not enabled). When split header feature is enabled, ARBS indicates the buffer size for header data. The maximum alternate buffer is limited to 1020, 1016 or 1008-bytes depending on the data bus widths (32-bit, 64-bit, or 128-bit, respectively). When ARBS = 0, Rx Buffer1 and Rx Buffer2 sizes are based on RBSZ field of DMA_CHn_RX_CONTROL. Width of ARBS field is 8, 7, or 6-bits depending on the data bus widths (32-bit, 64-bit, or 128-bit, respectively).	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

The DMA_CHn_RX_CONTROL2 register controls the Rx features such as Rx Descriptor Ring Length and Alternate Rx Buffer Size.

28.3.233 DMA_CHn_INTERRUPT_ENABLE : DMA Channel n Interrupt Enable Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1134 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	NIE	AIE	CDEE	FBEE	ERIE	ETIE	RWTE	RSE	RBUE	RIE	—	—	—	TBUE	TXSE	TIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TIE	Transmit Interrupt Enable When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled. 0: Transmit Interrupt is disabled 1: Transmit Interrupt is enabled	R/W
1	TXSE	Transmit Stopped Enable When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. When this bit is reset, the Transmission Stopped interrupt is disabled. 0: Transmit Stopped is disabled 1: Transmit Stopped is enabled	R/W
2	TBUE	Transmit Buffer Unavailable Enable When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled. 0: Transmit Buffer Unavailable is disabled 1: Transmit Buffer Unavailable is enabled	R/W
5:3	—	These bits are read as 0. The write value should be 0.	R/W
6	RIE	Receive Interrupt Enable When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled. 0: Receive Interrupt is disabled 1: Receive Interrupt is enabled	R/W
7	RBUE	Receive Buffer Unavailable Enable When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled. 0: Receive Buffer Unavailable is disabled 1: Receive Buffer Unavailable is enabled	R/W
8	RSE	Receive Stopped Enable When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled. 0: Receive Stopped is disabled 1: Receive Stopped is enabled	R/W
9	RWTE	Receive Watchdog Timeout Enable When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled. 0: Receive Watchdog Timeout is disabled 1: Receive Watchdog Timeout is enabled	R/W
10	ETIE	Early Transmit Interrupt Enable When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled. 0: Early Transmit Interrupt is disabled 1: Early Transmit Interrupt is enabled	R/W

Bit	Symbol	Function	R/W
11	ERIE	Early Receive Interrupt Enable When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled. 0: Early Receive Interrupt is disabled 1: Early Receive Interrupt is enabled	R/W
12	FBEE	Fatal Bus Error Enable When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled. 0: Fatal Bus Error is disabled 1: Fatal Bus Error is enabled	R/W
13	CDEE	Context Descriptor Error Enable When this bit is set along with the AIE bit, the Descriptor error interrupt is enabled. When this bit is reset, the Descriptor error interrupt is disabled. 0: Context Descriptor Error is disabled 1: Context Descriptor Error is enabled	R/W
14	AIE	Abnormal Interrupt Summary Enable When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_STATUS register: ● Bit 1: Transmit Process Stopped ● Bit 7: Rx Buffer Unavailable ● Bit 8: Receive Process Stopped ● Bit 9: Receive Watchdog Timeout ● Bit 10: Early Transmit Interrupt ● Bit 12: Fatal Bus Error ● Bit 13: Context Descriptor Error When this bit is reset, the abnormal interrupt summary is disabled. 0: Abnormal Interrupt Summary is disabled 1: Abnormal Interrupt Summary is enabled	R/W
15	NIE	Normal Interrupt Summary Enable When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_STATUS register: ● Bit 0: Transmit Interrupt ● Bit 2: Transmit Buffer Unavailable ● Bit 6: Receive Interrupt ● Bit 11: Early Receive Interrupt When this bit is reset, the normal interrupt summary is disabled. 0: Normal Interrupt Summary is disabled 1: Normal Interrupt Summary is enabled	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The DMA_CHn_INTERRUPT_ENABLE register enables the interrupts reported by the Status register.

28.3.234 DMA_CHn_RX_INTERRUPT_WATCHDOG_TIMER : DMA Channel n Receive Interrupt Watchdog Timer Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1138 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RWTU[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	RWT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RWT[7:0]	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CHn_STATUS register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W
17:16	RWTU[1:0]	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. For example, when RWT = 2 and RWTU = 1, the watchdog timer is set for 2 × 512 = 1024 system clock cycles. 0 0: 256 0 1: 512 1 0: 1024 1 1: 2048	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The DMA_CHn_RX_INTERRUPT_WATCHDOG_TIMER register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHn_STATUS register.

28.3.235 DMA_CHn_SLOT_FUNCTION_CONTROL_STATUS : DMA Channel n Slot Function Control and Status Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x113C + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	RSN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SIV[11:0]												—	—	ASC	ESC
Value after reset:	0	0	0	0	0	1	1	1	1	1	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is ● equal to the reference slot number or ● ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. **Note**: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/ fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0: Slot Comparison is disabled 1: Slot Comparison is enabled	R/W

Bit	Symbol	Function	R/W
1	ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is ● equal to the reference slot number given in the RSN field or ● ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0: Advance Slot Check is disabled 1: Advance Slot Check is enabled	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
15:4	SIV[11:0]	Slot Interval Value This field controls the period of the slot interval in which the Tx DMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 µs while the maximum value 4095 specifies the slot interval of 4096 µs. The default/reset value is 0x07C which corresponds to slot interval of 125 µs.	R/W
19:16	RSN[3:0]	Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.	R
31:20	—	These bits are read as 0. The write value should be 0.	R/W

The DMA_CHn_SLOT_FUNCTION_CONTROL_STATUS register contains the control bits for slot function and the status for Transmit path.

28.3.236 DMA_CHn_CURRENT_APP_TXDESC : DMA Channel n Current Application Transmit Descriptor Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1144 + 0x80 × n

Bit position:	31																												0
Bit field:	CURTDESAPTR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CURTDESAPTR[31:0]	Application Transmit Descriptor Address Pointer The DMA updates this pointer during Tx operation. This pointer is cleared on reset.	R

The DMA_CHn_CURRENT_APP_TXDESC register points to the current Transmit descriptor read by the DMA.

28.3.237 DMA_CHn_CURRENT_APP_RXDESC : DMA Channel n Current Application Receive Descriptor Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x114C + 0x80 × n

Bit position:	31																												0
Bit field:	CURRDESAPTR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CURRDESAPTR[31:0]	Application Receive Descriptor Address Pointer The DMA updates this pointer during Rx operation. This pointer is cleared on reset.	R

The DMA_CHn_CURRENT_APP_RXDESC register points to the current Receive descriptor read by the DMA.

28.3.238 DMA_CHn_CURRENT_APP_TXBUFFER : DMA Channel n Current Application Transmit Buffer Address Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1154 + 0x80 × n

Bit position:	31																												0
Bit field:	CURTBUFAPTR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CURTBUFAPTR[31:0]	Application Transmit Buffer Address Pointer The DMA updates this pointer during Tx operation. This pointer is cleared on reset.	R

The DMA_CHn_CURRENT_APP_TXBUFFER register points to the current Tx buffer address read by the DMA.

28.3.239 DMA_CHn_CURRENT_APP_RXBUFFER : DMA Channel n Current Application Receive Buffer Address Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x115C + 0x80 × n

Bit position:	31																												0
Bit field:	CURRBUFAPTR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CURRBUFAPTR[31:0]	Application Receive Buffer Address Pointer The DMA updates this pointer during Rx operation. This pointer is cleared on reset.	R

The DMA_CHn_CURRENT_APP_RXBUFFER register points to the current Rx buffer address read by the DMA.

28.3.240 DMA_CHn_STATUS : DMA Channel n Status Register (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1160 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	REB[2:0]			TEB[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	NIS	AIS	CDE	FBE	ERI	ETI	RWT	RPS	RBU	RI	—	—	—	TBU	TPS	TI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TI	Transmit Interrupt*1 This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. 0: Transmit Interrupt status not detected 1: Transmit Interrupt status detected	R/W
1	TPS	Transmit Process Stopped*1 This bit is set when the transmission is stopped. 0: Transmit Process Stopped status not detected 1: Transmit Process Stopped status detected	R/W
2	TBU	Transmit Buffer Unavailable*1 This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: ● Change the ownership of the descriptor by setting Bit 31 of TDES3. ● Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. 0: Transmit Buffer Unavailable status not detected 1: Transmit Buffer Unavailable status detected	R/W
5:3	—	These bits are read as 0. The write value should be 0.	R/W
6	RI	Receive Interrupt*1 This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. 0: Receive Interrupt status not detected 1: Receive Interrupt status detected	R/W
7	RBU	Receive Buffer Unavailable*1 This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. 0: Receive Buffer Unavailable status not detected 1: Receive Buffer Unavailable status detected	R/W
8	RPS	Receive Process Stopped*1 This bit is asserted when the Rx process enters the Stopped state. 0: Receive Process Stopped status not detected 1: Receive Process Stopped status detected	R/W
9	RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0: Receive Watchdog Timeout status not detected 1: Receive Watchdog Timeout status detected	R/W
10	ETI	Early Transmit Interrupt*1 This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. 0: Early Transmit Interrupt status not detected 1: Early Transmit Interrupt status detected	R/W
11	ERI	Early Receive Interrupt*1 This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. The setting of RI bit automatically clears this bit. 0: Early Receive Interrupt status not detected 1: Early Receive Interrupt status detected	R/W

Bit	Symbol	Function	R/W
12	FBE	Fatal Bus Error*1 This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. 0: Fatal Bus Error status not detected 1: Fatal Bus Error status detected	R/W
13	CDE	Context Descriptor Error*1 This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. 0: Context Descriptor Error status not detected 1: Context Descriptor Error status detected	R/W
14	AIS	Abnormal Interrupt Summary*1 Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_INTERRUPT_ENABLE register: ● Bit 1: Transmit Process Stopped ● Bit 7: Receive Buffer Unavailable ● Bit 8: Receive Process Stopped ● Bit 10: Early Transmit Interrupt ● Bit 12: Fatal Bus Error ● Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. 0: Abnormal Interrupt Summary status not detected 1: Abnormal Interrupt Summary status detected	R/W
15	NIS	Normal Interrupt Summary*1 Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_INTERRUPT_ENABLE register: ● Bit 0: Transmit Interrupt ● Bit 2: Transmit Buffer Unavailable ● Bit 6: Receive Interrupt ● Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. 0: Normal Interrupt Summary status not detected 1: Normal Interrupt Summary status detected	R/W
18:16	TEB[2:0]	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. This field is valid only when the FBE bit is set. This field does not generate an interrupt. ● Bit 18 0: No Error during data transfer by Tx DMA 1: Error during data transfer by Tx DMA ● Bit 17 0: Error during data buffer access 1: Error during descriptor access ● Bit 16 0: Error during write transfer 1: Error during read transfer	R
21:19	REB[2:0]	Rx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. This field is valid only when the FBE bit is set. This field does not generate an interrupt. ● Bit 21 0: Error during data transfer by Rx DMA 1: No Error during data transfer by Rx DMA ● Bit 20 0: Error during data buffer access 1: Error during descriptor access ● Bit 19 0: Error during write transfer 1: Error during read transfer	R

Bit	Symbol	Function	R/W
31:22	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA.

28.3.241 DMA_CHn_MISS_FRAME_CNT : DMA Channel n Miss Packet Counter (n = 0 to 7)

Base address: GMAC0 = 0x8010_0000
GMACm = 0x9200_0000 + 0x1_0000 × (m - 1) (m = 1, 2)

Offset address: 0x1164 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MFCO	—	—	—	—	MFC[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	MFC[10:0]	Dropped Packet Counters*1 This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in DMA_CHn_RX_CONTROL register. The counter gets cleared when this register is read.	R
14:11	—	These bits are read as 0.	R
15	MFCO	Overflow status of the MFC Counter*1 When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read. 0: Miss Frame Counter overflow not occurred 1: Miss Frame Counter overflow occurred	R
31:16	—	These bits are read as 0.	R

Note 1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CHn_RX_CONTROL register.

28.4 Architecture

28.4.1 AHB Slave Interface

The AHB slave interface provides access to the DMA, MTL, and MAC CSR space.

By default, the slave interface provides OKAY response to all CSR accesses. If SEEN field of the MAC_CSR_SW_Ctrl register is programmed to 1, GMAC provides error response when reserved registers within the CSR space are accessed.

28.4.2 AXI Master Interface

The DMA controller interfaces with the application through the AMBA 3 AXI interface. The AMBA 3 AXI bus interface provides the characteristics to support highly-effective data traffic throughput. The system bus utilization is maximized by allowing simultaneous read and write transfers initiated from different DMA channels. For example, the Tx descriptor read and Rx descriptor write-back (status update) operations can happen simultaneously. However, the Tx descriptor read and Tx descriptor write-back operations cannot happen simultaneously because the Tx DMA (or Rx DMA) does not initiate the next transfer unless the previous one is complete.

The AXI master interface allows multiple numbers of burst requests to be queued for Read or Write operation. The system bus utilization can be further enhanced by supporting Requests reordering and Data interleaving. This gives the AXI master the flexibility to dynamically and independently select multiple slaves for handling Priority Requests and Slow peripheral slaves.

28.4.2.1 Burst Splitting and Burst Selection

The AXI master splits the DMA requests into multiple bursts on the AXI system bus. Splitting is based on the DMA count, the software-controllable burst enable bits (FB, BLEN16, BLEN8, BLEN4), and the software-controllable burst types (INCR and INCR_ALIGNED). For more information, see DMA_SysBus_Mode register.

The AXI master also handles splitting the transfers that cross 4 KB address boundary, with an option to limit it to 1-KB address boundary. The Burst Length Select Priority is in the following sequence: FB, BLEN16, BLEN8, and BLEN4.

28.4.2.2 INCR Burst Type

If FB is disabled, the AXI master always chooses the maximum allowed burst length based on the BLEN16 bit (possible maximum burst lengths are 16). The AXI master chooses a burst length of any value less than the maximum enabled burst length (all lesser burst length enables are redundant) in the following cases:

- The DMA requests are not multiples of the maximum allowed burst length
- The 4K/1K address boundary crossing condition is enabled

For example, when only BLEN16, and BLEN4 are enabled, and the DMA requests a burst transfer of 38 beats size, the AXI master splits it into three bursts of 16, 16 and 6 beats size, respectively.

If FB is enabled, the burst length is based on the priority of the enabled bits in the following order: BLEN16, BLEN8, and BLEN4. When the DMA requests to transfer a burst, the AXI interface splits the requested bursts into multiple transfers by using only the enabled burst lengths. This splitting can occur in following cases:

- The requested burst is not a multiple of the maximum enabled burst
- The 4K/1K address boundary crossing condition is enabled

If the AXI interface cannot choose any of the enabled burst lengths, it selects the burst length as 1. For example, if only BLEN16, and BLEN4 are enabled and the DMA requests a burst transfer of size 38 beats, the AXI interface splits it into multiple bursts of size 16, 16, 4, 1, and 1 beats, respectively. The sequence is in decreasing burst lengths.

28.4.2.3 INCR_ALIGNED Burst Type

When the address-aligned burst type is enabled, then in addition to the burst splitting conditions explained in INCR Burst Type, the AXI interface splits the DMA requested bursts such that each burst length is aligned to the least significant bits of the start address. The AXI interface initially generates smaller bursts so that the remaining transfers can be transferred with the maximum possible (enabled) fixed burst lengths.

28.4.2.4 Outstanding Transactions

The AXI master supports configurable outstanding read/write requests on the AXI bus. You can control the outstanding requests by programming the DMA_SysBus_Mode register.

The AXI master supports up to 16 outstanding Read or Write requests on the AXI bus. You can also control these outstanding requests through software by programming bits [24:21] and bits [19:16] in the DMA_SysBus_Mode register. This is a useful workaround for any system-level issues with handling of multiple requests.

Note: The maximum number of outstanding requests is divided equally between the requests generated by the two internal masters (Rx DMA and Tx DMA). This means that each DMA is limited to a maximum of eight outstanding requests in each Read or Write channel. When you reduce the outstanding request (for example, to four) by programming the respective control bits, all outstanding requests can be from the same DMA. The minimum number of outstanding requests per channel is two.

28.4.2.5 Priority of AXI Requests

The descriptor transfers have higher priority than the data transfers. Therefore, if there are two requests, Rx Descriptor Read and Tx Data Read, the Rx Descriptor Read is given higher priority so that the next Rx Data Write (subsequent to Rx

Descriptor Read) need not wait for the Tx Data Read transfer to complete. If there are descriptor read requests from both DMAs, these requests are serviced based on the first-come first-serve basis. The Rx DMA has higher priority if descriptor read requests, generated from both DMAs, are in the same clock. Similarly, in the write channel, descriptor writes from any DMA have higher priority than the data-write transfers for the Rx DMA.

If the requests are generated from different channels simultaneously in the same clock, the request priority among the channels is: Channel 7, Channel 6, …, Channel 1, and Channel 0.

28.4.2.6 Bursts Reordering and Data Interleaving

The AXI protocol allows reordering of data transfers with different AXI-IDs with respect to the sequence of requests. It also allows data interleaving between transfers of different AXI-IDs for Read channels.

The requests from each internal master (Rx DMA and Tx DMA) are generated with different AXI-ID. Therefore, reordering and data interleaving can be performed as two DMAs operate independently and are allocated different address space on the slave memory.

The AXI master supports reordering and interleaving from the AXI slaves on the Read channel. Each DMA internally ensures that a Read request and Write request is never generated at the same time to the same address (it can occur for only descriptor accesses). The Tx DMA ensures that Tx Descriptor Read, Tx Data Read, and Tx Descriptor Write-Back requests are generated only after the previous requests are complete. The Rx DMA generates only Descriptor reads on the Read channel with a different ID. Therefore, data reordering and interleaving on the Read channel does not cause any problems in the MAC.

28.4.2.7 Posted Writes

In posted writes, the write channel of AXI master transfers an OKAY response to the DMA as soon as the last cycle or beat of data is accepted by the AXI interconnect. The AXI master sends this response without waiting for the response from the target AXI slave on the write response channel. In non-posted writes, the AXI master interface transfers the response received from the AXI slave channel to the DMA.

For transferring the Ethernet data to system memory, the Rx DMA always issues posted write requests to the AXI master interface. This enables pipelining of the data requests without delays. The AXI master does not support out-of-order write transfers. However, the Rx DMA ensures that the sequence is maintained for descriptor writes, descriptor reads, and data transfers.

For writing descriptors (status or timestamp), the DMA always issues the non-posted write requests. This is needed because the Transfer Complete Interrupt is generated based on the descriptor writes for which the DMA needs completion response from the memory slave. This ensures no race condition between the hardware and the software because the interrupt is generated only after the data and descriptor are written to the slave memory.

28.4.2.8 Error Response Handling

Whenever there is an error response from the AXI slave, the respective DMA channel which generated the request gets disabled. The AXI master asserts the interrupt (GMAC_SBD) when the corresponding "Fatal Bus Error" interrupt is enabled. Only the DMA whose specific transaction had the error response gets affected and goes to STOP state. The application can re-initialize that specific DMA and restart the operation. The traffic on the other channels does not get affected if an error is detected for a DMA Channel.

28.4.3 DMA Controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines, and a CSR space. The Tx engine transfers data from the system memory to the device port (MTL), whereas the Rx engine transfers data from the device port to the system memory. The DMA engine uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The DMA controller can be programmed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA supports up to 8 Tx and 8 Rx Descriptor lists (or DMA channels). The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. The offset is controlled by the DSL field of DMA_CHn_CONTROL register. The number of descriptors in the list is programmed in the respective Tx (or Rx) Descriptor Ring Length register. After processing the last descriptor in the list, DMA automatically jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the system memory. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

The GMAC supports the ring structure for the DMA descriptor. For more information on the descriptor, see section 28.17. Descriptors that describes the descriptor structure and how the DMA accesses the descriptors.

28.4.3.1 DMA Application Bus Burst Access

The DMA engines attempts to transfer data in a burst of maximum size as programmed in the PBL fields of Transmit Control and Receive Control registers of the respective DMA. The Rx and Tx descriptors are always accessed in the maximum possible (limited by PBL or 16 × 8/bus width) burst length for 16 bytes to be read. The burst transfers initiated by the DMA can be split into multiple burst transfers as per the Application Interface protocol (AXI) requirements and the settings of DMA_SysBus_Mode register.

The Tx DMA initiates a data transfer only when sufficient space is available in the MTL Tx Queue to accommodate either of the following:

- Bytes corresponding to the configured burst (PBL × bus_width/8)
- Remaining bytes in Tx Buffer without EOP
- Number of bytes till EOP

The Rx DMA initiates a data transfer in the following conditions:

- Sufficient data is available in MTL Rx Queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the Rx Queue

The DMA indicates the start address and the number of transfers required to the AXI master interface. When the AXI Interface is configured for fixed-length burst, it transfers the data by using the best combination of INCR4, INCR8, or INCR16 and SINGLE transactions. If EOP is reached before the fixed-burst ends on the AXI interface, dummy transfers are performed in-order to complete the fixed-burst. Otherwise [bit 0 of DMA_SysBus_Mode register is reset], the DMA transfers the data using INCR (undefined length) and SINGLE transactions.

When the AXI interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer initiated by the AXI is less than or equal to the size of the configured PBL.

Therefore, all subsequent beats start at an address that is aligned to the configured PBL.

(1) DMA Application Data Buffer Alignment

The Tx and Rx data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with address aligned to the bus width and dummy data (old data) in the invalid byte lanes. This typically happens during the transfer of the beginning or end of an Ethernet packet. The software driver should discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 28.5 Application data buffer alignment examples (1 of 2)

Buffer Read	If the Tx buffer address is 0x00000FF2 (for 32-bit data bus), and 15 bytes is to be transferred, the DMA reads five full words from address 0x00000FF0. But when transferring data to the MTL Tx queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL Tx queue, unless it is the end of packet.

Table 28.5 Application data buffer alignment examples (2 of 2)

Buffer Write	If the Rx buffer address is 0x0000FF2 (for 64-bit data bus) and 16 bytes of a received packet is to be transferred, the DMA writes 3 full words from address 0x00000FF0. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first Rx buffer of the packet. The DMA ignores the offset address and performs full word writes for the middle and the last Rx buffer of the packet.

(2) DMA Buffer Size Calculations

The DMA does not update the size fields in the Tx and Rx descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The Tx DMA transfers the exact number of bytes (indicated by buffer size field of TDES2) towards the MAC. If a descriptor is marked as first (FD bit of TDES3 is set), the DMA marks the first transfer from the buffer as SOP. If a descriptor is marked as last (LD bit of TDES3), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The Rx DMA transfers data to a buffer until the buffer is full or the end of packet is received from the MTL. When the FD bit of a descriptor is set, the amount of valid data in a buffer is accurately indicated by the buffer size field (programmed in DMA Channel Receive Control register) minus the data buffer pointer offset. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by the buffer size in bits [14:1] of Receive Control register). To compute the amount of valid data in this final buffer, the driver must read the packet length (PL bits of RDES3[14:0]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The Rx DMA always transfers the start of next packet with a new descriptor.

Note: Even when the start address of a Rx buffer is not aligned to the data width of system bus, the system should allocate a Rx buffer of a size aligned to the system bus width. For example, if the system allocates a Rx buffer of 1,024 bytes (1 KB) starting from address 0x1000, the software can program the buffer start address in the Rx descriptor to have a 0x1002 offset. The Rx DMA writes the packet to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual packet is written from location 0x1002. Therefore, the actual useful space in this buffer is 1,022 bytes, even though the buffer size is programmed as 1,024 bytes, because of the start address offset.

28.4.3.2 Transmission DMA

(1) Tx DMA Operation: Default (Non-OSP) Mode

The Tx DMA engine in default mode proceeds as follows:

1. The application sets up the Transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES3[31]) after setting up the corresponding data buffer(s) with Ethernet Packet data.
2. The application advances the Descriptor Tail pointer offset value of the Transmit Channel.
3. While in the Run state, the DMA runs an Arbitration cycle to select the next Tx DMA channel from which the packets requiring transmission should be processed.
4. The DMA fetches the descriptor from the application memory.
5. If the DMA detects one of the following conditions, the transmission from that channel is suspended and bit 2 and bit 16 of Status Register of corresponding DMA channel are set and the Tx Engine proceeds to step 11:
   - The descriptor is flagged as owned by the application (TDES3[31] = 0)
   - The Descriptor Tail pointer is equal to the Current Descriptor pointer in Ring Descriptor list Mode
   - An error condition occurs
6. If the acquired descriptor is flagged as owned by the DMA (TDES3[31] = 1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
7. The DMA fetches the Transmit data from the system memory and transfers the data to the MTL for transmission.
8. If an Ethernet packet is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3 through 7 are repeated until the end of Ethernet-packet data is transferred to the MTL.
9. When packet transmission is complete, if IEEE 1588 Timestamp feature was enabled for the packet (as indicated in the Tx status), the timestamp value obtained from MTL is written to the Tx descriptor (TDES0 and TDES1) that

contains the EOP buffer. The status information is written to this Tx descriptor (TDES3). The application now owns this descriptor because the Own bit is cleared during this step.
If timestamp feature is not enabled for this packet, the DMA does not alter the contents of TDES0 and TDES1.
By default, the Tx DMA places subsequent request after the current descriptor write request is completed to the descriptor memory. If posted descriptor write is enabled by setting DSPW bit in DMA_Mode register, the Tx DMA places subsequent request after the current descriptor write request is placed without waiting for its completion, thereby improving the throughput.

10. Bit 0 of Status register of corresponding channel is set after completing transmission of a packet that has Interrupt on Completion (TDES2[31]) set in its Last Descriptor. The DMA engine returns to step 3.
11. In the Suspend state, the DMA tries to acquire the descriptor again (and thereby return to step 3). A poll demand command is triggered by writing any value to the DMA_CH0_TxDesc_Tail_Pointer when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. If the application stopped the DMA by clearing bit 0 of Transmit Control register of corresponding DMA channel, the DMA enters the Stop state.
In non-OSP mode, it is not required for the driver/application to extract the packet status and release the descriptor for the packet, even though FD is set to 1. The driver must track the descriptor that has OWN = 0 and LD = 1, as 1; such a descriptor contains the transmission status for the packet. This indicates that descriptors up to this descriptor can be released for reuse by the driver/application for subsequent packets.

The Tx DMA transmission flow in default mode is shown in Figure 28.3.

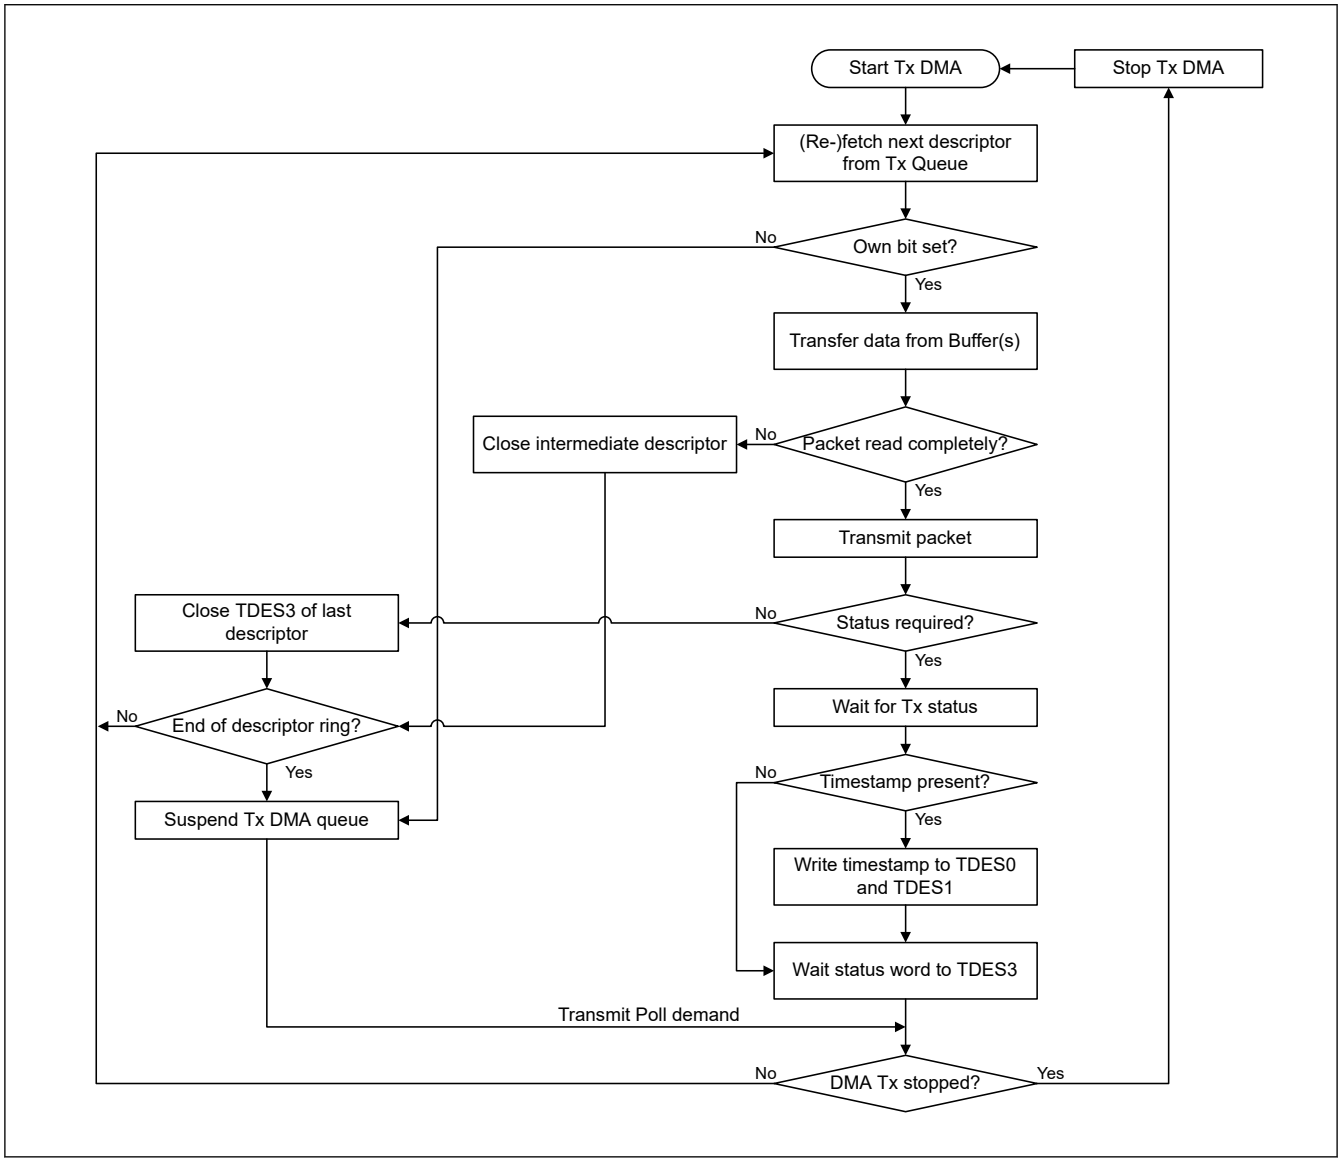


Figure 28.3 Tx DMA operation in default mode

(2) Tx DMA Operation: OSP Mode

In the Run state, if bit 4 is set in the Transmit Control Register of corresponding DMA channel, the Transmit process can simultaneously acquire two packets without closing the Status descriptor of the first packet. As the Transmit process finishes transferring the first packet, it immediately polls the Transmit Descriptor list for the second packet. If the second packet is valid, the Transmit process transfers this packet before writing the status information of the first packet.

In OSP mode, the Run state Tx DMA operates in the following sequence:

1. The DMA operates as described in step 1 to step 7 of the Tx DMA (default mode).
2. The DMA fetches the next descriptor without closing the last descriptor of previous packet.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to step 7.
4. The DMA fetches the Transmit packet from the system memory and transfers the packet to the MTL until the EOP data is transferred, closing the intermediate descriptors if this packet is split across multiple descriptors.
5. The DMA waits for the packet transmission status and timestamp of previous packet. When the status is available, the DMA writes the timestamp to TDES0 and TDES1 if such timestamp was captured (as indicated by a status bit). The DMA writes the status, with a cleared Own bit, to the corresponding TDES1, thus closing the descriptor.
   If Timestamp feature is not enabled for the previous packet, the DMA does not alter the contents of TDES2 and TDES3.
6. The Transmit interrupt is set (if enabled). The DMA fetches the next descriptor and proceeds to step 3 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (step 7).
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA does the following:
   (a) Writes the timestamp (if enabled for the current packet) to TDES0 and TDES1
   (b) Writes the status to the corresponding TDES1
   (c) Sets relevant interrupts and returns to Suspend mode

   If no status is pending and the application stopped the DMA by clearing bit 0 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state.
8. The DMA can exit Suspend mode and enter the Run state (goes to step 1 or step 2 depending on pending status) only after receiving a Transmit Poll demand in Transmit Descriptor Tail Pointer register of corresponding channel.

Note:
- The DMA fetches the next descriptor before closing the current descriptor. Therefore, the descriptor ring length must be more than two. Synopsys recommends having a minimum descriptor length of four.
- In the OSP mode, all except the last descriptor is closed immediately. The last descriptor is closed after the packet is transmitted on the line. Therefore, to minimize the complexity, the transmission status and only the required control bits are updated in the pending last descriptor of the previous packet.

The Tx DMA transmission flow in default mode is shown in Figure 28.4.

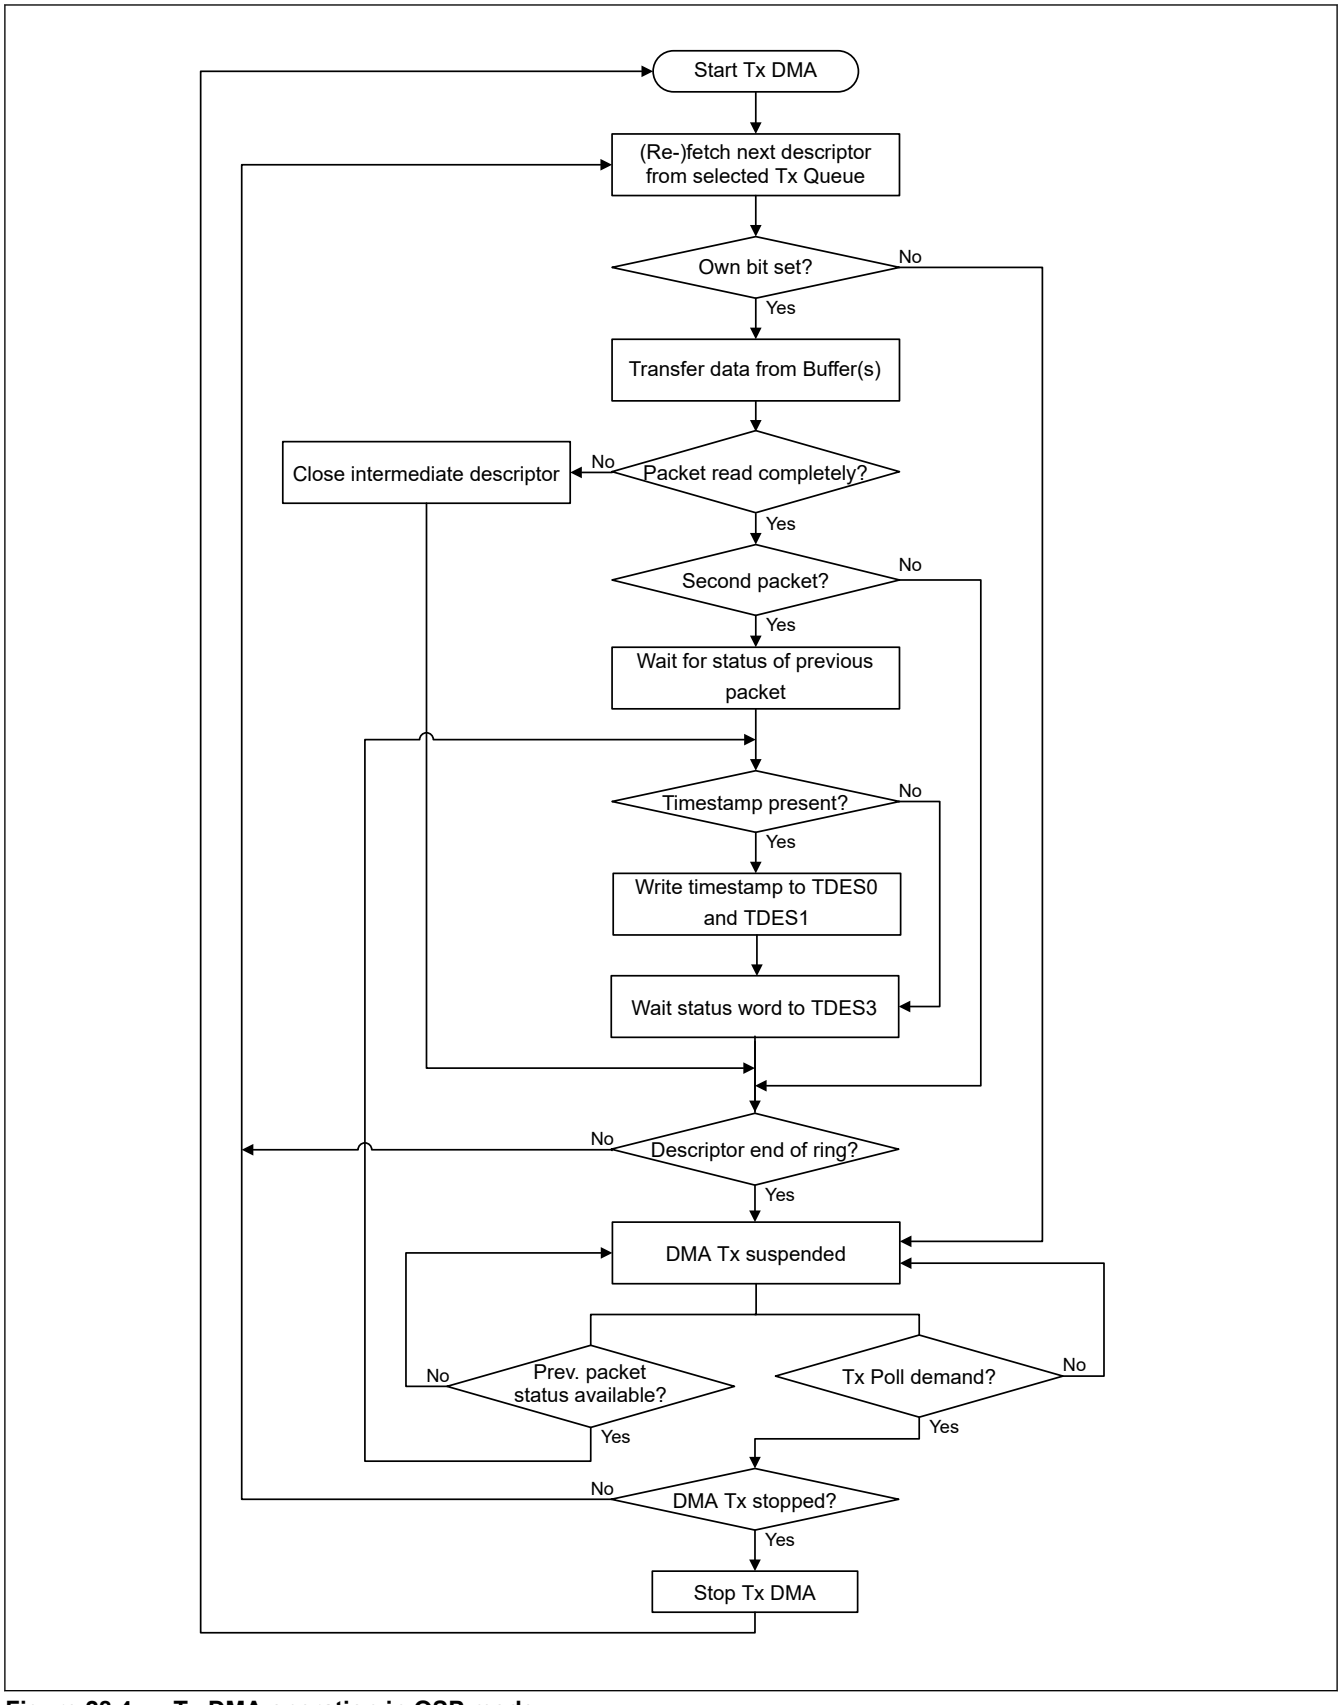

Figure 28.4 Tx DMA operation in OSP mode

(3) Transmit Packet Processing

The Tx DMA expects that the data buffers contain complete Ethernet packets, excluding preamble, pad bytes, and FCS fields. The DA, SA, and Type/Length fields contain valid data. If the Tx Descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet packets (excluding preamble), including the CRC bytes.

Packets can be data-chained and can span several buffers. Packets must be delimited by the First Descriptor (TDES3[29]) and the Last Descriptor (TDES3[28]). As transmission starts, the First Descriptor must have TDES3[29] set. When this occurs, the packet data is transferred from the application buffer to the MTL Tx Queue. Concurrently, if the current packet has the Last Descriptor (TDES3[28]) clear, the Tx Process attempts to acquire the Next Descriptor. The Tx Process expects this descriptor to have TDES3[29] clear. If TDES3[28] is clear, it indicates an intermediary buffer. If TDES3[28] is set, it indicates the last buffer of the packet.

After the last buffer of the packet has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 3 (TDES3) word of the descriptor that has the Last Descriptor bit set in Transmit Descriptor 3 (TDES3[28]). At this time, if Interrupt on Completion (TDES2[31]) is set, bit 0 of Status Register of corresponding DMA channel is set, the Next Descriptor is fetched, and the process repeats. The actual packet transmission begins after either of the following:

- The MTL Tx Queue has reached a programmable Transmit threshold (bits [6:4] of Transmit Operation Mode register of corresponding MTL Transmit Queue)
- A full packet is contained in the FIFO

You can also use the store-and-forward mode (bit 1 of MTL Transmit Operation Mode Register of a queue). In this mode, descriptors are released (Own bit TDES0[31] clears) when the DMA finishes transferring the packet.

Note: To ensure proper transmission of a packet and the next packet, you must specify a non-zero buffer size for the Transmit descriptor that has the Last Descriptor (TDES3[28]) set.

(4) Transmit Polling Suspended

Transmit polling can be suspended by any of the following conditions:

- The DMA detects a descriptor owned by the application (TDES3[31] = 0).
  To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command by writing the Tail Pointer register. If the DMA goes into SUSPEND state because of this condition, bit 15 and bit 2 of Status Register of corresponding DMA channel are set.
- A packet transmission is aborted when a Transmit error is detected because of underflow.
  The appropriate Transmit Descriptor 3 (TDES3) bit is set. When this condition occurs, the following bits are set and the information is written to Transmit Descriptor 0, causing the suspension:
  - Bit 14 of Status Register of corresponding DMA channel
  - Transmit Underflow bit of corresponding queue in MTL_Interrupt_Status
- The DMA detects that the Tail Pointer is equal to the Current descriptor closed by the it.
  To resume, the software driver must modify the Tail Pointer register.

In all conditions, the position in the Transmit List is retained. The retained position is that of the descriptor following the Last Descriptor closed by the DMA. The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause.

(5) Transmit Channel Arbitration

An arbiter provides access to multiple DMAs trying to access the Bus Interface Unit (BIU). Figure 28.5 shows the arbitration process.

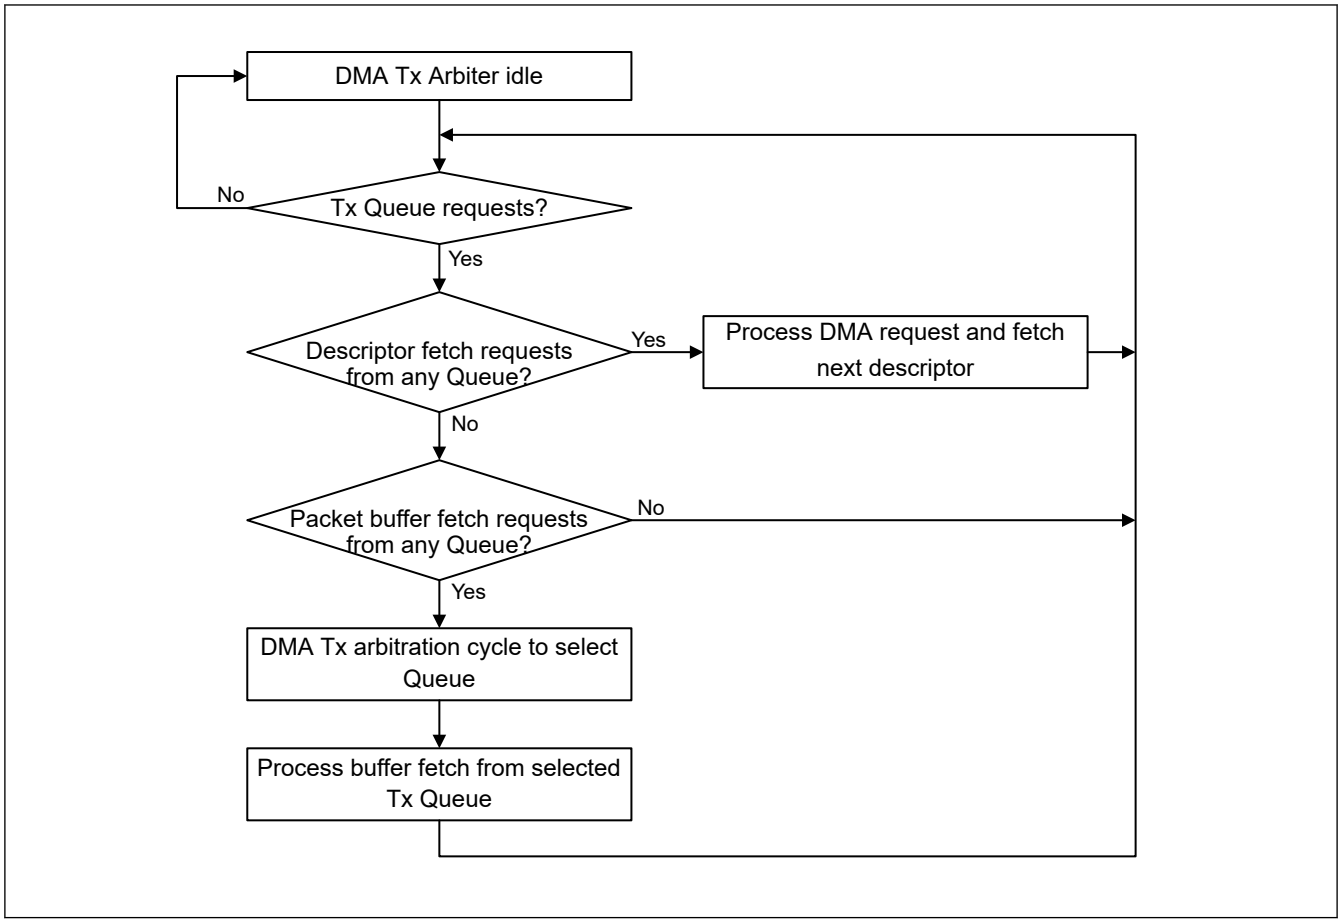

Figure 28.5 DMA transmit channel arbitration process

When there is a request in the Transmit DMA, the DMA arbiter checks the type of the request: packet buffer fetch or descriptor fetch request. The descriptor fetch requests have higher priority than the buffer requests. Therefore, when there is a descriptor fetch request, the DMA arbiter acknowledges the DMA channel that is requesting for a descriptor fetch. If there is no descriptor fetch request, the arbiter looks for packet buffer fetch requests.

The DMA arbiter acknowledges the descriptor fetch request of one DMA channel at a time. Descriptor fetch requests are granted using a fixed priority with the higher channel having higher priority (Channel 1 having priority over Channel 0, Channel 2 having priority over Channel 1 and so on). For packet buffer fetches, the DMA arbiter uses the programmed channel weight and priority to decide which channel to acknowledge. The DMA arbiter performs a burst-by-burst arbitration based on one of the following algorithms, which can be selected by programming the TAA field of the DMA_Mode register. For details, see the DMA_Mode register description.

- Weighted Strict Priority (WSP): In WSP arbitration mode, the arbiter first processes Channel 7 (or the last selected channel) followed by Channel 6, Channel 5, and so on. If a channel does not have a frame to transmit, the weight of the channel is reassigned to Channel7 (or the last selected channel). If Channel 7 has no frames to transmit, the remaining weight is assigned to Channel 6 and so on.
- Weighted Round Robin (WRR): In WRR arbitration mode, the arbiter first selects the channel with the highest weight programmed, and then the channel with next highest weight, and so on. If any channel does not have a frame to transmit, the weight of that channel gets equally distributed to all channels that have frames to transmit. The weight of the channel is programmed in the TCW field of the DMA_CHn_TX_CONTROL register.
- Fixed priority (FP): In Fixed priority mode, Channel 0 has the lowest priority and the last selected channel has the highest priority. The weight programmed in the Transmit Control register of a channel is ignored.

In WSP or WRR arbitration, the channel weight corresponds to the number of DMA burst transfers for which the DMA arbiter grants the bus to a channel. When a channel completes all the DMA burst transfers, the arbiter grants the bus to the next channel.

28.4.3.3 Receive DMA

(1) RX DMA Operation

In the Receive path, the DMA reads a packet from the MTL receive queue and writes it to the packet data buffers of the corresponding DMA channel. The ARI data at the start of the frame indicates the channel number to which the current frame must be written. If only one DMA channel is selected, this information is not provided.

Figure 28.6 shows the reception sequence for Rx DMA engine. The following list describes this sequence:

1. The application sets up the Rx descriptors (RDES0-RDES3) and the Own bit (RDES3[31]).
   The application must set the correct value in the Receive Descriptor Tail Pointer register of corresponding DMA channel.
2. When bit 0 of Receive Control register of corresponding DMA channel is set, the DMA enters the Run state.
   The DMA looks for free descriptors based on the Rx Current Descriptor and Descriptor Tail Pointer register values. If there are no free descriptors, the DMA Channel enters the suspend state and goes to step 11.
3. The DMA fetches the next available descriptor in the ring and decodes the receive data buffer address from acquired descriptors.
4. If IEEE 1588 timestamping is enabled and the timestamp is available for the previous packet, the DMA writes the timestamp (if available) to the RDES0 and RDES1 of current descriptor and sets the CTXT field (RDES3[30]).
5. The DMA processes the incoming packets and places these in the data buffers of acquired descriptor.
6. If the current packet transfer is not complete, the DMA closes the current descriptor as intermediate and goes to step 10.
7. The DMA takes the status of the Receive frame from the MTL and writes the status word to current descriptor with the Own bit cleared and the Last Descriptor bit set.
8. The DMA writes the Frame Length to RDES3 and VLAN Tag to RDES0. The DMA also writes the MAC control frame opcode, OAM control frame code, and extended status information (if available) to RDES1 of the last descriptor.
9. If IEEE 1588 Timestamp feature is enabled, the DMA stores the timestamp (if available). The DMA writes the context descriptor after the last descriptor for the current packet (in the next available descriptor).
10. If more descriptors are available in the Rx DMA Descriptor Ring, go to step 3; otherwise, go to the Suspend state (step 11).
11. The Receive DMA exits the Suspend state when a Receive Poll demand is given and the application advances the Receive Tail Pointer register of a channel.

The engine proceeds to step 2 and re-fetches the next descriptor.

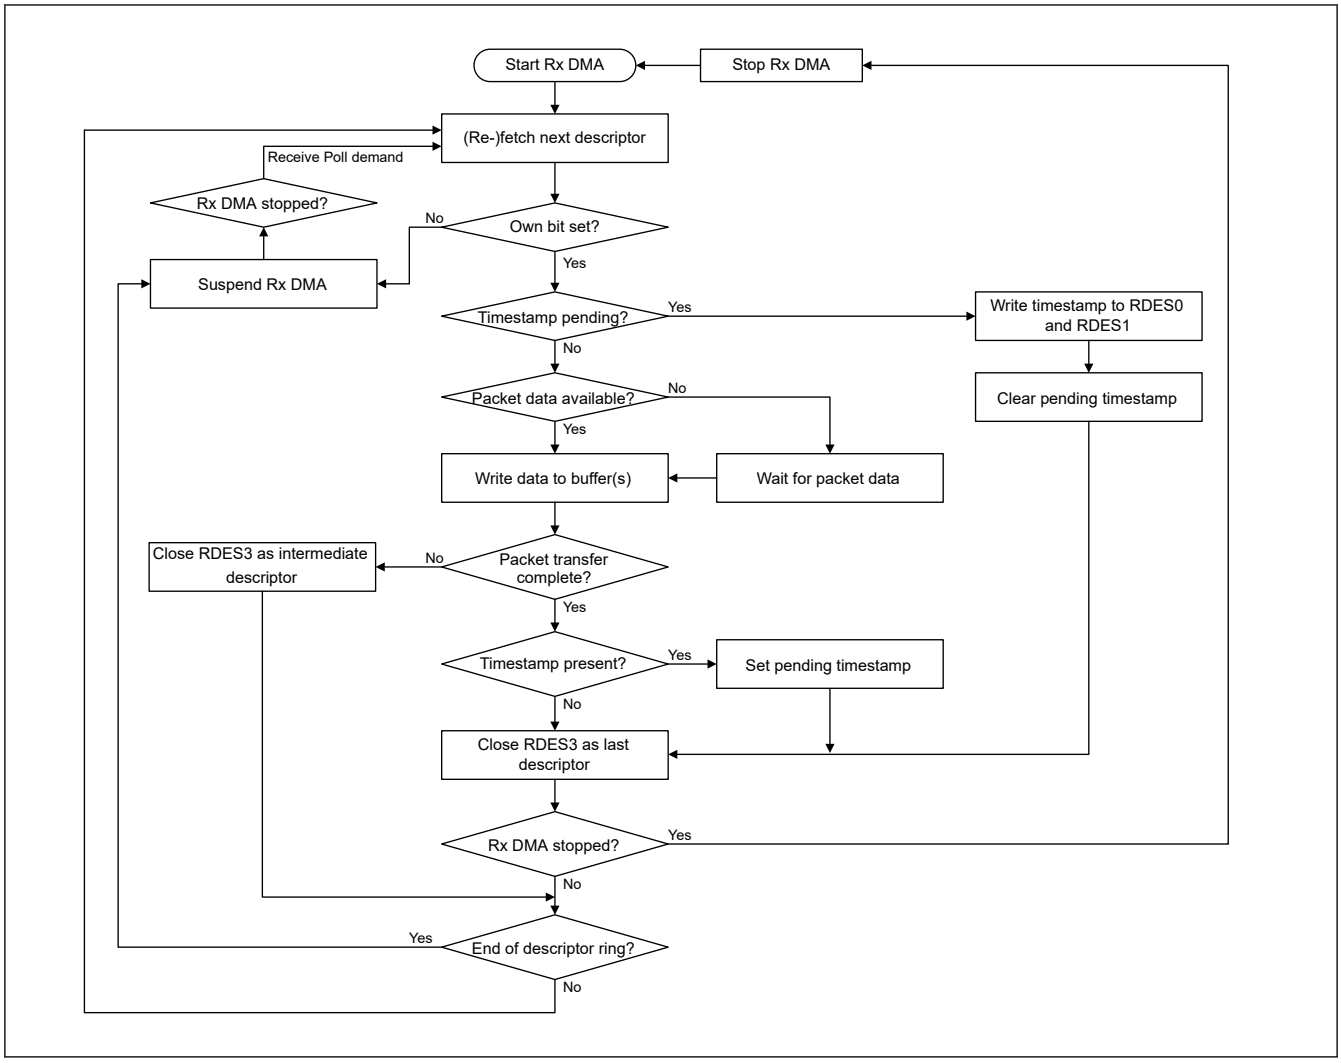

Figure 28.6 Rx DMA operation

(2) Receive Descriptor Acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming packet. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- Bit 0 of Receive Control Register of corresponding DMA channel is set immediately after being placed in the Run state.
- The Descriptor Tail pointer register value is ahead of the Current Descriptor acquired by the Rx DMA.
- The controller has completed packet reception, but the current Receive Descriptor is not yet closed.
- A Receive poll demand is issued (update of the Tail Pointer register).

(3) Receive Packet Processing

The sequence for processing a Receive packet is as follows:

1. The MAC transfers the received packets to the MTL memory only if the packet passes the address filter. If the packet fails the address filtering, it is dropped in the MAC block (unless bit 31 of MAC_Packet_Filter register is set).
2. If packet size is greater than or equal to configurable threshold bytes set for Rx Queue of MTL, or when the complete packet is written to the queue in the store-and-forward mode, the MTL block requests the DMA block to begin transferring the packet data to the Receive Buffer pointed by the current descriptor.
   Packets smaller than 64 bytes, because of collision or premature termination, are removed from the MTL Receive Queue.
3. When the DMA application Interface (AXI) becomes ready, it transfers the data and sets the following:

- If the packet fits in a single descriptor, the DMA sets both Last Descriptor (RDES3[28]) and First Descriptor (RDES3[29]).
- If the packets fit into more than one descriptor, the DMA sets the First Descriptor (RDES3[29]) to delimit the packet.

4. The DMA releases the descriptors by resetting the Own (RDES3[31]) bit to 0, either because the Receive buffer filled up or the last segment of the packet is transferred to the Receive buffer. The received packets status is updated in the last descriptor.
5. If Interrupt Enabled on Completion (RDES3[30]) bit is set in any of the Descriptors between the First and Last Descriptor of the Packet and bit 6 of Interrupt Enable register of corresponding DMA channel is set, the DMA sets bit 6 of Status register of corresponding DMA channel.

The same process repeats unless the DMA encounters a descriptor flagged as being owned by the application or when there are no more descriptors in the ring. When the DMA finds a descriptor owned by the application and if bit 7 of Interrupt Enable register of corresponding DMA channel is set, the Receive Process sets bit 7 of Status register of corresponding DMA channel and then enters the Suspend state. The position in the receive list is retained.

28.4.4 Transmit and Receive FIFOs

The Transmit FIFO (Tx FIFO) buffers the data transferred from the application to the GMAC. Similarly, the Receive FIFO (Rx FIFO) stores the packets received from the line until they can be transferred to the application. These are asynchronous FIFOs because they also transfer the data between the application clock and the MAC line clocks. TX FIFO and RX FIFO size are 8 KB respectively.

When multiple queues are selected, all Tx queues share the Tx FIFO memory and all Rx queues share the Rx FIFO memory. The application can program the size of the FIFO memory allocated to each Tx or Rx queue.

28.4.5 MAC Transaction Layer

The MAC Transaction Layer (MTL) provides the FIFO memory Interface to buffer and regulate the packets between the application system memory and the MAC. It also enables the data to be transferred between the application clock and MAC clock domains. The MTL layer has two data paths: Transmit path and Receive Path. The data path for both directions is 128-bit wide.

The MTL communicates with the application through Application Transmit Interface (ATI) on the Transmit path and Application Receive Interface (ARI) on the Receive path. The MTL also provides the MAC Control Interface (MCI) as a control path.

28.4.5.1 Transmit Path

The internal DMA handles all transactions for the Transmit path through ATI.

The internal DMA pushes the Ethernet packets read from the system memory into the corresponding queue. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the internal DMA.

The Tx queue has a default size of 2 KB. The fill level of the queue is indicated to the internal DMA (using PBL and watermark) so that it can initiate a data fetch in required bursts from the system memory. The internal DMA indicates the SOP and EOP as packet delimiters through ATI interface. In configurations with multiple queues, the internal DMA should also indicate the queue number for which the transaction is being addressed.

(1) Transmit Control Word

The following control information related to packet transmission is provided as a part of the Control Word through ATI interface:

- CRC Pad Control
- TCP/IP Checksum Insertion Control
- One-step Timestamping Control Correction
- Transmit Timestamp Enable

(2) Transmit Operation

The following two modes of operation trigger reading of the data towards the MAC:

- Threshold mode:
  In Threshold (or cut-through) mode, as soon as the number of bytes in the Queue cross the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to the MAC. The threshold level is configured by using the TTC bits of MTL_TxQ0_Operation_Mode register corresponding to an MTL queue.

- Store-and-forward mode:
  In store-and-forward mode, the MTL pops out the packet towards the MAC only when one or more of the following conditions are true:
  - A complete packet is stored in the Queue
  - The Tx FIFO becomes almost full
  - The ATI watermark becomes low

  The watermark becomes low when the requested Queue does not have space to accommodate the requested burst length on the ATI. Therefore, the MTL when operating in the store-and-forward mode allows packet transmission even if the packet length is bigger than the Tx Queue size.

The application can flush complete content of the Tx Queue by setting bit 0 (FTQ) of Transmit Operation Mode register corresponding to an MTL queue. This bit is self-clearing and initializes the Queue pointers to the default state. If the FTQ bit is set during a packet transfer from the MTL to the MAC, the MTL stops further transfer because the queue is considered to be empty. Therefore, an underflow event occurs at the MAC transmitter.

For information about the initialization and transmit operations for the MTL Layer, see (3) Initialization Flow through (8) Transmit Queue Flush Operation.

(3) Initialization Flow

Upon reset, the MTL is ready to manage the flow of data to and from the DMA and MAC. You need to initialize the Queue size for each of the queues by programming the TQS bits of MTL_TxQ0_Operation_Mode register corresponding to a Transmit queue. You also need to initialize the MAC block. The internal DMA controllers must be individually enabled through their respective CSRs.

(4) Single-Packet Transmit Operation

The following flow is valid when the GMAC is operating in non-OSP mode, that is, when bit 4 (OSP) of the DMA_CHn_TX_CONTROL (n = 0 to 7) register of the DMA channel is set to 0.

During a Transmit operation, the MTL block is a slave for the DMA controller. The general sequence of events for a Transmit operation is as follows:

1. If the system has data to be transferred, the DMA controller fetches the data from the application through the AXI master interface and starts forwarding it to the MTL. The DMA descriptor memory contains the information related to packet control which is used to drive the ATI Control Word. The DMA data buffer memory contains the packet data.
2. The MTL pushes the data received from the DMA into the corresponding queue. This process continues until the EOP is transferred.
3. When the threshold level is crossed or a full packet of data is received into the queue, the MTL reads the packet data and drives it to the MAC.
4. The queue controller continues to transfer data from the queue until a complete packet is transferred to the MAC.
5. When the packet transfer is complete, the MTL receives the status from the MAC and notifies the DMA controller.

Figure 28.7 shows the MTL single-packet transmit operation.

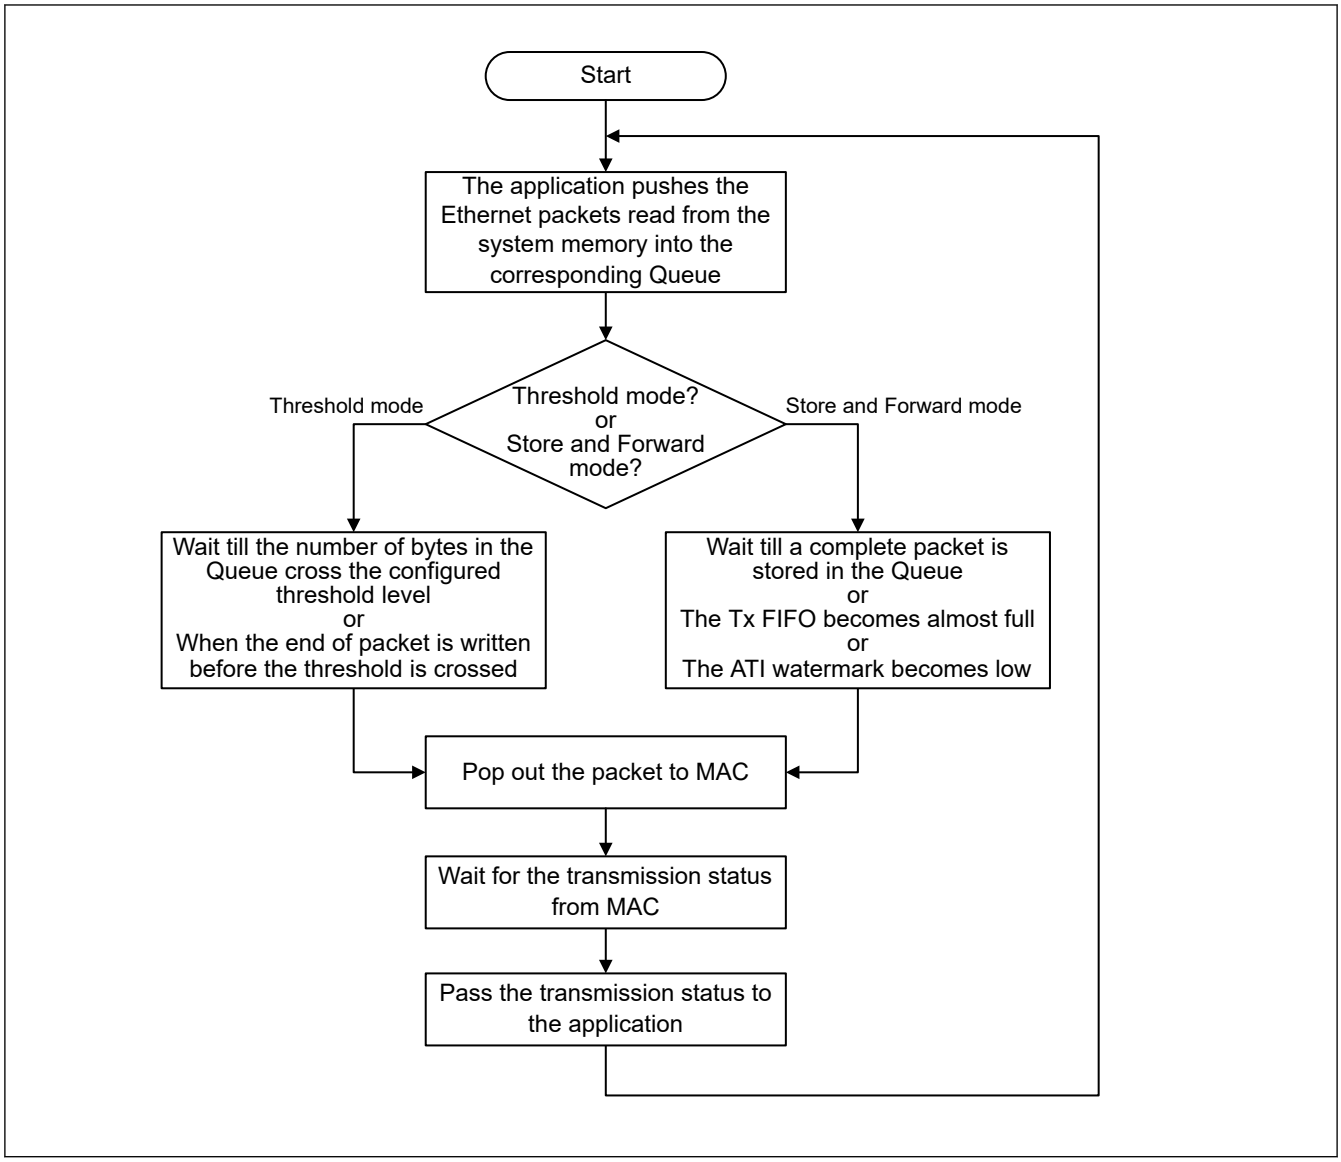

Figure 28.7 MTL single packet transmit flow

Note: When bit 1 (DTXSTS) of MTL_Operation_Mode register is set, the MTL does not provide any status to the DMA.

(5) Transmit Operation - Two Packets in the Buffer

The following flow is valid when the GMAC is operating in OSP mode, that is, when bit 4 (OSP) of the DMA_CHn_TX_CONTROL (n = 0 to 7) register of the DMA channel is set to 1.

The flow is similar to the flow described in (4) Single-Packet Transmit Operation. However, after fetching a packet DMA instead of waiting for the status, it continues to fetch another packet if available in the system memory. So, MTL can receive the second packet while it is processing the first packet. This flow improves the performance because the DMA can process two packets back to back before waiting for the status of the first packet.

(6) Relationship Between the Number of Tx DMA Channels and Tx Queues

The number of Tx DMA channels is always equal to the Tx queues. This is because the DMA is designed to arbitrate among multiple channels (to fetch the descriptor and packet data from the system memory) in terms of PBLs (Programmable Bursts Lengths). However, the Tx queues are packet-based storage memory. Therefore, one to one mapping is required between the DMA channels and Tx queues to maintain the packet-level coherency.

(7) Retransmission During Collision

While a packet is being transferred from the MTL to the MAC, a collision event can occur on the MAC line interface in half-duplex mode. The MAC indicates a Retry attempt to the MTL by giving the status even before the EOP is transferred from the MTL. The MTL then enables the retransmission by popping out the packet again from the queue.

After more than 96 bytes (or 548 bytes in 1000-Mbps mode) are read out towards the MAC, the Queue Controller frees up that space and makes it available to the application or the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the MAC indicates a late-collision event.

When a packet transmission is aborted because of underflow and a collision event immediately follows (initiating a retry), retry has higher priority than abort.

(8) Transmit Queue Flush Operation

The MTL allows a Tx Queue to be flushed at any moment through bit 0 of MTL_TXQn_OPERATIOn_MODE (n = 0 to 7) register.

1. The application pushes two packets into the Tx queue on the ATI interface.
2. The application performs a write to the Transmit Operation mode register of corresponding MTL queue and sets the Flush Transmit Queue bit.
3. The application reads back the same register to check the status of the Flush operation. The bit [0] is asserted high during CSR read access, indicating the progress of the Flush operation.
4. If the MTL has already transferred a (partial) packet to the MAC, then it terminates that immediately and clears the Tx Queue. The MTL waits for the status of the partial/full packet transfers to the MAC.
5. The MTL indicates the completion of the Flush operation by asserting internal signal, which clears bit 0 in Transmit Operation Mode register of corresponding MTL queue.

28.4.5.2 Receive Path

The MTL Rx module receives the packets from the MAC and pushes them into the Rx Queue. The status (fill level) of the queue is indicated to the DMA when it crosses the configured Receive threshold (RTC bits [1:0] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue), or the complete packet is received. The MTL also indicates the fill level of the queue so that the DMA can initiate preconfigured burst transfers towards the AXI interface.

(1) Receive Operation

During a Receive operation, the MTL is a slave for the MAC. The general sequence of events is as follows:

1. When the MAC receives a packet, it indicates the availability of receive data.
2. The MAC indicates the SOP and EOP delimiters.
3. The MTL accepts the data and pushes it into corresponding Rx queue.
4. After the EOP is transferred, the MAC drives the status word which is also pushed into the corresponding Rx queue by the MTL.
   In Threshold (cut-through) mode, the status words are stored after the packet EOP. In store-and-forward mode, the location for the maximum status words are reserved before writing the SOP and the status is written to reserved locations after writing the EOP.
5. If IEEE 1588 timestamp feature is enabled and the 64-bit timestamp is available along with the packet status, it is pushed into the Rx queue as a part of the status word. Therefore, one additional location is taken per packet to store the timestamp in the Rx queue.
6. The MTL takes the data out of the queue and sends it to the DMA depending on the mode.

(2) Threshold Mode

In the (default) Threshold mode, the MTL reads the data and indicates its availability to the DMA when one of the following occurs:

- Data bytes equal to the threshold amount are written to the Rx queue (RTC bits [1:0] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue)
- A full packet of data is received into the queue

Note: The MTL operates in dynamic threshold mode even though it is programmed for threshold mode. In dynamic threshold mode, MTL starts forwarding to the application only after it receives threshold number of bytes, split-header length, and DMA number from MAC.

(3) Store-and-Forward Mode

In the store-and-forward mode (when bit 5 of MTL_RxQ0_Operation_Mode register of a queue is set to 1), the initial Rx queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the Rx queue. In this mode, all error packets are dropped (if configured through bit 4 of MTL_RxQ0_Operation_Mode register of a queue) such that only valid packets are read and forwarded to the application.

(4) Multi-Packet Receive Operation

In Threshold mode, the packet status is available immediately after the packet data. In store-and-forward mode, the packet data is available after the packet status. The MTL is capable of storing any number of packets into the queue as long as it is not full.

If the MAC receives a packet when the corresponding Rx queue is full, the MTL ignores that packet. In addition, the MTL increments the overflow counter in the MTL_RxQ0_Missed_Packet_Overflow_Cnt of corresponding queue.

(5) Error Handling in Receive Operation

If the MTL Rx queue is full before it receives the EOP data from the MAC, the following happens:

1. An overflow is declared

2. The whole packet (including the status word) is dropped

3. The overflow counter in the DMA (Overflow Counter register of corresponding MTL queue) is incremented.

This is true even if bit 4 (FEP) of MTL_RxQ0_Operation_Mode register of corresponding MTL queue is set.

If the start address of such a packet has already been transferred to the Read Controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the Packet Length field is invalid. If the MTL Receive Queue is configured to operate in the store-and-forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL Rx Control logic can filter error and undersized packets, if enabled by using the FEP and FUP bits of MTL_RxQ0_Operation_Mode register of corresponding MTL queue. If the start address of such a packet has already been transferred to the Rx Queue Read Controller, that packet is not filtered. The start address of the packet is transferred to the Read Controller after the packet crosses the receive threshold set by bits [1:0] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue.

If the MTL Receive Queue is configured to operate in the store-and-forward mode, all error packets can be filtered and dropped. The MTL then stops transferring data to the DMA. It internally reads the rest of the packet and drops it. The MTL then starts the transfer of next packet (if available).

28.4.6 MAC

28.4.6.1 MAC Transmission

The MAC communicates with the application side with the MAC Transmit Interface (MTI), MAC Receive Interface (MRI), and MAC Control Interface (MCI).

The MAC transmission process is as follows:

1. Transmission is initiated when the MTL application pushes in data with the SOP signal asserted.
2. When the SOP signal is detected, the MAC accepts the data and begins transmitting to the GMII or MII.
   The time required to transmit the packet data to the GMII or MII after the application initiates the transmission depends on delay factors such as IPG delay, time to transmit preamble or SFD, and any back-off delays for half-duplex mode. While the packets data is being transmitted, the MAC can stop accepting the data received from the MTL.
3. After the EOP is transferred to the MAC, the MAC does one of the following:
   - The MAC completes the normal transmission and gives the transmission status to the MTL.

- If a normal collision (in half-duplex mode) occurs during transmission, the MAC gives the Transmit Status with retry bit set to the MTL. The MAC gives the Retry request till one of the following is true:
  - Packet is successfully transmitted
  - Maximum retry requests expire
    When maximum retry requests expire, the MAC aborts the packet transmission with Excessive Collision Transmit Status. The MAC accepts and drops all further data until the next SOP is received. The MTL block should retransmit the same packet from SOP on observing a Retry request (in the Status) from the MAC.
- If any one of the following occurs, the MAC aborts the packet transmission:
  - No carrier (half-duplex mode)
  - Loss of carrier (half-duplex mode)
  - Excessive deferral (half-duplex mode)
  - Late collisions (half-duplex mode)
  - Jabber

  The MAC accepts and drops all further data until the next SOP is received.

4. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received.
5. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet.

Figure 28.8 shows the MAC transmission process flow.

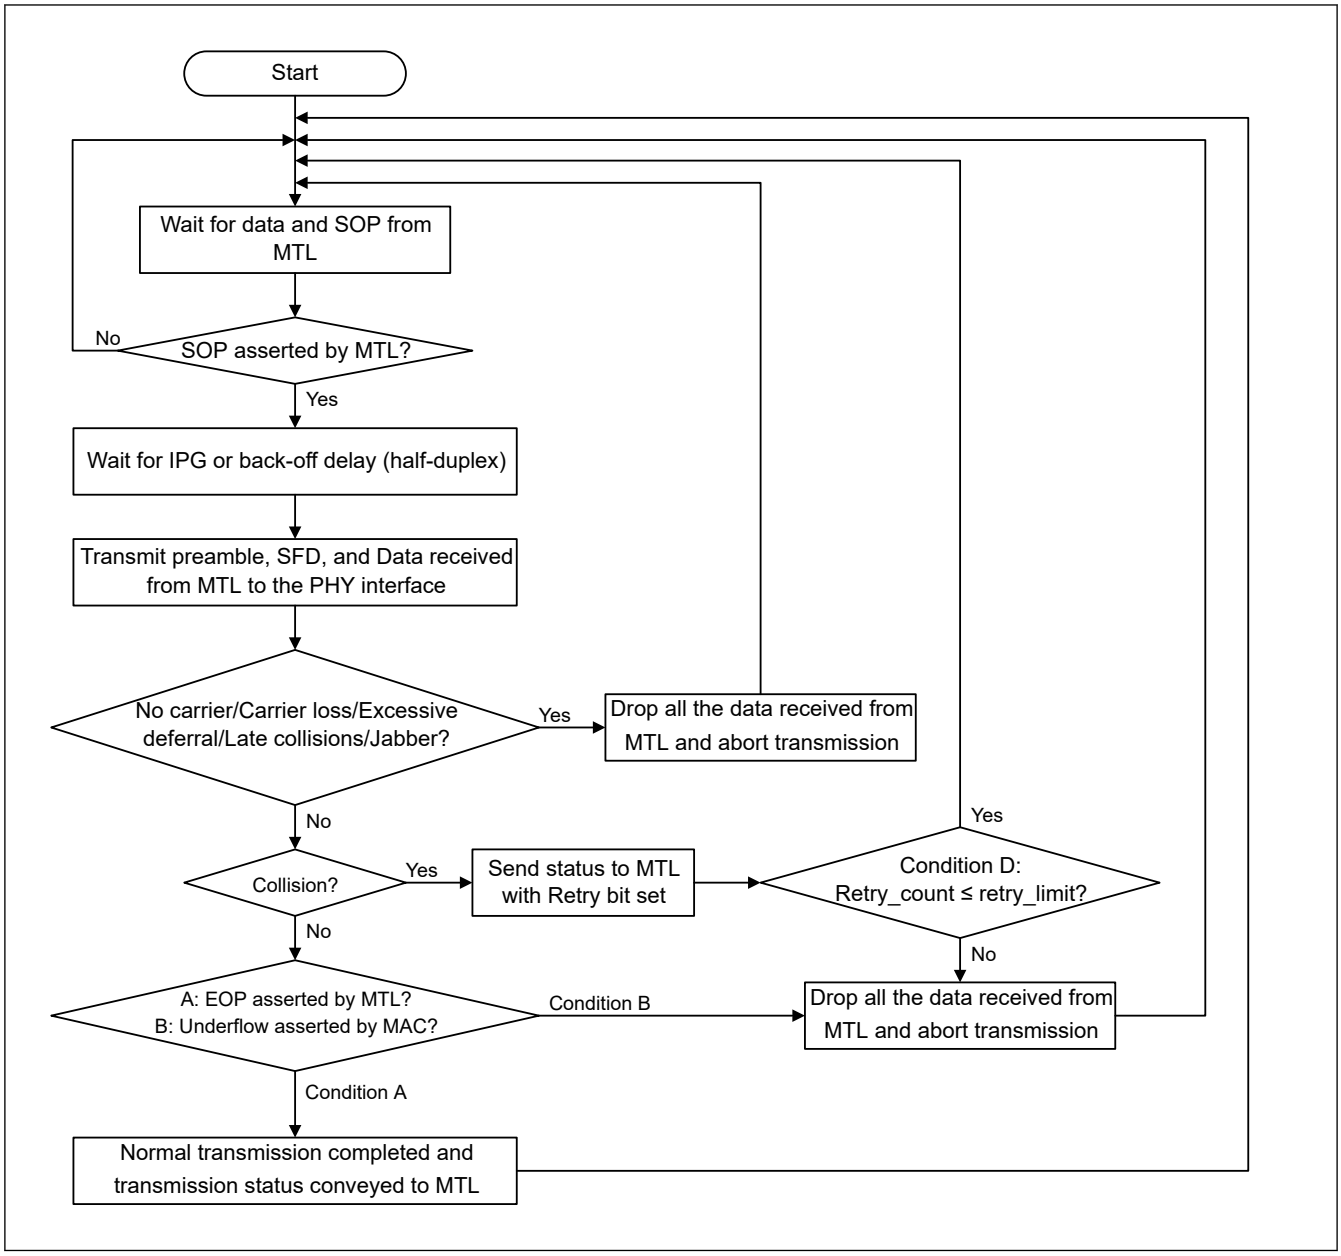

Figure 28.8 Overview of MAC transmission process flow

(1) Transmit Bus Interface Module

The MAC Transmit Bus Interface (TBU) accepts data in 128-bit wide bus and runs on the TX_CLK of GMII interface. The TBU module performs the following functions:

- Outputs the Transmit status to the application at the end of normal transmission or collision
- Outputs the Transmit snapshot register value
- Performs the Endian conversion of data bus by swapping the byte lanes and corresponding byte enables
- Converts the input data into an 8-bit bus towards the Transmit Packet Controller

(2) Transmit Packet Controller Module

The Transmit Packet Controller (TPC) module consists of eight registers to hold the data and the last data control received from the TBU.

The register provides a buffer between the application and the Transmit Protocol Engine (TPE) to regulate data flow.

When the number of bytes received from the application are less than 60 (DA+SA+LT+DATA), the state machine that interfaces with TBU automatically appends zeros to the packet being transmitted. This is done to make the data length

exactly 46 bytes to meet the minimum data field requirement of IEEE 802.3. You can program the MAC to not append any padding.

The cyclic redundancy check (CRC) for the Frame Check Sequence (FCS) field is calculated before transmission to the TPE module. This value is computed by the CTX module. The TPC module receives the computed CRC and appends it to the data being transmitted to the TPE module. When the MAC is programmed to not append the CRC value to the end of Ethernet packets, the TPC module ignores the computed CRC and transmits only the data received from the TBU module to the TPE module. An exception to this rule is that when the MAC is programmed to append pads for packets (DA+SA+LT+DATA) less than 60 bytes sent by the TBU module, the TPC module appends the CRC at the end of padded packet irrespective of the setting value.

(3) Transmit Protocol Engine Module

The Transmit Protocol Engine (TPE) module consists of a Transmit State Machine that controls the operation of Ethernet packet transmission.

The Transmit State Machine of this module contains the following features to meet the IEEE 802.3/802.3z specification:

- Generates preamble and SFD
- Generates jam pattern in the half-duplex mode after normal collision
- Generates carrier extension in the half-duplex (only in the GMII) mode when packet is smaller than 512 bytes
- Supports packet bursting in the half-duplex (only in the GMII) mode
- Supports jabber timeout
- Supports flow control for the half-duplex mode (backpressure)
- Generates Transmit packet status
- Contains timestamp snapshot logic for IEEE 1588 support

When the TPC module requests the TPE module for a new packet transmission, the Transmit State Machine sends out the preamble and SFD, followed by the data received. The preamble is defined as 7 bytes of 10101010b pattern and the SFD is defined as 1 byte of 10101011b pattern.

The collision window is defined as 1 slot time (512-bit times for 10/100 Mbps Ethernet and 4,096-bit times for 1,000 Mbps Ethernet). The jam pattern generation is applicable only to half-duplex mode, not to full duplex mode. In full-duplex mode, the Transmit State Machine ignores the COL signal from the PHY.

In MII mode, if a collision occurs any time from the beginning of the packet to the end of the CRC field, the Transmit State Machine sends a 32-bit jam pattern of 0x55555555 on MII to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the Transmit state machine completes the transmission of preamble and SFD, and then sends the jam pattern.

In GMII mode, if a collision occurs any time between the beginning of the packet and the end of the extension field, the Transmit State Machine sends a 32-bit jam pattern of 0x55555555 on GMII to inform all other stations of the collision. If the collision is seen during the preamble transmission phase, the Transmit State Machine completes the transmission of preamble and SFD, and then sends the jam pattern. If a collision occurs during the extension field, the Transmit State Machine sends a 32-bit jam pattern of 0x1F1F1F1F.

If the collision occurs after the collision window and before the end of the FCS field (or the end of Burst if the Packet Burst mode is enabled), the Transmit State Machine sends a 32-bit jam pattern and sets the late collision bit in the Transmit packet status.

Note: At the GMII or MII interface, the collision signal being asynchronous is checked by the transmitter after it is double-synchronized to TX_CLK domain. This additional latency delays the recognition of collision or late-collision event. When the output of COL signal synchronizer is asserted after the complete packet is transmitted, it is not recognized as collision even if the COL signal is high at the GMII interface before the end of transmission. Similarly, an assertion of COL signal at the GMII input at the last byte of normal collision window might be identified as late collision because of the synchronizer delay.

In GMII half-duplex mode (1000 Mbps), the Transmit State Machine ensures that all valid carrier events exceed a slot time of 4,096-bit times. To accomplish this, any Transmit packet shorter than 512 bytes from the TFC module is extended using a carrier extension. On GMII, this is signaled to the PHY by asserting TXER, de-asserting TXEN, and setting TXD[7:0] to 0x0F.

When the Packet Burst mode is enabled, only the first packet of the burst is carrier extended if it is shorter than 512 bytes. The carrier extension is not applicable for MII half-duplex and GMII or MII full-duplex modes. When the Packet Burst mode is enabled, the Transmit State Machine transmits a burst of packets (as long as packets are available from the TFC module) without releasing the carrier of the PHY. To accomplish this, the state machine inserts the carrier extension for a minimum IPG period (96-bit times) between the packets. The Transmit State Machine continues to burst packets as long as additional packets are available from the TPC module and a burst limit of 8,192-byte times has not been exceeded. If an additional packet is not available at the end of the IPG period in the middle of the burst, the Transmit State Machine releases the carrier by de-asserting TXER and TXEN signals on GMII.

Packet bursting is applicable only for the GMII half-duplex mode. It is not applicable in the MII and GMII full-duplex modes. In the GMII half-duplex mode, the size of the first packet in a packet burst should at least be equal to the slot time. If the first packet (including carrier extension) is less than the slot time, the MAC considers all data bytes, received for the first packet and subsequent packets, which end immediately after the slot time is reached as first packet in the burst. This may result in CRC error. However, if the packet burst ends (both RXDV and RXER go low) before the slot time, the subsequent packet is considered as a new packet. This behavior is according to the IEEE 802.3.

The TPE module maintains a jabber timer to stop the transmission of Ethernet packets if the TFC module transfers more than 2,048 (default) bytes. The timeout is changed to 10,240 bytes when the Jumbo packet is enabled.

The Transmit State Machine uses the deferral mechanism for flow control (backpressure) in the half-duplex mode. When the application requests to stop receiving packets, the Transmit State Machine sends a JAM pattern of (0x55) 32 bytes whenever it senses a reception of a packet, provided the Transmit flow control is enabled. This results in a collision and the remote station backs off. The application requests the flow control by setting BPA bit of the Flow Control Register of corresponding MTL queue. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort their transmissions because of excessive collisions.

If IEEE 1588 timestamp is enabled for the Transmit packet, this block takes a snapshot of the system time when the SFD is put onto the Transmit GMII or MII bus. The system time source is an external input from ETHSW.

Note: The Collision input is an asynchronous signal and should be asserted for at least 32-bit times (4 clocks for 1Gbps, and 8 clocks for slower speeds).

(4) Transmit Module

The Transmit (STX) module is responsible for scheduling the packet transmission on GMII or MII. It provides an enable signal to the TPE module after satisfying the IPG and back-off delays. The STX module performs the following functions:

- Maintains the inter-packet gap between two transmitted packets
  The STX module maintains an idle period of the configured inter-packet gap (IPG bits of MAC_Configuration register) between any two transmitted packets. If packets from the TPC arrive at the TPE module sooner than the configured IPG time, the TPE module waits for the enable signal from the STX module before starting the transmission on GMII or MII. The STX module starts its IPG counter as soon as the carrier signal of GMII or MII goes inactive. At the end of programmed IPG value, the module issues an enable signal to the TPE module in the full-duplex mode.
  In the half-duplex mode and when IPG is configured for 96-bit times, the STX module follows the rule of deference specified in the IEEE 802.3, Section 4.2.3.2.1. The module resets its IPG counter if a carrier is detected during the first two-thirds (64-bit times for all IPG values) of the IPG interval. If the carrier is detected during the final one-third of the IPG interval, the STX module continues the IPG count and enables the transmitter after the IPG interval.
- Implements the Truncated Binary Exponential Back-off algorithm
  The STX module implements the Truncated Binary Exponential Back-off algorithm when it operates in the half-duplex mode.

(5) Transmit CRC Generator Module

The MAC Transmit CRC Generator (CTX) module interfaces with the TFC module to generate CRC for the FCS field of the Ethernet packet.

The Transmit CRC Generator (CTX) module interfaces with the TFC module to generate CRC for the FCS field of the Ethernet packet.

The TPC module sends the packet data and any necessary padding to the CTX module through an 8-bit interface.

The CTX module calculates the 32-bit CRC for the FCS field of the Ethernet packet. The encoding is defined by the following generating polynomial:

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

The CTX module gets the byte data of Ethernet packet from the TPC module (DA + SA + LT + DATA + PAD) qualified with a Data Valid signal. The TPC also indicates to the CTX when to reset the previously calculated CRC and to start the new CRC calculation for the coming packet. The TPC module issues the start command before sending the new packet data for calculation. The calculated CRC is valid on the next clock after the data is received.

In GMII mode, the Data Valid signal is valid for every clock, from the first data byte through the last data byte. In MII mode, this signal is valid every alternate clock.

(6) MAC Transmit Flow Control Module

The Transmit Flow Control (FTX) module generates and transmits the Pause packets to the TFC module based on the flow control triggers in full-duplex mode. The TFC module receives the Pause packet from the FTX module, appends the calculated CRC, and sends the packet to the TPE module. For more information about flow control, see section 28.15. Flow Control.

28.4.6.2 MAC Reception

A receive operation is initiated when the MAC detects an SFD on GMII or MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

(1) Receive Protocol Engine Module

The Receive Protocol Engine (RPE) consists of the Receive State Machine which strips the preamble, SFD, and carrier extension of the received Ethernet packet (in half-duplex 1000-Mbps mode).

Figure 28.9 shows the Receive transmission flow in the RPE.

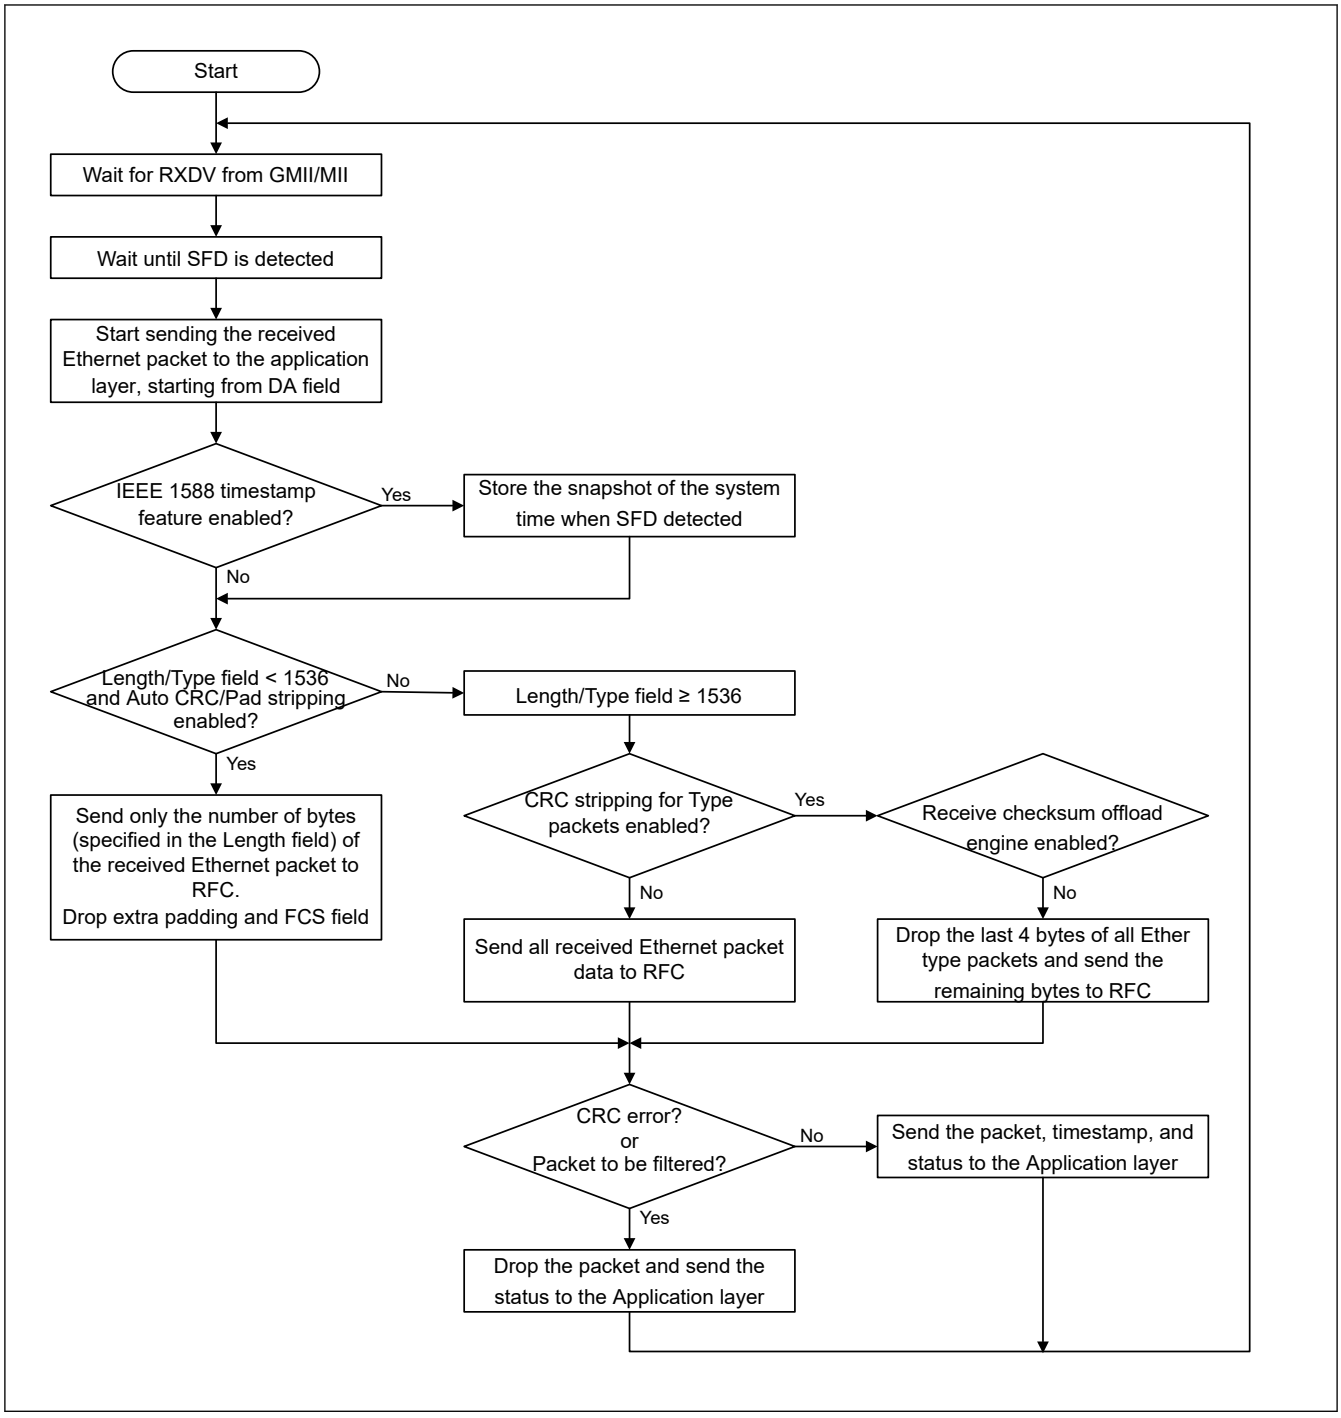

Figure 28.9 MAC receive flow transmission

The sequence is as follows:

1. When the RXDV signal of GMII or MII becomes active, the Receive State Machine of RPE starts looking for the SFD field (byte 0x5D in GMII mode; 0xD nibble in MII mode).
   The state machine drops received packets until it detects SFD.
2. When SFD is detected, the state machine begins sending the data of Ethernet packet to the RPC module, beginning with the first byte following the SFD (destination address).
3. If IEEE 1588 Timestamp feature is enabled, the RPE takes a snapshot of the system time at which SFD of any packet is detected on GMII or MII. If this packet is not dropped during MAC filtering, the timestamp is passed to the application. In MII mode, the RPE converts the received nibble data into bytes and forwards the valid packet data to the RFC module.
4. The Receive State Machine of the RPE module decodes the Length/Type field of the receiving Ethernet packet.

If the Length/Type field is less than 1,536 and if the MAC is programmed for the Auto CRC/Pad Stripping (Bit 20 of the MAC_Configuration register), the state machine sends the data of the packet up to the count specified in the Length/Type field and starts dropping bytes (including the FCS field). The state machine of the RPE module decodes the Length/Type field and checks for the Length interpretation.
In Audio Video (AV) mode, when you select additional Rx queues, the packets that are less than or equal to 16 bytes in length after pad stripping, always get dropped inside the MAC receiver. This happens even if the packets have passed the address filter and have no CRC error.
If the Length/Type field is greater than or equal to 1,536, the RPE module sends all received Ethernet packet data to the RFC module if you have not enabled the CRC stripping for Type packet in bit 21 of the MAC_Configuration register. However, if you have enabled the CRC stripping for Type packets and not enabled the Receive Checksum Offload Engine, the MAC strips and drops the last 4 bytes of all packets of Ether type before forwarding the packets to the application.

5. By default, the MAC is programmed for watchdog timer to be enabled, that is, packets larger than 2,048 (10,240 if Jumbo Packet is enabled) bytes, (DA + SA + LT + DATA + PAD + FCS) are cut off at the RPE module. In addition, you can use a programmable watchdog timer (Bit 16 of MAC_Watchdog_Timeout register) to override the fixed timeout of 2,048 or 10,240 bytes. You can disable the watchdog timer by programming bit 19 of MAC_Configuration register. However, even if the watchdog timer is disabled, a packet greater than 32 KB size is cut off and a watchdog timeout status is given.

At the end of every received packet, the RPE module generates received packet status and sends it to the RPC module. Control, missed packet, and filter fail status are added to the receive status in the RPC module.

Note:
- In half-duplex mode, the first packet in a burst should be at least slot time in length. If the first packet is smaller than the slot time, the MAC considers the bytes received up to the slot time as first packet, which results in CRC error for the packet.
- Packet bursting is applicable only for the GMII half-duplex mode. It is not applicable in the MII and GMII full-duplex modes. In the GMII half-duplex mode, the size of the first packet in a packet burst should at least be equal to the slot time. If the first packet (including carrier extension) is less than the slot time, the MAC considers all data bytes, received for the first packet and subsequent packets, which end immediately after the slot time is reached as first packet in the burst. This may result in CRC error. However, if the packet burst ends (both RXDV and RXER go low) before the slot time, the subsequent packet is considered as a new packet. This behavior is according the IEEE 802.3.

(2) Receive CRC Module

The Receive CRC (CRX) interfaces with the RPE module to check any CRC error in the packet being received. This module calculates the 32-bit CRC for received packet that includes the Destination address field through the FCS field.

The encoding is defined by the following generating polynomial:

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

The module gets the data from the RPE module (DA+SA+LT+DATA+PAD+FCS). The RPE module also sends a control signal that indicates the validity of the data. Irrespective of the Auto Pad or CRC strip, the CRX module receives the entire packet to compute the CRC check for received packet.

(3) Receive Packet Controller Module

The Receive Packet Controller (RPC) receives the Ethernet packet data and status from the RPE module.

The RPC module consists of a FIFO and two state machines for writing and reading the FIFO. The FIFO holds the received Ethernet packet data and byte enables, along with a control bit to indicate the last data. The state machines manage the FIFO and provide a packet buffering for the Ethernet packet being received from the RPE module. The following are main functions of the RPC module:

- Converting Data path — converts 8-bit data to 32-bit data to the RBU module
- Packet filtering
- Attaching the calculated IP Checksum input from IPC
- Updating the Receive Status and forwarding it to RBU

If RA bit of the MAC_Packet_Filter register is set, the RPC module initiates the data transfer to the RBU module when 4 bytes of Ethernet data are received from the RPE module. At the end of the data transfer, the RPC module sends out the

received packet status that includes the packet filter bits (SA Filterfail and DA Filterfail) and status from the RPC module. These bits are generated based on the filter-fail signals from the AFM module. This status bit indicates to the application whether the received packet has passed the filter controls (both address filter and Packet Filter controls from CSR). The RPC module does not drop any packet on its own in this mode.

If the RA bit is reset, the RPC module performs packet filtering based on the destination or source address. If the application does not want to receive any bad packets such as runt, CRC error packets, the application still needs to perform another level of filtering. The RPC module waits to receive the first 14 bytes of received data (type field) from the RPE module. Until then, the module does not initiate any transfers to the RBU module. After receiving the destination or source address bytes, the RPC checks the filter-fail signal from the AFM module for an address match. On detecting filter-fail from AFB, the packet is dropped at the RPC module and not transferred to the application.

On a delayed filter response from the AFM (this can only occur if you change the AFM logic), the RPC module waits until the FIFO is full, and then proceeds with the packet transfer to the RBU module. However, the RPC module still takes the delayed response from the AFM module and if it is a (DA or SA) filter failure, it drops the rest of the packet and sends the Rx Status Word (with zero packet-length, CRC Error and Runt Error bits set) immediately indicating the filter fail. If there is no response from the AFM until EOP is transmitted, the filter fail status in the Rx Status Word is updated accordingly.

When the optional PMT module is present and configured for power-down mode, this block drops all received packets and does not forward the packets to the application.

(4) Receive Flow Control Module

The Receive Flow Controller (FRX) detects the Pause packet being received and pauses the packet transmission for the delay specified within the received Pause packet. The FRX module is enabled only in the full-duplex mode.

(5) Receive Bus Interface Unit Module

The Receive Bus Interface Unit (RBU) converts the 32-bit data received from the RPC module into a 128-bit FIFO protocol. The RBU module interfaces with the MTL through the MAC receive interface (MRI). The RBU module also outputs the timestamp captured from the received packet, along with the status.

(6) Address Filtering Module

The Address Filtering (AFM) module performs the destination and source address checking function on all received packets and reports the address filtering status to the RPC module.

The address checking is done based on different parameters (Packet Filter register) chosen by the application. These parameters are inputs to the AFM module, and the AFM module reports the status of the address filtering based on the combination of these inputs. The AFM module does not filter the receive packets but reports the status of the address filtering (whether to drop the packet or not) to the RFC module. The AFM module also reports address filter status and whether the received packet is a multicast packet or a broadcast packet.

The AFM module probes the 8-bit receive data path between the RPE module and the RFC module and checks the destination and source address field of each incoming packet. The AFM module gets the physical (MAC) address of the station and the Multicast Hash table from CSR module for address checking. The CSR module provides the Packet Filter register parameters to AFM.

28.4.7 Interrupts

Interrupts can be generated as a result of various events in the GMAC controller. These events are captured in status registers, and interrupt enables are provided for each source of an interrupt such that the interrupt signal (GMAC_SBD) is asserted for an event only when the corresponding interrupt enable is set.

The interrupt status and corresponding enable registers are organized in an hierarchical manner so that it is easier for software to traverse and identify the source of an interrupt event quickly. When GMAC_SBD is asserted, the DMA_Interrupt_Status register is the first level that indicates the major blocks for the interrupt event source. This register is read-only, and it contains bits corresponding to each DMA channel (TX and RX pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- MAC_Interrupt_Status register
- MTL_Interrupt_Status register
- DMA_CHn_STATUS (n = 0 to 7) register

28.4.7.1 Interrupts from the MAC

Interrupts can be generated from the MAC as a result of various events in the MAC Receiver, Transmitter, or the optional modules/functions such as RMON counters, EEE and so on.

These interrupt events are combined with the events in the DMA on the GMAC_SBD signal. The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The MAC_Interrupt_Status register describes the events that can cause an interrupt from the MAC. The MAC interrupts are disabled by default. Each event can assert the interrupt on the GMAC_SBD signal when the corresponding bit is set in the MAC_Interrupt_Enable register.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt.

Note: By default, the MAC interrupt status bits are cleared when the register that contains the source of the interrupt is read. If RCWE bit in the MAC_CSR_SW_Ctrl register is programmed to 1, the MAC interrupt status bits are cleared when the bit that contains the source of the interrupt is explicitly written to 1.

28.4.7.2 Interrupts from MTL

GMAC can generate interrupts as a result of events in the MAC layer or in the MTL modules. These interrupt events are combined with the events in the DMA on the GMAC_SBD signal. The MTL interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software. In the MTL, the interrupts are mainly related to exception events in the TxQ or RxQ in the Transmit and Receive paths respectively. The interrupt status are captured and organized in a hierarchical manner in order to identify the root cause quickly.

The MTL_Interrupt_Status register identifies the top level modules that can cause the interrupt to be asserted. Bits [7:0] identify 8 Queues (Tx or Rx). They are read-only bits and the application should read the corresponding MTL_Qn_INTERRUPT_CONTROL_STATUS register to identify the exact cause and set the corresponding bits to 1 to clear the interrupt event. The assertion of interrupt due to these events is enabled by the corresponding enable bits in MTL_Qn_INTERRUPT_CONTROL_STATUS register.

28.4.7.3 Interrupts from DMA

As shown in Figure 28.10, GMAC_SBD interrupt is a level signal and gets de-asserted only when all the enabled interrupt events are cleared in their respective status registers and correspondingly all the bits in the DMA_Interrupt_Status register are cleared.

The DMA_CHn_STATUS register (n = 0 to 7) captures all the interrupt events of that Tx DMA and Rx DMA channel pair. The DMA_CHn_INTERRUPT_ENABLE register (n = 0 to 7) contains the corresponding enable bits for each of the interrupt event. There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by bits [15:14] of DMA_CHn_STATUS register (n = 0 to 7) respectively. The normal group is for events that happen during the normal transfer of packets (TI, RI, TBU) while the abnormal interrupt events are for error events. Interrupt events are cleared by writing 1 to the corresponding bit position. When all the enabled interrupt events are cleared (including the NIS and AIS), the interrupt source from the DMA Channel is cleared and the corresponding bit in DMA_Interrupt_Status register is also cleared.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. For example, Receive Interrupt bit [6] of DMA_CHn_STATUS register (n = 0 to 7) indicates that one or more packets were transferred to the application buffer. The driver must scan all descriptors, from the last recorded position to the first one, owned by the DMA to determine how many packets are received.

An interrupt is generated only once for multiple events. The driver must scan the DMA_Interrupt_Status register for the cause of the interrupt and clear the source in the respective Status register. The GMAC_SBD signal is cleared only when all the bits of DMA_Interrupt_Status register are cleared.

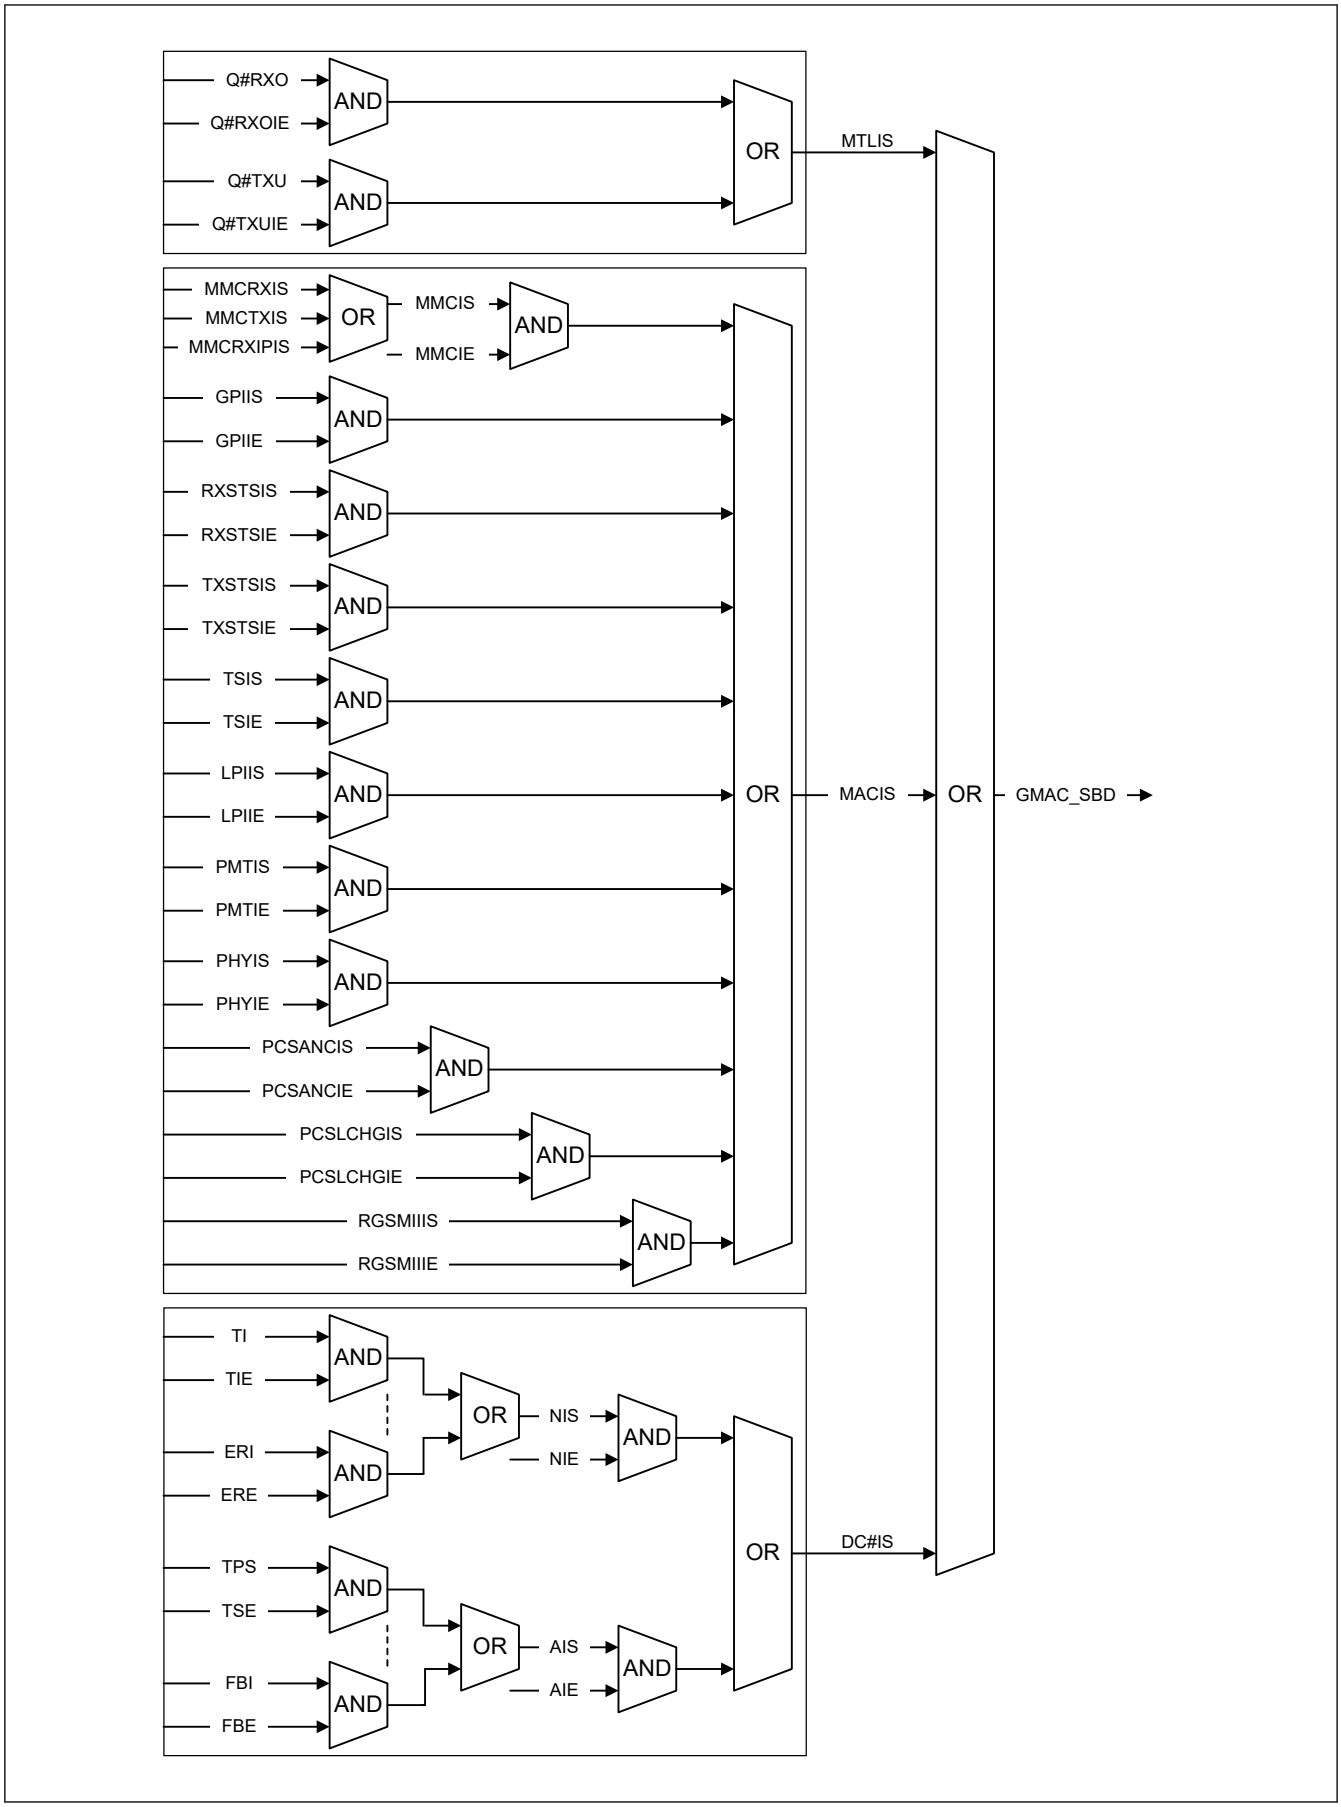

Figure 28.10 GMAC_SBD interrupt generation

28.4.7.4 Periodic Scheduling of Transmit and Receive Interrupt

To improve the throughput and performance, GMAC supports interrupt timer and transmit descriptor to generate interrupts periodically, instead of every DMA transfer.

It is not preferable to generate interrupts for every packet transferred by DMA (RI and TI) for system throughput performance reasons. The GMAC gives the flexibility to schedule the interrupt at regular intervals using two methods:

- Set Interrupt on Completion bit in Transmit descriptor (TDES2[31]) once for every "required" number of packets to be transmitted.
- Similarly, set the IOC (RDES3[30]) bit only at some specific intervals of Receive descriptors. This way, whenever a received packet transfer to system memory is complete and any of the descriptors used for that packet transfer has the IOC bit set, only then the RI event is generated.

In addition, an interrupt timer (DMA_CHn_RX_INTERRUPT_WATCHDOG_TIMER (n = 0 to 7)) is given for flexible control and periodic scheduling of Receive Interrupt. When this interrupt timer is programmed with a nonzero value, it gets activated as soon as the Rx DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt because the corresponding interrupt of completion IOC bit (RDES3[30]) is not set. When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in DMA_CHn_INTERRUPT_ENABLE register (n = 0 to 7). The timer is stopped and cleared before it expires, if the RI is set for a packet transfer whose descriptor's IOC was set. The timer is reactivated automatically after the next packet transfer is complete without the RI event being generated.

28.4.7.5 Per Channel Transfer Complete Interrupt

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) is reflected in DMA_CHn_STATUS register (n = 0 to 7). The TI bit is set whenever the Tx DMA channel closes the transmit descriptor in which the IOC (Interrupt On Completion - TDES2[31]) bit is set. Similarly, the RI bit is set whenever the Rx DMA channel closes the receive descriptor with LD bit set and in any of the descriptors used for transferring that packet, IOC (Interrupt Enable on completion - RDES3[30]) bit is set.

The common GMAC_SBD interrupt signal is asserted for the Transfer complete interrupts only when the corresponding interrupts are enabled in DMA_CHn_INTERRUPT_ENABLE register (n = 0 to 7).

The following per Channel Transfer Complete interrupt signals are also supported.

- GMAC_TXINTn (n = 0 to 7) (Transmit Per Channel Interrupts)
- GMAC_RXINTn (n = 0 to 7) (Receive Per Channel Interrupts)

The behavior of the RI, TI, GMAC_TXINTn (n = 0 to 7) and GMAC_RXINTn (n = 0 to 7) changes depending on the settings of INTM field bits [17:16] in DMA_Mode. Table 28.6 explains the Transfer Complete Interrupt behavior.

Table 28.6 Transfer complete interrupt behavior (1 of 2)

Interrupt Mode	Behavior of GMAC_TXINTn and GMAC_RXINTn	Behavior of TI/RI and GMAC_SBD
INTM = 0	A pulse is asserted on these output signals when corresponding TX/RX transfer complete event (for which IOC descriptor bits are enabled) is detected, irrespective of the corresponding interrupt status.	The TI/RI status signals are set whenever the Transfer Complete event is detected. The bits get cleared whenever the software driver writes'1' to these bits. The GNAC_SBD signal is asserted when ever the corresponding interrupts are also enabled in the DMA_CHn_INTERRUPT_ENABLE register (n = 0 to 7). The NIS status bit is asserted for RI/TI events.
INTM = 1	These signals reflect the value of corresponding TI/RI bits in the DMA_CHn_STATUS register (n = 0 to 7) when the corresponding interrupt enable is set. Therefore, they are level signals and are cleared by the application by writing 1 to the RI/TI status bits. This signal is not asserted when the corresponding interrupt enable bit is not set.	The GMAC_SBD signal and NIS status bit are not asserted for RI/TI events.

Table 28.6 Transfer complete interrupt behavior (2 of 2)

Interrupt Mode	Behavior of GMAC_TXINTn and GMAC_RXINTn	Behavior of TI/RI and GMAC_SBD
INTM = 2	In this mode, RI/TI interrupts are queued. These signals reflect the value of corresponding TI/RI bits in the DMA_CHn_STATUS register (n = 0 to 7) when the corresponding interrupt enable is set. They are level signals and cleared by software by writing 1 to the RI/TI status bits. However, it is set again if another TI/RI event(s) is detected before the TI/RI bits are cleared for the previous event.	The RI/TI status bits are set whenever the Transfer Complete event is detected and gets reset whenever software driver clears those bits by writing 1. However, if another Transfer Complete event is detected before it is cleared (serviced) by the software, then GMAC automatically set these status bits again.However, the GMAC_SBD signal is not generated based on TI/RI. The NIS status bit is not asserted for RI/TI events.

28.5 Station Management Agent

The application can access the PHY registers through the Station Management Agent (SMA). SMA is a two-wire Station Management interface (MIM).

28.5.1 Description of Station Management Agent

For MIM accesses, the maximum operating frequency of the MDC is 2.5 MHz, as specified in the IEEE 802.3. In the GMAC, the MDC clock is derived from the application clock, using a divider-counter. The divide factor depends on the clock range setting (CR field) in the MAC_MDIO_Address register.

Select the clock divide factor as mentioned in the description of CR field of MAC_MDIO_Address register, to meet IEEE specifications. However, if your system supports higher clock frequencies on the MIM interface, there is a provision to select a different divider.

Table 28.7 lists the MDIO frame structure.

Table 28.7 MDIO Clause 45 frame structure

Field	Description
IDLE	The mdio line is in tri-state; there is no clock on MDC signal.
PREAMBLE	32 continuous bits of value 1
START	Start of packet is 00b
OPCODE	• 00b • 01b • 10b • 11b
PHY ADDR	5-bit address select for one of 32 PHYs
DEV ADDR	5-bit address select for one of 32 devices
TA	Turnaround • Z0b: Read and post-read increment address • 10b: Write and address MDIO accesses Where Z is the tri-state level
DATA/ADDRESS	16-bit value: For an address cycle (OPCODE = 00b), this frame contains the address of the register to be accessed on the next cycle. For the data cycle of a write frame, this field contains the data to be written to the register. For read or post-read increment address frames, this field contains the contents of the register read from the PHY. • In address and data write cycles, the GMAC drives the MDIO line during the transfer of these 16 bits. • In read and post-read increment address cycles, the PHY drives the MDIO line during the transfer of these 16 bits.

The frame structure for Clause 22 frames is also supported. The C45E bit in the MAC_MDIO_Address register can be programmed to enable Clause 22 or Clause 45 mode of operation. Table 28.8 lists the Clause 22 frame format.

Table 28.8 MDIO Clause 22 frame structure (1 of 2)

Field	Description
IDLE	The mdio line is in tri-state; there is no clock on MDC.
PREAMBLE	32 continuous bits of value 1

Table 28.8 MDIO Clause 22 frame structure (2 of 2)

Field	Description
START	Start of packet is 01b
OPCODE	• 01b for Write • 10b for Read
PHY ADDR	5-bit address select for one of 32 PHYs
DEV ADDR	5-bit address to select the register within each MMD
TA	Turnaround • Z0b: Read and post-read increment address • 10b: Write and address MDIO accesses Where Z is the tri-state level
DATA/ADDRESS	Any 16-bit value: • In a write operation, the GMAC drives MDIO. • In read operation, the PHY drives MDIO.

In addition to normal read and write operations, the SMA also supports post-read increment address while operating in Clause 45 mode.

28.5.2 GMII/MII Management Write Operation

After the Station Management Agent receives the PHY address and the write data from the MAC CSR module, the SMA starts a Write operation to the PHY registers.

Figure 28.11 shows the flow for a write operation from the SMA module to the PHY registers.

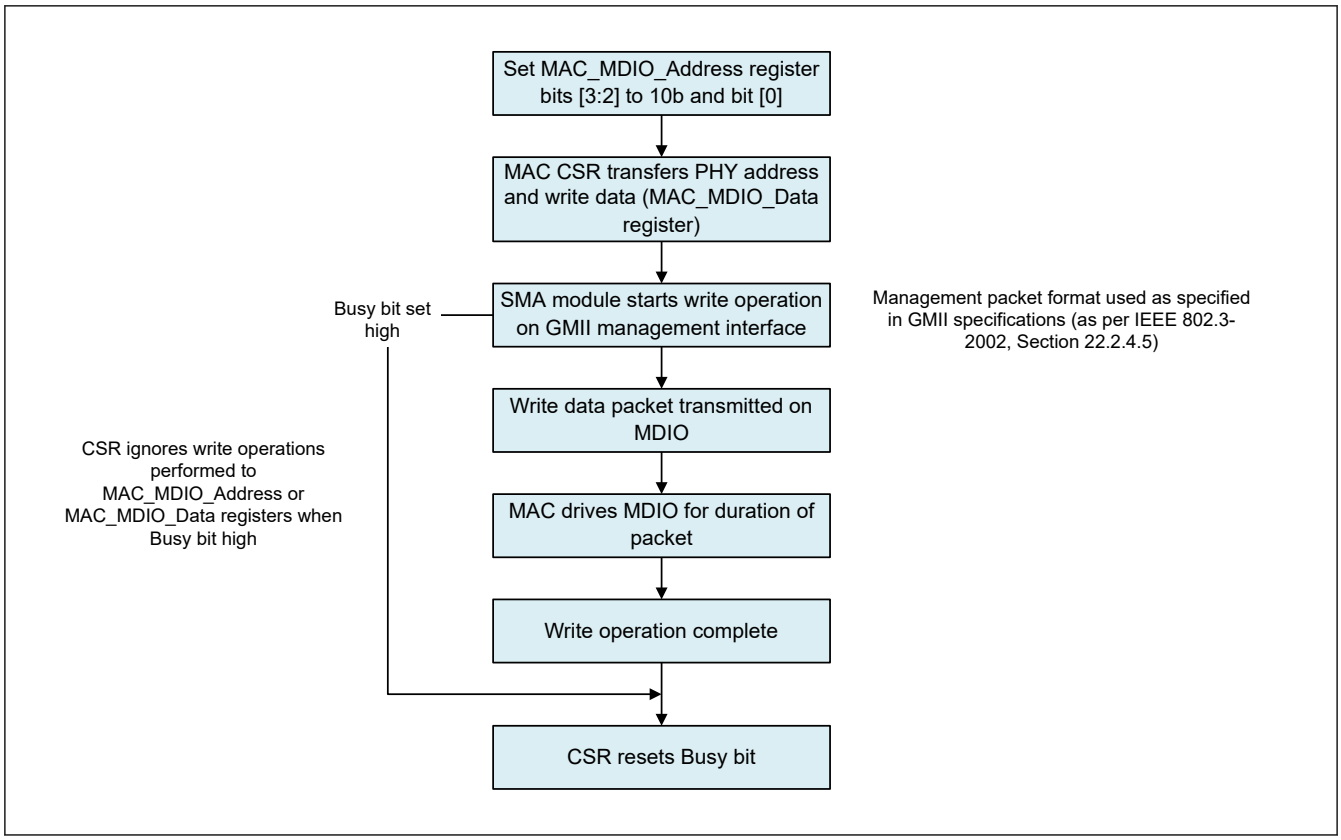

Figure 28.11 SMA write operation flow

When you set bits [3:2] to 01b and bit 0 in the MAC_MDIO_Address register, the MAC CSR module transfers the PHY address, the register address in PHY, and the write data (MAC_MDIO_Data register) to the SMA to initiate a Write operation into the PHY registers. At this point, the SMA module starts a Write operation on the GMII Management Interface using the Management Packet Format specified in the GMII specifications (as per IEEE 802.3-2002, Section 22.2.4.5). When the SMA module starts a Write operation, the write data packet is transmitted on the MDIO line. The MAC

drives the MDIO line for complete duration of the packet. The Busy bit is set high until the write operation is complete. The CSR ignores the Write operations performed to the MAC_MDIO_Address register or the MAC_MDIO_Data register during this period (the Busy bit is high). When the Write operation is complete, the SMA module indicates this to the CSR, and the CSR resets the Busy bit.

Table 28.9The packet format for the Write operation is shown in the following table:

Table 28.9 Packet format for write operation

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	1111…11	01	01	AAAAA	RRRRR	10	DDD…DDD	Z

28.5.3 GMII/MII Management Read Operation

After the Station Management Agent receives the PHY address and the register address in the PHY from the MAC CSR module, the SMA initiates a Read operation to the PHY registers.

The flow of a Management read operation is as follows:

1. Set bits [3:2] to 11b and bit 0 in the MAC_MDIO_Address register
2. The MAC CSR module transfers the PHY address and the register address in PHY to the SMA to initiate a Read operation in the PHY registers
3. The SMA module starts a Read operation on the GMII Management Interface using the Management Packet Format specified in the GMII specifications (as per IEEE 802.3-2002, Section 22.2.4.5).
4. When the SMA module starts a Read operation on the MDIO, the CSR ignores the Write operations to the MAC_MDIO_Address or MAC_MDIO_Data register during this period (the Busy bit is high) and the transaction is completed without any error on the MCI interface.
5. When the Read operation is complete, the SMA indicates this to the CSR.
6. The CSR resets the Busy bit and updates the MAC_MDIO_Data register with the data read from the PHY.

For more information about the communication from the application to the PHYs, see the Reconciliation Sublayer and Media Independent Interface Specifications sections of the IEEE 802.3z, 1000BASE Ethernet.

Table 28.10 lists the packet format for the read operation.

Table 28.10 Packet format for read operation

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	1111…11	01	10	AAAAA	RRRRR	Z0	DDD…DDD	Z

28.5.4 Preamble Suppression

The IEEE standard specifies 32-bit preamble (all-ones) for the MDIO frames. The GMAC provides controls to support preamble suppression. GMAC transmits MDIO frames with only 1 preamble bit. The preamble suppression can be enabled by setting PSE bit of MAC_MDIO_Address register.

28.5.5 Trailing Clocks and Back to Back transactions

The GMAC drives MDC clock on GMACn_MDC port for duration of the MDIO frame. There is no clock driven during the idle period. The trailing clocks feature can be used if the PHY needs the MDC clock to be active for some cycles after the MDIO frame. The NTC field in MAC_MDIO_Address register allows programming of trailing clocks from 0 to 7.

The GMAC supports Back to Back transactions which allows start of next MDIO frame even before the trailing clocks are completed for previous MDIO frame. This feature can be enabled by setting BTB bit in MAC_MDIO_Address register when trailing clocks feature is also enabled. When Back to Back transactions is enabled, the GMII Busy is cleared immediately after MDIO frame completion. This allows the software to issue the next command, which is executed by GMAC while trailing clocks are still on for the previous MDIO frame. When Back to Back transactions is not enabled, the GMII Busy is cleared after the trailing clocks are completed for MDIO frame.

28.5.6 Interrupt for MDIO Transaction Completion

GMAC can generate an interrupt on completion of MDIO read or write transactions. Therefore, the application need not poll the GMII Busy field of the MAC_MDIO_Address register to know the completion of MDIO commands.

28.6 Packet Filtering

28.6.1 Packet Filtering Sequence

Figure 28.12 shows the filtering sequence for Rx packets.

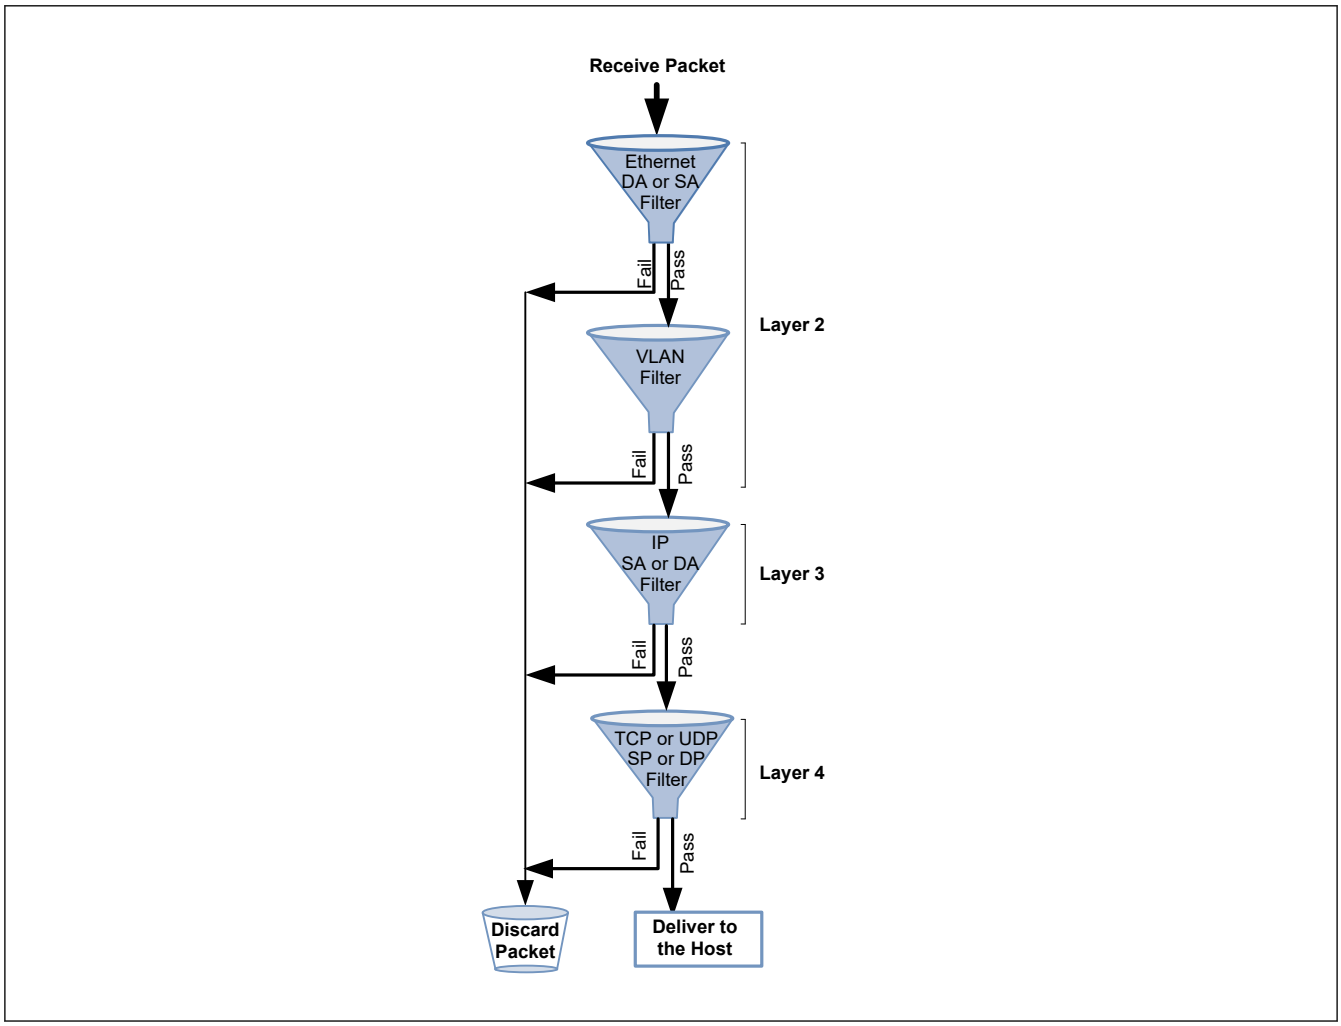

Figure 28.12 Packet filtering sequence

The sequence shown in Figure 28.12 is valid when all the filters (L2, VLAN, L3, L4) are active. If any of the Layer filters are not enabled, that filter is bypassed and the subsequent filter is applied. A packet that fails any of the filters is discarded. However, the discarded packet can be forwarded to the host based on the register control. For example, when bit RA of MAC_Packet_Filter register is set to 1, all discarded packets are forwarded to the host but with its packet status indicating the specific filter-failure. If RA = 0, bits VTFE and IPFE of MAC_Packet_Filter register controls if the packets that fail the VLAN filter and Layer 3-4 filter should be discarded or forwarded to the host.

28.6.2 Source Address or Destination Address Filtering

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet.

28.6.2.1 Unicast Destination Address Filtering

The MAC supports up to 32 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of MAC_Packet_Filter register is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. The default MacAddr0 is always enabled.

The MacAddr1 to MacAddr31 addresses are selected with an individual enable bit. You can mask each byte during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA.

In hash filtering mode (when HUC bit is set), the MAC performs imperfect filtering for unicast addresses using a 256-bit Hash table. For hash filtering, the MAC uses the upper 8 bits CRC of the received destination address to index the content of the Hash table. A value of 0x00 selects bit 0 of selected register, and a value of 0xFF selects bit 255 of Hash Table register. If the corresponding bit (indicated by the 8-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

28.6.2.2 Multicast Destination Address Filtering

To program the MAC to pass all multicast packets, set the PM bit in MAC_Packet_Filter register. If the PM bit is reset, the MAC performs the filtering for multicast addresses based on the HMC bit of the MAC_Packet_Filter register.

The multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 256-bit Hash table. The MAC uses the upper 6-bits CRC of received multicast address to index the content of the Hash table. A value of 0x00 selects bit 0 of selected register and a value of 0xFF selects bit 255 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

28.6.2.3 Hash or Perfect Address Filtering

To configure the DA filter to pass a packet when its DA matches either the Hash filter or the Perfect filter, set the HPF bit and the corresponding HUC or HMC bits in MAC_Packet_Filter register. This is applicable to both unicast and multicast packets. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to received packet.

28.6.2.4 Broadcast Address Filtering

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the DBF bit in MAC_Packet_Filter register.

28.6.2.5 Unicast Source Address Filtering

The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programmed in the SA registers. You can configure the MAC Address registers[1–31] to use SA instead of DA for comparison by setting bit 30 of corresponding register.

The MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in MAC_Packet_Filter register. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the SAF bit is set, the SA filter and DA filter result is AND'ed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

28.6.2.6 Inverse Filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of MAC_Packet_Filter register. The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 28.11 and Table 28.12 summarize the DA and SA filtering based on the type of packets received.

Note: When the RA bit of MAC_Packet_Filter register is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

Table 28.11 Destination address filtering

Packet Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA Filter Operation
Broadcast	1	x	x	x	x	x	x	Pass
	0	x	x	x	x	x	0	Pass
	0	x	x	x	x	x	1	Fail
Unicast	1	x	x	x	x	x	x	Pass all packets
	0	x	0	0	x	x	x	Pass on Perfect/Group filter match
	0	x	0	1	x	x	x	Fail on Perfect/Group filter match
	0	0	1	0	x	x	x	Pass on Hash filter match
	0	0	1	1	x	x	x	Fail on Hash filter match
	0	1	1	0	x	x	x	Pass on Hash or Perfect/Group filter match
	0	1	1	1	x	x	x	Fail on Hash or Perfect/Group filter match
Multicast	1	x	x	x	x	x	x	Pass all packets
	x	x	x	x	x	1	x	Pass all packets
	0	x	x	0	0	0	x	Pass on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	x	0	1	0	x	Pass on Hash filter match and drop Pause packets if PCF = 0x
	0	1	x	0	1	0	x	Pass on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	x	x	1	0	0	x	Fail on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	x	1	1	0	x	Fail on Hash filter match and drop Pause packets if PCF = 0x
	0	1	x	1	1	0	x	Fail on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x

Note: 'x' represents any value.

Table 28.12 Source address filtering

Packet Type	PR	SAIF	SAF	SA Filter Operation
Unicast	1	x	x	Pass all packets
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

Note: 'x' represents any value.

28.6.3 VLAN Filtering

28.6.3.1 VLAN Tag Perfect Filtering

In VLAN tag perfect filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

If VLAN tag perfect filtering is enabled, the MAC forwards the VLAN-tagged packets along with VLAN tag match status and drops the VLAN packets that do not match. You can also enable the inverse matching for VLAN packets by setting the VTIM bit of MAC_VLAN_Tag register. In addition, you can enable processing of S-VLAN tagged packets along with the default C-VLAN tagged packets by setting the ESVL bit of MAC_VLAN_Tag register. For details, see section 28.12. TCP/IP Offloading Features. The VLAN packet status bit (Bit 10 of RDES0) indicates the VLAN tag match status for the matched packets.

Note: The source or destination address has precedence over the VLAN tag filters. This means that a packet that fails the source or destination address filter is dropped irrespective of the VLAN tag filter results. By default, the VLAN tag-based perfect filter is available.

28.6.3.2 VLAN Tag Hash Filtering

The 16-bit VLAN Hash Table is used for group address filtering based on the VLAN tag. The VLAN Tag Hash Filtering feature can be enabled using the VTHM (VLAN Tag Hash Table Match Enable) bit of the MAC_VLAN_Tag register.

The MAC provides VLAN tag hash filtering with a 16-bit Hash table.

The MAC performs the VLAN hash matching based on the VTHM of the MAC_VLAN_Tag register. If the VTHM bit is set, the most significant four bits of CRC-32 of VLAN tag are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the MAC_VLAN_Hash_Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

Note:
- The 16 or 12 bits of VLAN Tag are considered for CRC-32 computation based on ETV bit in MAC_VLAN_TAG register.
- When ETV bit is reset, most significant four bits of CRC-32 of VLAN Tag are inverted and used to index the content of MAC_VLAN_Hash_Table register.
- When ETV bit is set, most significant four bits of CRC-32 of VLAN Tag are directly used to index the content of MAC_VLAN_Hash_Table register.

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.

Table 28.13 shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of MAC_Packet_Filter register is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 Normal Descriptor (Write-Back Format). When the RA bit is not set and the VTFE bit is set in MAC_Packet_Filter register, the packet is dropped if the final VLAN match status is Fail.

When VLAN VID is programmed to 0 in the VL field of MAC_VLAN_Tag register, all VLAN-tagged packets are considered as perfect matched but the status of the VLAN hash match depends on the VTHM and VTIM bits in MAC_VLAN_Tag register.

Table 28.13 VLAN match status

VID	VLAN Perfect Filter Match Result	VTHM bit	VLAN Hash Filter Match Result	VTIM bit	Final VLAN Match Status
VID = 0	Pass	0	x	x	Pass
	Pass	1	x	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID != 0	Pass	x	x	0	Pass
	Fail	0	x	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	x	1	Pass
	Pass	x	x	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

Note: 'x' represents any value.

28.6.3.3 Double VLAN Processing

This feature is referred as the double VLAN tagging feature in which the MAC can process two VLAN tags, namely inner and outer. With this feature, the GMAC supports the following:

- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status.

Table 28.14 lists the features supported by the MAC on the Receive side and the corresponding bits in the MAC_VLAN_Tag register.

Table 28.14 Double VLAN processing features in receive path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the ERIVLT bit.
C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EVLS and EIVLS bits.
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN Tag and Type in the Rx status based on the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN Tag type to match C-VLAN or S-VLAN based on the DOVLTC bit.

28.6.3.4 Extended Receive VLAN Filtering and Routing

The MAC Receiver can classify the received packets based on VLAN Tag and steer them to a specific Rx DMA channel. The MAC compares the received frame's VLAN Tag with all the enabled and relevant filters and provides a filtering result. If any of the perfect filters give a pass result and if the respective filter's DMA channel Number is enabled, the frame is routed to that DMA Channel.

In addition to filtering, routing can also be done. For details about routing, see Extended VLAN Based DMA Selection in (2) Dynamic (Per Packet) Mapping.

(1) Comparison Modes

For each VLAN Tag Filter, the application has the following comparison options:

- It can program the MAC to compare an outer VLAN Tag or an inner VLAN Tag with the programmed VID.
- It can choose if 12 or 16 bits of the VID field need to be compared.
- Type check can be disabled or enabled for each filter; if enabled, the application can choose if the VID comparison is for SVLAN or CVLAN type frames only.

For example, if a filter is enabled for 16 bits comparison, SVLAN Type, and Outer VLAN Tag, any single or double VLAN Tagged frames with Outer SVLAN Tags are compared with this filter, and a pass or fail result is obtained.

Note: The inner VLAN Tag comparison is applicable only if Double VLAN Tag processing is enabled through the parameter and the MAC_VLAN_Tag_Ctrl register bit.

(2) Filtering

When Extended RX VLAN Filtering & Routing feature is enabled, the application can enable both Perfect and Hash Filtering. The overall VLAN Filter Result is based on the perfect filter result and the Hash Filter result (if enabled). The filter result is passed to the application as part of the status bits.

Perfect Filtering is done based on the MAC_VLAN_Tag_Filter i registers. For each VLAN Tag Filter, the MAC compares the relevant VLAN Tag ID and gives a result. If any one of the VLAN Tag Filters gives a match, the frame is considered to have passed the VLAN Tag Filters. If the frame mismatches all the filters, the frame is considered to have failed the VLAN filter. This behavior is applicable only when the Inverse filtering is not enabled in the MAC_VLAN_Tag_Ctrl register.

If inverse filtering is enabled and the frame has mis-matched all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered as a fail. If none of the enabled filters can perform a comparison or if none of the filters are enabled, then the frame is bypassed to the application.

The overall filter result and the values programmed in the VTFE and RA fields of the MAC Filter register determine if the frame must be dropped or forwarded to the application.

- When RA = 1 or VTFE = 0
  The MAC forwards the frame, irrespective of the filter result.
- When RA = 0 and VTFE = 1
  The MAC forwards the frame only if the VLAN Tag filter status is pass. After forwarding a frame to the application, the relevant filter result is indicated through the status bits.

28.6.3.5 VLAN Filter Status

The Extended Receive VLAN Filtering & Routing feature provides two status bits to indicate the comparison result of the VLAN tags.

By default, the MAC indicates the VLAN Filter Status through one bit in the status – VF in RDES2. When Extended RX VLAN Filtering & Routing is enabled, two status bits are used to indicate the comparison result of VLAN tags. The Outer VLAN Tag Filter Pass and Inner VLAN Tag Filter Pass bits are defined in the following positions. The status indicated through these bits is highly dependent on the how the fields are programmed:

In RDES2:

- Bit 15: Outer VLAN Tag Filter Status
- Bit 14: Inner VLAN Tag Filter Status

Outer VLAN Tag Filter Status (OTS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Outer VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Outer VLAN Tag has either failed the relevant Outer VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Outer VLAN Tag Comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Outer VLAN Tag Comparison.
- This bit is valid for both Single and Double VLAN Tagged frames.

Inner VLAN Tag Filter Status (ITS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Inner VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Inner VLAN Tag has either failed the relevant Inner VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Inner VLAN Tag Comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Inner VLAN Tag Comparison.
- This bit is valid for only Double VLAN Tagged frames, when Double VLAN Processing is enabled.

The application must look at the status bits and the programming to determine if the Frame has passed or failed the VLAN Filter.

Table 28.15 and Table 28.16 list the possible Filter combinations and the corresponding filter results. These tables explain the scenarios when Double VLAN Processing and Hash VLAN filter are enabled in the design.

Legend for the Table 28.15

- VTIM: VLAN Tag Inverse Match Enable - bit 17 in the VLAN_Tag_Ctrl register.
- HFO: Hash Filter enabled for Outer VLAN Tag Comparison - bit 25 and bit 27 in the MAC_VLAN_Tag_Ctrl register.
- HFI5: Hash Filter enabled for Inner VLAN Tag Comparison - bit 25 and bit 27 in the MAC_VLAN_Tag_Ctrl register.

- PFO: Perfect Filter comparison enabled for Outer VLAN Tag - Any of the MAC_VLAN_Tag_Filter i registers is enabled (bit 16 is set) and programmed for Outer VLAN Tag comparison (bit 20 is set to 0).
- PFI: Perfect Filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter i Registers is enabled (bit 16 is set) and programmed for Inner VLAN Tag comparison (bit 20 is set to 1).
- OTS: Outer VLAN Tag Filter Status
- ITS: Inner VLAN Tag Filter Status

Table 28.15 lists the possible values of status bits (OTS and ITS) when at least one Perfect filter is enabled. Table 28.16 lists the possible values of status bits (OTS and ITS) when none of the perfect filters are enabled and only the VLAN Hash Filter is enabled.

Table 28.15 OTS and ITS bit values with at Least 1 perfect filter enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Table 28.16 OTS and ITS bit Values with only VLAN Hash Filter enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0
1	0	1	1/0	1/0

- When no perfect filters are enabled, any VLAN packet is considered to have bypassed the perfect filter.
- When VLAN Hash Filter is enabled for one of the Tags, the respective status bit depends on the result of the filter. Status bits are set to 0 when VLAN Hash Filter is not enabled.
- The value 1/0 for the ITS/OTS field indicate that the final result is dependent on the result of the enabled relevant filter.

Example 1:

The second row of Table 28.16 indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes at the least one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame does not pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2:

Last Row of Table 28.16 indicates that Inverse Filtering is enabled, Hash Filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame has the ITS bit set to 1. Otherwise, the bit is set to 0. OTS bit is set to 0 as comparison is not performed.

28.6.3.6 VLAN Stripping

Each of the VLAN Tags has individual control over stripping. The programming options of Always strip, never strip, strip on pass and strip on fail are available. Inner or Outer VLAN Tag Stripping is based on the pass or fail results of the individual tag. If a tag is bypassed by all the relevant filters, stripping is not applicable for the tag.

- If strip on Pass is enabled for the outer VLAN Tag, stripping is done only if the Outer VLAN tag has passed the relevant Filters. The Outer VLAN Tag Filter Result bit is set.
- If strip on Fail is enabled for the outer VLAN Tag, stripping is done only if the Outer VLAN Tag has failed relevant filters. The Outer VLAN Tag Filter Result Bit is reset.
- If the Outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), the tag is not stripped, though the Status Bit is still 0.
- As multiple filters are enabled, it is possible that the received VLAN frame matches more than one filters. The VLAN Tag's value is not always deterministic from the filter status bits.
- If the application strips the VLAN Tag based on the filter result, it might lose the VID. So, if stripping is enabled for any of the tags, the tag can be put in the status. The application must enable the respective "VLAN Tag in Status" bit [24] or bit [31] in the MAC_VLAN_Tag_Ctrl register.

28.6.3.7 VLAN Filter Fail Packets Queue

When VLAN filtering is enabled, the VLAN Filter Fail Packets can be routed to a programmable Queue (VFFQ) when RA = 1 or VTFE = 0 and the enable bit (VFFQE) for the queue is set.

1. RA and VTFE bits are implemented in the MAC_Packet_Filter register

2. VFFQ and VFFQE fields are implemented in the MAC_RxQ_Ctrl4 register

The packets that pass the VLAN filtering are routed based on the VLAN TAG priority field. The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. The packets that fail the VLAN filter are discarded if RA = 0 or VTFE = 1. However, when RA = 1 or VTFE = 0, the VLAN filter fail packets are still forwarded to the application. In such a scenario, when the VLAN Filter Fail Queue Enable (VFFQE) bit is set, the VLAN filter fail packets are forwarded to the Rx queue number programmed in the VFFQ bit. If VFFQE = 0, the Rx queue number is determined by the VLAN priority mapping as per the PSRQ fields.

Table 28.17 lists the Rx queue routing table for unicast tagged packets, with DA/SA Filter enabled.

Table 28.17 Rx queue routing table for unicast tagged packets (1 of 2)

RA	VFTE	SA/DA Filter Result	VLAN Filter Result	VFFQE	Queue Routing
x	x	Pass	Pass	x	PSRQ
0	0	Pass	Fail	0	PSRQ
0	0	Pass	Fail	1	VFFQ
0	x	Fail	x	x	DROPPED
0	1	Pass	Fail	x	DROPPED
1	x	Fail	x	0	UFFQ*1/PSRQ
1	x	Fail	x	1	UFFQ*1/PSRQ
1	x	Pass	Fail	0	PSRQ

Table 28.17 Rx queue routing table for unicast tagged packets (2 of 2)

RA	VFTE	SA/DA Filter Result	VLAN Filter Result	VFFQE	Queue Routing
1	x	Pass	Fail	1	VFFQ

Note: 'x' represents any value.
Note 1. When UFFQE is enabled else PSRQ.

28.6.4 Layer 3 and Layer 4 Filtering

The GMAC supports Layer 3 and Layer 4 based packet filtering. The Layer 3 filtering refers to the IP Source or Destination Address filtering in the IPv4 or IPv6 packets whereas Layer 4 filtering refers to the Source or Destination Port number filtering in TCP or UDP.

28.6.4.1 Description of Layer 3 and Layer 4 Filtering

When Layer 3 and Layer 4 filtering is enabled, the packets are filtered in the following way:

- Matched Packets: The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of MAC_Configuration register is set and one of the following conditions is true:
  - All enabled Layer 3 and Layer 4 fields match
  - At least one of the enabled field matches and other fields are bypassed or disabled

  When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides the status of the lowest filter where Filter 0 is the lowest filter and Filter 3 is the highest filter. For example, if Filter 0 and Filter 1 match, the MAC gives the status corresponding to filter 0.

Note: The source or destination address and VLAN tag filters (if enabled) have precedence over Layer 3 and Layer 4 filter. This means that a packet which fails the source or destination address or VLAN tag filter is dropped irrespective of the Layer 3 and Layer 4 filter results.

- Unmatched Packets: The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.
- When a packet is dropped, a partial packet with appropriate abort status may be received on MRI. This is because there is no buffer in the MAC receiver for storing the data until the TCP/IP fields are received and matched. However, the aborted or partial packets can be dropped in the MTL Rx FIFO. If the Rx FIFO operates in the Threshold (cut-through) mode and the threshold is programmed to a small value, such that packet transfer to application starts before the failed Layer 3 and Layer 4 filter results are available, the application may receive a partial packet with appropriate abort status.
- Non-TCP or UDP IP Packets: By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP packets.

Layer 3 Filtering

The GMAC supports perfect matching or inverse matching for IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits matching, that is, compare all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, you can enable the last four data registers of a register set to contain the 128-bit IP Source Address or IP Destination Address. The IP Source Address or Destination Address should be programmed in the order defined in the IPv6 specification, that is, the first byte of the IP Source Address or Destination Address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.

For IPv4 packet filtering, you can enable the second and third data registers of a register set to contain the 32-bit IP Source Address and IP Destination Address. The remaining two data registers are reserved. The IP Source Address or Destination Address should be programmed in the order defined in the IPv4 specification, that is, the first byte of IP Source Address and Destination Address in the received packet in the higher byte of the respective register.

Layer 4 Filtering

The GMAC supports perfect matching or inverse matching for TCP or UDP Source and Destination Port numbers. However, you can program only one type (TCP or UDP) at a time. The first data register contains the 16-bit Source

and Destination Port numbers of TCP or UDP, that is, the lower 16 bits for Source Port number and higher 16 bits for Destination Port number.

The TCP or UDP Source and Destination Port numbers should be programmed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP Source and Destination Port number in the received packet is in the higher byte of the register.

28.6.4.2 Layer 3 and Layer 4 Filters Registers

The MAC implements a set of registers for Layer 3 and Layer 4 based packet filtering. In a register set, there is a control register, such as MAC_L3_L4_CONTROLn (n = 0 to 7), to control the packet filtering. In addition, there are five address registers to program the Layer 3 and Layer 4 fields to be matched, such as:

- MAC_LAYER4_ADDRESSn (n = 0 to 7)
- MAC_LAYER3_ADDR0_REGn (n = 0 to 7)
- MAC_LAYER3_ADDR1_REGn (n = 0 to 7)
- MAC_LAYER3_ADDR2_REGn (n = 0 to 7)
- MAC_LAYER3_ADDR_REGn (n = 0 to 7)

You can configure the MAC to have up to four such independent set of registers.

28.7 IEEE 1588 Timestamp Support

The IEEE 1588 defines a Precision Time Protocol (PTP) which enables precise synchronization of time in measurement and control systems. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The GMAC supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP and IEEE 1588-2008 supports PTP transported over Ethernet. The GMAC provides programmable support for both standards.

The controller supports the following features:

- Provides an option to take snapshot of all packets or only PTP type packets
- Provides an option to take snapshot of only event messages
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent
- Provides an option to select the node to be a master or slave for ordinary and boundary clock
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status

28.7.1 IEEE 1588 Timestamp Support

28.7.1.1 Clock Types

The GMAC supports the following clock types:

- Ordinary Clock
- Boundary Clock
- End-to-End Transparent Clock
- Peer-to-Peer Transparent Clock

(1) Ordinary Clock

The ordinary clock has a single PTP state and a single physical port. In a domain, an ordinary clock supports a single copy of the protocol.

The ordinary clock in a domain supports a single copy of the protocol. The ordinary clock has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device

such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device.

The ordinary clock can be a grandmaster or a slave clock. It supports the following features:

- Sends and receives PTP messages. The timestamp snapshot can be controlled as described in MAC_Timestamp_Control.
- Maintains the data sets such as timestamp values

Table 28.18 shows the messages for which you can take the timestamp snapshot on the receive side for master and slave nodes.

Table 28.18 Ordinary Clock: PTP Messages for Snapshot

Master	Slave
Delay_Req	SYNC

For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the TSVER2ENA bit and selecting the snapshot mode in MAC_Timestamp_Control.

(2) Boundary Clock

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy, and signaling terminate in the protocol engine of the boundary clock and such messages are not forwarded. The PTP message type status given by the MAC helps you to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:

- The clock data sets are common to all ports of the boundary clock.
- The local clock is common to all ports of the boundary clock.

(3) End-to-End Transparent Clock

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between the slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the Ingress port to the Egress port.

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot must be taken at both Ingress and Egress ports only for the messages mentioned in Table 28.19. You can take the snapshot by setting the SNAPTYPSEL bits to 10 in the wMAC_Timestamp_Control register.

Table 28.19 End to End transparent clock: PTP messages for snapshot

PTP Messages
SYNC
Delay_Req

(4) Peer-to-Peer Transparent Clock

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer.

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer. The residence time of the Pdelay_Req and the associated Pdelay_Resp packets is added and inserted into the correction field of the associated Pdely_Resp_Followup packet. Therefore, support for taking snapshot for the event messages related to Pdelay is added as shown in Table 28.20.

Table 28.20 Peer-to-Peer transparent clock: PTP messages for snapshot

PTP Messages
SYNC
Pdelay_Req
Pdelay_Resp

28.7.1.2 Delay Request-Response Mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information.

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Figure 28.13 shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

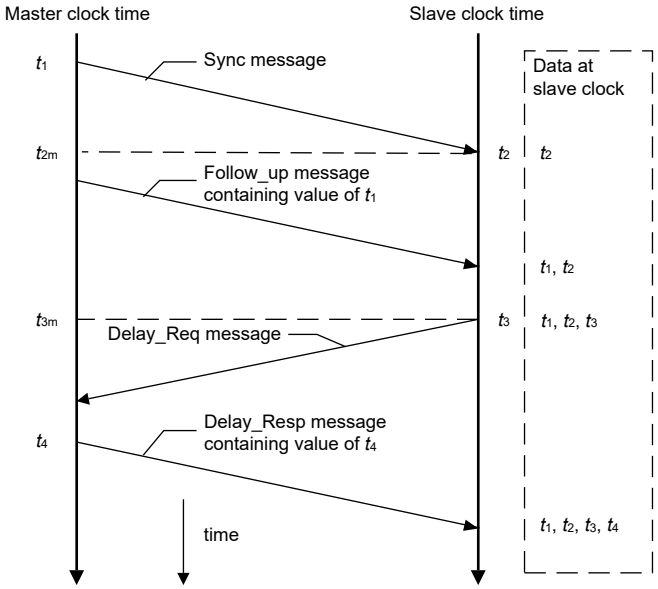

Figure 28.13 Networked time synchronization

As shown in Figure 28.13, PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at t1. This time must be captured for Ethernet ports at GMII or MII.
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, t3, at which this packet leaves the GMII or MII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the timing reference of the master.

Most of the PTP implementation is done in the software above the Ethernet/UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the GMII or MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

28.7.1.3 Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages. Figure 28.14 shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

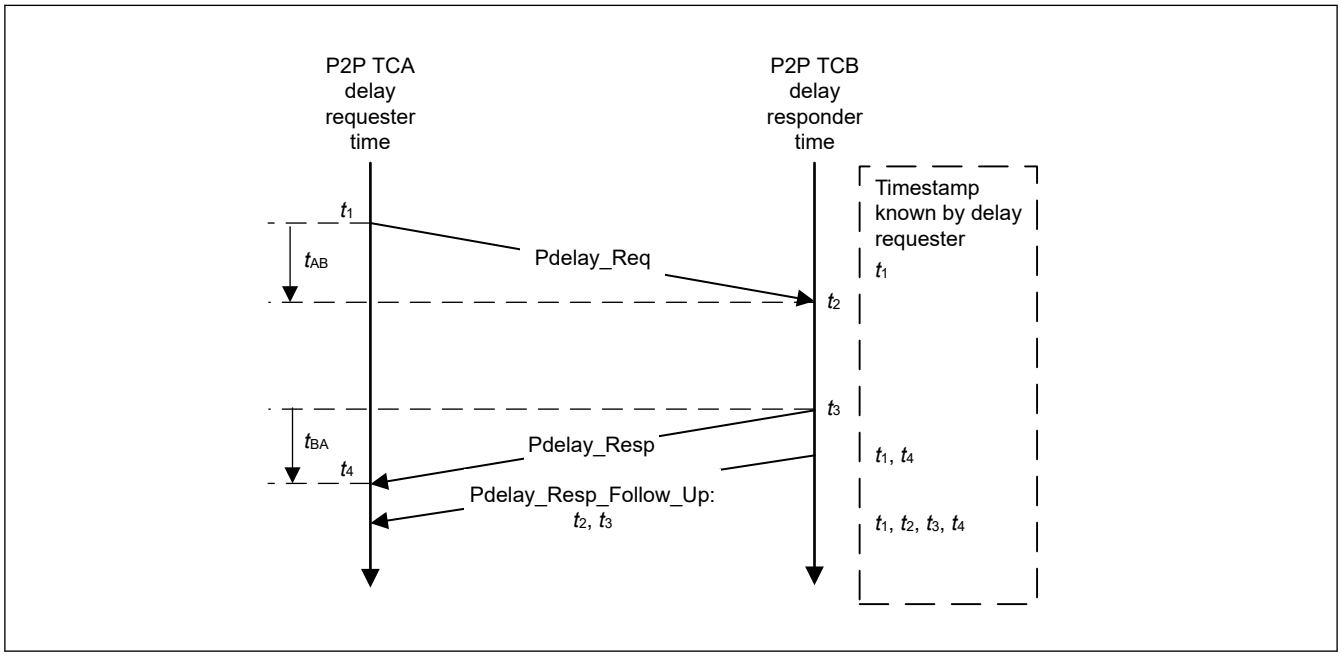

Figure 28.14 Propagation delay calculation in clocks supporting peer-to-peer path correction

As shown in Figure 28.14, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message.
   To minimize errors because of any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   - Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively
4. Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message.
5. Port 1 uses all four timestamps to compute the mean link delay.

28.7.1.4 Timestamp Correction

According to the IEEE 1588 specification, a timestamp must be captured when the PTP message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network. As the MAC takes the timestamp at an internal point far from the actual boundary of the node and network, this captured timestamp is corrected/updated for the ingress/egress path latency (including the delay in the PHY layers). Further correction is done for the inaccuracies/errors introduced due to the clock (GMII Tx, Rx clock) being different at the capture point as compared to the PTP clock that is used to generate the time. The resultant CDC (Clock Domain Crossing) circuits add error depending on the clock period of the GMII and PTP clocks.

28.7.1.5 Ingress Correction

In the Receive side the timestamp captured at the internal snapshot point is delayed (later in time) as compared to the time at which that packet's SFD bit is received at the port's boundary. Therefore, the captured timestamp must be reduced by the ingress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the MAC_Timestamp_Ingress_Corr_* registers.

The correction value consists of the following 3 components:

1. External latency in the PHY layer between boundary point and the input of the GMAC.
   If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum ingress latency. The software can read these registers and determine the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), the ingress latency must be determined from its datasheet or timing characteristics.
2. Internal latency from the input of the GMAC to the internal capture point
   The internal ingress latency can be read from the MAC_Ingress_Timestamp_Latency register. This is a read-only register and gives the latency in scaledNanoseconds format defined in IEEE 1588 Clause 5.3.2. The latency differs based on the active PHY interface (RGMII, RMII, so on) and the operating speed. Therefore, the software must read this register after any speed change in the MAC to determine the current internal latency.
3. CDC Synchronization

The CDC synchronization error is almost equal to 2 times the clock-period of the PTP clock (8 ns).

The values determined from these 3 components should be added by the software and must be written into the TSIC & TSICSNS fields of the MAC_Timestamp_Ingress_Corr_* registers.

Note: The value written to the register must be negative (two's complement), because it has to be subtracted from the captured timestamp. The MAC Receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1 ns. So the bit31 of TSIC must be set to 1 (for negative value) and bits [30:0] must be written with "10^9 - total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is -5 ns, then the value is 0xBB9A_C9FB.

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, the nanoseconds field of the captured timestamp is in binary format with a granularity of ~0.466 ns. Therefore, bits [30:0] must be written with "2^{31} - total ingress_correction_value" represented in binary with bit [31] = 1.

28.7.1.6 Egress Correction

In the Transmit side the timestamp captured at the internal snapshot point is earlier (advanced in time) as compared to the time at which that packet's SFD bit is output at the port's boundary. Therefore, the captured timestamp must be compensated by the egress latency and the errors in CDC sampling. This correction value must be etermined/calculated by the software and written into the MAC_Timestamp_Egress_Corr_* registers.

The correction value consists of the following 3 components:

1. External latency in the PHY layer between the output of the GMAC and the boundary of the port and the network
   If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum egress latency. The software can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), the egress latency must be determined from its datasheet or timing characteristics.
2. Internal latency from the internal capture point and the output of the GMAC
   This internal egress latency can be read from the MAC_Egress_Timestamp_Latency register. This is a read-only register and gives the latency in scaledNanoseconds format defined in IEEE 1588 Clause 5.3.2. The latency differs based on the operating speed. Therefore, the software must read this register after any speed change in the MAC, to determine the current internal latency.
3. CDC synchronization error

The CDC synchronization error value differs depending on the One-step timestamping mode. When One-step timestamping is enabled, the value = (1 × period of PTP_CLOCK (8 ns) + 4 × period of TX_CLK). Otherwise (Two-step timestamping mode), the value = −(2 × period of PTP_CLOCK (8 ns)).

28.7.1.7 PTP Processing and Control

Table 28.21 shows the common message header for the PTP messages. This format is taken from the IEEE 1588-2008.

Table 28.21 Message format defined in IEEE 1588-2008

Bits								Octet	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField *1								1	32
logMessageInterval								1	33

Note 1. control Field is used in version 1. In version 2, message Type field is used for detecting different message types.

There are some fields in the Ethernet payload that you can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP packets:

- PTP packets over IPv4
- PTP frames over IPv6
- PTP packets over ethernet

(1) PTP Packets Over IPv4

Table 28.22 provides information about the fields that are matched to control snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format defined in Table 28.21.

Table 28.22 IPv4-UDP PTP packet fields required for control and status (1 of 2)

Field Matched	Octet Position	Matched Value	Description
MAC Packet Type	12, 13	0x0800	IPv4 datagram
IP version and Header Length	14	0x45	IP version is IPv4
Layer 4 Protocol	23	0x11	UDP
IP Multicast Address (IEEE 1588 version 1)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed: • 224.0.1.129 • 224.0.1.130 • 224.0.1.131 • 224.0.1.132
IP Multicast Address (IEEE 1588 version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	• PTP Primary multicast address: 224.0.1.129 • PTP Pdelay multicast address: 224.0.0.107
UDP Destination Port	36, 37	0x013F, 0x0140	• 0x013F: PTP event messages • 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	74	0x00, 0x01, 0x02, 0x03, 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management

Table 28.22 IPv4-UDP PTP packet fields required for control and status (2 of 2)

Field Matched	Octet Position	Matched Value	Description
PTP Message Type Field (IEEE 1588 version 2)	42 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	43 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

(2) PTP Frames Over IPv6

Table 28.23 provides information about the fields that are matched to control the snapshots for the PTP packets sent over UDP over IPv6 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format defined in Table 28.21.

Table 28.23 IPv6-UDP PTP packet fields required for control and status

Field Matched	Octet Position	Matched Value	Description
MAC Packet Type	12, 13	0x86DD	IP datagram
IP version	14 (bits [7:4])	0x6	IP version is IPv6
Layer 4 Protocol	20 *1	0x11	UDP
PTP Multicast Address	38 – 53	FF0x:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:6B (Hex)	• PTP Primary multicast address: FF0x:0:0:0:0:0:0:0:181 (Hex) • PTP Pdelay multicast address: FF02:0:0:0:0:0:0:0:6B (Hex)
UDP Destination Port	56, 57 *1	0x013F, 0x0140	• 0x013F: PTP event messages • 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	94 *1	0x00, 0x01, 0x02, 0x03, 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management
PTP Message Type Field (IEEE 1588 version 2)	62 *1 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	63 *1 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

Note 1. control Field is used in version 1. In version 2, message Type field is used for detecting different message types.

(3) PTP Packets Over Ethernet

Table 28.24 provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format.

Table 28.24 Ethernet PTP packet fields required for control and status

Field Matched	Octet Position	Matched Value	Description
MAC Destination Multicast Address *1	0 – 5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses *2: • 01-1B-19-00-00-00 • 01-80-C2-00-00-0E *3
MAC Packet Type	12, 13	0x88F7	PTP Ethernet packet
PTP Control Field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management
PTP Message Type Field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	15 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

Note 1. The unicast address match of destination addresses (DA), programmed in MAC address 0 to 31, is used if the TSENMACADDR bit of MAC_Timestamp_Control register is set.
Note 2. IEEE 1588-2008, Annex F
Note 3. The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

28.7.1.8 Transmit Path Functions

The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the GMII or MII interface. The packets, for which the timestamps has to be captured can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. You need to specify the packets for which you want to capture timestamps. You can specify the packets by using the control bits in the Transmit descriptor. The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus connecting the timestamp automatically to the specific PTP packet. The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

28.7.1.9 Receive Path Functions

The MAC can be programmed to capture the timestamp of all packets received on the GMII or MII interface or to process packets to identify the valid PTP messages. Use the following options of the MAC_Timestamp_Control register to control the snapshot of the time to be sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type
  This feature controls the type of messages for which snapshots are taken.

Note: The GMAC also supports the PTP messages over VLAN packets.

Table 28.25 Timestamp snapshot dependency on register bits

SNAPTYPSEL	TSMSTRENA	TSEVNTENA	PTP Messages
00b	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00b	0	1	SYNC
00b	1	1	Delay_Req
01b	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up
01b	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01b	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10b	x	x	SYNC, Delay_Req
11b	x	x	Pdelay_Req, Pdelay_Resp

The DMA returns the timestamp to the software inside the corresponding Receive Descriptor. The extended status, containing the timestamp message status and the IPC status, is written in normal descriptor RDES1 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

28.7.2 IEEE 1588 System Time Source

To get a snapshot of the time, the MAC requires a reference system time in 64-bit format as defined in the IEEE 1588-2002. Reference system time is provided from Ethernet Switch module.

28.7.3 IEEE 1588 Auxillary Snapshot

28.7.3.1 IEEE 1588 Auxillary Snapshot

The auxiliary snapshot feature allows you to store a snapshot of the system time based on an external event. The event is considered to be the rising edge of the GMAC_PTPTRG or ELC signal.

Up to two auxiliary snapshot inputs and 4 depth of a single common auxiliary snapshot FIFO are available.

28.7.3.2 Description of IEEE 1588 Auxillary Snapshot

The snapshots taken for any input are stored in a common FIFO. The application can read the MAC_Timestamp_Status register to know the timestamp of which input is available for reading at the top of this FIFO.

The MAC stores these snapshots in a FIFO. Only 64-bits of the timestamp are stored in the FIFO. When a snapshot is stored, the MAC indicates this to the application with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, a snapshot trigger-missed status (ATSSTM) is set in the MAC_Timestamp_Status register. This indicates that the latest auxiliary snapshot of the timestamp is not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full.

When an application reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting the ATSFC bit in MAC_Auxiliary_Control register. When multiple snapshots are present in the FIFO, the count is indicated in bits [27:25] of MAC_Timestamp_Status register.

28.7.4 PTP Timestamp Offload Function

28.7.4.1 Introduction to PTP Timestamp Offload Function

PTP Timestamp Offload Function is an optional feature that enables the automatic generation of specific PTP packets when the MAC is working as a specific node in the PTP network.

These packets may be generated periodically or triggered by the host software. In other modes, this feature can parse the incoming PTP packets on the receiver, and automatically generate and respond to the required PTP packets. This helps in offloading certain functions of a PTP node with better accuracy and lower latency of responses.

28.7.4.2 Description of PTP Offload Function

Based on the programmed mode, the MAC generates PTP Ethernet messages periodically or from the application, or based on reception of a particular PTP message.

Table 28.26 indicates the PTP message generation criteria.

Table 28.26 PTP message generation criteria

SNAPTYPSEL	TSMSTRENA	TSEVNTENA	Mode	Criteria for Generation of PTP Messages	PTP Message Type Generated
00b	0	1	Ordinary or Boundary Slave	SYNC message reception	Delay_Req
00b	1	1	Ordinary or Boundary Master	Periodic or on trigger from application	SYNC
				Delay_Req message reception	Delay_Resp
01b	0	1	Transparent Slave	Periodic or on trigger from application	Pdelay_Req
				Pdelay_Req message reception	Pdelay_Resp
				SYNC message reception	Delay_Req
01b	1	1	Transparent Master	Periodic or on trigger from application	Pdelay_Req
				Pdelay_Req message reception	Pdelay_Resp
				Periodic or on trigger from application	SYNC
				Delay_Req message reception	Delay_Resp
11b	x	x	Peer-to-Peer Transparent	Periodic or on trigger from application	Pdelay_Req
				Pdelay_Req message reception	Pdelay_Resp
All other programming combinations are invalid for PTP Offload feature.					

Note: Clocks supporting peer delay mechanism must not generate delay request/delay response messages, according to IEEE 1588-2008 specification. However, the GMAC controller supports this for flexibility, with a programmable control bit (DRRDIS). You can use the DRRDIS bit to control the response generation for delay request/delay response message. For example, in transparent slave mode, delay request is generated in response to received sync only when the bit is reset.

For example, when the MAC is set as an Ordinary or Boundary Slave clock in the PTP network, it can respond to the reception of SYNC messages with an automatic generation and transmission of the corresponding Delay_Req message. Similarly, various other modes of operation are explained in Table 28.26.

The MAC supports the multicast communication model for the generation of SYNC and Pdelay_Req PTP messages. For instance, the Destination Address field of the generated PTP over Ethernet packet is the defined special multicast addresses (0x011B19000000 for all except peer delay mechanism messages and 0x0180C200000E for peer delay mechanism messages).

When the MAC responds to received SYNC, Delay_Req and Pdelay_Req PTP messages with special multicast destination address, it also uses the corresponding special multicast address in the DA field of the automatically generated Delay_Req, Delay_Resp, and Pdelay_Resp PTP messages, respectively.

When the MAC responds to received SYNC, Delay_Req and Pdelay_Req PTP messages with unicast destination address, it takes the SA field of the received packets and makes them as the DA field of the automatically generated Delay_Req, Delay_Resp, and Pdelay_Resp PTP messages, respectively.

At the same time, all the received PTP messages are forwarded to the application along with Rx status, indicating whether the response was generated by the MAC, if it satisfies the packet filtering logic of the MAC receiver

When the MAC automatically generates a PdelayReq or responds with a Delay_Req, the egress timestamp of these two PTP messages are provided in the Tx TS status (Tx Timestamp Status register and interrupt generated).

In addition to messageType and versionPTP fields match for basic PTP over Ethernet message detection, the following additional fields are matched to qualify the received PTP message type:

1. The domainNumber field is checked for a match against the value programmed in the CSR.
2. The twoStepFlag in flagField field is checked for one-step indication (0).

3. The transportSpecific field is checked for Default PTP over Ethernet (0x0) or 802.1AS mode (0x1) when enabled.

28.7.4.3 PTP Packet Generation

This section explains the format and content of the automatically generated PTP packets by the MAC when this mode is enabled. The template of the Common PTP Message Header is provided, as well as the detailed description of the fields of specific PTP packets generated.

Table 28.27 Common PTP message header and PTP message-specific fields

Filed	Description
messageType	The following encoded values are used for PTP message types: ● SYNC: 0x0 ● Delay_Req: 0x1 ● Pdelay_Req: 0x2 ● Pdelay_Resp: 0x3 ● Delay_Resp: 0x9
transportSpecific	The following transport protocol encoding is used: ● Default PTP over Ethernet: 0x0 ● 802.1AS mode: 0x1
versionPTP	It is always set to 2 because PTP version 2 is supported.
messageLength	There is no suffix supported, so this field contains the length of the PTP message that includes 34 byte PTP common header and the body specific to the message type. For SYNC and Delay_Req packets, this field contains 44, whereas for Delay_Resp, Pdelay_Req and Pdelay_Resp, it contains 54.
domainNumber	This contains the value from the MAC_PTO_Control register.
flagField	The following values are used: ● alternateMasterFlag (Octet 0 bit 0): 0 for SYNC and Delay_Resp ● twoStepFlag (Octet 0 bit 1): 0 for SYNC and Pdelay_Resp ● unicastFlag (Octet 0 bit 2): 0 for Multicast Address, 1 for Unicast Address
correctionField	For more information, see section 28.7.5.2. MAC Transmit PTP Mode.
sourcePortIdentity	This field takes the value programmed in the MAC_Source_Port_Identityx registers.
sequenceId	Pdelay_Resp and Delay_Resp use the same sequenceId field from received Pdelay_Req and Delay_Req PTP messages. For SYNC/Delay_Req, Pdelay_Req, a separate sequenceId counter is maintained. These sequenceId counters get incremented by 1 every time the corresponding message is generated and transmitted.
controlField	The following encoded values are used for controlField: ● SYNC: 0x00 ● Delay_Req: 0x01 ● Pdelay_Req: 0x02 ● Pdelay_Resp: 0x05 ● Delay_Resp: 0x03
logMessageInterval	● SYNC: This contains logSyncInterval from the corresponding MAC_Log_Message_Interval register. ● Delay_Resp: This contains the sum of DRSYNCR and logSyncInterval value taken from the MAC_Log_Message_Interval register for a multicast PTP message and 0x7F for unicast PTP message. ● Delay_Req, Pdelay_Req and Pdelay_Resp: 0x7F where logSyncInterval = log2 (Mean Value of Interval in seconds)
originTimestamp	This field is the captured egress timestamp for SYNC, Delay_Req, and Pdelay_Req PTP messages.
receiveTimestamp	For Delay_Resp PTP message, this is the ingress timestamp of the corresponding received Delay_Req PTP message.
requestingPortIdentity	For Delay_Resp and Pdelay_Resp PTP messages, this is the sourcePortIdentity field taken from the corresponding received Delay_Req and Pdelay_Req PTP messages.
requestReceiptTimestamp	For the Pdelay_Resp PTP message, this field is set to 0.

The MAC supports values of -15 to 15 for logSyncInterval fields, which translates to a range from 32.768 micro second (2^{-15}) to 2^{15} second. For a given value of log sync interval (N), the time interval between two SYNC packets is given by the following:

- $2^{(30+N)}$ ns, when N is negative (-1 to -15)
- 2^{N} seconds, when N is positive (0 to 15)

For example:

- When logSyncInterval is programmed to 1, the interval is 2^1; therefore, the SYNC message is sent once every 2 seconds.
- When logSyncInterval is programmed to -1, the interval is 2^{-1} = 0.536 seconds; therefore, the SYNC message is sent once every 536 milliseconds. The value is 0.536 seconds, because 2^{-30} = 1 ns.
- When logSyncInterval is programmed to -5, the interval is 2^{-5} = 33.55ms; therefore, the SYNC message is sent once every 33.55 milliseconds.

Note: The MAC uses the PTP system time to generate the intervals for periodic packet transmission. For negative values of log message interval programmed, the generated period may deviate from the value given by the equation $2^{(30+N)}$, because of the non-binary nature of the nanoseconds field of the system time.

28.7.5 One-Step Timestamp

28.7.5.1 Introduction to One-Step Timestamp

The GMAC supports the one-step timestamp feature. When the One step timestamp feature is enabled, the MAC identifies the offset in the packet and inserts the timestamp received from the application at that offset.

28.7.5.2 MAC Transmit PTP Mode

Depending upon the type of message and its mode, the MAC updates the following fields of Transmit PTP packets:

- correctionField in the PTP header of messages
- originTimestamp in SYNC, Delay_Req, and Pdelay_Req messages

Table 28.28 lists how the PTP mode is selected based on the settings of SNAPTYPSEL, TSMSTRENA, and TSEVNTENA bits of the MAC_Timestamp_Control register and the fields that are updated for the incoming PTP packets based on the message type in that mode, during the one-step timestamping operation.

Table 28.28 MAC transmit PTP mode and one-step timestamping operation (1 of 2)

Programming			Mode	Per Packet Control*1			Messages Processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE*2	OSTC*3	TTS*4	
x	x	x	N/A	1	x	x	Timestamp is captured and returned to application
x	x	x	N/A	x	0	x	OST operation is not performed (PTP packet is not modified)
00b	x	0	End-to-end transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
							Delay_Req (correction field for residence time and Egress Asym Cor)
00b	0	1	Ordinary or Boundary Slave	1	1	x	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym cor)
00b	1	1	Ordinary or Boundary Master	0	1	x	Sync (originTimestamp field) Sync (correction field for sub-nanosecond cor)
01b	x	0	End-to-End Transparent with support for peer delay mechanism	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Pdelay_Req (correction field for residence time and Egress Asym Cor)
						Ingress TS	Pdelay_Resp (correction field for residence time and Ingress Asym Cor)

Table 28.28 MAC transmit PTP mode and one-step timestamping operation (2 of 2)

Programming			Mode	Per Packet Control*1			Messages Processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE *2	OSTC*3	TTS*4	
01b	0	1	Ordinary or Boundary Slave with support for peer delay mechanism or Peer to Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor) (applicable only for Peer to Peer transparent clock operation)
				1	1	x	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym cor)
				1	1	x	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)
01b	1	1	Ordinary or Boundary Master with support for peer delay mechanism	0	1	x	Sync (originTimestamp field) Sync (correction field for sub-nanosecond cor)
				1	1	x	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)
10b	x	x	End-to-End Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Delay_Req (correction field for residence time and Egress Asym Cor)
11b	x	x	Peer-to-Peer Transparen	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
				1	1	x	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)

Note 1. The per packet control values provided here are the recommended settings used by devices in typical PTP operation, for the programmed mode.
Note 2. TTSE represents TTSE bit of transmit descriptor. The TTSE function is independent of the OST function and the programmed operation mode for OST. The MAC captures and returns the timestamp when the TTSE bit is set.
Note 3. OSTC represents OSTC bit of transmit descriptor.
Note 4. TTS represents the timestamp value provided in the TTSH, TTSL fields of transmit descriptor.

28.7.5.3 Enabling One-Step Timestamp

You can enable the one-step timestamp feature for a packet by setting OSTC field in the descriptor. For updating the correction field in certain PTP packets, the ingress timestamp must be given in the TSSL and TSSH fields.

28.7.5.4 One-Step Time Stamping for PTP Over UDP

GMAC supports one-step timestamp operation for PTP messages sent over UDP/IPv4 and UDP/IPv6. Because origin timestamp and/or correction field (based on the PTP message type and the programmed PTP mode) in the PTP message are updated as part of the one-step timestamp operation, it also requires update to the checksum field of the PTP message sent over UDP/IP.

In GMAC, checksum is updated for a packet, in the MTL before the packet is sent to the MAC where the PTP message is updated for one step timestamp operation. PTP requires the timestamp to be captured while the packet (SFD of the packet) is on the line and one step timestamp requires the origin timestamp and/or correction field to be updated in the PTP header while the packet is being transmitted on the line. Because the PTP message is present in the UDP payload, it is not possible to update the checksum field in the UDP header for modifications made to the PTP message, because it is already transmitted by then. Instead, the following options are supported that are in line with specification mentioned in Annex D & E of IEEE 1588-2008:

- When PTP message is sent over UDP/IPv4, the UDP checksum may be set to 0. The application must set the UDP checksum to 0 and set CIC to 0 or 1 while providing the packet to the MAC and the MAC does not update checksum for changes in origin timestamp or correction field.
- When PTP message is sent over UDP/IPv6, a transmitting node extends the UDP payload of all PTP messages by 2 octets beyond the end of the PTP message. The contents of the UDP checksum field or the final 2 octets of the UDP payload might be modified to ensure that the UDP checksum remains intact after modification of PTP fields. The application must add the two extra bytes at the end of the PTP message while providing the packet to the MAC and the MAC updates these two bytes to keep the checksum correct.

A programmable option (CSC field in MAC_Timestamp_Control register) supports UDP with non-zero checksum for IPv4. When set, the two bytes at the end of the PTP message are updated to keep the UDP checksum correct, similar to PTP over UDP/IPv6. So, the application must add two bytes at the end of the PTP message sent to the GMAC and GMAC updates these two bytes to keep the checksum correct.

Updating the pad bytes to keep the checksum correct requires the old value of correction field and/or origin timestamp in the packet. To get better latency and area, the application can set the origin timestamp field to zero, for PTP message in particular modes in which GMAC overwrites the origin timestamp. For example, GMAC operating in Ordinary/Boundary master mode overwrites the origin timestamp field of the sync message, when OSTC is set. Because the sync message is originated by the port operating in Ordinary/Boundary master mode, it is possible for the application generating the message to set the origin timestamp field to zero.

Transmit checksum engine is automatically enabled when this feature is selected. GMAC uses the transmit checksum engine to identify the start of PTP message in the UDP/IP packet. Checksum engine has the capability to detect some kind of errors in the header (L3) and payload (L4). Also is not computed for some type of packets, which is indicated by "No" in Table 28.55. For one step, operation the packet is free of those errors and have "Yes/Not applicable" for the corresponding packet type in Table 28.55. If an error is reported by the checksum engine or there is a "No" in Table 28.55, for PTP messages sent over UDP/IP, no update is performed on the PTP message. See section 28.12.1. Transmit Checksum Offload Engine for details about the errors detected by transmit checksum engine.

Note:
- The packet is sent with specific IP address and UDP port numbers and does not have IPv4 options/IPv6 extension headers. Applications must take care of these requirements before giving the packet to the GMAC. GMAC does not validate them. As PTP is identified by specific value in the UDP destination port and as GMAC does not look into these fields, it assumes an IP packet with OSTC set as a PTP packet, and it is the responsibility of the application to set the OSTC bit only for IP packets which contains PTP messages.
- For PTP over UPD/IPv6 and PTP over UDP/IPv4 with CSC set, the GMAC does not verify the presence of the two pad bytes, instead it overwrites the two bytes after the PTP message.
- When Enable One step timestamp for PTP over UDP/IP feature is selected, Enable Transmit TCP/IP Checksum offload feature is automatically enabled and this is enabled only for Queue 0 in multiple transmit queue configurations. If the application requires OST support for PTP messages sent over UDP/IP for packets sent from queues other than 0, transmit checksum engine must be manually enabled for those transmit queues. If checksum engine is not enabled, no updates are done for PTP messages sent over UDP/IP even though OSTC is set.
- One-Step timestamp operation is not supported for tunneled packets

28.8 Multiple Channels and Queues Support

This chapter describes how the GMAC supports multiple queues and channels.

28.8.1 Multiple Queues and Channels Support in the Transmit Path

28.8.1.1 Introduction to Multiple Queues Support in the Transmit Path

The GMAC supports up to eight Transmit DMA and Transmit queues. The number of Tx DMA channels is equal to the number of Tx queues and is direct one-to-one mapping. This enables the interleaving of packet/data transfer of multiple Tx DMA on the host/system bus and each Tx Queue is reserved for the corresponding Tx DMA. Therefore, the integrity of packet transfer by each Tx DMA is maintained in the Tx queue and enables efficient utilization of the host bus for data transfers among multiple Tx DMA without depending on the packet length, Transmit buffer availability and so on.

If two Tx DMAs are allowed to transfer data into the same Tx queue, when a Tx DMA starts a packet transfer, other Tx DMA cannot transfer data to the same Tx queue unless the previous packet transfer is complete. This means that the second

DMA remains idle until the first packet transferred is complete, which is effectively a one-to-one mapping of the Tx DMA to the Tx queue.

28.8.1.2 Description of Fixed Priority Scheme

The fixed priority scheme is the default priority scheme for the DMA channels. In fixed priority scheme, the channel with highest priority always wins the arbitration when it requests the bus. Table 28.29 provides information about the priority levels of DMA channels.

Table 28.29 Fixed Priority Scheme for DMA Channels

Priority Level	Channel
0 (low)	Channel 0
1	Channel 1
2	Channel 2
3	Channel 3
4	Channel 4
5	Channel 5
6	Channel 6
7 (high)	Channel 7

The Fixed Priority scheme does not necessarily cause "starving" of lower priority channels for the AXI bus because of the capabilities of the AXI protocol and characteristics of the TxDMA, described as follows:

- Read command requests from a TxDMA for a burst of data transfers is driven on a separate AXI channel and gets executed in one clock cycle itself. The actual data transfer starts on a separate AXI channel only after the request is accepted and it takes multiple clock cycles to complete with relatively large read access latencies.
- AXI master is free to drive out subsequent requests even before the previous data transfers are completed.
- A TxDMA requests for another data transfer only after the data transfer for its previous request is completed and transferred to the MTL TxQ and space is available in TxQ to take in the next request.
- It is possible to program to control the maximum number of outstanding requests, Requested Burst sizes by DMA, and the burst sizes of each data transfer on AXI.

Considering the previous points, it is possible to program such that the requests of all the TxDMAs are placed and executed on the AXI bus before the data transfer of the first TxDMA is completed and it raises the next request to the arbiter.

Effectively, all the TxDMA channels get equal access to AXI bus and the corresponding TxQs get filled up at the same rate. The data gets read out from the TxQs as per the Traffic Class scheduler in the MTL. So at a steady state (assuming that AXI bandwidth available to fetch data from system memory is always more than the operating line rate), the bandwidth for each channel is controlled by the priorities and settings of the Traffic Scheduler in the MTL.

28.8.1.3 Description of Weighted Strict Priority

In Weighted Strict Priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. The unused burst transfers of one or more channels are reallocated based on the priority. The channel with highest priority gets the unused burst transfer time before it is allocated to a channel with next highest priority.

The channel priorities are fixed. Channel 7 has the highest priority and Channel 0 has the lowest priority. When a channel uses the allocated burst transfers, the channel with next lower priority is processed. After processing the allocated bandwidth of all channels that had packets to transmit, any unused burst transfer time is allocated to the channel of the highest priority (if required), and then next highest priority (if required), and so on.

28.8.1.4 Description of Weighted Round Robin

GMAC supports a Weighted Round Robin (WRR) priority scheme, in which the weight can be programmed through the DMA_CHn_TX_CONTROL register. In Weighted Round Robin (WRR), all channels are serviced in round-robin order according to the weights settings. The TCW field of the MA_CHn_Tx_Control register provides the weight for each Transmit channel as shown in Table 28.30.

Table 28.30 Weight for DMA channels

TCW Field	Transmit Channel Weight
000b	1
001b	2
010b	3
011b	4
100b	5
101b	6
110b	7
111b	8

The configured weights correspond to the number of burst transfers given to a channel in one arbitration cycle. The unused or excess burst transfers are distributed equally to all channels.

28.8.2 Multiple Queues and Channels Support in the Receive Path

28.8.2.1 Introduction to Multiple Queues in the Receive Path

The GMAC supports up to eight Receive channels. The number of Rx channels is independent of the Rx queues.

28.8.2.2 Description of Multiple Channels and Queues in the Receive Path

The GMAC controller supports independent selection of the number of Rx DMA channels and the number of Rx Queues in the MTL Rx Buffer. Therefore, the packets from any Rx queue can be serviced by any of the Rx DMA. As all the packets of Rx Queues are stored in a shared RXFIFO buffer in MTL, the Rx scheduler selects the Rx queue whose packet data is to be transferred to the destination Rx DMA, which then forwards the packet data to the host memory. The sequence of events in time are as follows:

1. Each Rx DMA indicates whether it is ready to transfer data, that is, when the Rx DMA has fetched the descriptor and has a Receiver Buffer ready, to accept the packet data. Each Rx DMA also indicates the number of words that it can transfer, based on the space available in the Rx Buffer and the value programmed in the PBL field of its DMA_CHn_RX_CONTROL register.
2. The MTL Rx scheduler matches the number of bytes/packets available for transfer at the top of all Rx queues with the corresponding Rx DMA ready status and the number of bytes requested by it.
3. If there are multiple successful matches, the scheduler selects the Rx queue to be serviced, based on the arbitration schemes (Strict Priority or Weighted Strict Priority) decided by the RAA field of MTL_Operation_Mode register. In the Weighted Strict Priority scheme, the weights of each Rx queue is set in the RXQ_WEGT field of the corresponding MTL_RXQn_CONTROL register.
4. The MTL Rx controller fetches the data of the selected Rx queue from the shared RXFIFO memory and starts the transfer of the requested PBL number of bytes to the DMA block or until the end of packet and the corresponding Rx status is transferred (whichever is first).
5. After completing the current request, the scheduler repeats the process by starting a new arbitration cycle. However, it selects the same Rx queue for servicing, if the end of packet is not transferred and the RXQ_FRM_ARBIT field of the MTL_RXQn_CONTROL register is 1, for the Rx queue.

28.8.2.3 Rx Queue to DMA Mapping

The packets in the MTL Rx Queues can be routed to any one of the multiple DMA channels by programming the following registers:

- MTL_RxQ_DMA_Map0 register (for queues 0, 1, 2 and 3)
- MTL_RxQ_DMA_Map1 register (for queues 4, 5, 6 and 7)

The following types of Rx Queue to DMA mapping is possible through programming:

- Static Mapping

- Dynamic (Per Packet) Mapping

(1) Static Mapping

In Static Mapping mode, all packets of an Rx Queue are connected to a specific DMA channel.

In this mode, all of the packets of an Rx Queue are connected to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bits [3:0]) and Q0DDMACH (bit [7] = 0) of the MTL_RxQ_DMA_Map0 register.

Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each Queue.

(2) Dynamic (Per Packet) Mapping

In Dynamic (per packet) Mapping mode, the destination DMA channel is decided by the MAC receiver for each packet.

In this mode, the destination DMA channel of a packet being read from a Rx Queue is not constant but decided independently for each packet. For example, if you set the Q1DDMACH bit of the MTL_RxQ_DMA_Map0 register, the static mapping is disabled for Rx Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the MAC receiver for each packet, depending on the following in decreasing order of priority:

1. L3-L4 filter Based DMA Selection
   When the Enable Layer 3 and Layer 4 Packet Filter feature is enabled, the TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Address_Control register is selected as the destination DMA channel number provided DMCHEN bit of the same register is set.
   If none of the L3-L4 Registers give a comparison match, GMAC proceeds to the next step.
2. Extended VLAN Based DMA Selection
   Extended routing is applicable only if the VLAN Filter has passed. Routing is only based on Perfect Filter Result. Each perfect filter has a DMA Channel Enable and a DMA Channel Number field which can be programmed. Routing is applicable for a filter, only if the DMA Channel Enable bit is set.
   The frame is routed to the smallest Matching Filter's DMA Channel provided it is enabled. If that filter's DMA Channel number is not enabled, the frame gets routed to Channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1. Then the MAC checks if Filter 1's DMA Channel Number is enabled through programming. If yes, the frame gets routed to the programmed value; otherwise it gets routed to DMA. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame is routed based on DA based addressing or to Channel 0.
   If Hash Filter is also enabled, it is used to determine the Filter result only. Routing still depends on the enabled Perfect Filters. If none of the perfect filters are enabled or if all of them are bypassed, the VLAN Filter based routing is not done. The frame is routed through DA Based addressing or to Channel 0. If all the perfect filters give a fail result and the Hash Filter has passed, VLAN Filter result is a pass. However, routing is based on DA Based Addressing or to Channel 0. The behavior is similar when inverse filtering is enabled.
3. Ethernet DA-Based DMA Selection
   The DA address of the received packet is compared against the programmed DA values in MAC Address Registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the previous operations is able to make a successful match/decision, then the packet is routed to DMA Channel 0 by default.

(3) Broadcast/Multicast Packet Duplication

GMAC supports Broadcast/Multicast Packet Duplication feature to send the received Broadcast/Multicast packets to multiple DMA channels.

In a virtual system that supports multiple guest OS's (for instance, each OS owning a DMA), where each DMA could act as an independent Ethernet Node, there can be requirement to route the received multicast/broadcast packets to all/multiple DMA channels. This is implemented by having the MTL_RX_FIFO_read_controller to read the packet from the same queue multiple times and route the same packet to the specified multiple DMA channels.

Through software control, the DMA channel selection (DCS) field inside the MAC Address Registers are redefined to denote multiple DMA channels.

Note: Only the MAC_ADDRESSn_HIGH (n = 0 to 31) registers support Broadcast/Multicast packet duplication

The DCS field of the of MAC_ADDRESSn_HIGH (n = 0 to 31) registers determine the DMA channel number to which the received packet (that matches the MAC Address present in that register) must be routed.

For the MAC_ADDRESSn_HIGH (n = 0 to 31) registers, DCS is a programmable field that supports more than one DMA channel number to be selected.

The DCS field can hold any one of the following values:

- Binary value of the channel number when the PDC bit of the MAC_Ext_Configuration register is set to 0.
- One-hot value of the channel number when PDC bit of the MAC_Ext_Configuration register is set to 1.

To enable the Multicast/Broadcast packets to be routed to multiple DMA channels, use the DA based routing. Packet duplication is not supported in other DMA channel routing mechanisms such as Extended VLAN, or L3-L4 based routing. In other words, if the destination DMA channel is decided by the VLAN or L3-L4 filter result, it is routed only to the specific channel even if the DA of the packet matches the multicast address in the MAC_Address register.

The Packet Duplication feature is supported only on the highest MTL Queue configured. Therefore, packet duplication for Broadcast/Multicast packets requires that the MCBCQ field of MAC_RxQ_Ctrl1 register is programmed to the highest RxQ present in the configuration.

In a packet duplication, the MTL Read Controller sequentially transfers the same packet to all the required RxDMA. This packet is removed from the MTL FIFO only after the packet is transferred to all the selected DMA channels. Therefore this feature is suitable for smaller packet sizes or very low bandwidth traffic; to ensure that the MTL RxQ does not overflow due to the long period for which the packet remains in the queue during the packet duplication.

Note: When more than one bit is set for the DMA channel number, a packet that is not routed to the highest receive queue is routed to only one DMA channel as indicated by the lowest bit set in the DCS field of the MAC_ADDRESSn_HIGH (n = 1 to 31) register.

28.8.3 Priority Scheme for Tx DMA and Rx DMA

The GMAC DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin.

The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. The DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin. The DA bit of the DMA_Mode register specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a channel.

If you have enabled the Tx DMA and Rx DMA of a channel, you can specify which DMA gets the bus when the channel gets the control of the bus. You can set the priority between the corresponding Tx DMA and Rx DMA by using the TXPR field of the DMA_Mode register. For round-robin arbitration, you can use the PR field of the DMA_Mode register to specify the weighted priority between the Tx DMA and Rx DMA.

Table 28.31 provides information about the priority scheme between Tx DMA and Rx DMA.

Table 28.31 Priority scheme for Tx DMA and Rx DMA (1 of 2)

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority Schemes
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1

Table 28.31 Priority scheme for Tx DMA and Rx DMA (2 of 2)

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority Schemes
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

Note: Bits 14, 13, 12, 11, and 1 are not valid if one of the paths (Transmit or Receive) is not present in a channel. The Transmit and Receive paths are always present in Channel 0.

28.8.4 Selection of Tag Priorities Assigned to Rx Queues

The GMAC controller supports assigning tag priorities to Rx Queues through programming registers.

The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. The bit corresponding to the VLAN Tag priority can be set in the PSRQ field for assigning that priority to the Rx Queue. For example, if you want to assign VLAN Tag priority of 3 to Rx Queue 0, set bit [3] in PSRQ field of MAC_RxQ_Ctrl2 register. The VLAN Tag priority assigned to particular Rx Queue must be unique, that is, more than one Rx Queue cannot be assigned the same VLAN Tag priority. However, more than one VLAN Tag priorities can be assigned to same Rx Queue.

The settings in the PSRQ field is used for VLAN Tagged Rx packet routing to Rx Queues. The received VLAN Tagged Rx packet is routed to Rx Queue that has the VLAN Tag priority match.

28.8.5 Distribution of Rx Packets from MAC to Rx Queues

The GMAC controller provides multiple Rx queues to support classification and distribution of ingress packets. The MAC receiver pushes the ingress packets to the Rx queues based on packet type (tagged, untagged, multicast, PTP, AVB, and so on), tag priorities, MAC packet filter results, preemptable or express packet, and so on. The distribution is controlled by the settings of the MAC_RxQ_Ctrl* and MAC_Packet_Filter register fields.

GMAC additionally supports distribution of ingress packets based on user-defined Type field of the ingress packets when TBRQE field (bit [29]) of the MAC_RxQ_Ctrl1 register is enabled. You can program up to 8 Type for matching, in the MAC_TMRQ_REGSn registers which is accessible through MAC_Indir_Access_Ctrl and MAC_Indir_Access_Data registers.

Table 28.32 shows MAC_TMRQ_REGSn register specification.

Table 28.32 MAC_TMRQ_REGSn register specification

Bit	Symbol	Function	R/W
15:0	TYP	Type field Value Specifies the type value of packet that needs to be compared with received Ethernet packet. This field is valid when programmed to a value greater than or equal to 0x0600.	R/W
18:16	TMRQ	Type Match Rx Queue Number Specifies the receive queue number to which the packet needs to be forwarded on detecting a type match.	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W
20	PFEX	Preemption or Express Packet This bit specifies if it is a preemption packet or express packet.	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Based on the packet filter settings, the MAC receiver decides to either drop or forward the Ingress packet. For details, see section 28.6.1. Packet Filtering Sequence. However, the results of Layer 3 and Layer 4 filtering, mentioned in section

28.6.4. Layer 3 and Layer 4 Filtering are not considered for the distribution of ingress packets into the Rx queues. Only the results of DA/SA/VLAN filters mentioned in section 28.6.2. Source Address or Destination Address Filtering and section 28.6.3. VLAN Filtering are applicable.

Filtering of the broadcast packets is exclusively controlled by the DBF field, bit [5] of the MAC_Packet_Filter register. The filtering of multicast packets is controlled by the PM field, bit [4] of the MAC_Packet_Filter register, in addition to the DA/SA match.

By default, packets that fail any of the DA/SA filters, are dropped by the MAC Receiver. However, packets that fail the DA/SA/VLAN filter can still be forwarded to the application when the RA field of the MAC_Packet_Filter register is 1. Even when RA field is 0, VLAN filter fail packets can be forwarded if the VTFE field of the MAC_Packet_Filter register is 0.

The ingress packets go through the following operations in the decreasing order of priority.

1. RA = 0: Ingress packets are dropped if any one of the following condition is true.
   - DA/SA filter fail
   - VLAN filter fail and VTFE field of the MAC_Packet_Filter register is 1
2. RA = 1: Ingress packets that fail the DA/SA filter are also forwarded to the Rx queue as mentioned in Table 28.33.
3. RA = 1 and VTFE = 0: Ingress tagged packets that pass the DA/SA filter but fail the VLAN filter, are forwarded to the Rx queue as mentioned in Table 28.34.
4. Ingress packets that pass the DA/SA/VLAN filters are forwarded to the Rx queue
   - Table 28.35 shows the routing priority in the decreasing order when OMCBCQ field of the MAC_RxQ_Ctrl1 register is 0.
   - Table 28.36 shows the routing priority in the decreasing order when OMCBCQ field of the MAC_RxQ_Ctrl1 register is 1.

Table 28.33 Routing DA/SA failed packets to Rx queue

Packet Type	TSN Type	Destination Rx Queue Determined By
Broadcast/Multicast	Express	if MFFQE = 1, MFFQ; else if VFFQE = 1, VFFQ; (only for tagged packets) else RxQ0
Unicast	Express	if UFFQE = 1, UFFQ; else if VFFQE = 1, VFFQ; (only for tagged packets) else RxQ0
All	Preemptable	FPRQ field

Table 28.34 Routing DA/SA pass but VLAN filter fail packets to Rx queue

TSN Packet Type	Destination Rx Queue Determined By
Express	if VFFQE = 1, VFFQ; else RxQ0
Preemptable	RQ field

Table 28.35 Priority routing of filter pass packets when OMCBCQ = 0 (1 of 2)

Packet Type	TSN Type	Tagged	Destination Rx Queue Determined By
Broadcast/Multicast	Express	Yes	if MCBCQEN = 1, MCBCQ; else if TBRQE = 1, TMRQ; else PSRQ
		No	if MCBCQEN = 1, MCBCQ; else if TBRQE = 1, TMRQ; else UPQ
Unicast AVTP Control	Express	No	AVCPQ
		Yes	if TACPQE = 1, AVCPQ; else PSRQ
Unicast PTP over Ethernet	Express	No	PTPQ
		Yes	PTPQ or PSRQ based on the value of TPQC.

Table 28.35 Priority routing of filter pass packets when OMCBCQ = 0 (2 of 2)

Packet Type	TSN Type	Tagged	Destination Rx Queue Determined By
Remaining Unicast	Express	No	If TBRQE = 1, TMRQ; else UPQ
		Yes	If TBRQE = 1, TMRQ; else PSRQ
All Packets	Preemptable	No	If TBRQE = 1, TMRQ; else FPRQ
		Yes	If TBRQE = 1, TMRQ; else PSRQ

Table 28.36 Priority routing of filter pass packets when OMCBCQ = 1

Packet Type	TSN Type	Tagged	Destination Rx Queue Determined By
All AVTP Control	Express	No	AVCPQ
		Yes	if TACPQE = 1, AVCPQ; else PSRQ
All PTP over Ethernet	Express	No	PTPQ
		Yes	PTPQ or PSRQ based on TPQC
Remaining Broadcast/Multicast	Express	Yes	if MCBCQEN = 1, MCBCQ; else if TBRQE = 1, TMRQ; else PSRQ
		No	if MCBCQEN = 1, MCBCQ; else if TBRQE = 1, TMRQ; else UPQ
Remaining Unicast	Express	No	if TBRQE = 1, TMRQ; else UPQ
		Yes	if TBRQE = 1, TMRQ; else PSRQ
All Packets	Preemptable	No	if TBRQE = 1, TMRQ; else FPRQ
		Yes	if TBRQE = 1, TMRQ; else PSRQ

Note: 1. The fields mentioned in Table 28.33 through Table 28.36 belong to MAC_RxQ_Ctrl0, MAC_RxQ_Ctrl1, MAC_RxQ_Ctrl2, MAC_RxQ_Ctrl3, or MAC_RxQ_Ctrl4 registers.

2. If the RxQ pointed by the various fields in Table 28.33 through Table 28.36 is not enabled in the MAC_RxQ_Ctrl0 register as per the packet type, the packet is written to
   - RxQ0 for Express packets
   - FPRQ field for Preemptable packets

   If RxQ0/FPRQ is not enabled, the packet is dropped.

3. If the AV8021ASMEN field of the MAC_Timestamp_Control register is 1, MAC receiver checks only for untagged PTP packet. Tagged packet with PTP payload are considered as Remaining (Unicast/Broadcast/Multicast) tagged packets in Table 28.33 through Table 28.36.

28.8.6 Audio Video Bridging

28.8.6.1 Introduction to AV Feature

The GMAC supports the AV data transfer in 100 Mbps and 1000 Mbps modes. The AV feature enables transmission of time-sensitive traffic over bridged local area networks (LANs). The following standards define various aspects of the AV feature implementation:

- IEEE 802.1Qav-2009: Allows the bridges to provide time-sensitive and loss-sensitive real-time audio video data transmission (AV traffic). It specifies the priority regeneration and controlled bandwidth queue draining algorithms that are used in bridges and AV traffic sources.
- IEEE 802.1Qat-2009: Allows the network resources to be reserved for specific traffic streams traversing a bridged local area network.
- IEEE 802.1AS-2011: Specifies the protocol and procedures used to ensure that the synchronization requirements are met for time-sensitive applications such as audio and video across bridged and virtual-bridged LANs consisting of LAN media where the transmission delays are fixed and symmetrical. For example, IEEE 802.3 full-duplex links include the maintenance of synchronized time during normal operation followed by addition, removal, or failure of network components and network reconfiguration.

While the AVB standards were originally designed for Audio and Video over standard Ethernet, extending these to control streams would additionally benefit the industrial and automotive sectors. Time Sensitive Networking (TSN) is a set of standards developed by the Time Sensitive Networking Task Group with the intent to extend the future AVB enhancements to other sectors that could benefit.

Bridges are increasingly used to interconnect devices that support scheduled applications (for example, industrial automation, process control and vehicle control). The IEEE 802.1Qbv-2015 (Enhancements to Scheduling Traffic) provides performance assurances of latency and delivery variation to enable these applications in an engineered LAN while maintaining the existing guarantees for the credit-based shaper and best-effort traffic.

The IEEE 802.3br (Interspersing Traffic) and IEEE 802.1Qbu (Frame Preemption) enables the suspension of a large preemptable packet being transmitted by the MAC layer to allow one or more express packets to be transmitted before the transmission of the preemptable packet is resumed. This provides the capability to schedule express traffic packets with minimal delays/latencies or at predictable times with efficient utilization of the line bandwidth.

As per the IEEE specification for 802.1Qbv, 802.1Qbu, and 802.3br, the TSN features are supported only in the following modes:

- Full duplex
- 100 Mbps or higher link speed
- Pause or no flow control
- When Qbv schedule is enabled for time-sensitive traffic, Pause is likely to interfere with the Qbv schedules. So, it is recommended not to enable PAUSE when Qbv scheduler is enabled.
- Two or more Tx queues (for Qbv) configured and enabled
- One or more Express Queues and one or more Preemption queues on both transmit and receive (for Qbu/802.3br) configured and enabled.

28.8.6.2 Transmit Path Functions

When the GMAC controller supports the AV Bridging feature, you can enable and disable certain functions associated with the transmit path.

When you select the AV feature, the Transmit paths of Queue 0 and the highest enabled queue are enabled by default.

The Transmit path of Queue 0 supports the strict priority algorithm, and it is used for best-effort traffic. For a queue, the strict priority algorithm determines that a packet is available for transmission if the queue contains one or more packets. When the threshold mode for MTL Tx FIFO is enabled, the strict priority algorithm determines that a packet is available for transmission if the queue contains a partial packet of size equal to the programmed threshold limit.

The Transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive as per the algorithm.

You can disable the credit-based shaper algorithm for all queues or lower-priority queues. For example, you can either disable the credit-based shaper algorithm for Queue 1 and Queue 2 or only for Queue 1. You should not disable the credit-based shaper algorithm for Queue 2 and enable it for Queue 1. When you disable the credit-based shaper algorithm for a queue, the channel uses the default strict priority algorithm.

Each Transmit DMA has a separate descriptor chain for fetching the transmit data. The Transmit channel that gets the access to the system bus depends on the DMA arbiter.

The Transmit path has a shared FIFO (MTL layer) for each queue. The data fetched by the DMA is put in the respective part of the FIFO. The MTL Tx Queue Scheduler controls which part of the FIFO data is transmitted by the MAC. If the credit-based shaper algorithm is enabled for a queue, the corresponding queue is selected for transmission if the following conditions are true:

- If the packet is available in the channel and has a positive or zero credit.
- If the higher priority queue has no packet waiting in the FIFO.

If the credit-based shaper algorithm is disabled for all queues, the packet to be transmitted from a queue is selected based on the priority scheme described in Table 28.37.

Table 28.37 Weight for DMA channels

TCW Field	Transmit Channel Weight
000b	1
001b	2
010b	3
011b	4
100b	5
101b	6
110b	7
111b	8

28.8.6.3 Receive Path Functions

When the GMAC controller supports the AV Bridging feature, you can enable and disable certain functions associated with the receive path.

When you select the AV feature, the Receive path of Queue 0 is enabled by default. All traffic is received on this channel. You can enable the Receive paths of additional queues. By enabling the Receive paths of multiple channels, you can demultiplex the received data to send the packets into separate receive channels.

To differentiate between the AV and non-AV traffic, the MAC provides a status that indicates if it is an AV packet and its corresponding VLAN Priority tag value. This status is updated in the Extended Status field of the Receive descriptor as explained in section 28.17.5. Receive Descriptor. All received packets with the EtherType field of 0x22F0 are detected as AV packets. The AV packets can be of the following two types:

- AV data packets: The AV data packets are always tagged. The tagged AV data packets are received based on the programmed priority value. To specify the channel to which an AV packet with a given priority must be sent, program bits [15:8] in the Transmit Flow Control Register of the corresponding queue.
- AV control packets: The AV control packets can be either tagged or untagged. The untagged AV control packets are received on Queue 0 by default. To receive these packets on any other queue, you can program bits [2:0] of the MAC_RxQ_Ctrl1 register. Similar to the AV data packets, the tagged AV control packets are received based on the programmed priority value.

In addition to the AV packets, you can receive the untagged PTP packets on any queue. By default, the PTP packets (tagged or untagged) are received on Queue 0. To receive these packets on any other queue, you need to program bits [6:4] of the MAC_RxQ_Ctrl1 register.

28.8.6.4 Credit-Based Shaper Algorithm

The MTL Queue Scheduler uses the credit-based shaper algorithm to arbitrate the AV traffic in all queues and the legacy Ethernet traffic in Queue 0. You can program the additional queues to use the credit-based shaper algorithm.

The following sections provide information about how you can implement the credit-based shaper algorithm:

- Credit Value
- idleSlopeCredit and sendSlopeCredit Values
- Bandwidth Status

(1) Credit Value

The credit value is part of the credit-based sharper algorithm used by the MTL Queue Scheduler.

The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps and 8 ns for 1000 Mbps. The credit to be added or subtracted per cycle can be fractional based on the required idleSlope and sendSlope values, as described in Table 28.38.

Table 28.38 Credit value per transmit cycle example

Mode	Values	Description
100 Mbps	• portTransmitRate = 100 Mbps • idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class) • sendSlope = 30 Mbps	• credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when best-effort packet is being transmitted. • credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class packet is being transmitted.

The DMA stores the queue traffic in the respective part of the Tx FIFO based on the slot number in the transmit descriptor (if enabled) or the bandwidth availability on the AMBA AXI application bus.

The credit for a queue builds up only when the packet is available but it cannot be transmitted because the MAC is sending a packet from another queue. The GMAC supports another mode in which the credit can build up in advance for a queue in which no packet is available in respective part of the FIFO. This enables sending a burst of high priority traffic in a queue as soon as the data is available. You can enable this mode with bit 3 of the CBS Control registers of corresponding queues.

When reset, the accumulated credit parameter in the credit-based shaper algorithm is set to zero if there is positive credit, and there is no packet to transmit in a queue. The credit does not accumulate when there is no packet waiting in a queue and other queues are transmitting. When set, the accumulated credit parameter in the credit-based shaper algorithm is not reset to zero if there is positive credit and no packet to transmit in a queue. The credit accumulates even when there is no packet waiting in a queue and other queues are transmitting.

(2) idleSlopeCredit and sendSlopeCredit Values

The idleSlopeCredit and sendSlopeCredit values are programmable.

The software must program the idleSlopeCredit and sendSlopeCredit values. The programmed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, 2.8 × 1024 = 2867 and 1.2 × 1024 = 1229. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values. This means that if computed hiCredit and loCredit values are 12,000 bits and 3,036 bits respectively, the values to be programmed in the hiCredit and loCredit registers of the corresponding channel are 12000 × 1024 bits and two's complement of 3036 × 1024, respectively.

(3) Bandwidth Status

The hardware maintains the status of the actual bandwidth consumed by each higher priority queue in the CBS status registers. This enables the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previous programmed slot interval (1, 2, 4, 8, or 16 slots of 125 µs) in a queue. The status register is updated even if the credit-based shaper algorithm is not enabled for a queue. The number of slots over which the average bits transmitted per slot are computed is programmed in bits [6:4] of the CBS control register of the respective queue. For example, if you have programmed two slots, the average bits are computed over slot numbers 0–1, 2–3, 4–5, and so on.

The value programmed in the idleSlopeCredit register of a queue is proportional to the bandwidth reserved for the queue. The software can allocate any bandwidth that is not used by the higher priority queue to the reserved bandwidth of the lower priority queue.

A lower priority queue, which is using the credit-based shaper algorithm, cannot use the unused reserved bandwidth of any higher priority queue that is using the credit-based shaper algorithm. However, a lower priority queue, which is using the strict-priority algorithm, can use the unused reserved bandwidth of any higher priority queue that uses the credit-based shaper algorithm. For example, Queue 1 and Queue 2 use the credit-based shaper algorithm (with reserved bandwidth of 50% and 25%, respectively) and Queue 0 uses the strict-priority algorithm. If Queue 1 uses only 40% of reserved bandwidth, the remaining 10% is used by Queue 0. Queue 2 cannot exceed the reserved bandwidth of 25%.

28.8.6.5 Slot Number Function and Audio Video Bridging

(1) Introduction to Slot Number Function

When the AV feature is enabled, you can use the slot number function to schedule the data fetching from the system memory by the DMA. This feature is useful when the source AV data needs to be transmitted at specific intervals.

You can program the slot number at which the DMA should fetch the data from system memory in the Transmit Descriptor Word 3 (TDES3). This 4-bit field allows the application to schedule data up to 16 slots; a programmable slot interval that ranges from 1 µs to 4096 µs and granularity of 1 µs. This field is applicable only for the AV channels.

(2) Description of Slot Number Function

When the DMA fetches a Tx descriptor, it compares the slot number of the Tx descriptor with the internally generated reference slot interval. The slot interval is a counter that is updated based on a programmable slot interval (with range from 1 µs to 4096 µs) of the IEEE 1588 system time. In addition, the slot interval counter is initialized to zero when the seconds field of the system time is incremented, that is, the sub-second counter rolls over. The DMA fetches the data only if it matches the current slot or the next slot. The DMA remains in the descriptor fetch state till there is a match.

To enable the DMA to fetch the data only if it matches the current slot or the next two slots, you can program bit 1 of the Slot Function Control and Status register of the corresponding DMA channel.

Note: If the slot number in the descriptor is less than the reference slot number, the DMA takes it as a future slot.

You can enable the check for slot number by setting bit 0 of the Slot Function Control and Status register of corresponding DMA channel. When this check is not enabled, the packets are fetched immediately after the descriptor is read. In addition, bits [19:16] indicate the value of the reference slot number in DMA.

28.8.7 Queue Modes

You can enable a Tx queue for generic/AV traffic. The queues are enabled for generic queuing using WRR or WSP algorithms.

For enabling a Tx queue for AV, the queuing is based on the CBS or SP algorithms.

You can enable an Rx queue for generic, or AV traffic. A particular queue enabled for generic/AV based routing is determined by the RXQn_EN field of corresponding queue. The following list explains how Rx queues are enabled based on the selected features:

- Multiple Rx queues without AV feature
  All queues are enabled for generic queuing based on the VLAN Tag priority. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. By default untagged packets are routed to Receive queue specified in UPQ field of MAC_RxQ_Ctrl1 register. Queue 0 is the default value of UPQ field. You can override the default value with any other value, for the UPQ field. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register.
- Multiple Rx queues with AV feature
  AV feature is enabled for all selected Rx queues. The queuing is done based on the VLAN Tag priority for DCB data packets. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register. The AV control packets (tagged or untagged) are routed based on the AVCPQ field of the MAC_RxQ_Ctrl1 register. The PTP over Ethernet packets are routed based on the AVPTPQ field of MAC_RxQ_Ctrl1 register.

28.8.7.1 Programming Guidelines for Disabling Flow Control in AV Queues

The GMAC supports programming of same priorities for AV and DCB enabled Rx queues, when both coexist. For example, priority 1 can be programmed in PSRQ[n] field corresponding to Rx Queue enabled for AV in MAC_RxQ_Ctrl2 /3 register and same priority 1 can be programmed in PSRQ[n] field corresponding to Rx Queue enabled for DCB in MAC_RxQ_Ctrl2 /3 register, at the same time. When AV and DCB operation coexists, it requires that the Flow Control is disabled for AV enabled queues. See section 28.18.11.4. Disabling Flow Control for AV Enabled Queues.

28.8.8 Queue Priorities

You can program the priority of an Rx queue corresponding field of MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. The priority should be assigned in the following order:

1. AV queue (high priority)
2. DCB queue (medium priority)
3. Best-effort queue (low priority)

28.9 Enhancements to Scheduled Traffic (EST)

The IEEE 802.1Qbv-2015 defines the schedule for each of the queues on every egress port which makes the implementation aware of traffic arrival schedule. This information can be used to block the lower priority traffic from transmission in this time window/slot. This ensures that scheduled traffic is forwarded from sender to receiver through all the network nodes with a deterministic delay.

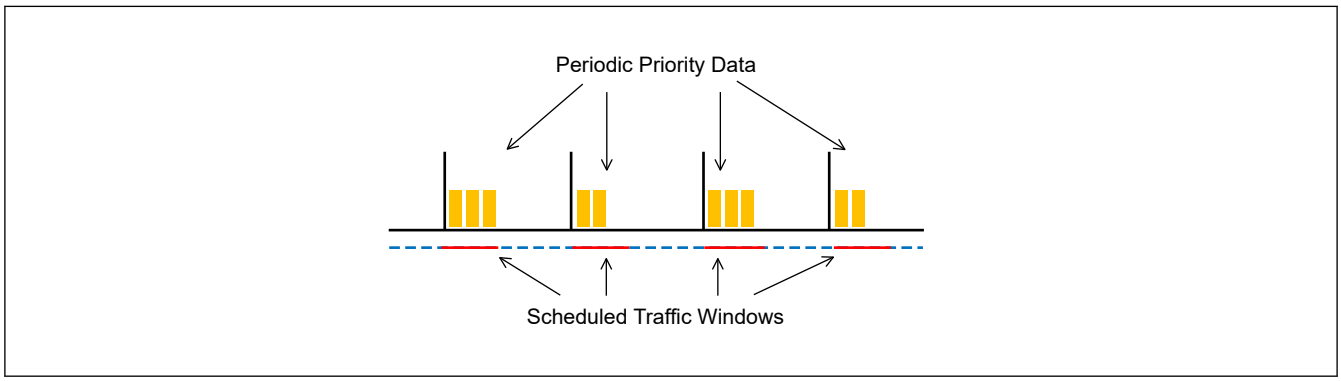

Figure 28.15 Weighted round robin example

One of the important requirements to achieve a low latency is to ensure there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations while starting a transmission.

As shown in Figure 28.16, if an interfering frame begins transmission just before the start of a reserved time period, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

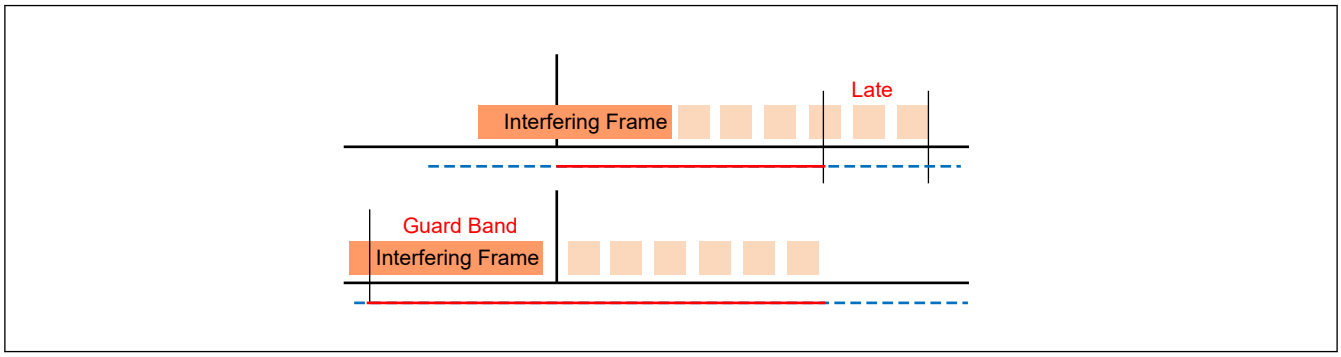

Figure 28.16 Implementing a guard band to avoid delays due to interfering frames

A larger guard band equates to a less efficient use of network bandwidth. However, with the implementation of IEEE802.1Qbu (frame preemption), this issue is addressed. Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

28.9.1 Frequently Used Terms in EST

Following are some of the frequently used terms in the EST support and their definitions.

- Gate Control List
  The list in the hardware memory that holds the gate controls and the associated time intervals.
- Gate Controls
  For a given schedule (row in gate control list) there is a Gate Open (O) and Gate Close (C) state associated with each TC. The set of O or C values, whose width is same as configured TCs is called the Gate Controls. Example: CCOCOOCO means TC7 = C, TC6 = C, TC5 = O and so on.
- Time Interval

Time interval (in nano seconds) is a 24-bit field in the Gate Control list that indicates the time for which the associated gate controls are valid.

- Base Time Register
  Each Gate Control List is associated with a 64-bit Base Time Register that holds the start time (in PTP format) for the list.

28.9.2 Updates to the Transmit Scheduling to Support EST

To support EST, following updates are required to the transmit scheduling:

- Implementation of Gate Control List (GCL)
- Enforcing gate controls in the scheduler
- Accounting for Gate Open (O) duty cycle in the computation of idleSlope (CBS)

28.9.2.1 Implementation of Gate Control List (GCL)

Figure 28.17 shows block diagram from the IEEE 802.1Qbv spec that illustrates how the gate control list governs the gate close(C) and open(O) events based on the schedule provided for each event.

GCL has the following two parts:

- Time Interval
  Defines the time in nano seconds for which the gate controls are valid and should be applied before reading the next gate controls from the list. Width of 24 to represent a maximum of 16ms schedule interval respectively. Supports left shift of the time interval up to 7 bits to be able to apply a multiplication factor from 1 to 128 ns (in steps of 2^n). The maximum value (post shifting) of this field must be 999,999,999 ns.

- Gate Control
  Defines the Open (O) represented by logic 1 or Close (C) represented by logic 0 state for the gate of each TC.

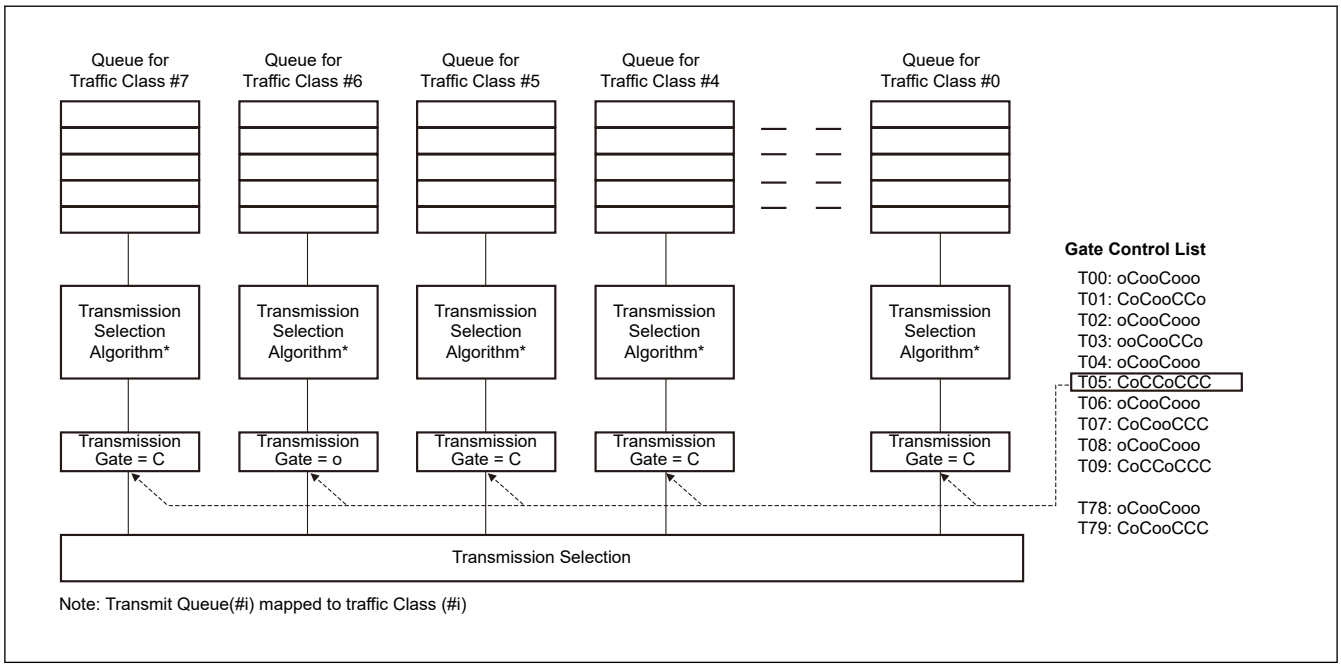

Figure 28.17 Block diagram from IEEE 802.1 Qbv Specification - GCL Governing Gate Close and Open Events

The implementation of GCL consists of the following two Gate Control Lists:

- HWOL - Hardware Owned List which is a list for hardware access.
- SWOL - Software Owned List which is a list for software access.

The access to these lists is mutually exclusive. The ownership to the list is set by hardware in the SWOL field of MTL_EST_Status register. Following table provides the implementation details of GCL.

Table 28.39 External memory used for holding the two gate-control lists

Gate Control (up to 8 bits)	Time Interval (ns) 16, 20, or 24 bits	
OOCCCCCC	T0	HWOL or SWOL
OOOOCCCC	T1	
CCCCOOCC	T2	
CCCCCCOO	T3	
I	I	
I	I	
OCOCOCOO		
OOOOCCCC	T last	
OOOOCCCC	T0	SWOL or HWOL
OOOOCCCC	T1	
OOCCCCCC	T2	
OOOOCCCC	T3	
I	I	
I	I	
OCOCCCCC		
OOCCCCCC	T last	

28.9.2.2 Registers Related to Gate Control List

Following are the set of 4 registers (one for each GCL) related to GCL. These registers are implemented through Indirect Addressing using the MTL_EST_GCL_Control and MTL_EST_GCL_Data registers.

1. 64-bit Base Time Register (BTR)
2. 40-bit Cycle Time (CTR)
3. m-bit Time Extension (TER)
4. 9-bit [Gate Control] List Length (LLR)

(1) Base Time Register (BTR)

Base Time Register is a 64-bit register that holds the start time to execute the GCL. The format of the BTR is same as the PTP format (upper 32-bits holds time in seconds and lower 32 bits hold time in nano seconds).

(2) Cycle Time Register (CTR)

Cycle Time Register is a 40-bit register that holds the time at which the execution of the GCL should be repeated. The Cycle Time Register consists of an 8-bit value in seconds, and a 32-bit value in nano seconds (similar to the PTP time format with truncated seconds register).

For a given Gate Control List the start time is "Base Time" + N × "Cycle Time" where N is an integer value representing the iteration number starting with 0 for first iteration. If the Gate Control List execution takes longer than the Cycle time, then the list is truncated at the Cycle Time and the subsequent loop begins at Cycle Time.

(3) Time Extension Register (TER)

Time Extension Register (TER) is a 31-bit register that holds the amount of time (in nano seconds) the current Gate Control List can be extended before switching to the new Gate Control List. This is useful to avoid small fragments of the current list before switching to a new list.

(4) List Length Register (LLR)

List Length Register (LLR) is an 9-bit register for a GCL depth of 512 that holds the integer value of the length of the GCL (that is the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals to the LLR value.

28.9.3 Transmission Gating Implementation

A Bridge or an end station can be enhanced to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines if the queued frames can be selected for transmission.

For a TC, the transmission gate can be in one of the following two states:

1. OPEN
   Queued frames are selected for transmission, in accordance with the definition of the transmission selection algorithm associated with the TC.
2. CLOSED
   Queued frames are not selected for transmission.

A frame on a traffic class queue is not available for transmission if the transmission gate is in the closed state or if there is insufficient time available to transmit the entirety of that frame before the next gate-close event associated with that queue.

The implementation has visibility to the current schedule of gate controls and the immediate next schedule of the gate controls. So the maximum Gate Open period does not exceed the sum of the two Time Intervals. This is because, a frame is selected for transmission only if the gate is currently Open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

The implementation must know the frame size before the transmission, so that the transmission overruns can be avoided and only the frames that can complete are scheduled at all times. This can be achieved by

- Programming the OVHD field (bits [5:0]) of the MTL_EST_Ext_Control register with fixed overhead of the IPG or EIPG, preamble, and scheduler delay
- Automatic prediction of variable overhead due to the offloads enabled for a packet in the MAC transmitter. Consider the following while programming the EST related fields for correct scheduling of packets:
  - Speeds: 1Gpbs/100 Mbps
  - PTOV in ns: 9 PTP clock cycles
  - CTOV in ns: 3 PTP + 3 Transmit clock cycles
  - Per packet slot interval in ns:
  - (packet size + overhead + IPG or EIPG + preamble) × (time to transmit 1 byte)
  - overhead, scheduler delay in bytes is calculated as follows:
    (11 + X) Tx clock cycles
    where,
    If Tx COE is selected, X = 2. Otherwise, X = 0

The implementation adequately compensates for the implementation delays in the data transfer from the buffer to the line by offsetting the current time with all the relevant delays (provided by the CTOV field of MTL_EST_Control register). This ensures that the schedule provided is always accurately implemented at the line.

Note:
- An overhead is added to the packet size to account for the scheduler delay, IPG or EIPG, and Preamble overheads on the line. Therefore for a 128 byte frame to be transmitted, the Gate Open window should at least be able to accommodate 128 + overhead bytes.
- In 100 Mbps mode of operation, the rounding down error is about 0.4%. For example, the Gate open duration must be at least 1035 bytes for transmitting 1000 Byte Frames at a speed of 100 Mbps (31 bytes for scheduler delay, line overheads, and 4 Bytes for rounding down error).
- The minimum time interval for GCL entry should be equal to the time required to transmit fragment size + scheduler delay + IPG/EIPG + Preamble overheads.

28.9.4 Idle Slope Computation Updates

When EST is enabled, credit is accumulated only when the gate is open; therefore, the effective data rate of the idleSlope must be increased to reflect the duty cycle for the transmission gate associated with the queue.

The idleSlope is computed based on the GateOpenTime and OperCycleTime values. Program the idleSlope registers (implemented one per CBS enabled TC) based on the following equation. The existing MTL register has sufficient bit width to accommodate the new values for idleSlope.

idleSlope = (operIdleSlope(N) × OperCycle/GateOpenTime)

28.9.5 Operational Details of GCL

Set the switch to software List, the SSWL field of the MTL_EST_Control register, so that hardware can access the programmed gate control list. The first set of gate controls are applied when the current time is equal to the value in the Base Time Register (BTR) and is held until the programmed "Time Interval" value.

To avoid transmission overruns, one additional gate control event is always read ahead from the list. This enables the GCL to determine the next gate close events (if any) for the TCs that are open.

The scheduling based on the Gate Open state and Time Interval of only the current and subsequent schedule. An internal accumulator is used to add the time intervals when gate controls are applied. BTR + Accumulator holds the time at which the next set of gate controls are to be applied.

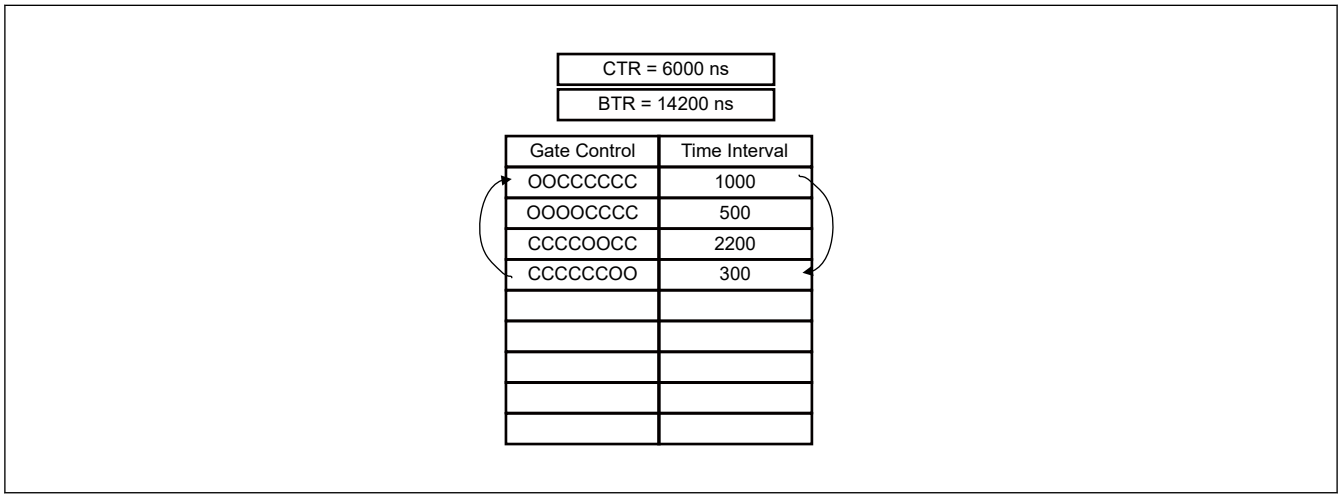

Figure 28.18 Block diagram from IEEE 802.1 Qbv Specification - GCL Governing Gate Close and Open Events

The GCL is read progressively from the first row adhering to the schedule. The read operations continue until the List Length (from LLR Register) is reached and the execution of the list restarts at BTR + CTR time. At this point the BTR is incremented by value in CTR to mark the beginning of a new cycle. In the absence of any gate controls, all the gates are deemed to be in Open state, during the execution of the list.

In cases where the execution time of the list is greater than the CycleTime, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

Table 28.40 GCL and associated registers - BTR and CTR (1 of 2)

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17900	CCCCCCOO	4000	14200
18200	OOOOOOOO	0	20200
20200	OOCCCCCC	1000	20200

Table 28.40 GCL and associated registers - BTR and CTR (2 of 2)

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
21200	OOOOCCCC	1500	20200

In the example in Table 28.40, the execution starts at 14200 and the first set of Gate Controls "OOCCCCCC" are applied immediately. As the time interval is 1000 ns the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns as shown in Figure 28.19. As there are no gate controls available after the execution of the last gate control and before the next iteration of the loop, the gates are deemed to be in open state during that time period as depicted at time 18200 in Table 28.40.

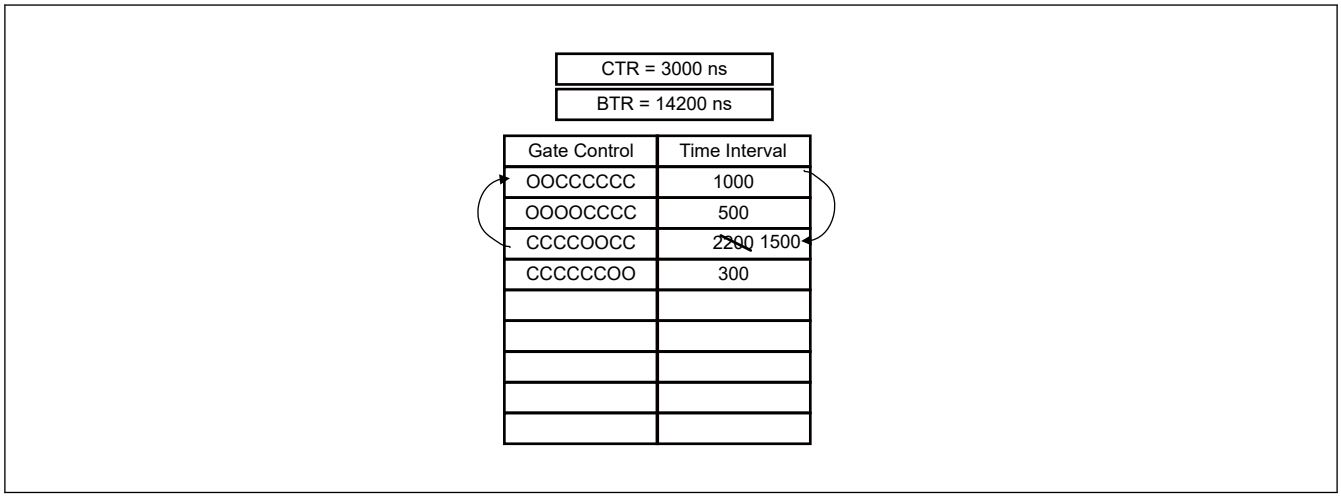

Figure 28.19 GCL and Associated Registers - BaseTime and CycleTime List Execution Time > CycleTime

As the list execution takes longer than the allocated CycleTime, the list is truncated and the list is started from the BTR + CTR as shown in Table 28.41.

Table 28.41 GCL and associated registers - BTR and CTR, execution time > cycle time

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17200	OOCCCCCC	1000	17200
18200	OOOOCCCC	1500	17200
18700	CCCCOOCC	3700	17200

While applying the third set of gate controls, the BTR + CycleTime (17200) < BTR + Accumulator (17900), so the list is truncated and execution switches to a new iteration at 17200.

28.9.6 Installing a New GCL

When a new software programmed GCL is available and must be executed at the new BTR value, the switch to the new GCL can happen in one of the following ways.

- New Base Time aligned with current schedule
- New Base Time unaligned with current schedule

28.9.6.1 New Base Time Aligned with Current Schedule

If the choice of cycle time for the new gating cycle is unchanged from the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle (new BTR) is an integer multiple of the current cycle time (+ current BTR), then the new gating cycle exactly lines up with the old gating cycle, that is, the cycle start times for the new gating cycle is same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating

cycle to be installed and executed with no timing issues. The implementation completes the execution of an iteration of the current list and switches to the new list at the beginning of the BaseTime listed in the new list.

If (New BaseTime ≥ Current Time) ConfigChangeTime = New BaseTimeElse If (New BaseTime < Current Time)

1. Set the BTRError
2. ConfigChangeTime = (New BaseTime + N × New CycleTime)

where N is the smallest integer for which the relation ConfigChangeTime ≥ CurrentTime and (N ≤ 8) is TRUE.

When N > 8 the hardware cannot auto recover and the loop count value in BTRError reporting is set to 1111b requiring the software to reprogram the New Base Time.

Figure 28.20 shows the installation of the new GCL along with the timelines.

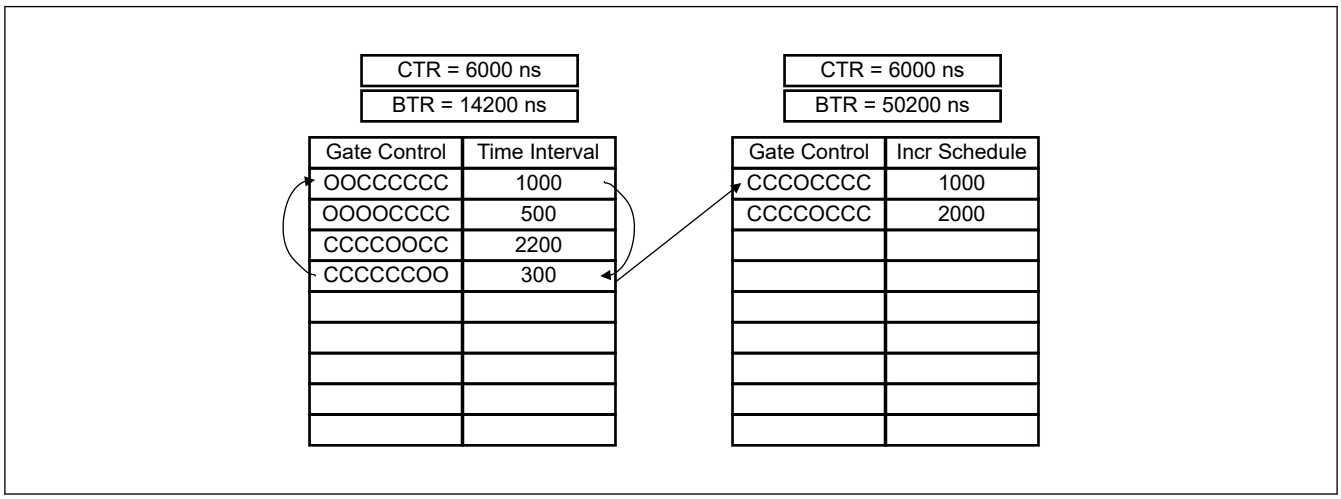

Figure 28.20 Switching to a new configuration that is aligned with the existing configuration

In the example, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point the new GCL is processed as a natural extension to the existing GCL.

Table 28.42 GCL and associated registers - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47900	CCCCCCOO	4000	44200
48200	OOOOOOOO	0	50200
50200	CCCOCCCC	1000	50200
51200	CCCCOCCC	3000	50200
53200	OOOOOOOO	0	56200

28.9.6.2 New Base Time Unaligned with Current Schedule

If new CycleTime differs from current CycleTime or New BaseTime is in the future and is not an integer multiple of current CycleTime, then the old and new cycles do not line up; when new BaseTime is reached (when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short cycle. The Cycle Time Extension Register (related to the current configuration list) allows this extension of the last old cycle to be done in a defined way; if the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle before new BaseTime is reached is extended so that it ends at new BaseTime.

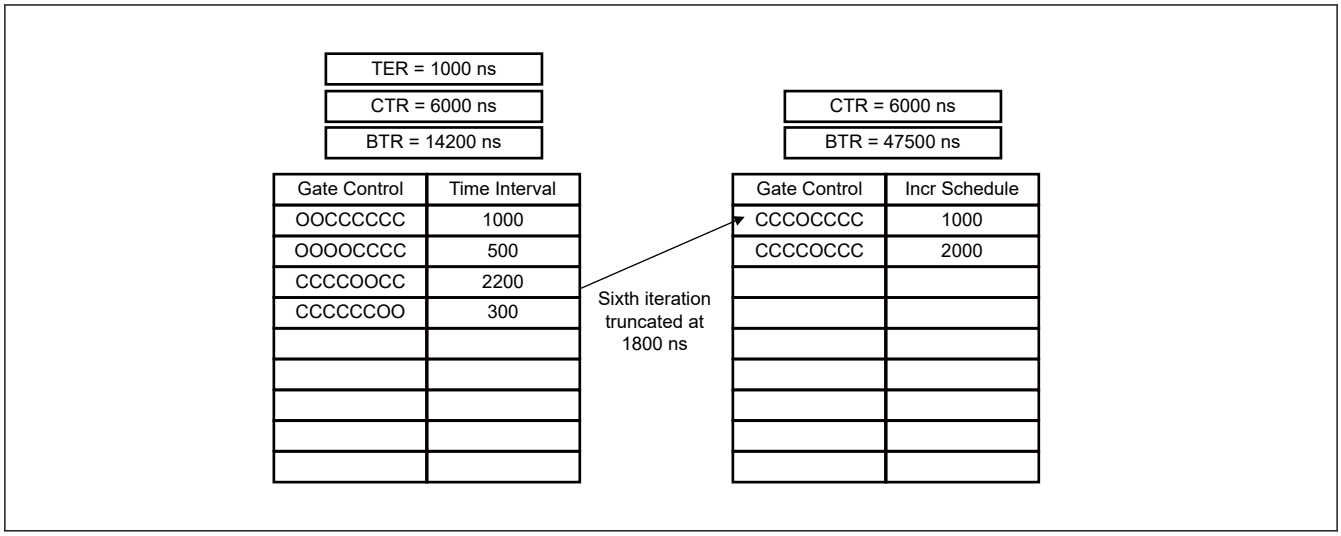

Figure 28.21 Switching to new list truncating the current list

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR so the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 28.43 Extending to new list by truncating the current list

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47500	CCCOCCCC	4000	44200
48500	CCCCOCCC	0	50200
50500	OOOOOOOO	1000	50200

Following is an example where the current configuration list is extended instead of starting a new iteration as the extension time of 800 ns is less than the allowed cycle extension time (TER) of 1000 ns.

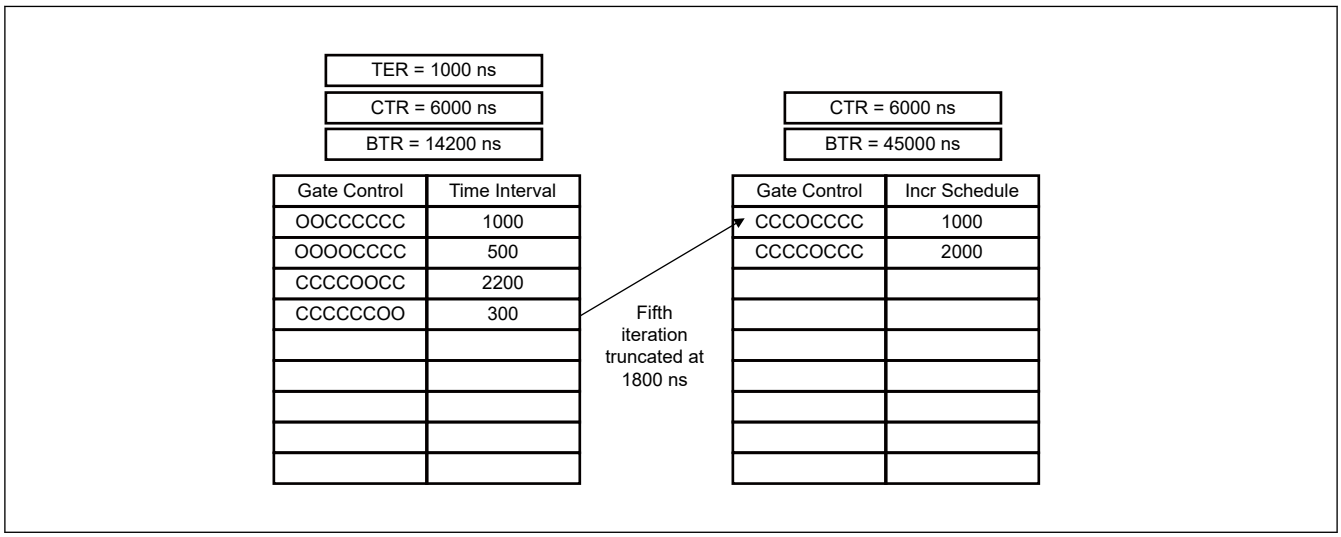

Figure 28.22 Switching to new list by extending the current list

Table 28.44 Switching to new list by extending the current list

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
38200	OOCCCCCC	1000	38200
39200	OOOOCCCC	1500	38200
39700	CCCCOOCC	3700	38200
41900	CCCCCCOO	4000	38200
42200	OOOOOOOO	0	44200
45000	CCCOCCCC	1000	45000
46000	CCCCOCCC	3000	45000
48000	OOOOOOOO	0	51000

28.9.7 Impact of Transmit Scheduling Algorithms on EST

When EST is used in isolation, the Gate Control List manages the final open/close state of the Queues along with the checks carried out by the Transmission Selection Algorithm in MTL. As the Gate Controls operate on a predefined repetitive schedule, it is recommended to use Strict Priority or Credit Based Shaper (CBS) scheduling algorithms.

The algorithm is applied only among the group of queues that open simultaneously. To ensure Queues whose gates are "Open" get priority, these algorithms are modified to treat "gate open" queues and "gate closed" queues as separate groups giving priority to gate open queues.

For example, consider 4 queues (Q3, Q2, Q1, Q0) with weights 4:3:2:1; Q3 & Q2 are in Open state in slot one slot, while Q1 & Q0 are in Open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the Q3 & Q2 are serviced in the ratio of 4:3 for the duration the slot is open.
2. In the second slot, the queues Q1 & Q0 are serviced in the ratio of 2:1.
3. Fresh arbitration is started every time a slot is opened.

In other words, the traffic does not get distributed in the intended ratio of 4:3:2:1; but as two groups with different ratios and only for the duration of the slot when the gates are open continuously.

28.10 Frame Preemption (FPE)

28.10.1 Overview of the Frame Preemption

The IEEE 802.1Qbv-2015 defines the schedule for each of the queues on every egress port which makes the implementation aware of traffic arrival schedule. This information can be used to block the lower priority traffic from transmission in this time window/slot. This ensures that scheduled traffic is forwarded from sender to receiver through all the network nodes with a deterministic delay.

One of the important requirements to achieve a low latency is to ensure there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations while starting a transmission.

If an interfering frame begins transmission just before the start of a reserved time period, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

A larger guard band equates to a less efficient use of network bandwidth. However, with the implementation of IEEE802.1Qbu (frame preemption), this issue is addressed. Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

Note: Internal loopback is not supported for preempted frames

28.10.2 Description of the Frame Preemption

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame; the preemptable frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following two abstractions of the MAC are used:

- A preemptable MAC, called pMAC, which carries the preemptable traffic.
- An express MAC, called eMAC, which carries the express traffic.

In the implementation, only parts of the MAC that holds the state during preemption is replicated and represented as pMAC and eMAC. The MAC uses the following two ways to puts on hold, the transmission of the preemptable traffic, in the presence of express traffic:

- The MTL scheduler interrupts the preemptable traffic that is currently being transmitted.
  When the preemption capability is active, the MAC interrupts the transmission and reception of preemptable frames. A preempted fragment can be followed by zero or more express frames, before the continuation fragments. The preemptable frame can be fragmented any number of times, however, the minimum final and non-final fragment length criterion must be is met.
  However, interleaving of more than 1 preemptable packet is not permitted. This implies that if a preemptable packet is fragmented by an express packet, another preemptable packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.
- The MTL scheduler prevents starting the transmission of preemptable traffic.
  When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received.

Note: Queue0 can be an express queue when FPE is enabled and EST is disabled.

28.10.3 Enabling the Frame Preemption

Enable the frame preemption feature by setting EFPE field of the MAC_FPE_CTRL_STS register.

28.10.4 GCL Modification to Support FPE

In the EST-only configuration, the GCL entry has up to 24 bits of Time Interval and up to 8 high order bits representing the Gate Open/Close state requirements as shown in Table 28.45.

Table 28.45 Gate control list when FPE is disabled

Gate Control (up to 8 bits)	Time Interval(ns) (16, 20 , or 24 bits)
OOCCCCCC	T0
OOOOCCCC	T1
CCCCOOCC	T2
CCCCCCOO	T3
|	|
|	|
OCOCOCOO	T126
OOOOCCCC	T127

EST only supports SetGate operation, which implies that the gates are set to either open or close at a given time interval.

However, when both Frame Preemption (FPE) and EST are enabled, the GCL also supports Set-and-Hold-MAC and Set-and-Release-MAC operations, in addition to the SetGate operation.

To enable the support of hold and release operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first Queue (Q0) is always programmed to carry preemption traffic and therefore it is always Open. The bit corresponding to Q0 is renamed as Release/Hold MAC control.

The TX Queues whose packets are preemptable are indicated by setting the PEC field of the MTL_FPE_CTRL_STS register. The GCL bit of the corresponding Queue is ignored and considered as always "Open". So, even if the software writes a "0" ("C"), it is ignored for such queues.

Table 28.46 Gate control list when FPE is enabled

Gate Control (up to 7 bits)	Release/Hold Indication	Time Interval (ns) (16, 20 , or 24 bits)
CCCOOOO	0	T0
CCCCOOO	0	T1
OCCCOOO	1	T2
COCCOOO	1	T3
CCOCOOO	1	T4
CCCOOOO	0	T5
CCCCOOO	0	T6

When the Release/Hold bit transitions from a '0' to '1', a Set-and-Hold-MAC operation is performed. This marks the cease of the preemptable traffic. This is achieved by sending a Hold request to MTL "ha" ns in advance (where ha is the time interval mentioned in the Hold Advance (HADV) field of the MTL_FPE_Advance register).When the elease/Hold bit transitions from a '1' to '0' a Set-and-Release-MAC operation is performed. This marks the resuming of the preemptable traffic. This is achieved by sending a Release request to MTL "ra" ns in advance (where ra is the time interval mentioned in the Release Advance (RADV) field of the MTL_FPE_Advance register).The preemptable traffic is blocked for the time duration the Release/Hold bit is set to a '1' in the Gate Control List.

Note: HADV is the advance time to initiate the hold state. Ideally HADV should be programmed to a value of minimum fragment size, which should be smaller than the time interval (minimum fragment size + IPG + Preamble overheads in nanoseconds)

28.10.5 Impact of Preemption on CBS

In CBS, the definition of "Transmit" is as follows:

- TRUE for the duration of frame transmission from the queue;
- FALSE when frame transmission from the queue is complete.

When CBS algorithm is used along with frame preemption, the value of "Transmit" is TRUE only while the frame is being transmitted by the MAC. If the frame transmission is delayed or interrupted (for instance, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue, or the start of express frame is delayed because a preemptable frame is being transmitted) the value of "Transmit" is FALSE until transmission of the frame commences or is resumed.

Also, the value of "Transmit" is FALSE during the transmission of any overhead that is a consequence of frame preemption. For example, additional frame overhead (mCRC, Fragment Count) that is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of Transmit is FALSE, and credit is positive value, the credit value is set to zero if here is no preemptable frame from the queue for which transmission is in progress but has been interrupted.

28.10.6 mPacket Format

When the preemption capability is active, MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. A express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

Figure 28.23 shows the format of the mPacket. It contains an express packet, a complete preemptable packet or the initial fragment of a preemptable packet. Figure 28.23 (b) shows the format of an mPacket containing a continuation fragment of a packet.

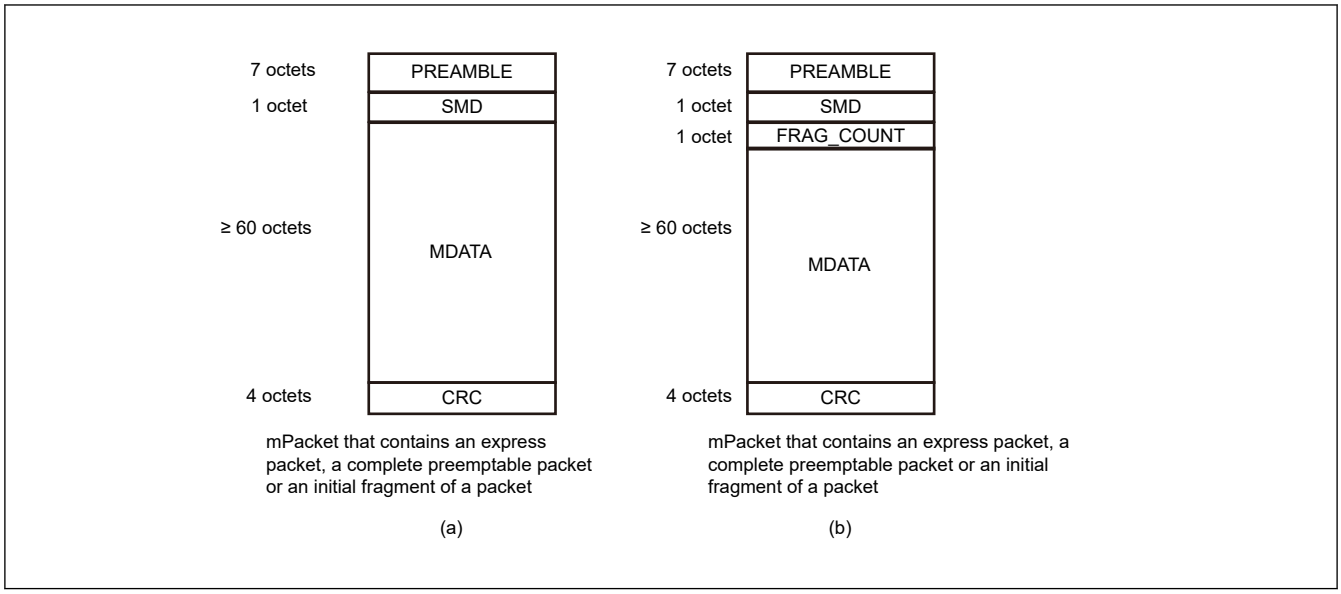

Figure 28.23 mPacket formats

Preamble

The preamble in the mPacket shown in Figure 28.23 (a) contains seven octets. The preamble in the mPacket shown in Figure 28.23 (b) contains six octets. Each octet contains the value of 0x55 (transmitted in order from left to right 10101010).

Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. Table 28.47 lists the valid SMD values.

Table 28.47 Possible SMD values of mPacket

mPacket Type	Notation	Frame Count	Value
verify packet	SMD-V	—	0x08
respond packet	SMD-R	—	0x19
express packet	SMD-E	—	0xD5
preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

frag_count

A frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet.

Table 28.48 Possible frag_count values (1 of 2)

frag_count	Value
0	0xE6

Table 28.48 Possible frag_count values (2 of 2)

frag_count	Value
1	0x4C
2	0x7F
3	0xB3

mData

The contents of the packet from the MAC, starting with the first byte after the SFD to the last byte before the FCS are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

CRC

The CRC field contains a cyclic redundancy check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket by performing an XOR of the calculated 32-bit CRC value of the fragment and a value of 0x0000FFFF.

Summary of Packet Formats

- Express Packet
  7 bytes of PREAMBLE, SMD-E, Data, and CRC
- Complete Preemptable Packet
  7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, CRC
- Initial Fragment (non-final) of Preemptable Packet
  7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, mCRC
- Continuation fragments (non-final) of Preemptable packet
  6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, mCRC
- Final fragment of Preemptable packet
- 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, CRC

Note: When Frame Preemption is enabled, the MAC receiver communicates the exceptions related to received preempted fragments (incorrect fragment sequencing, missed fragment, and so on) to MTL layer by reporting it as CRC error. Software should not set the DCRCC (Disable CRC Checking for Received Packets) bit of MAC_Ext_Configuration register to 1; otherwise the MTL layer might forward the unintended preempted fragments to the application.

Table 28.49 Current and previous SMD values (1)

SMD-C3	FC2	SMD-C3	FC3
SMD-C3	FC3	SMD-C3	FC0

28.10.7 Transmit Preemption

28.10.7.1 MTL Tx Preemption

To support preemption MAC should have more than 1 TX queue with at least 1 Queue designated as Express Queue. (and 1 queue designated as preemption queue). When FPE is enabled (setting EFPE = 1 in MAC_FPE_CTRL_STS register), the MTL preempts a preemptable frame, when a "hold" request is asserted (EST/Qbv configured and enabled) express frames are available for transmission, that is, frame is present in MTL FIFO and is qualified for arbitration, after ensuring that the minimum mPacket mData field size is met.

Therefore, preemption occurs only if at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the AFSZ field of the MTL_ FPE_CTRL_STS register. Preemption does not occur until at least 64 × (1 + AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all the preemptable queues are blocked and only the express queues are allowed to arbitrate (if more than one express queue has traffic) and transmit.

Continuation fragment of the preempted frame is the first frame to be transmitted after "release" request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

Note: All the PTP packets should be transmitted as express packets.

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface qualified by SoF and EoF.

- Express Frame
- Preemption Frame (Full or Fragment)
- Continuation Fragment (non-Final or Final)

Table 28.51 Preemption control values on MTI interface for various frame types (1 of 2)

Qualifier	Preemption Control Value	Frame Type
SoF	00b	Start Express
SoF	01b	Start Preemption

Table 28.51 Preemption control values on MTI interface for various frame types (2 of 2)

Qualifier	Preemption Control Value	Frame Type
SoF	10b	Continuation Fragment
SoF	11b	Reserved
EoF	00b	End of Frame
EoF	01b	End of Fragment

If the SOF and EOF are sent in the same cycle on the MTI interface, the mti_preemp_ctrl (Preemption Control Value) for EoF is taken as 00b, End of Frame.

MTL should wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame. Fragment status is described in detail in the Tx Fragment Status section

28.10.7.2 MAC Tx Preemption

MAC supports preemption by implementing the functionality needed to generate the mPackets as described in section 28.10.6. mPacket Format.

Based on the Preemption Control value received on the MTI interface (qualified with SoF and EoF), MAC determines the frame type (shown in Table 28.51) and generates mPackets accordingly.

When the preemption capability is active, MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value.

The SMD-E value is the same as the SFD value so the SFD of an express packet does not need to be replaced.

28.10.7.3 Tx Fragment Status

MAC sends Tx fragment status to indicate successful transmission of fragmented mPackets.

In case of a transmission error (underflow, jabber, and so on) the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. In case of receiving an error status for a transmitted fragment, the MTL drops the remaining fragments and does not send any more continuation fragments.

28.10.8 Receive Preemption

28.10.8.1 MAC Receive Preemption

When FPE is enabled, the MAC Receiver passes the incoming packets and differentiates between Express packets and preemptable packets. An SMD containing an SMD-E indicates express packet, and SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when MAC has not completed receiving the previous preempted packet, MAC sets a CRC Error status for the previously received partial packet.

When an SMD-S is detected, MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket . If the last four bytes of the mPacket do not match CRC, that indicates the end of the packet with or without a CRC error as per the CRC check result. If the last four octets of the mPacket match, that indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, MAC checks the following:

1. A preempted packet is in progress
2. The frame count indicated by the SMD matches the frame count of the packet in progress
3. The frag_count value indicates the next fragment count.

If any of these checks fail, the mPacket is discarded and MAC sets a CRC Error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, timestamp, length fields and so on) and can process any received Express packets before the continuation fragment is received.

The MAC Receiver sends a "dummy status" for all the mPacket fragments successfully received and sends the Rx status with the final fragment. If an error is detected during any of the fragments the Rx status is sent and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal on the MRI interface qualified by SOF and EOF.

1. Express Frame
2. Preemption Frame (Full or Fragment)
3. Continuation Fragment (non-Final or Final)

Table 28.52 Preemption control values on MRI interface for various frame types

Qualifier	Preemption Control Value	Frame Type
SoF	00b	Start Express
SoF	01b	Start Preemption
SoF	10b	Continuation Fragment
SoF	11b	Reserved
EoF	00b	End of Frame
EoF	01b	End of Fragment

If the SOF and EOF are sent in the same cycle on the MRI interface, Preemption Control Value for EoF is taken as '0' indicating End of Frame.

28.10.8.2 Data Alignment

When a received frame cannot be fragmented on any byte boundary, MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment as shown in Figure 28.24.

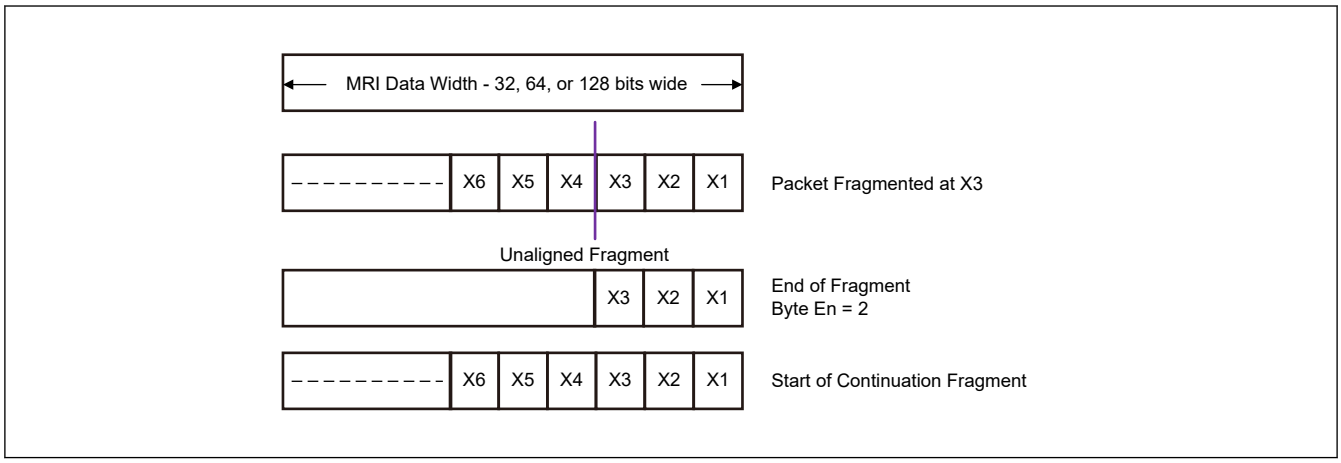

Figure 28.24 Data alignment feature of MAC

MTL can choose to ignore the partial data (based on Byte Enable value) that comes with End of Fragment and instead use the "data width aligned" data received in the first beat of the next continuation fragment.

28.10.8.3 MTL Receive Preemption

The MTL Rx must have at least 2 Rx queues to support FPE function as the preemptable packets and the express packets must be routed to separate Rx queues. The destination Rx queue of a received packet is controlled by MAC_RxQ_Ctrl[n] registers. Program these registers such that Preemptable traffic and express traffic are not routed to the same Rx queue. As the queue mapping for tagged packets is based on VLAN user-priority field, this implies that priority of preemptable and express packets are mutually exclusive. In other words, packets of a certain priority (traffic class) are either express or preemptable but cannot be both.

For the preemptable frames, in addition to the PSRQ (Priority Selected in Rx queue) based queue routing, a programmable "Frame Preemption Residue Queue" (FPRQ) is supported to route all other Preemption Packets received (Untagged, SA/DA or VLAN Filter Fails forwarded due to RA being set or VTFE being reset).

Table 28.53 Queue routing for various preemption packet types

Preemption Packet Type	Queue Routing
AV Tagged Packets passing the SA/DA and VLAN filters	PSRQ
DCB/Generic Tagged Packets passing the SA/DA and VLAN filters	PSRQ
Tagged Packets failing the SA/DA and VLAN filters without setting the Receive All (RA = 0) or setting VTFE = 1	Dropped
All other packets OR when RA = 1	FPRQ

The express frames use Queue 0 as a default queue. So, in case of filter failures, Queue0 must not be used for receiving preemption frames.

When a fragment is received, it is pushed into its destination Rx queue. When this packet is preempted, and is followed by an express packet, it is pushed/stored in a different Rx queue. The MTL saves the context of the preempted frame, and processes one or more express frames. When the continuation fragment arrives, it restores the saved context and pushes the remainder of the fragmented frame into its Rx queue.

28.10.8.4 MTL Receive Arbitration

On the ARI Interface, data is fetched from the MTL Rx FIFO based on the arbitration selected in the MTL_Operation_Mode register. Frame based arbitration can be used only when all the MTL Preemption Queues operate in Store and Forward mode. Otherwise, there is loss of bandwidth on the ARI interface as all the fragments of a preemptable packet are not available. Therefore, express packets received between the fragments are blocked until all the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either Threshold (cut through) or Store and forward modes of operation, PBL based arbitration is recommended over Frame based arbitration. In case of PBL based arbitration, the watermark check is always performed and the arbitration/transfer of data in terms of chunks of "PBL" size of data which is almost similar to the concepts of "fragments". Therefore the express queue packets get blocked for less time as well as the ARI interface transfers the data without loss of efficiency.

28.10.9 Received Preemption Frames Support in Offload Engines

When Frame Preemption is enabled, all the packets processed by the Offload Engines (ARP, PTO) and PMT, PTP, and PAUSE packets must be received as express/normal packets. These offload engine logic and functions do not recognize preemption frames.

28.10.10 Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the Verify and Respond mPackets, even when FPE is not enabled by software. When MAC detects valid Verify/Respond mPackets, it notifies the software by setting the RVER and RRSP fields of MAC_FPE_CTRL_STS register respectively. Optionally an interrupt can be generated. As such packets have empty (all-zero) data payload, they are dropped inside the MAC and not forwarded to the MRI.

Software can set the SVER and SRSP fields of MAC_FPE_CTRL_STS register to request MAC to transmit Verify and Respond mPackets respectively. Upon successful transmission of these frames, MAC clears the SVER/SRSP bits and sets the TVER & TRSP fields of MAC_FPE_CTRL_STS register. Optionally an interrupt can be generated when these events occur.

Note: 1. For the preemption frames received with CRC error indication, ignore the following status fields:
- Packet length
- Dribble error indication
- Runt frame indication

2. When FPE is configured, Forward Undersized Good Packets (FUP) bit of MTL_RxQ_Operation_Mode register should not be set.

3. When FPE is configured, do not disable CRC checking on receive. This is required because, internally, FPE error fragments are identified using CRC checks. For details, see the DCRCC field in the MAC_Ext_Configuration register.
4. Express and preemption traffic must be routed to different DMAs.

28.10.11 Frame Preemption and MMC Counter and Interrupt Registers

The following MMC counters and associated Interrupt registers are instantiated/present in the MAC.

Table 28.54 MMC counters and associated interrupt registers

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame Assembly Error Counter	A 32-bit counter that provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.	MMC_Rx_Packet_Assembly_Err_Cntr
Frame SMD Error Counter	A 32-bit counter that provides the number of received MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame	MMC_Rx_Packet_SMD_Err_Cntr
Frame Assembly OK Counter	A 32-bit counter that provides the number of MAC frames that were successfully reassembled	MMC_Rx_Packet_Assembly_Ok_Cntr
MAC Rx Fragment Counter	A 32-bit counter that provides the number of additional mPackets received due to preemption	MMC_Rx_FPE_Fragment_Cntr
MAC Tx Fragment Counter	A 32-bit counter that provides the number of additional mPackets transmitted due to preemption	MMC_Tx_FPE_Fragment_Cntr
Hold Request Counter	A 32-bit counter that maintains the count of number of times a hold request is given to MAC	MMC_Tx_Hold_Req_Cntr

28.10.11.1 Additional Registers Associated With MMC Interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- MMC_FPE_Tx_Interrupt
- MMC_FPE_Tx_Interrupt_Mask
- MMC_Rx_Interrupt
- MMC_FPE_Rx_Interrupt_Mask

28.11 Time-Based Scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. This is an optional feature. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance even before packet is ready/available. It reduces the overhead on the software and avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.
- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

28.11.1 Description of Time-Based Scheduling

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes:

- Full duplex mode
- Link speed is 100Mbps or higher

Note: • In EST enabled configurations the ESTM mode bit setting impacts the time-based scheduling feature only when the DUT processes the GCL list.

- Slot number is meaningful only after GCL is active. So, start the GCL list before enabling the Time-Based Scheduling (TBS) and Enhancements to Scheduled Traffic (EST) features. If GCL is not started, all gates are deemed open and if packets do not make progress, TxQ creates back pressure.

28.11.2 Definitions Used

Following are the definitions specific to the time-based scheduling feature:

- Launch Time
  The time beyond which MTL can schedule the packet for transmission.
- Fetch Time
  The time beyond which the Tx DMA can schedule a packet-fetch from the host memory.
- Expiry Time
  The time beyond which the packet is dropped by MTL.

28.11.2.1 Launch Time

The launch time is specified in the Enhanced Normal Descriptor. For details, see section 28.17.6. Enhanced Descriptor for Time-Based Scheduling section 28.17.6. Enhanced Descriptor for Time-Based Scheduling.

When the launch time is specified, it is valid only for the specific frame that is scheduled for transmission. The launch time is reset after the transmission of one frame.

Following are the two formats of the launch time.

- Normal/Absolute Format
- EST/Offset Format

Normal/Absolute Format

In this format, the Launch time is an absolute time value at which the packet is launched for transmission.

The launch time is interpreted in the Normal/Absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based System/PTP Time (bits [39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of System Time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24 bits of the Launch Time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of Launch time is 256 seconds,

- Launch Time is greater than current System Time when its value is between System Time[39:8] and System Time[39:8] + 128 sec
- Launch Time is less than current System Time when its value is between "System Time[39:8] + 128 sec" and "System Time[39:8] + 256 sec", because this is a modulo 256 computation.

EST/Offset Format

In this format, the Launch time is a offset value relative to the time indicated by the Base Time Register (BTR) of the GCL list provided in the GCL Slot Number (GSN). The value in the BTR is always updated to the start time of the current loop of the GCL.

For each packet, the GSN value and the Launch Time value are specified in the Enhanced Transmit Descriptor.

The launch time offset is a 32-bit value; the upper 8-bit represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL Slot Number. The value of the Launch Time Offset must be smaller than the value of the Cycle Time (specified in the CTR register that is implemented when EST is enabled).

If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bit of Launch Time offset should be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as,

Launch Time = Launch GSN BTR[63:0] + (Launch Time Offset[31:0] << 8), which is compared with the System Time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

GCL Slot Number (GSN)

A modulo 16 counts of the GCL loop count is implemented and known as GSN. The count is incremented for every new GCL loop; installation of new GCL list does not impact the count. The current GCL slot number can be obtained by reading the CGSN field of the MTL_EST_Status register.

The maximum value of GSN is 15. Therefore, GSN values between Current GSN (CGSN field of MTL_EST_Status register) and CGSN + 8 represent current or future slots; all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between CGSN and CGSN+8, for correct interpretation of time.

28.11.2.2 Launch Expiry Time

Normal/Absolute Mode

In the normal mode, when the LEOV (Launch Expiry Offset Valid bit of MTL_TBS_CTRL register) is set, the Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determines the maximum amount of time a frame is eligible for launch, starting from the time the frame becomes eligible for launch.

The Launch Expiry Offset is a 24-bit value defined in 256 ns units, with a maximum possible value of 999,999,999 ns (0x3B9AC9FF).

Launch Expiry Time = (Launch Time[39:8] + LEOS[32:8]) × 256 ns

The packet with a specific Launch time is considered eligible for transmission when the Launch time is less than the System Time and (if LEOV is set) the System Time is less than the Launch Expiry time.

When the System time is greater than the Launch Expiry time the frame is categorized as expired and is dropped from the MTL FIFO.

Note: 1. For correct interpretation and meaningful operation, the Fetch, Launch, and Launch Expiry time should never be set to a value larger than Current System Time + 128 sec; such a value is interpreted as time that has already elapsed.

2. In full duplex mode, the frames dropped from the MTL FIFO have Error Summary (bit 15) and Excessive Deferral (bit 3) of TxStatus set.

EST/Offset Mode

In the EST mode of operation, when the LEOV field of the MTL_TBS_CTRL register is set, the launch expiry GSN offset (LEGOS field of the MTL_TBS_CTRL register) and Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determine the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch Expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999ns or CTR-1 ns.

The Launch Expiry GSN is computed as follows:

Launch Expiry GSN = (Launch GSN + LEGOS + CCMA)

Where,

CCMA is the CTR Carry due to Modulo addition. This value is 1 if ((Launch Time Offset + LEOS) << 8) is equal to or greater than CTR. When CCMA = 1,

Launch Expiry Offset = (Launch Time Offset+ LEOS) - CTR

When CCMA = 0,

Launch Expiry Offset = (Launch Time Offset + LEOS).

Launch Expiry Time = Launch Expiry GSN BTR[63:0] + Launch Expiry Time Offset.

When LEOV is not set, Launch Expiry Time is not checked.

When LEOV is set, and

- the system time is greater than the Launch Expiry time, the frame is dropped from MTL FIFO. The frame is considered as expired.
- the launch time is smaller than the System Time and Launch Expiry Time is greater than system time, the frame is considered eligible for launch.

Note: 1. Max value of LEGOS is 7. This implies that when LEOV is set, the frame has a maximum life time of < 8 GCL loop iterations after it becomes eligible for Launch.
2. The slot number of the First GCL List executed each time after EST is enabled, is zero.

28.11.2.3 Fetch Time

The Fetch Time can also be indicated for each packet by the software. This is done by setting FTOV field of DMA_TBS_CTRL register.

If the FTOV filed is not set, the Fetch Time Offset is not valid and the DMA fetches packets without any time constraints.

The fetch time accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

Normal/Absolute Mode

In the Normal mode fetch time derived/calculated by reducing the time specified in the Fetch Time Offset (FTOS) field of DMA_TBS_CTRL register from the given Launch time.

Normal mode of operation, the Fetch Launch Time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The Fetch time is 32-bits and is compared against System Time[39:8] to determine the Eligible for fetching the frame:

- The Fetch time is defined as "greater" than System Time if the Fetch Time is in the range of "System Time[39:8]" and "System Time[39:8] + 128 sec". The frame is considered as not-eligible for fetch.
- The Fetch time is defined as "smaller" than the System Time if the Fetch time is in the range of "System Time[39:8] + 128 sec" and "System Time[39:8] + 256 sec". The frame is considered as eligible for fetch.

This is a modulo 256 computation.

EST/Offset Mode

In the EST/Offset mode, the Fetch GSN Offset (FGOS field of MTL_TBS_CTRL register) provides the Slot Number offset to be deducted from the Launch GSN. In this case the FTOS value should be the smaller of 999,999,999ns or CTR-1 ns.

If (Launch Time Offset ≥ FTOS):

Fetch Time Offset = ((Launch Time Offset - FTOS) × 256 ns)

CBFS(CTR Borrow for Fetch Subtraction) = 0

If (Launch Time Offset < FTOS)

Fetch Time Offset = CTR + ((Launch Time Offset - FTOS) × 256 ns)

CBFS (CTR Borrow for Fetch Subtraction) = 1

The Fetch GSN is computed as follows:

Fetch GSN = Launch GSN - FGOS - CBFS

Fetch Time = Fetch GSN BTR[63:0] + Fetch Time Offset

The frame is marked eligible for DMA fetch when the fetch time is smaller than the System Time.

Note: Max value of FGOS is 7. This implies that when FTOV is set, the frame can be fetched at a maximum of <8 GCL loop iterations before it becomes eligible for Launch.

DMA Operations Sequence

Following is the sequence of operation when FTOV = 1.

1. Fetch the first Enhanced Normal Descriptor (FD is set).
2. If LTV is set and Fetch enabled, compute the Fetch Time based on the Launch Time. Wait for the System Time to be greater than Fetch Time.
3. Read the Frame (Data) from the host memory and transfer to MTL FIFO.
4. Close the Normal Descriptor.
5. Fetch the next Normal Descriptor (if the previous Descriptor was not the Last).
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD is set).

After the Last Descriptor of a frame, the next enhanced normal descriptor should be programmed with a new Launch Time and with LTV bit set. Otherwise, the subsequent frames are processed without any time restrictions.

Control Word (MTL)

Time-based scheduling ensures that a packet is allowed to arbitrate for transmission only if the System Time is greater than the Launch Time.

In MTL,

- Launch Time and GSN, use the same field that is used to hold the 64-bit timestamp value for OSTC (One Step Timestamping Correction). If the LTV bit is set and OSTC bit is not set, the Time Stamp field is interpreted as Launch Time. Launch Time uses the fields meant for OSTC TimeStamp[39:8] and GSN uses OSTC TimeStamp[43:40] field.

When the MTL TXFIFO Read Controller reads the first control word, it checks bit-31 to determine if the frame has a valid Launch Time. If bit-31 is set, it reads the subsequent control words to get the Launch Time.

Impact on Transmission Selection Algorithm

Time-Based Scheduler does not directly influence the Transmission Selection Algorithm but has an indirect influence as it determines if a queue is eligible to participate in the scheduling.

If a frame of a specific queue has a valid Launch Time, the Time Based Scheduler ensures that the frame participates in Transmit Scheduling (TRC Scheduler) only after the Launch time has elapsed.

The gating done by Time-Base scheduler is only for the Scheduling (picking frame for Transmission). It might not alter any other characteristics and behavior of the frame. For example, the Frame waiting for the Launch time to lapse, continues to gain credits in CBS, and the CBS credits are not lost as the frame is marked as available but not ready. Strict Priority or CBS are recommended Transmit Scheduling algorithms for the TBS implementation because, scheduling for TBS enabled queues are more predictable.

28.11.3 Time-Based Scheduling Flow

Figure 28.26 shows the time-based scheduling flow.

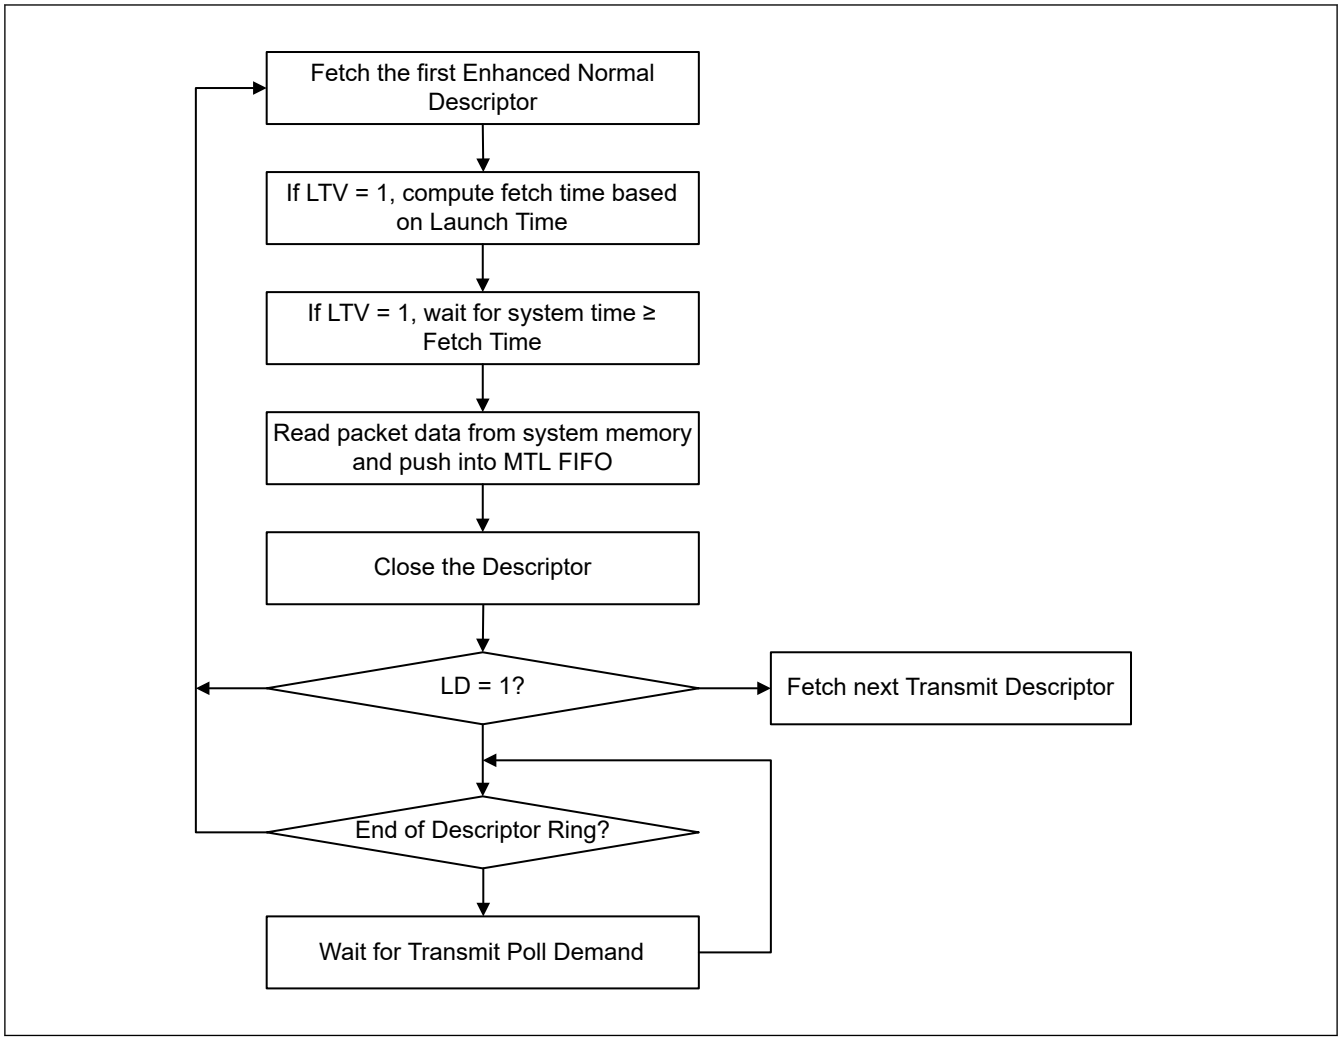

Figure 28.26 Time-based scheduling flow

28.12 TCP/IP Offloading Features

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. Therefore, the MAC has an optional Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, and error detection in the Receive path.

The TCP Segmentation Offload (TSO) engine is useful in offloading the TCP segmentation functions to the hardware.

28.12.1 Transmit Checksum Offload Engine

28.12.1.1 Overview of Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum and inserts it in the Tx packet. This feature helps in reducing the load on the software and can improve the overall throughput of the system.

28.12.1.2 Description of Transmit Checksum Offload Engine

The checksum offload engine module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 bits [17:16]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if the GMAC is configured for Threshold (cut-through) mode.

Note: You must make sure that the Tx FIFO is deep enough to store a complete packet before that packet is transferred to the MAC transmitter. The reason being that when space is not available to accept the programmed burst length of data, then the MTL Tx FIFO starts reading to avoid dead-lock. In such a case, the COE fails as the start of the packet header is read out before the payload checksum can be calculated and inserted. Therefore, you must enable the checksum insertion only in the packets that are less than the number of bytes, given by the following equation:

Packet size < TxQSize - (PBL + 5) × (132/8),

Where,

- TxQSize is indicated by TQS field of MTL_TXQn_OPERATIOn_MODE register.
- PBL = TxPBL field in the DMA_CHn_TX_CONTROL register.

(1) IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

Note: IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (bit 0 in Table 28.75). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

(2) TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

Note: For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 0x0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 0x0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (bit 12 in Table 28.75). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When

this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Table 28.55 describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as "No" in the table.

Note: You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in section 28.12.1.2. Description of Transmit Checksum Offload Engine because it might result in incorrect checksum insertion or unexpected behavior.

Table 28.55 Transmit checksum offload engine functions for different packet types

Packet Type	Hardware IP Header Checksum Insertion	Hardware TCP/UDP Checksum Insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in section 28.12.1.2. Description of Transmit Checksum Offload Engine.	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in section 28.12.1.2. Description of Transmit Checksum Offload Engine.	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Authentication • Any other next header field in main or extension headers	 • Not applicable • Not applicable • Not applicable • Not applicable • Not applicable • Not applicable • Not applicable • Not applicable	 • Yes • No • Yes • No • No • Yes • No • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	 • Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	 • No • No
IPv6 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	 • Not applicable • Not applicable	 • No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

28.12.2 Receive Checksum Offload Engine

28.12.2.1 Overview of Receive Checksum Offload Engine

GMAC provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path. The MAC verifies the checksum field of the received packet with the internally calculated checksum and provides the status.

28.12.2.2 Description of Receive Checksum Offload Engine

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

Packets with TCP/IP errors (header or payload) are dropped in MTL when DIS_TCP_EF bit of the MTL_RXQn_OPERATIOn_MODE register is reset and FEP bit is set.

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Table 28.56 describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

Note: The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 28.56 Receive checksum offload engine functions for different packet types (1 of 2)

Packet Type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Any other next header field in main or extension headers	 • Not applicable • Not applicable • Not applicable • Not applicable • Not applicable • Not applicable • Not applicable	 • Yes • No • Yes • Yes • No • Yes • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	 • Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	 • No • No

Table 28.56 Receive checksum offload engine functions for different packet types (2 of 2)

Packet Type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv6 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	 • Not applicable • Not applicable	 • No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

28.12.2.3 Enabling the Receive Checksum Offload Engine

Set the IPC bit of the MAC_Configuration register.

28.12.2.4 Header-Payload Split

The MAC is capable of identifying the boundary between header and payload of the received packet and store them into separate buffers. This feature is useful for multiple reasons:

- Header buffers can be located in faster memory/cache while Payload buffers are located in slower DRAM memory. This enables the software stack to process the headers faster
- Buffers used for payload can be directly forwarded to the application layer without the need to copy the payload into application buffer
- In case Large Receive Offload (LRO) function is implemented in software/driver layer, it is easy to link the buffers of multiple and contiguous payload data and form a bigger packet with a new header. This reduces the number of packets forwarded to the upper layer and thus improves system software performance

The GMAC supports multiple methods and packet types for header-payload splitting. This is controlled by the setting the SPLM field in MAC_Ext1_cfg register and described in Table 28.57.

Table 28.57 Split header support depending on the packet type

Packet Type	SPLM	Description
TCP or UDP packet	00b (L3/L4 Split)	The DMA writes the Ethernet header + IP header + TCP or UDP header into the header buffer.
IP packet (not TCP/UDP)		The DMA writes the Ethernet header + IP header into the header buffer.
Non-IP packet		The DMA does not split the header and payload
Any packet	01b (L2 Split)	The DMA writes the Ethernet header • For AV type packets using AV type Split Offset (SAVO) when split AV Enable (SAVE) field is set to 1. • For non-AV type packets using SPLOFST
IP packet	10b (Combination of L2 or L3/L4 Split)	L3/L4 split
Non-IP packet		L2 split
NA	11b	Reserved

Note:
- L3/L4 split is applicable for IP packets that are either untagged or VLAN stripped. If VLAN tag is retained in the packet forwarded to the DMA, L3-L4 split is not performed. When SPLM field is set to 2, L2 Split is performed for IP packets which are VLAN tagged.
- For AV packets, program the SAVE and SAVO fields of the MAC_Ext1_Cfg register to specify an alternative L2 split value.

The IP header includes IPv4 options in case of a IPv4 packet, and IPv6 extension headers in case of IPv6 frames. The points at which the L3/L4 header is split are shown in Figure 28.27.

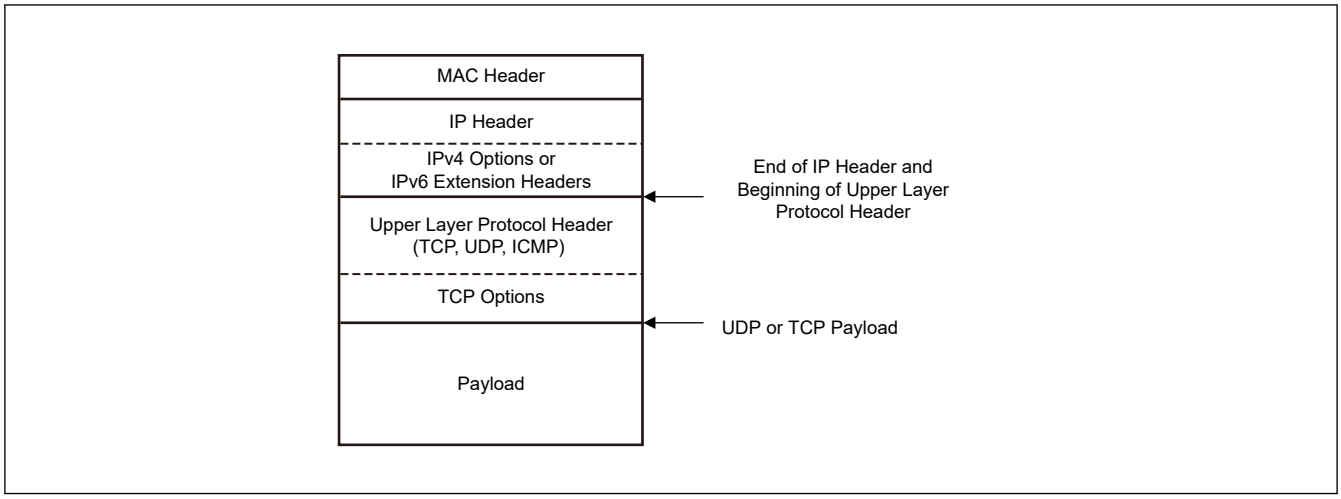

Figure 28.27 L3/L4 header split points

Figure 28.28 shows the L2 Split boundary. In this mode, the header payload boundary is determined for received packets at a fixed length offset starting from the Length/Type field, as indicated by the SPLOFST field of the MAC_Ext_Cfg1 register. This mode is applicable for all received packets when SPLM = 01b and only for non-IP packets when SPLM = 10b. For details, see section 28.3. Register Descriptions.

Table 28.58 shows the split offset for various packet types, when SPLOFST field is set to 2.

The split offset reference is always from the beginning of LT field, whether the VLAN tag is present or stripped.

For details about the descriptor structure for the split header feature, see section 28.17.3. Descriptor Structure for Split Header Support .

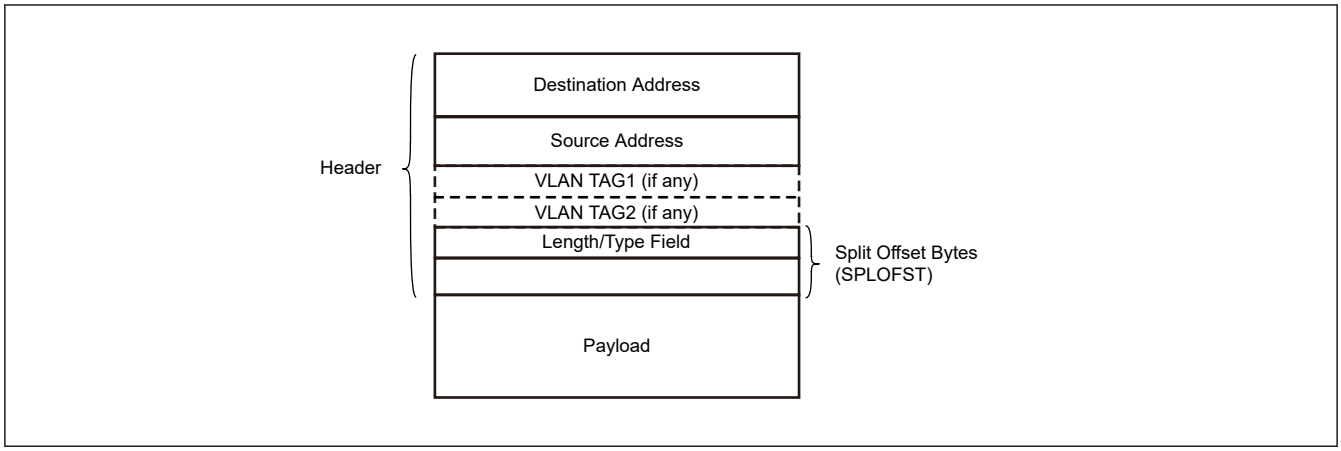

Figure 28.28 Header split

Table 28.58 Split offset calculation example: SPLOFST = 2

Packet Type	Split Offset (From the Beginning of LT Field)
Untagged packet	DA + SA + LT = 14
Single VLAN tagged packet with VTAG stripped	
Double VLAN tagged packet with both VTAGs stripped	
Single VLAN tagged packet with no stripping	DA + SA + VTAG + LT = 18
Double VLAN tagged packet with only one VTAG stripped	
Double VLAN tagged packet with no stripping	DA + SA +2 × VTAG + LT = 22

28.12.3 Using the IPv4 ARP Offload Engine

28.12.3.1 Introduction to IPv4 ARP Offload Engine

GMAC supports the Address Recognition Protocol (ARP) Offload for IPv4 packets. This feature allows the processing of the IPv4 ARP request packet in the receive path and generating corresponding ARP response packet in the transmit path. GMAC generates the ARP reply packets for appropriate ARP request packets. The ARP packet for IPv4 is L2 layer packet with Length/Type of 0x0806.

28.12.3.2 Description of IPv4 ARP Offload Engine

The ARP offloading process is as follows:

1. The MAC receiver gets an ARP request if the Target Protocol Address of request matches the IPv4 address programmed in the L3 register of the MAC.
2. The MAC generates an ARP reply packet.
3. The MAC copies the Sender Hardware Address field in the ARP request to the following fields:
   - DA field of the Ethernet packet header
   - Target Hardware Address field of the ARP reply packet
4. The MAC copies the Sender Protocol Address field in the ARP request to the Target Protocol Address field in the ARP reply packet.
5. The MAC places its MAC address in the following fields:
   - SA field of the Ethernet packet header
   - Sender Hardware Address field of the ARP reply packet
6. The MAC copies the Target Protocol Address field in the ARP request to the Sender Protocol Address field in the ARP reply packet.
7. The MAC sets the opcode field in ARP reply packet to 2 indicating ARP reply.
8. The MAC recalculates the CRC and performs padding for generated ARP reply packet.
9. The MAC transmitter sends the ARP reply.

The MAC processes only one ARP request at a time. It does not store the fields of multiple ARP requests. If the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC does not generate the ARP reply for new ARP request. The MAC forwards the new ARP request packet to application with ARP Reply Not Generated (Bit 34) status bit set. However, in power-down mode, if the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC drops the new ARP request.

If the Disable CRC check bit of the MAC Extension Configuration bit is set, then the MAC does not check for valid CRC of a ARP request Packet. It can generate an ARP response packet if the other conditions are valid.

The ARP request Packet must always have a valid CRC.

Note: When the received ARP request is less than 64 bytes packet length, GMAC does not send a ARP response. It is treated as normal packet and forwarded to the application based on the GMAC filter settings.

28.13 Power Management and Energy Efficient Ethernet

28.13.1 Overview of Low-Power Management

The GMAC supports the following techniques to save power.

- Magic Packet
- Remote Wakeup

The Magic Packet and Remove Wakeup techniques are used to save power in the host system when it is idle (Sleep mode) and has to be woken up only at the reception of specific packets from the Ethernet network. In the Sleep mode, the power to the host logic along with majority of the GMAC (except the MAC receiver logic), can be shut down. On receiving the

specific packets from the network, the MAC provides the trigger to restore the power to the host system and come back to normal state.

The (EEE) mode is compliant with the IEEE 802.3az-2010 standard. It is primarily targeted to save power in the Ethernet port when there is no traffic on the line. In this mode, the host indicates to the far-end that it does not have any packets to transmit for near future and puts the transmitter port (MAC Controller, PCS and PHY layers) into low-power mode. Similarly, the Receiver port can also be put into low-power mode when the far-end host indicates that it does not have any traffic to transfer. This allows significant saving of power in the Ethernet port (mainly in the PHY) with intermittent and bursty traffic profile. The triggering of entry and exit out of the EEE mode is controlled by the MAC and is supported within the GMAC.

Simultaneous operation of the EEE mode along with any or both the other power saving modes is also supported in GMAC.

28.13.1.1 Description of Magic Packet Mode

This section describes the power saving through magic packet detection.

Note:
- The magic packet feature is based on the Magic Packet technology white paper from Advanced Micro Device (AMD).
- The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programmed in WD bit of MAC_Configuration register and PWE bit in MAC_Watchdog_Timeout register.
- The value programmed in DCRCC bit of MAC_Ext_Configuration register is applicable to a magic packet.
- When you enable the low-power mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL Rx Queue or the application. The MAC comes out of the low-power mode when a remote wake-up packet is received and the corresponding detection is enabled.

In the Magic Packet based power saving is a mode, the reception of valid magic packet by MAC receiver triggers an exit from low-power mode. The MAC enters power saving mode when PWRDWN bit of MAC_PMT_Control_Status register is programmed to 1. Exit from the magic packet based low-power mode is enabled by setting the MGKPKTEN bit of MAC_PMT_Control_Status register to 1.

The magic packet contains a unique pattern at any offset after the Destination address, Source address, and Length/Type fields. In addition to the unique pattern matching, the MAC receiver also checks for the following, to detect the received packet as a valid magic packet:

- The packet must be addressed to it (Destination Address of the received packet should perfect match the MAC_Address0_High and MAC_Address0_Low registers) or with multicast/broadcast address
- The packet must not have length error, FCS error, dribble bit error, GMII error, and collision
- The packet must not be runt (length including Ethernet header and FCS is at least 64 bytes)

The content of the unique pattern in magic packet is described as

- 6 bytes of all-ones (0xFFFFFFFFFFFF) called the synchronization stream. There can be more than six bytes of 0xFF, but last 6 are considered.
- The synchronization stream is immediately followed by 16 repetitions of Destination address field of the packet (MAC Address (MAC_Address0_High and MAC_Address0_Low registers) or multicast/broadcast address)
- No break or interruption between synchronization stream and first repetition of Destination address field or within its 16 repetitions

If the MAC address of a node is 0x001122334455, the MAC scans for the following data sequence:

Destination Address Source Address Length/Type…… FF FF FF FF FF FF

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

…CRC

28.13.1.2 Description of Remote Wakeup Packet Mode

This section describes the Remote Wakeup Packet based power saving mode.

Note:
- The remote wake-up packet feature is implemented based on the Device Class Power Management Reference Specification and various implementation-specific white papers.
- The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programmed in WD bit of MAC_Configuration register and PWE bit in MAC_Watchdog_Timeout register.
- The value programmed in DCRCC bit of MAC_Ext_Configuration register is applicable to a magic packet.
- When you enable the low-power mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL Rx Queue or the application. The MAC comes out of the low-power mode when a remote wake-up packet is received and the corresponding detection is enabled.

In the Remote Wakeup Magic Packet based power saving mode, the reception of expected remote wakeup packet by MAC receiver triggers the exit from low-power mode. The MAC enters power saving mode when PWRDWN bit of MAC_PMT_Control_Status register is programmed to 1. Exit from the remote wakeup based low-power mode is enabled by programming RWKPKTEN bit of MAC_PMT_Control_Status register to 1.

The MAC implements a filter lookup table (programmed through MAC_RWK_Packet_Filter register) in which CRC, offset, and byte mask of the pattern embedded in remote wakeup packet and the filter operation commands are programmed.

The pattern embedded in the remote wakeup packet is located at any offset after the Destination address and Source address fields. In addition to the CRC match for the pattern, the MAC receiver also checks the following, to detect the received packet as a valid remote wakeup packet:

- The packet must be addressed to it (Destination Address of the received packet should perfect match the MAC_Address0_High and MAC_Address0_Low registers) or with multicast/broadcast address.
- The packet must not have length error, FCS error, dribble bit error, GMII error, and collision.
- The packet must not be runt (length including Ethernet header and FCS is at least 64 bytes).

When a valid remote wakeup packet is received, the MAC receiver sets the RWKPRCVD bit in MAC_PMT_Control_Status register and triggers the interrupt on GMAC_PMT. The PMTIS bit in MAC_Interrupt_Status register is set when power-gating is not enabled in low-power mode. An interrupt is triggered to the application via GMAC_SBD when interrupt is enabled (PMTIE bit in MAC_Interrupt_Enable register is set) and CSR clock is not gated off in low-power mode.

Remote Wake-Up Packet Filters

When Remote Wakeup based power saving mode is selected, it allows selection of 4 Remote Wakeup Filters. The Remote Wakeup Filters structure is shown in Table 28.59.

Table 28.59 Remote wake-up packet filter register

wkupfmfilter_reg0	Filter 0 Byte Mask							
wkupfmfilter_reg1	Filter 1 Byte Mask							
wkupfmfilter_reg2	Filter 2 Byte Mask							
wkupfmfilter_reg3	Filter 3 Byte Mask							
wkupfmfilter_reg4	RSVD	Filter 3 Command	RSVD	Filter 2 Command	RSVD	Filter 1 Command	RSVD	Filter 0 Command
wkupfmfilter_reg5	Filter 3 Offset		Filter 2 Offset		Filter 1 Offset		Filter 0 Offset	
wkupfmfilter_reg6	Filter 1 CRC-16				Filter 0 CRC-16			
wkupfmfilter_reg7	Filter 3 CRC-16				Filter 2 CRC-16			

The Remote Wakeup Filters are arranged in blocks of 4 filters each and each such block have eight 32-bit wide registers, that is, wkuppktfilter_reg0-7. The fields of Remote Wakeup Filter are as follows:

Filter i Byte Mask

The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2 and 3) to determine whether or not a packet is a wake-up packet.

- The MSB (31st bit) must be zero.

- Bit j[30:0] is the byte mask.
- If bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored

Filter i Command

The 4-bit filter i command controls the filter i operation.

- Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet
- Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC-16 value. Bit 2, along with bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2".
- Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. The details are as follows:
  - The And_Previous bit setting is applicable within a set of 4 filters.
  - Setting of And_Previous bit of filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect.
  - If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered.
  - If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.
- Bit 0 is the enable for filter i. If bit 0 is not set, filter i is disabled.

Filter i Offset

The filter i offset register defines the offset (within the packet) from which the filter i examines the packets.

- This 8-bit pattern-offset is the offset for the filter i first byte to be examined.
- The minimum allowed offset is 12, which refers to the 13th byte of the packet.
- The offset value 0 refers to the first byte of the packet.

Filter i CRC-16

The filter i CRC-16 register contains the CRC-16 value calculated from the pattern and the byte mask programmed in the Remote Wakeup filter register.

- The 16-bit CRC calculation uses the following polynomial:
  $G(x) = x^{16} + x^{15} + x^2 + 1$
- Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:
  - 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC-16 calculation.
  - 8-bit Offset Pointer: Specifies the byte to start the CRC-16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC-16 calculations.

The Remote Wakeup Filter registers are implemented as 8 indirect access registers (wkuppktfilter_reg[n]) and accessed by application through MAC_RWK_Packet_Filter register. When the Remote Wakeup Filters are to be programmed, the entire set of wkuppktfilter_reg registers must be written. The wkuppktfilter_reg register is programmed by sequentially writing the eight register values in MAC_RWK_Packet_Filter register for wkuppktfilter_reg0, wkuppktfilter_reg1, …, wkuppktfilter_reg7 respectively. The wkuppktfilter_reg register is read in a similar way. The MAC updates the wkuppktfilter_reg register current pointer value in RWKPTR field of MAC_PMT_Control_Status register.

Note:
- If the MAC_RWK_Packet_Filter register is accessed in byte or half-word mode, the internal counter to access the appropriate wkuppktfilter_reg is incremented when CPU accesses Lane 3.
- When MAC_RWK_Packet_Filter register is written, the content is transferred from CSR clock domain to PHY receive clock domain after the write operation, there should not be any further write to the MAC_RWK_Packet_Filter register until the first write is updated in PHY receive clock domain. Otherwise, the second write operation does not get updated to the PHY receive clock domain. Therefore, the delay between two writes to the MAC_RWK_Packet_Filter register should be at least 4 cycles of the PHY receive clock.

28.13.1.3 PMT Interrupt

The PMT interrupt is asserted when a valid remote wake-up packet is received. In addition to GMAC_SBD, the GMAC_PMT signal is asserted. The GMAC_PMT signal, synchronous to the Rx clock domain, is provided so that you can stop the application clock when the MAC is in the power-down mode. As the GMAC_PMT signal is generated in the PHY Rx clock domain, it is not cleared immediately when the MAC_PMT_Control_Status register is read.

This is because the resultant clear signal has to cross to the PHY Rx clock domain, and then clear the interrupt source. This delay is at least 4 clock cycles of Rx clock and can be significant when the GMAC is operating in the 10 Mbps mode. When the application clears the PWRDWN bit in Remote Wake-Up Packet Detection register, the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

28.13.2 Energy Efficient Ethernet (EEE)

EEE is an operational mode that enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps, 1000 Mbps, and 10 Gbps. The GMAC supports the IEEE 802.3az-2010 for EEE.

The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionalities to save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

28.13.2.1 Transmit Path Functions

The transmit path functions include tasks that the MAC must perform to make the PHY to enter the LPI state.

In the transmit path, the software must set the LPIEN bit of the MAC_LPI_Control_Status register to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER field of MAC_LPI_Control_Status register. The PHY Link Status bit of the MAC_LPI_Control_Status register indicates the link status of the PHY.

Note:
- According to the standard (IEEE 802.3az-2010), the PHY must not stop the TxCLK clock during the LPI state in the MII (10 or 100) mode. However, the MAC can stop the GTX_CLK clock during the LPI state in the GMII (1000) mode.
- According to the standard (IEEE 802.3az-2010), the LPI mode is supported only in the full-duplex mode. Therefore, you must not enable the LPI mode when the MAC Transmitter is configured for the half-duplex mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts TX_EN
2. Asserts TX_ER
3. Sets TXD[3:0] to 0x1 (for 100 Mbps) or TXD[7:0] to 0x01 (for 1,000 Mbps)

The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.

4. Updates the status (TLPIEN bit of MAC_LPI_Control_Status register) and generates an interrupt

To bring the PHY out of the LPI state, that is, when the software resets the LPIEN bit, the MAC performs the following tasks:

1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern
2. Starts the LPI TW TIMER
   The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the MAC_LPI_Timers_Control register.
3. Updates the LPI exit status (TLPIEX bit of the MAC_LPI_Control_Status register) and generates an interrupt

Note:
- If the MAC is in the Tx LPI mode and the Tx clock is stopped, the application should not write to CSR registers that are synchronized to Tx clock domain.
- If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC transmitter comes out of the LPI mode.

28.13.2.2 Automated Entry/Exit of LPI mode in Transmit Path

The MAC transmitter can be programmed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period of time or has a packet to transfer. These modes are enabled and controlled by MAC_LPI_Control_Status register.

When LPITXA (bit [19]) and LPITXEN (bit [16]) of MAC_LPI_Control_Status register are set, the MAC transmitter enters LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter exits the LPI IDLE state and clear the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition, when bit [20] (LPIATE) is also set, the MAC transmitter enters LPI IDLE state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in MAC_LPI_Entry_Timer. In this mode also, the MAC transmitter exits the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that reentry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of LPI IDLE state by programming the LPITXEN bit.

28.13.2.3 Receive Path Functions

The receive path functions include the tasks that the PHY and MAC must perform when the PHY receives signals from the link partner to exit the LPI state.

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER
2. The PHY sets RXD[7:0] to 0x01
3. The PHY de-asserts RX_DV
   The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.
4. The MAC updates the RLPIEN bit of the MAC_LPI_Control_Status register and immediately generates an interrupt

Note:
- If the LPI pattern is detected for a very short duration (that is, less than two cycles of Rx clock), the MAC does not enter the Rx LPI mode.
- If the duration between end of the current Rx LPI pattern and start of the next Rx LPI pattern, is very short (that is, less than two cycles of Rx clock), then the MAC exits and again enters the Rx LPI mode. The MAC does not give the Rx LPI Exit and Entry interrupts

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.

2. The MAC updates the RLPIEX bit of the MAC_LPI_Control_Status register and generates an GMAC_SBD interrupt immediately. The GMAC_LPI interrupt is also asserted.

Figure 28.29 shows the behavior of RX_ER, RX_DV, and RXD[3:0] signals during the LPI mode transitions.

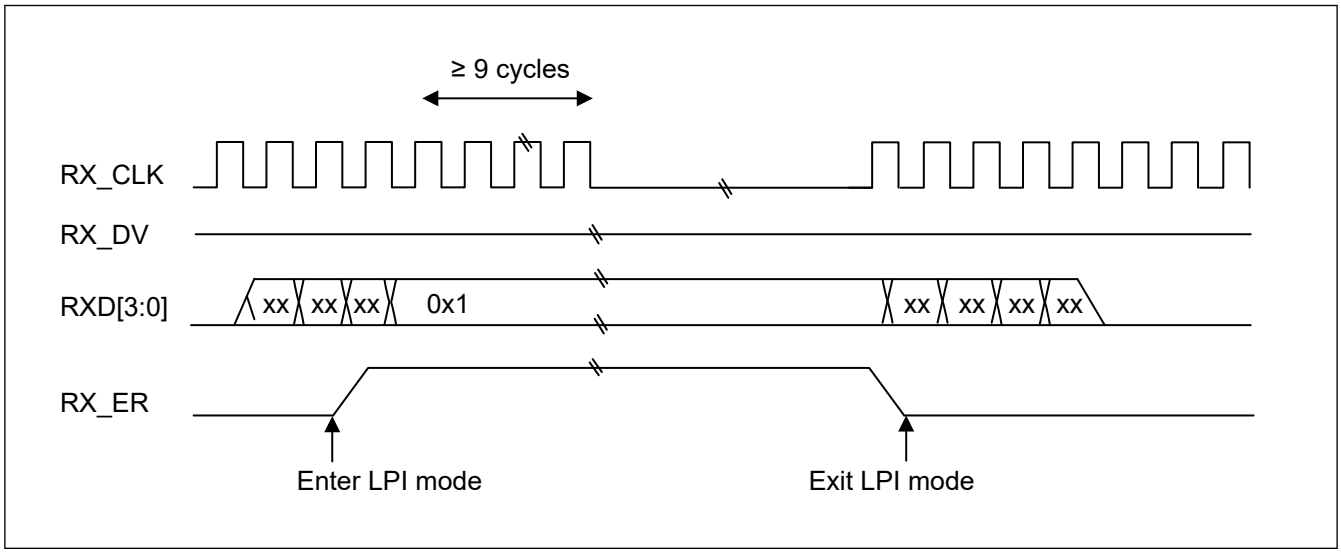

Figure 28.29 LPI transitions (receive)

Note:
- If the RX_CLK_stoppable bit (in the PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, the PHY may halt the RX_CLK at any time more than nine clock cycles after the start of the LPI state as shown in Figure 28.29.
- If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC receiver comes out of the LPI mode during reset. If the LPI pattern is still received after the reset is de-asserted, the MAC receiver again enters the LPI state.
- If the RX clock is stopped in the RX LPI mode, the application should not write to the CSR registers that are being synchronized to the RX clock domain.
- When the PHY sends the LPI pattern, if EEE feature is enabled, the MAC automatically enters the LPI state. There is no software control to prevent the MAC from entering the LPI state.

28.13.2.4 EEE Registers

The following are the registers related to Energy Efficient Ethernet features:

- MAC_LPI_Control_Status
- MAC_LPI_Timers_Control
- MAC_LPI_Entry_Timer

For detailed description of these registers, see section 28.3. Register Descriptions.

28.13.2.5 LPI Timers

The transmitter maintains the LPI LS TIMER, LPI TW TIMER, and LPI AUTO ENTRY TIMER timers.

Following are the LPI timers that are loaded with the respective values from the MAC_LPI_Timers_Control and MAC_LPI_Entry_Timer registers:

- LPI LS TIMER
  The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. You can enable the monitoring of the LUD bit of the MAC_PHYIF_Control_Status register by setting the PLSEN bit of MAC_LPI_Control_Status register.
  The link status is indicated to the MAC by the LNKSTS bit of the MAC_PHYIF_Control_Status register or the value programmed by the software in the PLS bit of the MAC_LPI_Control_Status register. If the link status is not available in the MAC_PHYIF_Control_Status, the software should get the PHY link status by reading the PHY register and accordingly update the PLS bit.

This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in bits25:16] of the MAC_LPI_Timers_Control register. The GMII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE 802.3-az-2010. The LPI LS TIMER is 10-bit wide. Therefore, the software can program up to 1023 milliseconds.

- LPI TW TIMER
  The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programmed in bits [15:0] of LPI_Timers_Control register. The terminal count of the timer is the value of resolved Transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count.
  The MAC supports the LPI TW TIMER in units of microsecond. The LPI TW TIMER is 16-bit wide. Therefore, the software can program up to 65535 micro seconds.
- LPI AUTO ENTRY TIMER
  This timer counts in steps of eight microseconds, the time for which the MAC transmit path has to remain in idle state (no activity), before the MAC Transmitter enters the LPI IDLE state and starts transmitting the LPI pattern. This timer is enabled when LPITE bit in MAC_LPI_Control_Status register is set.

Note: Program the PLS bit of MAC_LPI_Control_Status to 0 before switching between the GMII and MII modes. This resets the internal timers. If the mode is changed after the LPI LS TIMER or LPI TW TIMER starts, the change in the Tx clock frequency can result in incorrect timeout.

28.13.2.6 LPI Interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The interrupt GMAC_SBD is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the MAC_LPI_Control_Status register.

When the MAC exits the Rx LPI state, then in addition to the GMAC_SBD, the GMAC_LPI is asserted. You can use the GMAC_LPI signal to trigger the external clock-gating circuitry to restore the application clock to the MAC. The GMAC_LPI signal, synchronous to the Rx clock domain, is provided so that you can stop the application clock when the MAC is in the LPI state.

The GMAC_LPI signal is generated in the Rx clock domain. It may not be cleared immediately after the MAC_LPI_Control_Status register is read. This is because the clear signal, generated in CSR clock domain, has to cross the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the GMAC is operating in the 10Mbps mode.

28.14 MAC Management Counters

GMAC supports a set of registers known as MAC Management Counters that store statistics on the received and transmitted packets.

28.14.1 MAC Management Counters

The GMAC supports storing the statistics about the received and transmitted packets in registers that are accessible through the application.

The counters in the MAC Management Counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two status registers containing interrupts generated (receive and transmit), and Interrupt Enable registers (receive and transmit). These registers are accessible from the Application. Each register is 32-bits wide. 8-, 16- and 32-bit accesses are allowed as long as the address is word-aligned. The MMCs are accessed using transactions, in the same way the CSR address space is accessed.

The MMC counters are free running. There is no separate enable for the counters to start. If a particular MMC counter is present in the RTL, it starts counting when corresponding packet is received or transmitted. The Receive MMC counters are updated for packets that are passed by the Address Filter (AFM) block. The statistics of packets, dropped by the AFM

module, are not updated unless they are runt packets of less than 6 bytes (DA bytes are not received fully). To get statistics of all packets, set bit 0 in the MAC_Packet_Filter register.

The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet packets.

28.14.2 Address Assignments

The MMC registers follow a certain naming convention and their descriptions use certain terminologies that you should know.

The MMC register naming conventions are as follows.

- "tx" as a prefix or suffix indicates counters associated with transmission
- "rx" as a prefix or suffix indicates counters associated with reception
- "_g" as a suffix indicates registers that count only good packets
- "_gb" as a suffix indicates registers that count packets regardless of whether they are good or bad.

The following definitions define the terminology used in MMC register descriptions.

- Transmitted packets are considered "good" if transmitted successfully. In other words, a transmitted packet is good if the packets transmission is not aborted because of any of the following errors:
  - Jabber Timeout
  - No Carrier or Loss of Carrier
  - Late Collision
  - Packet Underflow
  - Excessive Deferral
  - Excessive Collision
- Received packets are considered "good" if none of the following errors exists:
  - CRC error
  - Runt packet (shorter than 64 bytes)
  - Alignment error (in 10/100 Mbps only)
  - Length error (non-Type packet only)
  - Out of Range (non-Type packet only, longer than 1518 bytes)
  - GMII_RXER Input error
- The maximum transmit frame size depends on the frame type, as follows:
  - Untagged frame maxsize = 1,518
  - VLAN Frame maxsize = 1,522
  - Jumbo Frame maxsize = 9,018
  - JumboVLAN Frame maxsize = 9,022
- The maximum receive packet size depends on the packet type and control bits (JE, S2KP, GPSLCE and EDVLP), as shown in the Table 28.60.

Table 28.60 Size of the maximum receive packet (1 of 2)

JE	S2KP	GPSLCE	EDVLP	Untagged Frame maxsize in bytes	Single VLAN Frame maxsize in bytes	Double VLAN Frame maxsize in bytes
1	x	x	1	9018	9022	9026
0	1	x	x	2000	2000	2000
0	0	1	1	GPSL	GPSL+4	GPSL+8
0	0	0	1	1518	1522	1526
1	x	x	0	9018	9022	9022

Table 28.60 Size of the maximum receive packet (2 of 2)

JE	S2KP	GPSLCE	EDVLP	Untagged Frame maxsize in bytes	Single VLAN Frame maxsize in bytes	Double VLAN Frame maxsize in bytes
0	0	1	0	GPSL	GPSL+4	GPSL+4
0	0	0	0	1518	1522	1522

Note: • The MMC counters registers at the following offset addresses are of type Read-Only and have the default value of 0:
  – 0x0714 to 0x0778
  – 0x0780 to 0x07E4
  – 0x0810 to 0x0844
  – 0x0850 to 0x0884

28.15 Flow Control

28.15.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

28.15.1.1 Flow Control in Full-Duplex Mode

GMAC supports full-duplex flow control operations.

In full-duplex mode, the GMAC uses the following packet type for flow control:

- IEEE 802.3x Pause packets

(1) Pause Packet Structure

Table 28.61 describes the fields of a Pause packet.

Table 28.61 Pause packet fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets
PT	Contains Pause time specified in the PT field of the MAC_Q0_Tx_Flow_Ctrl register

(2) Pause Packet Control

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

Similarly, when the hw_flowctrl is asserted, the MAC generates and transmits a single Pause packet. If the hw_flowctrl remains asserted at a configurable number of slot times before the Pause time runs out, the MAC transmits a second Pause packet. This process is repeated as long as the hw_flowctrl remains active. If the hw_flowctrl goes inactive prior to the sampling time, the MAC transmits a Pause packet with zero Pause time (if the DZPQ bit in MAC_Q0_Tx_Flow_Ctrl register is set to 0) to indicate to the remote end that the Receive buffer is ready to receive new data packets.

28.15.1.2 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a

packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Table 28.62 describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of MTL_RxQ0_Operation_Mode register
- TFE bit of MAC_Q0_Tx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Flow control is similar for all queues.

Table 28.62 Tx MAC flow control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs back-pressure when bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set.
1	1	0	The MAC transmitter performs back-pressure when bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set. In addition, the MAC Tx performs back-pressure when Rx Queue level crosses the threshold set by bits [10:8] of MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the Pause packet when bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set.
1	1	1	The MAC transmitter sends the Pause packet when bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set. In addition, the MAC Tx sends a Pause packet when Rx Queue level crosses the threshold set by bits [10:8] of MTL_RxQ0_Operation_Mode register.

28.15.1.3 Enabling Transmit Flow Control

To independently enable Transmit Flow Control for each Rx queue, set the TFE bit in the MAC_Q0_Tx_Flow_Ctrl register.

28.15.1.4 Triggering Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end. The application can request the MAC to send a Pause packet or initiate back-pressure by using either of the following methods:

- Software Trigger: In this method, the application sets the FCB_BPA bit in the corresponding MAC_Q0_Tx_Flow_Ctrl register.
- Hardware Trigger: In this method, the application triggers the flow control by asserting the flow control based on the Rx Queue (hw_flowctrl).

The hw_flowctrl is triggered based on the following:

- Rx Queue Threshold: The flow control operation of the MAC is enabled when the EHFC bit of corresponding MTL_RXQn_OPERATIOn_MODE register is set. The flow control signal to the MAC is asserted when the fill level of the Rx queue crosses the threshold configured in RFA field of MTL_RXQn_OPERATIOn_MODE register. This flow control signal is de-asserted when the fill-level of the queue is lower than the threshold configured in the RFD field. The hardware flow control generated based on the Rx Queue threshold crossing condition is applicable only when the Rx queue size is 4,096 bytes or more.

Note: The RFA sets the threshold at which the flow control is triggered and the MAC schedules to send a PAUSE frame to be sent by the local transmitter.

The remote transmitter can continue to send packets until it receives this PAUSE packet. So the RXQ needs space to take in this data even after the flow-control is triggered, to avoid overflow and loss of packets.

The max-space required that is calculated theoretically can be 2 max-sized packets + a little more assuming that the read from the RXFIFO is not occurring during this whole time.

Theoretically, this makes RFA = 4 or more, which implies that RxQ must have at the least 4 KB size.

Practically, the system works with RFA = 2 (Full – 2 KB, with very little probability of overflow).

If you have FIFO size less than 4K, with RFA = 2, the flow control is triggered with 1000B in the RxQ, which is less than max packet size.

The RFA field MTL_RXQn_OPERATIOn_MODE register is used for activating the Flow Control.

These bits control the threshold (fill-level of Rx queue) at which the flow control is activated.

For Example: If your RXQ size is 2K and you set the RFA to 1K; as soon as 1K is received, Flow Control is activated. If you send a packet of 1500 bytes (which is allowed as per spec), flow-control is triggered even before you receive a complete packet. This reduces the throughput considerably.

If your RXQ size is 4K, you can set the RFA to 2K, so that you are able to receive the whole packet.

28.15.2 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet.

Note: Receive pause packets should have a frame size of 64 bytes.

28.15.2.1 Description of Receive Flow Control

The Receive Flow Control is implemented by the MAC based on the bit value of the respective register, and the destination address and different fields of the received packet.

Table 28.63 describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_Rx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Table 28.63 Rx MAC flow control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

If RFE bit is enabled, the MAC transmitter is blocked when the 802.3x Pause packet is received.

The following list describes the Rx flow control:

1. The MAC checks the destination address of the received Pause packet for either of the following:
   - Multicast destination address: The DA matches the unique multicast address specified for the control packet (0x0180C2000001).
   - Unicast destination address: The DA matches the content of the MAC Address Register 0 and the UP bit of MAC_Rx_Flow_Ctrl register is set.
     If the UP bit is set and the MAC processes Pause packets with unicast destination address in addition to the unique multicast address.
2. The MAC decodes the following fields of the received packet:
   - Type field: This field is checked for 0x8808.
   - Opcode field: This field is checked for 0x0001 (Pause packet).
   - Pause Time field: The Pause time (for Pause packet) is captured to determine the time for which transmitter needs to be blocked.
3. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC transmitter does the following:
   - For 802.3x Pause packets, the MAC pauses the transmission of any data packet for the duration of the decoded Pause Time value multiplied by the slot time (64 byte times).
4. The MAC transfers the received control packet to the application based on the setting of the PCF field in MAC_Packet_Filter register.

If subsequent Pause packets are received before the earlier Pause Time expires, the MAC updates the Pause Timer with new value.

28.15.2.2 Enabling Receive Flow Control

To enable Pause Flow Control, set the RFE bit in the MAC_Rx_Flow_Ctrl register.

28.16 Loopback Mode

The MAC supports Loopback of transmitted packets to its receiver.

28.16.1 Guidelines for Using Loopback Mode

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip, you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets may get corrupted in the loopback FIFO.

The Transmit and Receive clocks can have an asynchronous timing relationship. Therefore, an asynchronous FIFO is used to make the loopback path of the TXD to the Receive path. The asynchronous FIFO is 10-bits (6-bits in 10/100 Mbps mode) wide to accommodate TXD, TXEN, and TXER. The depth of FIFO is five in 1000 Mbps mode and nine in 10/100 Mbps mode. The FIFO is free-running to write on the write clock and read on every read clock.

At the start of each packet read out of the FIFO, the Write and Read pointers get re-initialized to have an offset of 2 (4 in 10/100 Mbps mode). This avoids overflow or underflow during a packet transfer. This also ensures that the overflow or underflow occurs only during the IPG period between the packets. The FIFO depth of five or nine is sufficient to prevent data corruption for packet sizes up to 9,022 bytes with a difference of 200 ppm between (G)MII Transmit and Receive clock frequencies. Therefore, bigger packets should not be looped back because they may get corrupted in this loopback FIFO.

At the end of every received packet, the Receive Protocol Engine module generates received packet status and sends it to the Receive Packet Controller module. The control, missed packet, and filter fail status are added to the Receive status in the Receive Packet Controller module.

The MAC does not process ARP or PMT packets that are looped back.

28.16.2 Enabling Loopback Mode

To enable loopback feature, program the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive MII or GMII interface, irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding transmit PHY interface block, on to the Ethernet line.

Note:
- During loopback, the data/packet is reflected on gmii_txd signal.
- Preemption is not supported in loopback mode.

28.17 Descriptors

28.17.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The GMAC supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

Note: There is no limit for the number of descriptors that can be used for a single packet.

28.17.2 Descriptor Structure

The GMAC supports the ring structure for DMA descriptor as shown in Figure 28.30.

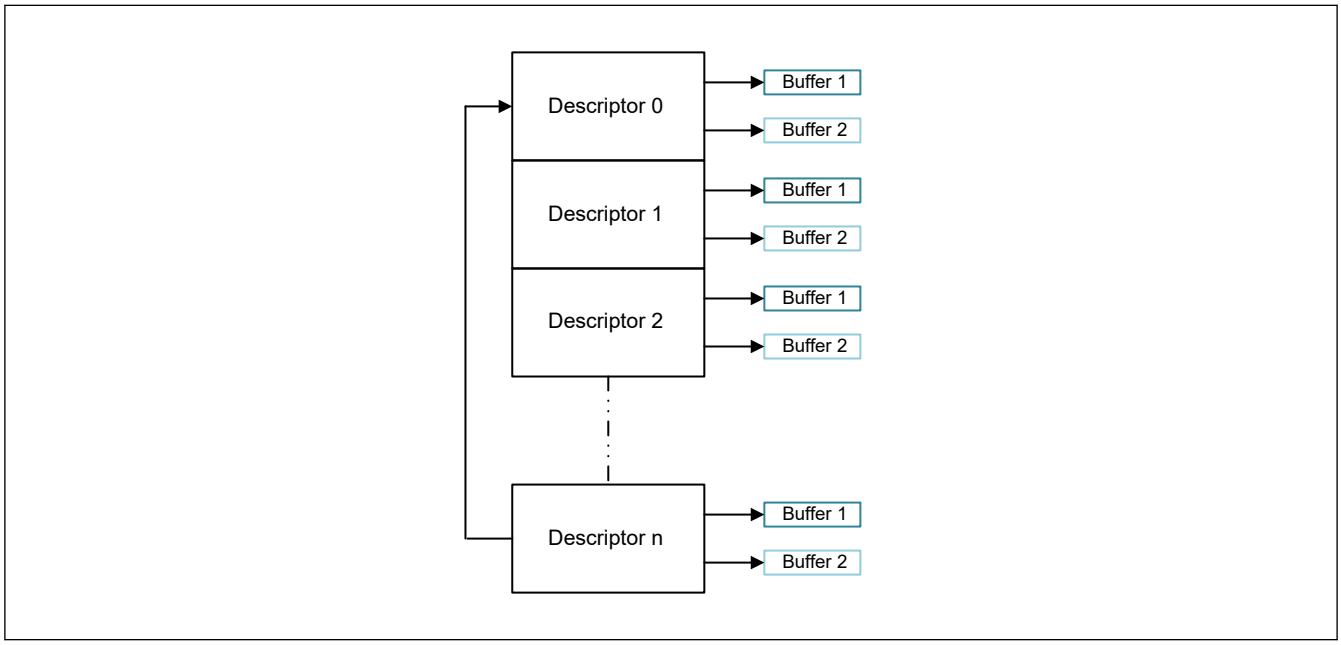

Figure 28.30 Descriptor ring structure

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CHn_CONTROL register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CHn_TXDESC_RING_LENGTH)
- Receive Control 2 Register (DMA_CHn_RX_CONTROL2)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer;

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer;

The DMA automatically wraps around the base address when the end of ring is reached, as shown in Figure 28.31.

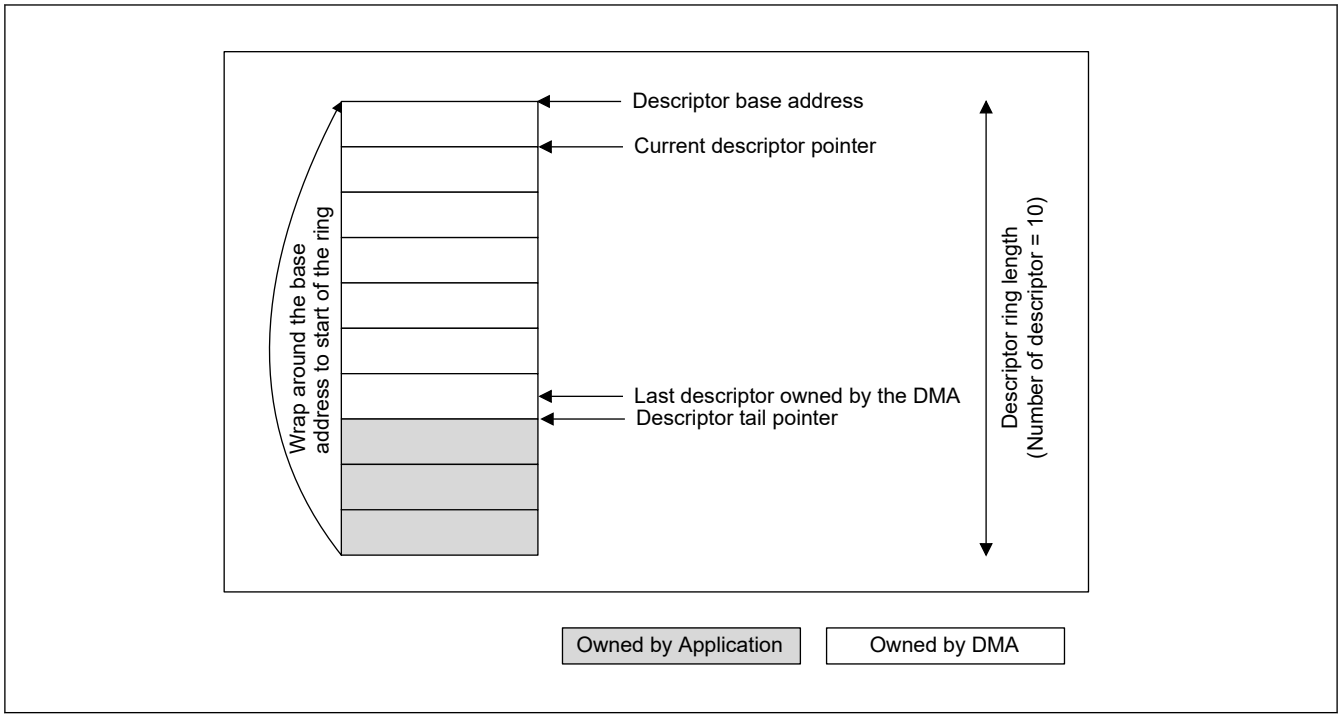

Figure 28.31 DMA descriptor ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

28.17.3 Descriptor Structure for Split Header Support

GMAC supports splitting the incoming receive packet header such that the header and the payload are stored in different buffers (buffer-1 and buffer-2) in the system memory. For details about splitting header on receive packets, see section 28.12.2.4. Header-Payload Split.

Figure 28.32 shows the descriptor structure without the Split Header feature. Figure 28.33 shows the descriptor structure with the Split Header feature.

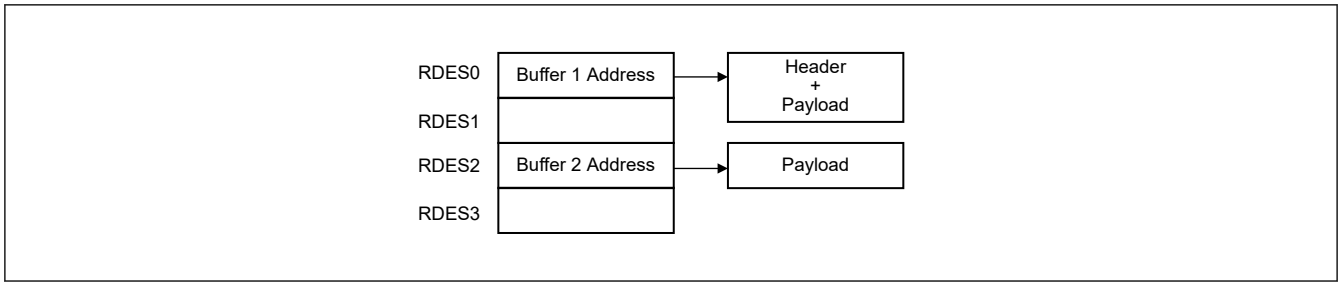

Figure 28.32 Descriptors without split header feature

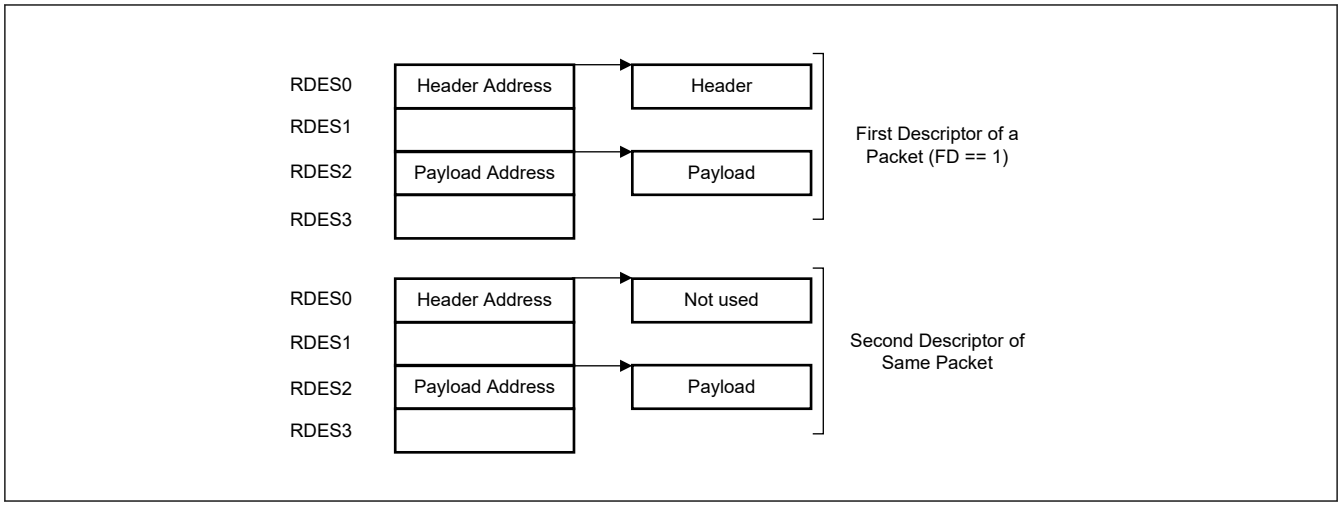

Figure 28.33 Descriptors with split header feature

The DMA writes the header of the received packet by using the header address to which the RDES0 in the first descriptor is pointing (FD bit of RDES3 is set). The DMA writes the payload of the received packet into the buffer address to which the RDES2 is pointing. For subsequent descriptors (FD is set to 0), the address to which RDES0 (Header address) is pointing is not used. The payload is written only to buffers to which the RDES2 (payload address) is pointing.

The HDSMS field of the MAC_Rx_Configuration register indicates maximum header size allowed for splitting the header data in the received packet based on the value programmed. When the ARBS field of the DMA_CHn_RX_CONTROL register is programmed to a non-zero value, ARBS field indicates Receive Buffer size for buffer-1 and the RBSZ field indicates receive buffer size for buffer-2. The ARBS field can be set to 0.

The value in the HDSMS field should be greater than or equal to the Buffer-1 size indicated by ARBS field for all the channels.

Table 28.64 lists how DMA processes a packet based on the packet type.

Table 28.64 Split header support depending on the packet type

Packet Type	SPLM	Description
TCP or UDP packet	00b (L3/L4 Split)	The DMA writes the Ethernet header + IP header + TCP or UDP header into the header buffer.
IP packet (not TCP/UDP)		The DMA writes the Ethernet header + IP header into the header buffer.
Non-IP packet		The DMA does not split the header and payload
Any packet	01b (L2 Split)	The DMA writes the Ethernet header based on split offset (SPLOFST) into the header buffer.
IP packet	10b (Combination of L2 or L3/L4 Split)	L3/L4 split
Non-IP packet		L2 split
NA	11b	Reserved

The IP header includes IPv4 options in case of IPv4 packet and IPv6 extension headers in case of IPv6 frames. The points at which the header is split are shown in Figure 28.34.

Note:
- The VLAN tag stripping must be set for the split function. For instance, the DMA separates the header and payload of an untagged packet only. So, when a tagged packet is received, the program GMAC such that the VLAN tags are deleted/stripped from the received packets.
- L3/L4 split is applicable for IP packets that are either untagged or VLAN stripped. If VLAN tag is retained in the packet forwarded to the DMA, L3-L4 split is not performed. However, if SPLM field is set to 2, L2 split is performed for VLAN tagged IP packets.
- For AV packets, to specify an alternative L2 split value, use the SAVE and SAVO fields of the MAC_Ext1_Cfg register.
- L2 Split is not supported for packets with variable preamble

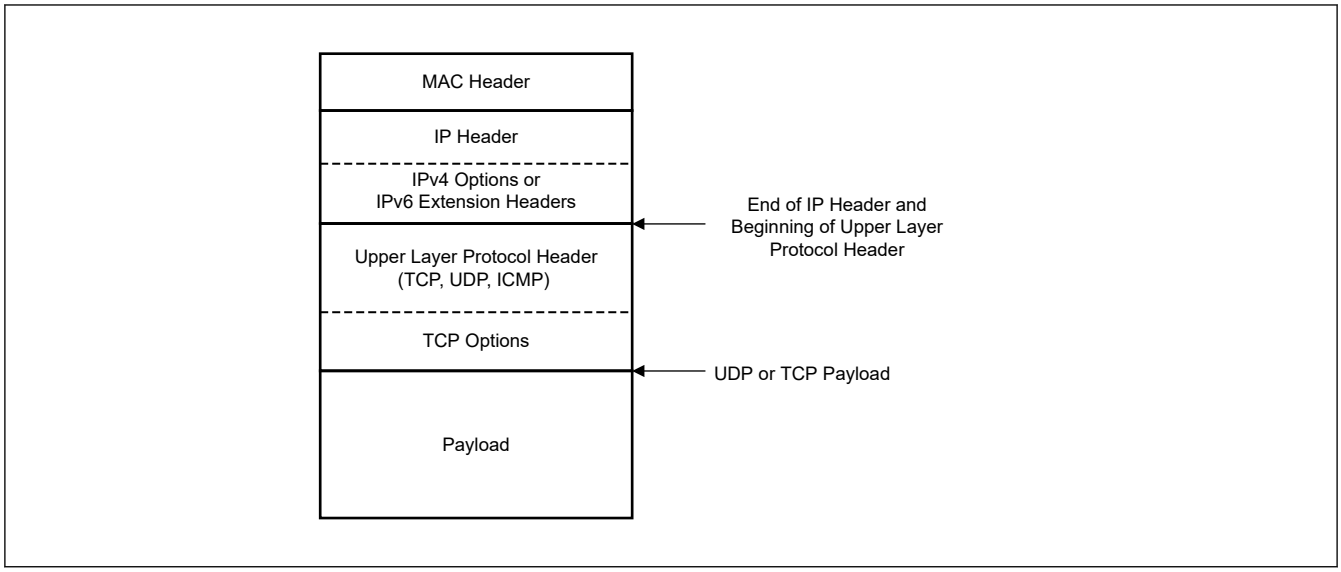

Figure 28.34 Header split points

Table 28.65 lists the header length availability in RDES2.

Table 28.65 Header Length Availability in RDES2

First Descriptor (FD) Value	Last Descriptor (LD) Value	Header Length Availability in RDES2
0	1	Header length not available
1	0	HL[9:0] for all packets
1	1	For IP packets, HL[9:0] For non-IP packets, HL[9:2]

The DMA writes the header length in RDES2 of the first receive descriptor (RDES3[29] (FD bit) is set) for the packet. The packet length is written in RDES3 of the last receive descriptor (RDES3[28] (LD bit) set).

The buffer length for the payload is set by the driver through the RBSZ field in the corresponding DMA Channel Register 2 (Receive Control Register).

The DMA fills receive buffers fully in all except the last descriptor. The header length is taken to be the value based on the bits programmed in the HDSMS field (bits [22:20]) of MAC_Extended_Configuration register.

28.17.4 Transmit Descriptor

The DMA in GMAC requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format.

28.17.4.1 Transmit Normal Descriptor (Read Format)

Table 28.66 shows the Read Format for a Transmit normal descriptor. Table 28.67 through Table 28.70 describe the read format for the Transmit Normal Descriptors: TDES0, TDES1, TDES2, and TDES3.

Table 28.66 Transmit descriptor read format

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TDES0	Buffer 1 Address																															
TDES1	Buffer 2 Address																															
TDES2	IOC	TTSE	Buffer 2 Length														RES	Buffer 1 Length															
TDES3	OWN	CTXT	FD	LD	OPC		Reserved			SLOTNUM or THL				TSE	CIC		Reserved															

Table 28.67 TDES0 normal descriptor (read format)

Bit	Name	Description
31:0	BUF1AP	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1.

Table 28.68 TDES1 normal descriptor (read format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 Address Pointer This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment.

Table 28.69 TDES2 normal descriptor (read format)

Bit	Name	Description
31	IOC	Interrupt on Completion This bit controls the setting of TI and ETI status bits in the DMA_CHn_STATUS register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit.
30	TTSE	Transmit Timestamp Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set.
29:16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
15:14	—	Reserved. The write value should be 0.
13:0	B1L	Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length.

Table 28.70 TDES3 normal descriptor (read format) (1 of 2)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context Type This bit should be set to 0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.

Table 28.70 TDES3 normal descriptor (read format) (2 of 2)

Bit	Name	Description
27:26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of bits [27:26]: ● 00b: CRC and Pad Insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. ● 01b: CRC Insertion (Disable Pad Insertion) The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. ● 10b: Disable CRC Insertion The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. ● 11b: CRC Replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.
25:23	—	Reserved. The write value should be 0.
22:19	SLOTNUM or THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CHn_SLOT_FUNCTION_CONTROL_STATUS. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
18	—	Reserved. The write value should be 0.
17:16	CIC	Checksum Insertion Control These bits control the checksum calculation and insertion. The following list describes the bit encoding: ● 00b: Checksum Insertion Disabled. ● 01b: Only IP header checksum calculation and insertion are enabled. ● 10b: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. ● 11b: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid only for the first descriptor.
15:0	—	Reserved. The write value should be 0.

28.17.4.2 Transmit Normal Descriptor (Write-Back Format)

The write-back format of the Transmit Descriptor includes timestamp low, timestamp high, OWN, and Status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

Table 28.71 shows the write-back format of the Transmit Descriptor. Table 28.72 through Table 28.75 describe the write-back format for the Transmit Normal Descriptors: TDES0, TDES1, TDES2, and TDES3.

Table 28.71 Transmit descriptor write-back format (1 of 2)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TDES0	Timestamp Low																															
TDES1	Timestamp High																															
TDES2	Reserved																															

Table 28.71 Transmit descriptor write-back format (2 of 2)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TDES3	OWN	CTXT	FD	LD	Reserved				DE	Reserved					TTSS	RES		JT	FF	PCE	LoC	NC	LC	EC	Collision Count				ED	UF	DB	IHE

Table 28.72 TDES0 normal descriptor (write-back format)

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and the Timestamp status (TTSS) bit is set.

Table 28.73 TDES1 normal descriptor (write-back format)

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding transmit packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set.

Table 28.74 TDES2 normal descriptor (write-back format)

Bit	Name	Description
31:0	—	Reserved.

Table 28.75 TDES3 normal descriptor (Write-Back Format) (1 of 2)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the GMAC DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 0.
30	CTXT	Context Type This bit should be set to 0 for Normal descriptor.
29	FD	First Descriptor This bit indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor This bit is set to 1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
27:24	—	Reserved
23	DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor Errors can be: ● Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. ● All 1s ● CTXT is set to 1 along with LD or FD bits set to 1. Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA sets the TI bit in the DMA_CHn_STATUS register. Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:18	—	Reserved
17	TTSS	Tx Timestamp Status This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES0 and TDES1 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.

Table 28.75 TDES3 normal descriptor (Write-Back Format) (2 of 2)

Bit	Name	Description
16:15	—	Reserved
14	JT	Jabber Timeout This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
13	FF	Packet Flushed This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.
12	PCE	Payload Checksum Error This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when Bus Error is detected during packet transfer.
11	LoC	Loss of Carrier This bit indicates that Loss of Carrier occurred during packet transmission (that is, the carrier sense signal (CRS) was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
10	NC	No Carrier This bit indicates that the carrier sense signal (CRS) form the PHY was not asserted during transmission.
9	LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode and 512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set.
8	EC	Excessive Collision This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
7:4	CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
3	ED	Excessive Deferral This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register. When TBS is enabled in full duplex mode and this bit is set, it indicates that the frame has been dropped after the expiry time has reached.
2	UF	Underflow Error This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: ● The DMA encountered an empty Transmit Buffer while transmitting the packet ● The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL_Interrupt_Status register.
1	DB	Deferred Bit This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
0	IHE	IP Header Error When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. In full duplex mode, when EST/Qbv is enabled and this bit is set, it indicates the frame drop status due to Frame Size error or Schedule Error.

28.17.4.3 Transmit Context Descriptor

The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature.

The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction and VLAN Tag ID for VLAN insertion feature. Write back is done on a context descriptor only to reset the OWN bit.

Note: The VLAN Tag IDs and MSS values, provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA. When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet. The Inner VLAN Tag Control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

Table 28.76 shows the format of the Transmit Context descriptor. Table 28.77 through Table 28.80 describe the format for the Transmit Context Descriptors: TDES0, TDES1, TDES2, and TDES3.

Table 28.76 Transmit context descriptor format

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TDES0	Timestamp Low																															
TDES1	Timestamp High																															
TDES2	Reserved																															
TDES3	OWN	CTXT	RES		OSTC	TCV	RES		CDE	Reserved																						

Table 28.77 TDES0 context descriptor

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

Table 28.78 TDES1 context descriptor

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

Table 28.79 TDES2 context descriptor

Bit	Name	Description
31:0	—	Reserved

Table 28.80 TDES3 context descriptor (1 of 2)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the GMAC DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit immediately after the read.
30	CTXT	Context Type This bit should be set to 1 for Context descriptor.
29:28	—	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCV	One-Step Timestamp Correction Input or MSS Valid When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid.

Table 28.80 TDES3 context descriptor (2 of 2)

Bit	Name	Description
25:24	—	Reserved
23	CDE	Context Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the context descriptor. Context Descriptor Errors can be: ● Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. ● All 1s. ● CD, LD, and FD bits set to 1. Note 1: When the Context Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA sets the TI bit in the DMA_CHn_STATUS register Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent. Note3: This error is categorized as an abnormal event; recovery is only by issuing a software reset (DMA stopping-reconfiguring-restarting recovery mechanism is not supported)
22:0	—	Reserved

28.17.5 Receive Descriptor

The DMA in GMAC attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive Descriptors are present:

- Normal descriptors
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as "Normal" Descriptors with the content as shown in Receive Normal Descriptor (Read Format). The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA closes the descriptor with the corresponding packet status. The format of this status is given in the section 28.17.5.2. Receive Normal Descriptor (Write-Back Format).

For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA writes the extended status to the next descriptor (without processing or using the Buffers/ Pointers embedded in that descriptor). The format and content of the descriptor write back is described in section 28.17.5.3. Receive Context Descriptor.

28.17.5.1 Receive Normal Descriptor (Read Format)

The read format for a Receive Normal descriptor is made up of a header or Buffer 1 address, reserved field, payload or Buffer 2 or Next Descriptor address, a 30-bit reserved filed, OWN bit, and an interrupt bit.

Table 28.81 shows the Read Format for a Receive Normal Descriptor.

Table 28.81 Receive normal descriptor read format

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDES0	Header or Buffer 1 Address																															
RDES1	Reserved																															
RDES2	Payload or Buffer2 or Next Descriptor Address																															
RDES3	OWN	IOC	Reserved				BUF2V	BUF1V	Reserved																							

Note: In the Receive Descriptor (Read Format), if the Buffer Address field is all 0s, GMAC does not transfer data to that buffer and skips to the next buffer or next descriptor.

Table 28.82 RDES0 normal descriptor (read format)

Bit	Name	Description
31:0	BUF1AP	Header or Buffer 1 Address Pointer When the SPH bit of DMA_CHn_CONTROL register of a channel is reset, these bits indicate the physical address of Buffer 1. When the SPH bit is set, these bits indicate the physical address of Header Buffer where the Rx DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[3:0] as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

Table 28.83 RDES1 normal descriptor (read format)

Bit	Name	Description
31:0	—	Reserved

Table 28.84 RDES2 normal descriptor (read format)

Bit	Name	Description
31:0	BUF2AP	Payload or Buffer 2 Address or Next Descriptor Pointer These bits indicate the physical address of Buffer 2. When the SPH bit of the DMA_CHn_CONTROL register is set, the buffer address pointer must be bus width-aligned, that is, BUF2AP[3:0] = 0x0. LSBs are ignored internally. When the SPH bit of the DMA_CHn_CONTROL register is reset, there is no limitations on the RDES2 value. However, the RxDMA uses the LS Bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[3:0] and writes to the complete location.

Table 28.85 RDES3 normal descriptor (read format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the GMAC DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	IOC	Interrupt Enabled on Completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
29:26	—	Reserved
25	BUF2V	Buffer 2 Address Valid When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid. The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data.
24	BUF1V	Buffer 1 Address Valid When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data.
23:0	—	Reserved

28.17.5.2 Receive Normal Descriptor (Write-Back Format)

Table 28.86 shows the write-back format for a Receive Normal descriptor.

Table 28.86 Receive normal descriptor (write-back format) (1 of 2)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RDES1	OAM Sub-Type Code or MAC Control Packet Opcode																TD	TSA	PV	PFT	PTP Message Type				IPCE	IPCB	IPV6	IPV4	IPHE	Payload Type		

Table 28.86 Receive normal descriptor (write-back format) (2 of 2)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDES2	L3L4FM			L4FM	L3FM	MAC Address Match or Hash Value								HF	DAF	SAF	OTS	ITS	Reserved			ARPNR	L3/L4 Header Length									
RDES3	OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	Length / Type Field			ES	Packet Length														

Table 28.87 RDES0 normal descriptor (write-back format)

Bit	Name	Description
31:16	IVT	Inner VLAN Tag This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set. This is valid when VLAN tag stripping are enabled.
15:0	OVT	Outer VLAN Tag This field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.

Table 28.88 RDES1 normal descriptor (write-back format) (1 of 2)

Bit	Name	Description
31:16	OPC	OAM Sub-Type Code, or MAC Control Packet opcode OAM Sub-Type Code If bits [18:16] of RDES3 are set to 111b, this field contains the OAM sub-type and code fields. MAC Control Packet opcode If bits [18:16] of RDES3 are set to 110b, this filed contains opcode.
15	TD	Timestamp Dropped This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow.
14	TSA	Timestamp Available When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 1 (RDES1) and word 0 (RDES0). This is valid only when the Last Descriptor bit (RDES3 [28]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
13	PV	PTP Version This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format.
12	PFT	PTP Packet Type This bit indicates that the PTP message is sent directly over Ethernet.
11:8	PMT	PTP Message Type These bits are encoded to give the type of the message received: ● 0x0: No PTP message received ● 0x1: SYNC (all clock types) ● 0x2: Follow_Up (all clock types) ● 0x3: Delay_Req (all clock types) ● 0x4: Delay_Resp (all clock types) ● 0x5: Pdelay_Req (in peer-to-peer transparent clock) ● 0x6: Pdelay_Resp (in peer-to-peer transparent clock) ● 0x7: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) ● 0x8: Announce ● 0x9: Management ● 0xA: Signaling ● 0xB–0xE: Reserved ● 0xF: PTP packet with Reserved message type
7	IPCE	IP Payload Error When this bit is set, it indicates either of the following: ● The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. ● The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. ● The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this bit is set.
6	IPCB	IP Checksum Bypassed This bit indicates that the checksum offload engine is bypassed.

Table 28.88 RDES1 normal descriptor (write-back format) (2 of 2)

Bit	Name	Description
5	IPV6	IPv6 header Present This bit indicates that an IPV6 header is detected. When the SPH bit of the DMA_CHn_CONTROL register is set, the IPV6 header is available in the header buffer area to which RDES0 is pointing.
4	IPV4	IPV4 Header Present This bit indicates that an IPV4 header is detected. When the SPH bit of the DMA_CHn_CONTROL register is set, the IPV4 header is available in the header buffer area to which RDES0 is pointing.
3	IPHE	IP Header Error When this bit is set, it indicates either of the following: ● The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. ● The IP datagram version is not consistent with the Ethernet Type value. ● Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either bit 5 or bit 4 is set.
2:0	PT	Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): ● 000b: Unknown type or IP/AV payload not processed ● 001b: UDP ● 010b: TCP ● 011b: ICMP ● 110b: AV Tagged Data Packet ● 111b: AV Tagged Control Packet ● 101b: AV Untagged Control Packet ● 100b: IGMP if IPV4 Header Present bit is set else DCB (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 000b.

Table 28.89 RDES2 normal descriptor (write-back format) (1 of 2)

Bit	Name	Description
31:29	L3L4FM	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: ● 000b: Filter 0 ● 001b: Filter 1 ● 010b: Filter 2 ● 011b: Filter 3 ● 100b: Filter 4 ● 101b: Filter 5 ● 110b: Filter 6 ● 111b: Filter 7 This field is valid only when bit 28 or bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter.
28	L4FM	Layer 4 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: ● Layer 3 fields are not enabled and all enabled Layer 4 fields match ● All enabled Layer 3 and Layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by bits [31:29].
27	L3FM	Layer 3 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: ● All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed ● All enabled filter fields match When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by bits [31:29].
26:19	MADRM	MAC Address Match or Hash Value When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register.
18	HF	Hash Filter Status When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits [26:19] indicate the hash value.

Table 28.89 RDES2 normal descriptor (write-back format) (2 of 2)

Bit	Name	Description
17	DAF	Destination Address Filter Fail When this bit is set, it indicates that the packet failed the DA Filter in the MAC.
16	SAF	Source Address Filter Fail When this bit is set, it indicates that the packet failed the SA Filter in the MAC.
15	OTS	VLAN Filter Status The bit is redefined as Outer VLAN Tag Filter Status (OTS). This bit is valid for both Single and Double VLAN Tagged frames
14	ITS	Inner VLAN Tag Filter Status (ITS) This bit is valid only for Double VLAN Tagged frames. For more information, see the Filter Status topic.
13:11	—	Reserved
10	ARPNR	ARP Reply Not Generated When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time).
9:0	HL	L3/L4 Header Length This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the Buffer 1 address of corresponding descriptor. If header length is zero, this field is not valid. It implies that the MAC did not identify and split the header.

Table 28.90 RDES3 normal descriptor (write-back format) (1 of 2)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the GMAC DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: ● The DMA completes the packet reception ● The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 0 to this bit for normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} ● 00b: Intermediate Descriptor ● 01b: First Descriptor ● 10b: Reserved ● 11b: Descriptor Error (due to all 1s) Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data. Receive DMA sets the CDE field of the DMA_CHn_STATUS register but does not the RI field even when IOC field is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	FD	First Descriptor When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet. See the CTXT bit description for details of using the CTXT bit and FD bit together.
28	LD	Last Descriptor When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
26	RS1V	Receive Status RDES1 Valid When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
25	RS0V	Receive Status RDES0 Valid When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.

Table 28.90 RDES3 normal descriptor (write-back format) (2 of 2)

Bit	Name	Description
24	CE	CRC Error When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
23	GP	Giant Packet When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). Note: Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
21	OE	Overflow Error When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. Note: This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
20	RE	Receive Error When this bit is set, it indicates that the RXER signal is asserted while the RXDV signal is asserted during packet reception. This error also includes carrier extension error in the GMII and half-duplex mode. Error can be of less or no extension, or error (rxd != 0f) during extension.
19	DE	Dribble Bit Error When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
18:16	LT	Length/Type Field This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: ● 000b: The packet is a length packet ● 001b: The packet is a type packet. ● 011b: The packet is a ARP Request packet type ● 100b: The packet is a type packet with VLAN Tag ● 101b: The packet is a type packet with Double VLAN Tag ● 110b: The packet is a MAC Control packet type ● 111b: The packet is a OAM packet type ● 010b: Reserved
15	ES	Error Summary When this bit is set, it indicates the logical OR of the following bits: ● RDES3[24]: CRC Error ● RDES3[19]: Dribble Error ● RDES3[20]: Receive Error ● RDES3[22]: Watchdog Timeout ● RDES3[21]: Overflow Error ● RDES3[23]: Giant Packet This field is valid only when the LD bit of RDES3 is set.
14:0	PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

28.17.5.3 Receive Context Descriptor

This descriptor is read-only for the application. Only the DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The bit 30 of RDES3 indicates the context type descriptor.

Table 28.91 shows the format for a Receive Context Descriptor.

Table 28.91 Receive context descriptor format

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RDES1	Timestamp High																															
RDES2	Reserved																															
RDES3	OWN	CTXT	DE	Reserved																												

Table 28.92 RDES0 context descriptor

Bit	Name	Description
31:0	RTSL	Receive Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

Table 28.93 RDES1 context descriptor

Bit	Name	Description
31:0	RTSH	Receive Packet Timestamp High The DMA updates this field with most significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

Table 28.94 RDES2 context descriptor

Bit	Name	Description
31:0	—	Reserved

Table 28.95 RDES3 context descriptor

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: ● The DMA completes the packet reception ● The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context descriptor. The DMA writes 1 to this bit for context descriptor. When CTXT and DE bits are used together, {CTXT, DE} ● 00b: Reserved ● 01b: Reserved ● 10b: Context Descriptor ● 11b: Descriptor Error Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data. Receive DMA sets the CDE bit in DMA_CHn_STATUS register but does not set the RI field even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	DE	Descriptor Error See the CTXT bit description for details of using the DE bit along with CTXT bit.
28:0	—	Reserved

28.17.6 Enhanced Descriptor for Time-Based Scheduling

The time-based scheduling feature needs Enhanced Descriptors (that are 32 bytes) to be enabled on all the DMA channels that intend to use the feature (by setting the EDSE bit of DMA_CHn_TX_CONTROL register).

The structure of 32-byte Descriptor for the Context and the Normal Descriptor in Read and Write formats are described in the following sections:

28.17.6.1 Enhanced Normal Descriptor - Read

Table 28.96 Enhanced normal descriptor - read

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETDES4	LTV	Reserved																			GCL Slot Number				Launch Time [31:24]							
ETDES5	Launch Time [23:0]																								Reserved							
ETDES6	Reserved																															
ETDES7	Reserved																															
TDES0	Header or Buffer 1 Address																															
TDES1	Buffer 2 Address																															
TDES2	IOC	TTSE/TMWD	Buffer 2 Length														VTIR		Header or Buffer 1 Length													
TDES3	OWN	CTXT	FD	LD	OPC		SAIC		SLOTNUM or THL					TSE	CIC		RES	Frame Length													
	TCP Payload Length																															

Table 28.97 ETDES4 enhanced normal descriptor - read

Bit	Name	Description
31	LTV	Launch Time Valid indicates the Launch Time (LT) and GSN fields present in the descriptor are valid. The LTV must be set only if the FD bit of the descriptor is not set.
30:12	—	Reserved
11:8	GSN	GCL slot number associated with the packet
7:0	LT	Launch Time [31:24] associated with the packet

Table 28.98 ETDES5 enhanced normal descriptor - read

Bit	Name	Description
31:8	LT	Launch Time [23:0] associated with the packet
7:0	—	Reserved

Table 28.99 ETDES6 enhanced normal descriptor - read

Bit	Name	Description
31:0	—	Reserved

Table 28.100 ETDES7 enhanced normal descriptor - read

Bit	Name	Description
31:0	—	Reserved

For details of the other fields, see section 28.17.4.1. Transmit Normal Descriptor (Read Format).

28.17.6.2 Enhanced Normal Descriptor - Write

Table 28.101 Enhanced normal descriptor - write (1 of 2)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETDES4	LTV	Reserved																			GCL Slot Number				Launch Time [31:24]

TDES1	Timestamp High																															
TDES2	Reserved																															
TDES3	OWN	CTXT	FD	LD	Reserved				DE	Reserved					TTSS	EUE	ES	JT	FF	PCE	LoC	NC	LC	EC	Collision Count				ED	UF	DB	IHE

For details of LTV, GSN and LT fields, see section 28.17.6.1. Enhanced Normal Descriptor - Read.

For details of the other fields, see section 28.17.4.2. Transmit Normal Descriptor (Write-Back Format).

Note:
- In both the write back formats, no modifications can be done to the extended 16 bytes. The rest of the 16 bytes (TDES0 to TDES3) are written back as per the previous 16 bytes Descriptor format.
- Fetch time when enabled overrides the AV slot function
- When an unaligned new GCL list (with a different CTR) is installed, it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding Fetch, Launch, and Launch expiry as the CTR and BTR values get updated while the frame is being processed

28.17.6.3 Enhanced Context Descriptor - Read

Table 28.102 Enhanced context descriptor - read

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

For details of the other fields, see section 28.17.4.3. Transmit Context Descriptor.

28.18 Programming

28.18.1 Initializing DMA

Complete the following steps to initialize the DMA:

1. Provide a software reset. This resets all of the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the completion of the reset process (poll bit 0 of the DMA_Mode, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the DMA_SysBus_Mode register:
   (a) AAL
   (b) Fixed burst or undefined burst
   (c) OSR_LMT
   (d) If fixed length value is enabled, select the maximum burst length possible on the AXI Bus (bits [3:1])
4. Create a descriptor list for transmit and receive. In addition, ensure that the descriptors are owned by DMA (set bit 31 of descriptor TDES3/RDES3). For more information about descriptors, see section 28.17. Descriptors.
5. Program the Transmit and Receive Ring length registers (DMA_CHn_TXDESC_RING_LENGTH (n = 0 to 7) and DMA_CHn_RxDesc_Ring_Length (n = 0 to 7). The ring length programmed must be at least 4.
   The descriptor address from the start to the end of the ring must not cross the 4 GB boundary.
6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CHn_TXDESC_LIST_ADDRESS (n = 0 to 7) and DMA_CHn_RXDESC_LIST_ADDRESS (n = 0 to 7)). Also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CHn_TXDESC_TAIL_POINTER (n = 0 to 7) and DMA_CHn_RXDESC_TAIL_POINTER (n = 0 to 7)).
7. Program the settings of the following registers for the parameters like maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of Tx DMA, RBSZ in case of Rx DMA, and so on:
   - DMA_CHn_CONTROL (n = 0 to 7)
   - DMA_CHn_TX_CONTROL (n = 0 to 7)
   - DMA_CHn_RX_CONTROL (n = 0 to 7)
8. Enable the interrupts by programming the DMA_CHn_INTERRUPT_ENABLE (n = 0 to 7) register.
9. Start the Receive and Transmit DMAs by setting SR (bit 0) of the DMA_CHn_RX_CONTROL (n = 0 to 7) and ST (bit 0) of the DMA_CHn_TX_CONTROL (n = 0 to 7) register.
10. Repeat steps 4 to 9 for all the Tx DMA and Rx DMA channels selected in the hardware.

28.18.2 Initializing MTL Registers

The Transaction Layer (MTL) registers must be initialized to establish the transmit and receive operating modes and commands.

Complete the following steps to initialize the MTL registers:

1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation in case of multiple Tx and Rx queues.
2. Program the Receive Queue to DMA mapping in MTL_RxQ_DMA_Map0 and MTL_RxQ_DMA_Map1 registers.
3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register.
   (a) Transmit Store and Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode
   (b) Transmit Queue Enable (TXQEN) to value 10b to enable Transmit Queue0
   (c) Transmit Queue Size (TQS)
4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
   (a) Receive Store and Forward (RSF) or RTC in case of Threshold mode
   (b) Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD)
   (c) Error Packet and undersized good Packet forwarding enable (FEP and FUP)

(d) Receive Queue Size (RQS)

5. Repeat previous two steps for all MTL Tx and Rx queues.

28.18.3 Initializing MAC

The MAC configuration registers establish the operating mode of the MAC. These registers must be initialized before initializing the DMA.

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. If more than one MAC address is enabled, program the MAC addresses appropriately.
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_Packet_Filter register:
   (a) Receive All
   (b) Promiscuous mode
   (c) Hash or Perfect Filter
   (d) Unicast, multicast, broadcast, and control frames filter settings
3. Program the following fields for proper flow control in the MAC_Q0_Tx_Flow_Ctrl register:
   (a) Pause time and other Pause frame control bits
   (b) Transmit Flow control bits
   (c) Flow Control Busy
4. Program the MAC_Interrupt_Enable register, as required.
5. Program the appropriate fields in the MAC_Configuration register. For example: Inter-packet gap while transmission and jabber disable.
6. Set bit 0 and 1 in the MAC_Configuration register to start the MAC transmitter and receiver.

To support Jumbo Transmit/Receive packets, follow these steps:

- In the MAC_configuration register
  1. Set JE field to 1
  2. Set JD and WD fields to 0
     To avoid giant packet error reporting
  3. Set GPSLCE field to 1
  4. Set GPSL field of the MAC_Ext_Configuration register to a value > 9026

To support Transmit/Receive packets, up to 16K, follow these steps:

- In the MAC_configuration register,
  1. Set JD and WD fields to 1
     To avoid giant packet error reporting
  2. Set GPSLCE field to 1
  3. Set GPSL field of the MAC_Ext_Configuration register to 16383

28.18.4 Performing Normal Receive and Transmit Operation

During normal operation of the GMAC, normal and transmit interrupts are read, descriptors polled, the DMA is suspended (if it does not own descriptors), and values of current host transmitter or receiver descriptor pointers are read for debugging.

For normal operation, complete the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive).

2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CHn_TXDESC_TAIL_POINTER and DMA_CHn_RXDESC_TAIL_POINTER).
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (DMA_CHn_CURRENT_APP_TXDESC and DMA_CHn_CURRENT_APP_RXDESC).
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (DMA_CHn_CURRENT_APP_TXBUFFER and DMA_CHn_CURRENT_APP_RXBUFFER).

28.18.5 Stopping and Starting Transmission

Complete the following steps to pause the transmission for some time. The steps are provided for Channel 0.

1. Disable the Transmit DMA by clearing bit 0 (ST) of DMA_CHn_TX_CONTROL (n = 0 to 7) register.
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TxQ0_Debug register (TRCSTS is not 01b and TXQSTS = 0).
3. Disable the MAC transmitter and MAC receiver by clearing bit (RE) and bit 1(TE) of the MAC_Configuration register.
4. Disable the Receive DMA, after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of MTL_TxQ0_Debug register, PRXQ = 0 and RXQSTS = 00b).
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in MTL_TxQ0_Debug register and RXQSTS is 0 in MTL_RxQ0_Debug register).
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

Note:
- Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. These parameters are changed by software only when the MAC transmitter and receiver are not active.
- Similarly, do not change the DMA-related configuration when Transmit and Receive DMA are active.

28.18.6 Programming Guidelines for Switching to New Descriptor List in RxDMA

Switching to a new descriptor list is different in the Rx DMA compared to the Tx DMA. Switching to a new descriptor list is permitted when the RxDMA is in SUSPEND state, as clarified by the following points:

- Generally, RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND due to descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames are lost because of an RxFIFO Overflow. Therefore, the software is allowed to create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

28.18.7 Programming Guidelines for Multi-Channel Multi-Queuing

28.18.7.1 Transmit

1. Program the Transmit queue size in the TQS field of MTL_TXQn_OPERATIOn_MODE register. Based on the value programmed in the TQS field, the size of the queue is determined. In the Transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the Channel-to-Queue mapping is fixed.
2. For a queue to be used, enable the ST bit of DMA_CHn_TX_CONTROL register and corresponding TXQEN in MTL_TxQn_Operation Mode register.
3. Program the scheduling method in the SCHALG field of MTL_Operation_Mode register.
4. In case of CBS algorithm in AVB queues, the MTL_TXQn_ETS_CONTROL, MTL_TXQn_SENDSLOPECREDIT, MTL_TXQn_HICREDIT and MTL_TXQn_LOCREDIT registers need to be programmed as required.

28.18.7.2 Receive

1. Program the Receive queue size in the RQS field of MTL_RXQn_OPERATIOn_MODE Register. Based on the value programmed in RQS field, the size of the queue is determined.
2. Enable SR bit of statically or dynamically mapped DMA_CHn_RX_CONTROL Register and corresponding RXQnEN in MAC_RxQ_Ctrl0 register.
3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
   (a) PTP Packets: Based on the programming of PTPQ in MAC_RxQ_Ctrl1 register.
   (b) AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RxQ_Ctrl1 register.
   (c) VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ7-0 of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 Register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 7.
   (d) The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers.
   The priorities set in PSRQ7-0 should be unique.
4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
   (a) Program the RAA field of MTL_Operation_Mode register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
   (b) Program the MTL_RXQn_CONTROL register to decide the weights and the packet arbitration for each RxQ.
   (c) If static mapping is programmed in MTL_RxQ_DMA_Map0/1 register (QnDDMACH is reset to 0), bits QnMDMACH and others need to be programmed to select the channel for which each queue is mapped.
   (d) Set QnDDMACH bit in MTL_RxQ_DMA_Map0/1 register to select dynamic mapping of packets in each RxQueue.
   (e) In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address register.

28.18.7.3 Programming Guidelines for Recovering from DMA Channel Failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

(1) Recovering from the Receive DMA Channel Failure

Follow these steps if you get bus error in the Receive DMA channel:

1. Set the RPF bit to 1. This flushes all the packets one after the other. This step is optional. However, setting this bit prevents HOL (head-of-line) blocking in the Rx queues when packets sent to the RxDMA are stopped due to bus error.
2. Re-program the specific Registers of the DMA channel.
3. Start the DMA channel.

(2) Recovering from the Transmit DMA Channel Failure

1. Stop the specific DMA channel, even if it is in active state.
2. Flush the corresponding MTL queue.
3. Re-program the specific Registers of the DMA channel.
4. Start the DMA channel.

Note: Due to the known limitations in the design, reprogramming the DMA channel registers might not always be successful in recovering from a Bus Error. If GMAC is not fully functional after reprogramming the DMA, as a workaround, issue a Soft Reset to recover from the Bus Error.

28.18.7.4 Programming Guidelines for Disabling Receive Queue

Follow these steps to disable specific receive queue

1. Disable the receiver by setting the RE field of the MAC_Configuration register to 0.
2. Read the MAC_Debug register (ensure that RPESTS and RFCFCSTS fields are 0) and MTL_RXQn_DEBUG registers of all the Rx queues.
3. When MTL_RXQn_DEBUG registers are read as 0, disable the intended Rx queue by programming the corresponding fields in the MAC_RxQ_Ctrl0 register.
4. Enable the receiver by setting the RE field of MAC_Configuration register to 1.

28.18.8 Programming Guidelines for GMII Link State Transitions

28.18.8.1 Transmit and Receive Clocks Running when Link Down

Complete the following steps when the link is down but the Transmit and Receive clocks are running.

1. Disable the Transmit DMA by clearing bit 0 (ST) of DMA_CHn_TX_CONTROL (n = 0 to 7) Register.
2. Disable the MAC receiver by clearing bit 2 (RE) of MAC_Configuration register.
3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TxQ0_Debug register (TRCSTS is not 01). Or, Flush the Tx FIFO for faster empty operation.
4. Disable the MAC transmitter by clearing bit 1(TE) of the MAC_Configuration register.
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in MTL_TxQ0_Debug register and RXQSTS is 0 in MTL_RxQ0_Debug register).
6. After the link is up, read the PHY registers to know the latest configuration and accordingly program the MAC registers.
7. Restart the operation by starting the Tx DMA, and then enabling the MAC Transmitter and Receiver. You do not need to disable the Rx DMA. As the Receiver is disabled, the FIFO does not get any data in the Rx FIFO.

28.18.8.2 Transmit and Receive Clocks Stopped when Link Down

Complete the following steps when the link is down and the Transmit and Receive clocks are stopped:

1. Disable the MAC Transmitter and Receiver by clearing bits RE and TE of MAC_Configuration register. This does not take effect immediately as the clocks are absent.
2. Wait until the link is up and the clocks are restored.
3. Wait for the completion of the transfer of any partial frame, if any, at time of stopping of Transmit/Receive clock. This can be checked by reading the MAC_Debug register (should be all-zero). Some old packets may still remain in the TXFIFO as the MAC Transmitter is stopped.
4. Read the PHY registers to know the latest operating mode and accordingly program the MAC registers.
5. Restart the MAC Transmitter and Receiver by setting RE and TE bits.

28.18.9 Programming Guidelines for IEEE 1588 Timestamping

28.18.9.1 Initialization Guidelines for System Time Generation

You can enable the timestamp feature by setting bit 0 of the MAC_Timestamp_Control register. However, it is essential that the timestamp counter be initialized after this bit is set. Complete the following steps during GMAC initialization:

1. Mask the Timestamp Trigger interrupt by clearing the bit 12 of MAC_Interrupt_Enable register.
2. Set bit 0 of MAC_Timestamp_Control register to enable timestamping.
3. If one-step timestamping is enabled
   (a) To enable one-step timestamping, program bit 27 of the TDES3 Context Descriptor.
   (b) Program registers MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.
4. Enable the MAC receiver and transmitter for proper timestamping.

Note: If timestamp operation is disabled by clearing bit 0 of MAC_Timestamp_Control register, repeat all these steps to restart the timestamp operation.

28.18.10 Programming Guidelines for PTP Offload Feature

28.18.10.1 Programming Guidelines to Enable Automatic Periodic Generation of PTP Sync Messages

Follow these steps to enable automatic periodic generation of PTP sync messages:

1. Program SNAPTYPSEL, TSMSTRENA, and TSEVNTENA fields of MAC_Timestamp_Control register to 0, 1, and 1 respectively, to configure the node as Ordinary or Boundary Master (1, 1, and 1 for Transparent Master).
2. Program the PTOEN bit and DN field of MAC_PTO_Control register to enable PTP Offload feature and domain Number to send in egress PTP Sync message.
3. Program the ASYNCEN bit of MAC_PTO_Control register to enable periodic generation of PTP Sync messages.
4. Program the 80-bit Source Port Identity in MAC_Source_Port_Identity0, MAC_Source_Port_Identity1 and MAC_Source_Port_Identity2 registers to send in egress PTP Sync message.
5. Program the LSI field of MAC_Log_Message_Interval register to program the periodicity of the PTP Sync messages. For example, value of 1 corresponds to 2^1 which translates to PTP Sync message every 2 seconds and value of 0xFF (twos complement of -1) corresponds to 2^{-1} which translates to PTP Sync message every 0.536 seconds.
6. Program the TSIE bit of MAC_Interrupt_Enable register to enable generation of Timestamp Interrupt.
7. Wait for GMAC_SBD interrupt generated on setting of TXTSSIS bit in MAC_Timestamp_Status register, which indicates that the timestamp for PTP Sync message is captured in MAC_Tx_Timestamp_Status_Seconds and MAC_Tx_Timestamp_Status_Nanoseconds registers.

28.18.10.2 Programming Guidelines to Enable Periodic Generation of PTP Pdelay_Req Messages

Follow these steps to enable automatic periodic generation of PTP Pdelay_Req messages

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of MAC_Timestamp_Control register to 1, 0, and 1 respectively to configure the node as Transparent Slave (1, 1, and 1 for Transparent Master OR 3, X, and X for Peer-to-Peer Transparent).
2. Program the PTOEN bit and DN field of MAC_PTO_Control register to enable PTP Offload feature and domain Number to send in egress PTP Pdelay_Req message.
3. Program the APDREQEN bit of MAC_PTO_Control register to enable periodic generation of PTP Pdelay_Req messages.
4. Program the 80-bit Source Port Identity in MAC_Source_Port_Identity0, MAC_Source_Port_Identity1 and MAC_Source_Port_Identity2 registers to send in egress PTP Pdelay_Req message.
5. Program the LMPDRI field of MAC_Log_Message_Interval register to program the periodicity of the PTP Pdelay_Req messages.
   For example, value of 1 corresponds to 2^1 which translates to PTP Pdelay_Req message every 2 seconds and value of 0xFF (twos complement of -1) corresponds to 2^{-1} which translates to PTP Pdelay_Req message every 0.536 seconds.
6. Program the TSIE bit of MAC_Interrupt_Enable register to enable generation of Timestamp Interrupt.
7. Wait for GMAC_SBD interrupt generated on setting of TXTSSIS bit in MAC_Timestamp_Status register, which indicates that the timestamp for PTP Sync message is captured in MAC_Tx_Timestamp_Status_Seconds and MAC_Tx_Timestamp_Status_Nanoseconds registers.

28.18.10.3 Programming Guidelines to Enable Generation of PTP Response Messages for Ordinary or Boundary Master Mode

Follow these steps to enable generation of PTP response messages for Ordinary or Boundary Master mode (Periodic PTP Sync messages generated and PTP Delay_Resp message generated in response to PTP Delay_Req message):

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of MAC_Timestamp_Control register to 0, 1, and 1 respectively.

2. Program the PTOEN bit and DN field of MAC_PTO_Control register to enable PTP Offload feature and domain Number to match with ingress PTP Delay_Req message and send in egress PTP Delay_Resp message.
3. Program the 80-bit Source Port Identity in MAC_Source_Port_Identity0, MAC_Source_Port_Identity1 and MAC_Source_Port_Identity2 registers to match with ingress PTP Delay_Req message and send in egress PTP Delay_Resp message.
4. Program the DRSYNCR and LSI fields in MAC_Log_Message_Interval register, the sum of both these fields is updated in logMinDelayReqInterval field of PTP Delay_Resp message.

28.18.10.4 Programming Guidelines to Enable Generation of PTP response messages for Ordinary or Boundary Slave Mode

Follow these steps to enable generation of PTP response messages for Ordinary or Boundary Slave mode (PTP Delay_Req message generated in response to PTP Sync message):

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of MAC_Timestamp_Control register to 0, 0, and 1 respectively.
2. Program the PTOEN bit and DN field of MAC_PTO_Control register to enable PTP Offload feature and domain Number to match with ingress PTP Sync message and send in egress PTP Delay_Req message.
3. Program the 80-bit Source Port Identity in MAC_Source_Port_Identity0, MAC_Source_Port_Identity1 and MAC_Source_Port_Identity2 registers to match with ingress PTP Sync message and send in egress PTP Delay_Req message.
4. Program the DRSYNCR field in MAC_Log_Message_Interval register to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync messages.

28.18.10.5 Programming Guidelines to Enable Generation of PTP response messages for Transparent Slave Mode

Follow these steps to enable generation of PTP response messages for Transparent Slave mode (PTP Delay_Req message generated in response to PTP Sync message, PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req messages generated)

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of MAC_Timestamp_Control register to 1, 0, and 1 respectively.
2. Program the PTOEN bit and DN field of MAC_PTO_Control register to enable PTP Offload feature and domain Number to match with ingress PTP Sync or Pdelay_Req message and send in egress PTP Delay_Req or Pdelay_Resp or Pdelay_Req message.
3. Program the 80-bit Source Port Identity in MAC_Source_Port_Identity0, MAC_Source_Port_Identity1 and MAC_Source_Port_Identity2 registers to match with ingress PTP Sync or Pdelay_Req message and send in egress PTP Delay_Req or Pdelay_Resp or Pdelay_Req message.
4. Program the DRSYNCR and LMPDRI fields in MAC_Log_Message_Interval register to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync messages and periodicity of the PTP Pdelay_Req messages.
5. Program the TSIE bit of MAC_Interrupt_Enable register to enable generation of Timestamp Interrupt.
6. Wait for GMAC_SBD interrupt generated on setting of TXTSSIS bit in MAC_Timestamp_Status register, which indicates that the timestamp for PTP Sync message is captured in MAC_Tx_Timestamp_Status_Seconds and MAC_Tx_Timestamp_Status_Nanoseconds registers for egress PTP Pdelay_Req and Pdelay_Resp messages.

28.18.10.6 Programming Guidelines to Enable Generation of PTP response messages for Transparent Master Mode

Follow these steps to enable generation of PTP response messages for Transparent Master mode (PTP Delay_Resp message generated in response to PTP Delay_Req message, PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req or Sync messages generated):

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of MAC_Timestamp_Control register to 1, 1, and 1 respectively.

2. Program the PTOEN bit and DN field of MAC_PTO_Control register to enable PTP Offload feature and domain Number to match with ingress PTP Delay_Req or Pdelay_Req message and send in egress PTP Delay_Resp or Pdelay_Resp or Pdelay_Req or Sync message.
3. Program the 80-bit Source Port Identity in MAC_Source_Port_Identity0, MAC_Source_Port_Identity1 and MAC_Source_Port_Identity2 registers to match with ingress PTP Delay_Req or Pdelay_Req message and send in egress PTP Delay_Resp or Pdelay_Resp or Pdelay_Req or Sync message.
4. Program the DRSYNCR, LSI and LMPDRI fields in MAC_Log_Message_Interval register, the sum of DRSYNCR and LSI is updated in logMinDelayReqInterval field of PTP Delay_Resp message and periodicity of the PTP Sync or Pdelay_Req messages.
5. Program the TSIE bit of MAC_Interrupt_Enable register to enable generation of Timestamp Interrupt.
6. Wait for GMAC_SBD interrupt generated on setting of TXTSSIS bit in MAC_Timestamp_Status register, which indicates that the timestamp for PTP Sync message is captured in MAC_Tx_Timestamp_Status_Seconds and MAC_Tx_Timestamp_Status_Nanoseconds registers for egress PTP Sync, Pdelay_Req and Pdelay_Resp messages.

28.18.10.7 Programming Guidelines to Enable Generation of PTP response messages for Peer-to-Peer Transparent Mode

Follow these steps to enable generation of PTP response messages for Peer-to-Peer Transparent mode (PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req messages generated):

1. Program the SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of MAC_Timestamp_Control register to 3, X, and X respectively.
2. Program the PTOEN bit and DN field of MAC_PTO_Control register to enable PTP Offload feature and domain Number to match with ingress PTP Pdelay_Req message and send in egress PTP Pdelay_Resp message.
3. Program the 80-bit Source Port Identity in MAC_Source_Port_Identity0, MAC_Source_Port_Identity1 and MAC_Source_Port_Identity2 registers to match with ingress PTP Pdelay_Req message and send in egress PTP Pdelay_Resp message.
4. Program the LMPDRI field in MAC_Log_Message_Interval register to indicate periodicity of the PTP Pdelay_Req messages
5. Program the TSIE bit of MAC_Interrupt_Enable register to enable generation of Timestamp Interrupt
6. Wait for GMAC_SBD interrupt generated on setting of TXTSSIS bit in MAC_Timestamp_Status register, which indicates that the timestamp for PTP Sync message is captured in MAC_Tx_Timestamp_Status_Seconds and MAC_Tx_Timestamp_Status_Nanoseconds registers for egress PTP Pdelay_Req and Pdelay_Resp messages.

28.18.11 Programming Guidelines for AV Feature

After you enable the AV feature in the GMAC controller, there are several programming tasks to be followed:

- Initializing the DMA
- Enabling slot number checking
- Enabling average bits per slot reporting
- Disabling flow control for AV-enabled queues (receive flow control)

28.18.11.1 Initializing the DMA in Audio Video Feature

The first step in programming the AV feature is to initialize the DMA.

1. Provide a software reset to reset all internal registers and logic (bit 0 in DMA_Mode register) of GMAC.
2. Wait for the completion of the reset process. Poll bit 0 of the DMA_Mode register, which is cleared only after the reset operation is completed.
3. Program the fields to initialize the DMA register by setting the values in DMA_Mode register.
4. Create a proper descriptor list for transmit and receive. In addition, ensure that the DMA owns the Transmit and Receive descriptors. When OSF mode is used, at least two TX descriptors are required. For more information about descriptors, see section 28.17. Descriptors.

5. Make sure that your software creates three or more different transmit or receive descriptors in the list before reusing any of the descriptors.
6. Program the Transmit and Receive Ring length registers (DMA_CHn_TXDESC_RING_LENGTH (n = 0 to 7) and DMA_CHn_RX_CONTROL2 (n = 0 to 7)). The ring length programmed must be at least 4.
7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CHn_TXDESC_LIST_ADDRESS (n = 0 to 7), DMA_CHn_RXDESC_LIST_ADDRESS (n = 0 to 7)). In addition, you must program the Transmit and Receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CHn_TXDESC_TAIL_POINTER (n = 0 to 7) and DMA_CHn_RXDESC_TAIL_POINTER (n = 0 to 7)).
8. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register:
   (a) Transmit Store and Forward (TSF)
   (b) Transmit Threshold Control (TTC)
   (c) Transmit Queue Enable (TXQEN) to value 10b to enable Transmit Queue0
   (d) Transmit Queue Size (TQS)
9. Enable the interrupts by programming the DMA_CHn_INTERRUPT_ENABLE (n = 0 to 7) register.
10. Repeat steps 4 through 9 for all additional channels of AV feature.
11. Program the CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers of the AVQueues
12. Start the Receive and Transmit DMA by setting bit 0 of the DMA_CHn_TX_CONTROL (n = 0 to 7) register and bit 0 of the DMA_CHn_RX_CONTROL (n = 0 to 7) register.

28.18.11.2 Enabling Slot Number Checking

These steps should be completed after step 11 and before step 12 of section 28.18.1. Initializing DMA.

You can use the slot number check feature to specify the intervals at which the DMA Channels mapped to AV Queues fetch the frames from the AXI bus. This feature is useful for a uniform and periodic transfer of the AV traffic from the host memory. Complete the following steps to enable the slot number checking:

1. Enable timestamping by following the steps described in section 28.18.9.1. Initialization Guidelines for System Time Generation.
2. Make sure that the SLOTNUM field (bits 22:19) of TDES3 Normal Descriptor (Read Format) contains a valid slot number. You can read the current reference slot number from the DMA_CHn_SLOT_FUNCTION_CONTROL_STATUS (n = 0 to 7).
3. Set bit 0 (ESC) of the Slot Function Control and Status register of a channel to enable the slot number checking.

28.18.11.3 Enabling Average Bits Per Slot Reporting

You can enable the ability to report the average bits that are transmitted in a slot.

The CBS Status register of the additional AV channels provides information about the average bits that are transmitted in a slot. The software can asynchronously read this register to retrieve information about the average bits transmitted per slot. Complete the following steps to enable average bits per slot reporting:

1. Enable timestamping by following the steps described in the section 28.18.9.1. Initialization Guidelines for System Time Generation.
2. Program bits [6:4], SLC, of the MTL_TXQn_ETS_CONTROL register of a channel with the number of slots over which the average transmitted bits per slot need to be computed.
3. Enable bit 9(ABPSSIE) of the MTL_Qn_INTERRUPT_CONTROL_STATUS register of a channel to generate the average bits per slot interrupt.
   - The frequency of this interrupt depends on the value programmed in step 2. For example, when you program value 0 in the SLC field, the interrupt is generated at every 125 micro-second.
   - When not required, you can disable this interrupt to stop the interrupt flooding.
4. Read bits [16:0], ABS, from the MTL_TXQn_ETS_STATUS register of a channel on each interrupt.

- The software can read the ABS bits in polling mode even if the ABPSIE bit is not enabled. When high, bit 1 (ABPSIS) of the MTL_TXQn_ETS_STATUS register indicates that a new value is updated in the ABS field.

28.18.11.4 Disabling Flow Control for AV Enabled Queues

(1) Receive Flow

Program the EHFC (Enable Hardware Flow Control) bit of corresponding Rx Queue's MTL_RXQn_OPERATIOn_MODE register to 0.

28.18.12 Programming Guidelines for Energy Efficient Ethernet

During the GMAC initialization, after you enable the (EEE) you can program how to enter and exit Tx LPI mode:

28.18.12.1 Entering and Exiting the Tx LPI Mode

EEE enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of Physical layers to operate in the Low-Power Idle (LPI) mode. In the Transmit path, the software must set the LPIEN bit of the MAC_LPI_Control_Status register to indicate to the MAC to stop transmission and initiate the LPI protocol.

Follow these steps while initializing GMAC:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values.
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode.)
3. Program bits [25:16] and bits [15:0] in MAC_LPI_Timers_Control register.
4. Read the link status of the PHY chip by using the MDIO interface and update bit 17 of MAC_LPI_Control_Status accordingly. This update should be done whenever the link status in the PHY chip changes.
5. Program the MAC_1US_Tic_Counter as per the frequency of the clock used for accessing the CSR slave port.
6. Program the MAC_LPI_Entry_Timer register (LPIET) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
7. Set LPITE and LPITXA (bits [20:19]) of MAC_LPI_Control_Status register to enable the auto-entry into LPI and auto-exit of MAC from LPI state.
8. Program the MAC_1US_Tic_Counter as per the frequency of the clock used for accessing the CSR slave port.
9. Program the MAC_LPI_Entry_Timer register (LPIET) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
10. Set LPITE and LPITXA (bits [20:19]) of MAC_LPI_Control_Status register to enable the auto-entry into LPI and auto-exit of MAC from LPI state.
11. Set bit 16 of MAC_LPI_Control_Status register to make the MAC Transmitter enter the LPI state. The MAC enters the LPI mode after completing all scheduled packets and remains IDLE for the time indicated by LPIET. It sets the TLPIEN (bit [0]) after entry to LPI state.
12. When a packet is scheduled for transmission (when the TxDMA comes out of IDLE state or when a packet is presented at ATI or MTI interface), the MAC Transmitter exits LPI state automatically. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission.
13. MAC Transmitter re-enters LPI state if it remains IDLE for LPIET time and sets the TLPIEN bit and the entry-exit cycle continues.
14. Reset LPITXEN in case the application wants to over-ride the auto-entry/exit modes and make the MAC Transmitter exit the LPI state directly.

Note: To ensure MAC enter the LPI state only after completion of transmission of all the queued frames in the Tx FIFO, you should set bit 19 in MAC_LPI_Control_Status register.

28.18.13 Programming Guidelines for Header Payload Split Receive

The Header-Payload Split support is an optional feature that can be enabled by

1. Setting the SPH field in the DMA_CHn_CONTROL register
2. Selecting the Header-Payload split option by setting the SPLM field of MAC_Ext_Cfg1 register.

The DMA can process the header and payload of the received packets separately.

Note: In case of L3/L4 header-payload split, if the IPv4 header length or IPv6 payload length fields are corrupt, the split might not always happen at the correct boundary.

Note:
- When the SPH field in the DMA_CHn_CONTROL register is set to 1, Buffer 1 of only the first descriptor is used with buffer size indicated by the HDSMS filed of MAC_Ext_Configuration.
- Buffer 2 of the first descriptor and subsequent descriptors are used with buffer size indicated by the RBSZ field of the DMA_CHn_RX_CONTROL register.
- When the HL field of the first descriptor (RDES2) is zero, it indicates packet is not split into header and payload.
- When the HL field of the first descriptor (RDES2) is non-zero, it indicates that the packet is split into header and payload.

28.18.14 Programming Guidelines for VLAN Filtering on Receive

Complete the following steps to program VLAN filtering on receive:

1. Program MAC_VLAN_Tag register for the following bit to select the filtering method:
   (a) ETV: Enable 12-bit VLAN Tag Comparison or 16-bit VLAN Tag comparison.
   (b) VTHM: VLAN Tag Hash Table Match Enable.
   (c) ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP)
   (d) ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)
   (e) DOVLTC: Ignores VLAN Type for Tag Match
   (f) VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching
2. Program VL field of MAC_VLAN_Tag register for the 12-bit or 16-bit VLAN tag.
3. If Hash filtering of VLAN tag is enabled, program MAC_VLAN_Hash_Table register. When ETV bit is reset, upper 4 bits of the calculated CRC-32 of VLAN Tag are inverted and used to index the content of MAC_VLAN_Hash_Table register. When ETV bit is set, upper 4 bits of calculated CRC-32 of VLAN Tag are used to index the content of MAC_VLAN_Hash_Table register. For example, when ETV bit is set, a hash value of 1000b selects bit 8 of the VLAN Hash table. When ETV bit is reset a hash value of 1000b selects bit 7 of the VLAN Hash table.

28.18.15 Programming Guidelines for Extended VLAN Filtering and Routing on Receive

For the indirect access of the per VLAN Tag registers, follow these steps:

- Write
  1. Write the required data into the MAC_VLAN_Tag_Data register.
  2. Program the OFS field of MAC_VLAN_Tag_Ctrl register with the required Filter Register offset and command type to the CT field. For a write command, set this bit to 0.
  3. Write 1 to the OB field and wait until the OB bit is reset before performing the next write. This is to ensure that the appropriate VLAN Tag Filter Register has been programmed.
- Read
  1. Program the OFS field of the MAC_VLAN_Tag_Ctrl register with the required register's offset and command type to the CT field. For a read command, set this bit to 1.
  2. Write 1 to the OB field and wait till the OB bit is reset. The appropriate VLAN Tag Filter register value is available in the MAC_VLAN_Tag_Data register.

28.18.16 Programming Guidelines for EST

Program the gate control values and time intervals in the Software Owned Gate Control List (SWOL) along with the other EST related registers that are described in section 28.3. Register Descriptions, to appropriate values. The following sub-sections provide step by step details for programming the GCL and the other EST related registers.

28.18.16.1 Programming the GCL and GCL Linked Registers

Follow these steps to program the Gate Control List (GCL) and the four other registers implemented per GCL.

1. The GCL and the four other GCL-linked registers should be accessed through indirect addressing using the MTL_EST_GCL_Control and MTL_EST_GCL_Data registers. The SWOL field of the MTL_EST_Status register indicates if GCL0 or GCL1 is owned by software.
2. To program the GCL, write the 32-bit write data to MTL_EST_GCL_Data register. Then program MTL_EST_GCL_Control register to write the write address and other control information.
3. In the MTL_EST_GCL_Data register, Write Data consists of up to 8 bits (configurable) of Gate Controls and up to 24 bits (configurable) of Time Interval. Gate Close is indicated by programming a '0' and Gate Open is indicated by programming a '1'. For a 4-TC and 20-bit Time Interval Configuration, the data width is 24-bits and the remaining 8-bits are reserved/read-only. The data should be written in the following format.
   {0x00, TC3, TC2, TC1, TC0, 20-bit Time Interval} where TCx = 0 or 1.
4. MTL_EST_GCL_Control register: Program the SRWO bit to 1 (to start a Write Op) and program the address and R/W fields appropriately.
5. Poll and check for the SRWO bit to be cleared by hardware to indicate the completion of the previous operation before initiating a new R/W operation using the same indirect addressing mode.
6. Repeat steps 3, 4, 5 until the programming of the GCL is completed.
7. Using the indirect addressing method, program the BTR, CTR, TER and LLR registers. Set the GCRR bit in the MTL_EST_GCL_Control register appropriately. The GCRR bit interprets the address field as belonging to these registers (instead of the GCL).

After programming of the GCL and the related registers, program the MTL_EST_Control register to allow hardware to own and process the GCL.When the List Length (as indicated in LLR) is 1, the associated Time Interval should be smaller than the value of the Cycle Time Register. Otherwise, an error is reported (as detailed in the Error handling section) as a single set of gate controls add no value in the TSN context.

Note: The time unit in all the GCL related registers is seconds and nano-seconds. In cases where internally generated PTP System Time is used, the nano-seconds field must be programmed to use the Digital Rollover mode. The TSCTRLSSR field of MAC_Timestamp_Control must be set to 1.

28.18.16.2 Programming the EST Registers

After completing the steps mentioned in section 28.18.16.1. Programming the GCL and GCL Linked Registers, program the MTL_EST_Control register.

1. Set the Current Time Offset Value and Time Internal Left Shift fields of the MTL_EST_Control register appropriately. Also, set the Enable EST (EEST) and Switch to SWOL (SWOL) bits.
2. This enables GMAC to own and process the new GCL and switch to the new GCL at the BTR value. If enabled, GMAC generates an interrupt when the switch to the new list occurs.
3. Software must address any other interrupts received during the hardware execution of the GCL.

Set the SSWL field in the MTL_EST_Control register to handoff to the controller.

The SSWL is reset/cleared by the controller when it successfully switches to the new list. The controller also flips the SWOL bit to indicate the new GCL that the software owns.

To install a new GCL, program the GCL it owns (indicated by SWOL bit) as described in section 28.18.16.1. Programming the GCL and GCL Linked Registers and then program the MTL_EST_Control register as described. Ensure that the new BTR is set to an appropriate value to avoid BTRError that might need software intervention in some cases.

To avoid transmission overruns, the packet length (frame size) information should be available at all times. Therefore, program the packet length in the first descriptor of every Tx frame.

28.18.17 Programming the Launch Time in Time-Based Scheduling

The Launch Time is programmed in the Enhanced Normal Transmit Descriptors and is driven as a control word in MTL as follows:

The OSTC and Launch Time features are mutually exclusive and should not be used together; in case of a conflict (if OSTC = LTV = 1 in MTL), priority is given to OSTC and the Launch Time is ignored.

If a context descriptor is received with a valid OSTC values immediately before receiving a first normal descriptor with LTV bit set, then the LTV is ignored.

28.19 Usage Notes

28.19.1 Known Issue and Workaround

There are known issues in GMAC. Please consider workaround when using related function.

Table 28.104 Known issue and workaround (1 of 2)

No.	Issue	Workaround
1	The EST (Enhancements to Scheduled Traffic) scheduler switches to the next Gate Control List (GCL) after executing the current Gate-Control List (GCL) regardless of the difference between the Cycle Time Register (CTR) value, and sum of the Base Time Register (BTR) and Time Intervals (TI) of the GCL rows whose execution is complete. If the GCL execution takes longer than the cycle time, the GCL is truncated at the cycle time, and the subsequent loop begins at BTR + N × Cycle Time, where N represents the iteration number, an integer. However, in the following situations, the GCL incorrectly updates the internal BTR twice. As a result, the GCL skips the execution of the next GCL loop: ● CTR value is lesser or greater than GCL loop execution time. ● The difference between the CTR and the sum of the BTR and Time Intervals of completely executed GCL rows is less than 8 PTP clock periods (8 × 8 ns = 64 ns).	Program the CTR, BTR, and Time Intervals of the GCL rows such that the difference between the CTR and the sum of the BTR and time intervals of fully executed GCL rows must be greater than 8 PTP clock periods (64 ns). Alternatively, the CTR must be equal to the sum of the BTR and Time Intervals of the fully executed GCL rows.
2	The DMA fetches and processes descriptors up to the one located prior to the Tail Pointer (DMA_CHn_TxDesc_Tail_Pointer and DMA_CHn_RxDesc_Tail_Pointer). It generates Buffer Unavailable Interrupt, and enters suspend state. When the software updates the Tail Pointer, the DMA exits the suspend state, fetches, and processes further descriptors if the Tail Pointer is moved ahead. Otherwise, the DMA remains in suspend state and generates Buffer Unavailable Interrupt to indicate to the software that there are still no descriptors to fetch and process, even after the Tail Pointer update. This prompts the software to take corrective action. However, when Tail Pointer is updated with same address, the DMA incorrectly exits suspend state, fetches and processes descriptor pointed by Tail Pointer and beyond. This continues if the DMA finds a 1 in the OWN bit position in the descriptors yet to be set or made available to the DMA for processing. This results in unintended packets to be transmitted.	Do not program the Tail Pointer with same value, especially when the Buffer Unavailable Interrupt is due to the DMA hitting the Tail Pointer limit.
3	When the Enhancements to Scheduling Traffic (EST) feature is enabled, an extraneous IPG (that is, more than the programmed minimum IPG) is observed even when back-to-back packets are available for scheduling. The waiting period until the current packet is completely forwarded to the MAC transmitter for scheduling the next eligible packet results in an extraneous IPG of approximatively two clock cycles of the MAC transmitter clock, converted to bit times based on the operating speed.	The software must program the Time Interval (TI) to accommodate the extraneous IPG based on the number of packets that are expected to be scheduled. For example, one-Gbps speed mode, the TI must be increased by at least a value that is equal to (clock period (8 ns) × extra IPG (2)). That is, by 16 ns per data packet.

Table 28.104 Known issue and workaround (2 of 2)

No.	Issue	Workaround
4	When Credit Based Shaper (CBS) is enabled for a Transmit Queue (TXQ), the packet that is available in a TXQ is scheduled for transmission when the TXQ accumulates zero or positive credit. When the current credit is negative or when a packet is available in the Transmit Queue and is waiting for the opportunity to be scheduled for transmission, the MAC increments the credit. Equally, during the actual packet transfer, the MAC decrements the credit. The rate at which the MAC increments or decrements the credit depends on the percentage of the total bandwidth that is reserved for the TXQ. As per the IEEE 802.1Qav standard, the MAC must decrement the credit also when the packet overheads are transmitted. These overheads include the preamble bytes before the start of packet, CRC/FCS bytes, and the minimum 12-byte Inter Packet Gap (IPG) after the end of the packet data transfer. However, the MAC decrements the credit only up to the last byte of the packet data (that is, the last byte of the Frame Check Sequence (FCS) transfer) and increments the credit during the subsequent nominal IPG period that is associated with that packet.	You must compute the additional/extra bandwidth that the TXQ consumes due to the defective algorithm. For this, you must use the below formula and example, substituting the values with the average length of the packets that are transmitted for the use case. Then, you must program the parameters that determine the fractional bandwidth for this TXQ to reflect the lesser percentage, such that the effective programmed fractional bandwidth is closer to the desired one. Formula: Additional/ Extra bandwidth = ((# of packets × 12 bytes) / (Total number of bytes that is transmitted in that window, including the preamble bytes of each packet)) x Fractional bandwidth that is programmed for the TXQ. Example: If you program a 30% bandwidth for a TXQ which transfers a stream of 100 packets of 128 bytes length, the additional consumed bandwidth is equal to (30% × (100 × 12) / (100 × (8 + 128))) ≈ 2.65%. Effectively, this TXQ then receives 32.65% of total bandwidth instead of the programmed 30%.

29. Ethernet Switch (ETHSW)

29.1 Overview

With the ethernet switch function, this LSI enables to build the network topology such as line and ring type without external switching hub. This switch has also TSN (Time Sensitive Networking) capability like 802.1AS-Rev, 802.1Qbv, and 802.1Qbu/802.3br. Additionally, four pulse generators are attached to the switch to generate arbitrary pulse synchronous to network time and to capture the network time. Use of the ethernet switch and mode setting are controlled by the related registers. The specifications of the ethernet switch are summarized in following table.

Table 29.1 Ethernet Switch Specifications

Parameter	Description
Function	• Three external ports and one internal port • Integrated 10/100/1000 MACs with flexible rate PHY interface up to 1 Gbps • 3 Gbps non-blocking switching capacity • Hardware switching look-up providing a learning capacity of up to 4K MAC addresses. • VLAN table for 32 VLANs • VLAN manipulation functions on receive (VLAN insert) and transmit (VLAN removal/overwrite) • Priority Classification based on VLAN priorities, Ipv4 TOS/Ipv6 COS with programmable mapping, frame type and freely configurable frame pattern matching. • Support for 802.3br frame preemption on all Ethernet ports (management port not supported) at 10/100/1000 M speeds. • Configurable Time Multiplexed (TDMA) output queue scheduler supporting real-time network infrastructures using time slots for bandwidth reservation enabling deterministic delays • Standard Frame size support (1536) or extended frame sizes up to 1700 bytes or Jumbo frames up to 10 KB (depends on memory availability). • Configurable cut-through or store-and-forward forwarding individually per port • Hardware learning/aging without software involvement • MAC per port statistics • MAC optional support for half-duplex in 10/100 Mbps • MAC supporting Energy-Efficient Ethernet (EEE) with automatic or application controlled power state transitioning and signaling. • Switch statistics for total frames processed/discarded • Support selectable managed or unmanaged mode of operation with self-initialization. • Hardware allows for implementation of Rapid Spanning Tree Protocol (RSTP) Software. • Hardware allows for use of the switch in IEEE 1588 environments • Integrated MACs with timestamping capabilities; • IEEE 1588 1-step correction field updates on transmitted frames • Independent two timer module are available for timestamping and time for TDMA. • Frame pre-emption (802.1Qbu / 802.3br) • Cyclic Queuing and Forwarding (802.1Qch) • Support forwarding rule for the TSN-IA profile • Support a MAC source address filtering function • Exclusive forwarding of BPDU frames to/from management port. • Mirroring function to allow copying of frames to management port and others • Flexible frame snooping function to allow copying of frames to management port • Supports configurable VLAN switching such as flooding, when MAC address lookup to be omitted • Support Multicast, Broadcast with flooding control to avoid unnecessary duplication of frames • Programmable Multicast destination port mask (within lookup table entries) to restrict frame duplication for individual multicast addresses • Can be used in managed implementations with bridge protocol frame support (e.g. Spanning Tree protocols) or unmanaged implementations • Device Level Ring (DLR) hardware support option to implement beacon based nodes without burdening application processor with beacon frame processing. • Parallel Redundancy Protocol (PRP) support option with automatic and transparent redundant frame management. • Integrated Hub function for half-duplex repeater network infrastructure use. • Receive pattern match function for executing tasks based on specific frame reception. • Ingress filtering and frame header manipulation (active stream identification, flow metering) with Enhanced Frame Parser • 4 units Additional Timer function (Synchronous pulse can be generated at arbitrary timing based on switch timer time). • Event link (output) (Ethernet Switch Timer pulse event, Ethernet Switch TDMA timer event) • Module-stop function (Module-stop state can be set to reduce power consumption)

Figure 29.1 is a block diagram of the Ethernet interface.

Gray modules and registers are described in section 27, Ethernet Subsystem, section 28, Ethernet MAC (GMAC), and section 30, EtherCAT Slave Controller (ESC). See the related sections regarding the other registers and modules which are needed to operate the ethernet switch.

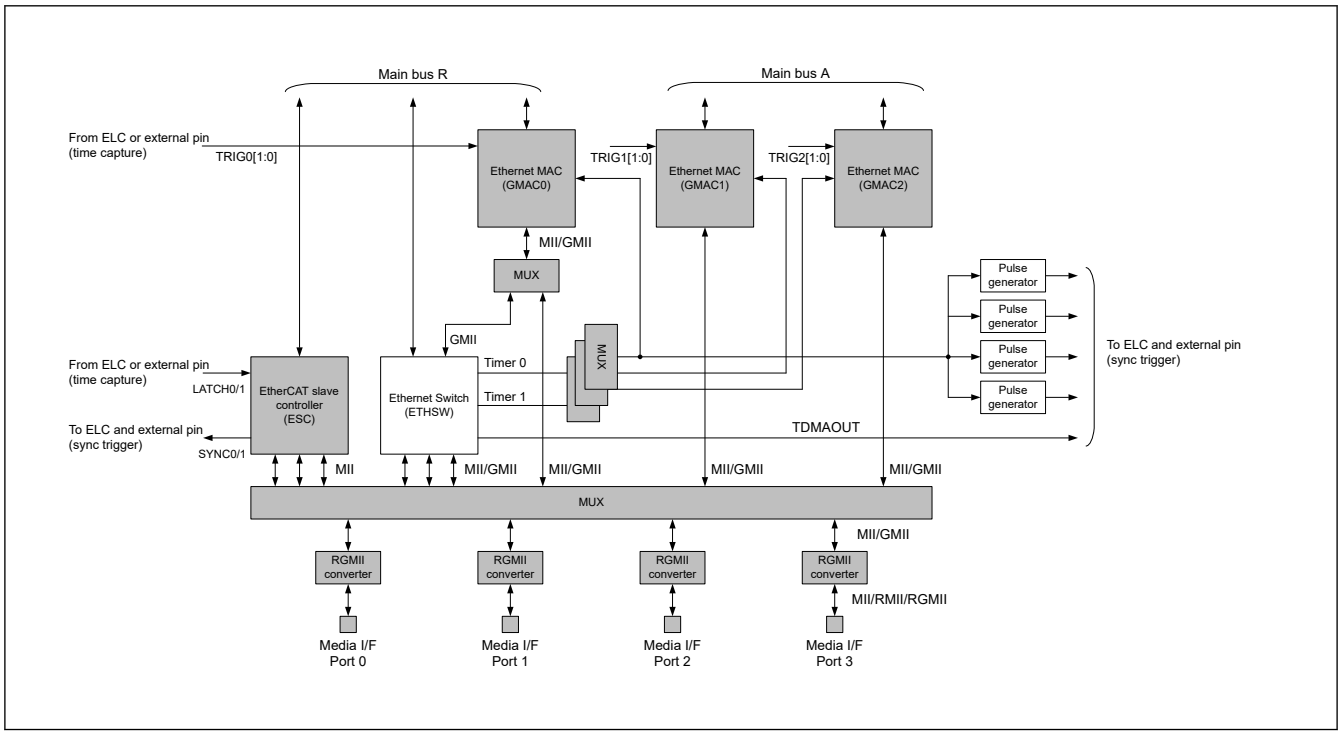

Figure 29.1 Block diagram of the ethernet interface

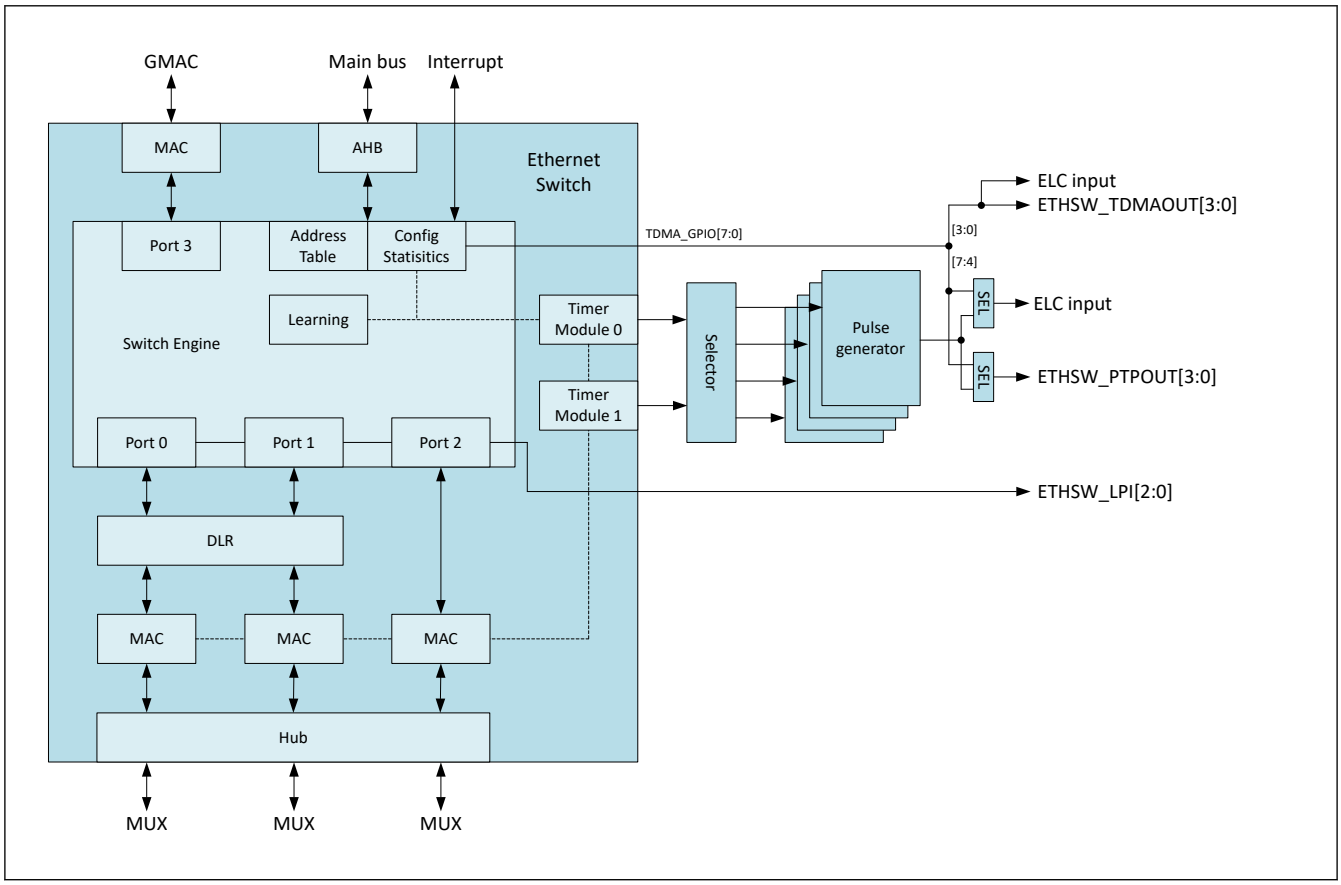

Figure 29.2 Ethernet switch overview

Table 29.2 Input/Output Pins of the ETHSW

Pin Name	I/O	Description
ETHSW_LPI0	Output	Port 0 MAC status indicating that it is currently receiving Low-Power-Idle sequences from the PHY
ETHSW_LPI1	Output	Port 1 MAC status indicating that it is currently receiving Low-Power-Idle sequences from the PHY
ETHSW_LPI2	Output	Port 2 MAC status indicating that it is currently receiving Low-Power-Idle sequences from the PHY
ETHSW_PTPOUT0 to ETHSW_PTPOUT3	Output	Ethernet Switch timer pulse output or TDMA timer output (TDMA_GPIO[4:7])
ETHSW_TDMAOUT0 to ETHSW_TDMAOUT3	Output	Ethernet Switch TDMA timer output (TDMA_GPIO[0:3])
ETHSW_PHYLINK0 to ETHSW_PHYLINK2	Input	Ethernet switch PHY link status input
ETHSW_MDC	Output	Management data clock output
ETHSW_MDIO	I/O	Management data I/O

29.2 Register Map

29.3 Register Description

ETHSW has "Ethernet Switch" and "PTP pulse generator" (See previous figure). Registers for setting "Ethernet Switch" and "PTP pulse generator" are described in following sections.

Before setting these registers, setting registers SWCTRL and SWDUPC in Network SS is necessary. See section 27.3.7. SWCTRL : Switch Core Control Register and section 27.3.8. SWDUPC : Switch Core Duplex Mode Register.

The application must not assume that registers containing more than one field result in atomic write operations when modifying multiple fields. One example is the BR_CONTROL_Pn register in which PREEMPT_ENA should be written last when enabling preemption to avoid false start conditions (for instance, setting VERIFY_DIS to 1 together with PREEMPT_ENA can result in a VERIFY frame to be transmitted).

29.3.1 Switch Base Registers

29.3.1.1 REVISION : Switch Core Version Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0000

Bit position:	31																												0
Bit field:	REV[31:0]																												
Value after reset:	0	1	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	REV[31:0]	Revision Fixed value 0x42000600	R

29.3.1.2 SCRATCH : Scratch Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x04

Bit position:	31																												0
Bit field:	SCRATCH[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SCRATCH[31:0]	The Scratch Register provides a memory location to test the register access. It returns all written data in inverted form.	R/W

29.3.1.3 PORT_ENA : Port Enable Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x08

Bit position:	31											19				16												3		0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	RXENA[3:0]				—	—	—	—	—	—	—	—	—	—	—	—	TXENA[3:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	TXENA[3:0]	Transmit Enable Mask One bit per port. The switch will transmit frames only to ports enabled in this mask. Frames directed to a disabled port are discarded. The exception is all BPDU frames originating from the management port, to which this mask does not apply, allowing to transmit frames to disabled ports (see section 29.3.1.9. MGMT_CONFIG : Management Configuration Register).	R/W
15:4	—	The read values are undefined. The write value should be 0.	R/W
19:16	RXENA[3:0]	Receive Enable Mask One bit per port. The switch will serve only input ports that are enabled in this mask.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The enable bits (both per port bits) reset defaults are controlled by STRAP_SX_ENB bit and STRAP_HUB_ENB bit of SWCTRL register.

STRAP_SX_ENB = 0, STRAP_HUB_ENB = 0: RXENA = 0x0, TXENA = 0x0.

STRAP_SX_ENB = 0, STRAP_HUB_ENB = 1: RXENA = 0x3, TXENA = 0x3.

STRAP_SX_ENB = 1, STRAP_HUB_ENB = 0: RXENA = 0x7, TXENA = 0x7.

STRAP_SX_ENB = 1, STRAP_HUB_ENB = 1: RXENA = 0xF, TXENA = 0xF.

STRAP_SX_ENB and STRAP_HUB_ENB are described in section 27.3.7. SWCTRL : Switch Core Control Register.

29.3.1.4 UCAST_DEFAULT_MASK0 : Unicast Default Mask Register 0

Base address: ETHSW = 0x8012_0000

Offset address: 0x0C

Bit position:	31																												3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	UCASTDM[3:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	1	1	1	1

Bit	Symbol	Function	R/W
3:0	UCASTDM[3:0]	Default Unicast Resolution 1 bit per port. For unicast frame flooding resolution, the default output port list if the destination address is not found in the MAC Lookup table.	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

The UCAST_DEFAULT_MASK0 register is used to mask unicast frames of each port of the ethernet switch. When the destination address is unicast and not found in the address table, the frame is transferred to the ports where the mask is enabled.

29.3.1.5 VLAN_VERIFY : Verify VLAN Domain Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x10

Bit position:	31											19			16													3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	VLANDISC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—	VLANVERI[3:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	VLANVERI[3:0]	Verify VLAN Domain 1 bit per port (bit 0 = port 0) When this bit is set to 1 (enabled), a frame is accepted from the port as valid only when the input port is a member of the VLAN domain of the frame. When this bit is set to 0 (disabled), frames are forwarded without VLAN domain checking.	R/W
15:4	—	The read values are undefined. The write value should be 0.	R/W
19:16	VLANDISC[3:0]	Discard Unknown 1 bit per port (bit 16 = port 0). When set and a frame is received with a VLAN ID that is unknown, or has no VLAN tag, the frame is discarded and not forwarded (the default broadcast is ignored).	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.6 BCAST_DEFAULT_MASK0 : Broadcast Default Mask Register 0

Base address: ETHSW = 0x8012_0000

Offset address: 0x14

Bit position:	31																											3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BCASTDM[3:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	1	1	1	1

Bit	Symbol	Function	R/W
3:0	BCASTDM[3:0]	Default Broadcast Resolution 1 bit per port. For broadcast/flooding resolution, the default output port list.	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

The BCAST_DEFAULT_MASK0 register is used to mask broadcast frames of each port of the ethernet switch. When the destination address is broadcast, the frame is transferred to the ports given in this mask.

29.3.1.7 MCAST_DEFAULT_MASK0 : Multicast Default Mask Register 0

Base address: ETHSW = 0x8012_0000

Offset address: 0x18

Bit position:	31																											3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCASTDM[3:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	1	1	1	1

Bit	Symbol	Function	R/W
3:0	MCASTDM[3:0]	Default Multicast Resolution 1 bit per port. Used for multicast/flooding resolution. The default output port list is used instead of the BCAST_DEFAULT_MASK, when the received frame carries a multicast address.	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

The MCAST_DEFAULT_MASK0 register is used to mask multicast frames of each ports of the ethernet switch. When the destination address is multicast, the frame is transferred to the ports given in this mask.

29.3.1.8 INPUT_LEARN_BLOCK : Input Learning Block Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x1C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	LEARNDIS[3:0]				—	—	—	—	—	—	—	—	—	—	—	—	BLOCKEN[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	BLOCKEN[3:0]	Blocking Enable 1 bit per port, enable blocking (bit 0 = port 0)	R/W
15:4	—	The read values are undefined. The write value should be 0.	R/W
19:16	LEARNDIS[3:0]	Learning Disable 1 bit per port, disable learning (bit 16 = port 0)	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The INPUT_LEARN_BLOCK register is used to set the address learning function and frame blocking function of each port of the ethernet switch.

When blocking is enabled for a port (bit = 1), only Bridge Protocol data units are accepted on that input, all other frames are discarded. When learning is disabled for a port (bit = 1), source address lookup and learning do not occur. Both functions operate independently from each other.

Note: Source addresses from incoming BPDU frames are not learned, independent of these settings (to avoid table updates if for example, loops exist).

29.3.1.9 MGMT_CONFIG : Management Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	PORTMASK[3:0]				PRIORITY[2:0]			—	—	—	MGMT_DISC	MGMT_EN	DISCARD	ENABLE	MSG_TRANS	—	PORT[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	x	x	x	x	x	1	0	0	x	0	0	1	1

Bit	Symbol	Function	R/W
3:0	PORT[3:0]	The Port number of the port that should act as a management port. Keep the initial value.	R/W
4	—	The read value is undefined. The write value should be 0.	R/W
5	MSG_TRANS	Set (latched) when a BPDU message is transmitted from the management port to any output port. This bit can be used for handshaking to indicate that the port mask bits are used and can now be changed again by setting it to 0. The bit is not asserted for normal frames and is reset by writing into the register. Will assert regardless of whether the frame was transmitted successfully or not. The control bit MGMT_EN must be set to 1.	R/W
6	ENABLE	If set, all Bridge Protocol Frames (BPDU) are forwarded exclusively to the management port specified in bits [3:0]. If cleared, Bridge Protocol Frames (BPDU) are forwarded as any other frame or discarded if the discard bit is set.	R/W

Bit	Symbol	Function	R/W
7	DISCARD	If set, BPDU frames are discarded always.	R/W
8	MGMT_EN	If set, BPDU frames received at the management port are forwarded to the ports given in the portmask given in this register, bypassing the normal forwarding decisions (except forced forwarding). If cleared, Bridge Protocol Frames (BPDU) are forwarded as any other frame or discarded if the discard bit is set.	R/W
9	MGMT_DISC	This bit is the same as DISCARD (bit 7) but for the management port.	R/W
12:10	—	The read values are undefined. The write value should be 0.	R/W
15:13	PRIORITY[2:0]	Priority to use for transmitted BPDU frames if non-zero. The setting is ignored if it is 0 (normal priority resolution operates). This bit can be used to put a management frame in a high-priority output queue for fast delivery.	R/W
19:16	PORTMASK[3:0]	Portmask for transmission of management frames. When the management port transmits a frame to the switch, it is forwarded to all ports in this portmask (bit 16 = port 0, bit 17 = port 1, …, bit 19 = port 3). When the mask is all 0, the frame is forwarded normally (either from the MAC address lookup or multicast flooding). Forced forwarding takes precedence over this portmask and management frames are forwarded as specified by the forced forwarding portmask if active. When using forced forwarding, this portmask must be written with all 0.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The MGMT_CONFIG register is used to configure the bridge management port of the ethernet switch and to enable the management port that receives bridge protocol frames. It is necessary to set the internal interface port (port 3) in the management port.

29.3.1.10 MODE_CONFIG : Mode Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x24

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	STATSRESET	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	CUT_THRU_EN[3:0]				—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	0	0	0	0	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
7:0	—	The read values are undefined. The write value should be 0.	R/W
11:8	CUT_THRU_EN[3:0]	Port Cut through Support Enable One bit per port. Bit 8 = port 0, bit 9 = port 1, bit 10 = port 2, bit 11 = port 3. When a port is enabled for cut through, a frame received is forwarded to the destination before completion of the frame reception. Cut through is possible only if both ports (where frame is received and is forwarded) have the cut through bit set. Otherwise, the frame is forwarded in normal store and forward behavior.	R/W
30:12	—	The read values are undefined. The write value should be 0.	R/W
31	STATSRESET	Reset Statistics Counters Command. When set during a write, all statistics counters are cleared. When this bit is set to 1, the write values of all other bits are ignored. Set this bit to 0 when writing other bits.	R/W

The MODE_CONFIG register is used to reset the statistics counter in the ethernet switch.

29.3.1.11 VLAN_IN_MODE : VLAN Input Manipulation Mode Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x28

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	P3VLANINMD[1:0]		P2VLANINMD[1:0]		P1VLANINMD[1:0]		P0VLANINMD[1:0]	
Value after reset:	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	P0VLANINMD[1:0]	Port 0 Define Behavior of VLAN Input Manipulation Function 0 0: Mode 1 0 1: Mode 2 1 0: Mode 3 1 1: Mode 4	R/W
3:2	P1VLANINMD[1:0]	Port 1 Define Behavior of VLAN Input Manipulation Function 0 0: Mode 1 0 1: Mode 2 1 0: Mode 3 1 1: Mode 4	R/W
5:4	P2VLANINMD[1:0]	Port 2 Define Behavior of VLAN Input Manipulation Function 0 0: Mode 1 0 1: Mode 2 1 0: Mode 3 1 1: Mode 4	R/W
7:6	P3VLANINMD[1:0]	Port3 Define Behavior of VLAN Input Manipulation Function 0 0: Mode 1 0 1: Mode 2 1 0: Mode 3 1 1: Mode 4	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.12 VLAN_OUT_MODE : VLAN Output Manipulation Mode Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x2C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	P3VLANOUTMD[1:0]		P2VLANOUTMD[1:0]		P1VLANOUTMD[1:0]		P0VLANOUTMD[1:0]	
Value after reset:	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	P0VLANOUTMD[1:0]	Port 0 Define Behavior of VLAN Output Manipulation Function 0 0: No output manipulation 0 1: Mode 1, Strip Mode 1 0: Mode 2, Tag Through 1 1: Mode 3, Transparent	R/W
3:2	P1VLANOUTMD[1:0]	Port 1 Define Behavior of VLAN Output Manipulation Function 0 0: No output manipulation 0 1: Mode 1, Strip Mode 1 0: Mode 2, Tag Through 1 1: Mode 3, Transparent	R/W
5:4	P2VLANOUTMD[1:0]	Port 2 Define Behavior of VLAN Output Manipulation Function 0 0: No output manipulation 0 1: Mode 1, Strip Mode 1 0: Mode 2, Tag Through 1 1: Mode 3, Transparent	R/W
7:6	P3VLANOUTMD[1:0]	Port 3 Define Behavior of VLAN Output Manipulation Function 0 0: No output manipulation 0 1: Mode 1, Strip Mode 1 0: Mode 2, Tag Through 1 1: Mode 3, Transparent	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.13 VLAN_IN_MODE_ENA : VLAN Input Mode Enable Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x30

Bit position:	31																												3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VLANINMDEN[3:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	VLANINMDEN[3:0]	Enable the input processing according to the VLAN_IN_MODE for a port (1 bit per port).	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.14 VLAN_TAG_ID : VLAN Tag ID Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x34

Bit position:	31																15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VLANTAGID[15:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	VLANTAGID[15:0]	The VLAN type field (TPID) value to expect to identify a VLAN tagged frame. Default value is 0x8100.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

The VLAN_TAG_ID register is used to set a VLAN tag ID to identify a VLAN tagged frame. In valid IEEE802.1Q, a VLAN tag ID is defined as 0x8100.

29.3.1.15 BCAST_STORM_LIMIT : Broadcast Storm Protection Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x38

Bit position:	31																16	15													0
Bit field:	BCASTLIMIT[15:0]																	TMOUT[15:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TMOUT[15:0]	Timeout in steps of 65535 switch operating clock cycles.	R/W
31:16	BCASTLIMIT[15:0]	Number of broadcast frames (-1) that can be accepted on a port during a timeout period. If more are received, they are discarded. The counter is implemented per port independently. However, the limit is used for all ports. When 0, no limit is set. The value is set 1 less (for example, set 9 to allow 10 frames).	R/W

29.3.1.16 MCAST_STORM_LIMIT : Multicast Storm Protection Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C

Bit position:	31																16														0
Bit field:	MCASTLIMIT[15:0]																	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
15:0	—	The read values are undefined. The write value should be 0.	R/W
31:16	MCASTLIMIT[15:0]	Number of multicast frames (-1) that can be accepted on a port during a timeout period. If more are received, they are discarded. The counter is implemented per port independently. However, the limit is used for all ports. When 0, no limit is set.	R/W

The timeout setting is taken from the value configured in BCAST_STORM_LIMIT[15:0]. Here only the number of acceptable multicast frames is configured.

29.3.1.17 MIRROR_CONTROL : Port Mirroring Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x40

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	EG_DA_MATCH	EG_SA_MATCH	ING_DA_MATCH	ING_SA_MATCH	EG_MAP_EN	ING_MAP_EN	MIRROR_EN	—	—	PORT[1:0]	
Value after reset:	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PORT[1:0]	The port number of the port that acts as the mirror port and receives all mirrored frames. Valid setting range is 0 to 3.	R/W

Bit	Symbol	Function	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	MIRROR_EN	Mirroring 0: Disabled 1: Enabled	R/W
5	ING_MAP_EN	If set, the ingress map is enabled (MIRROR_ING_MAP).	R/W
6	EG_MAP_EN	If set, the egress map is enabled (MIRROR_EG_MAP).	R/W
7	ING_SA_MATCH	If set, only frames received on an ingress port with a source address matching the value programmed in MIRROR_ISRC registers are mirrored. Other frames are not mirrored.	R/W
8	ING_DA_MATCH	If set, only frames received on an ingress port with a destination address matching the value programmed in MIRROR_IDST registers are mirrored. Other frames are not mirrored.	R/W
9	EG_SA_MATCH	If set, only frames transmitted on an egress port with a source address matching the value programmed in MIRROR_ESRC registers are mirrored. Other frames are not mirrored.	R/W
10	EG_DA_MATCH	If set, only frames transmitted on an egress port with a destination address matching the value programmed in MIRROR_EDST registers are mirrored. Other frames are not mirrored.	R/W
31:11	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.18 MIRROR_EG_MAP : Port Mirroring Egress Port Definition Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x44

Bit position:	31																												3			0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EMAP[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	EMAP[3:0]	Port Mirroring Egress Port Definitions 1 bit per port. When this bit is 1 (enabled), frames destined to the port(s) are mirrored to the mirror port.	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.19 MIRROR_ING_MAP : Port Mirroring Ingress Port Definition Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x48

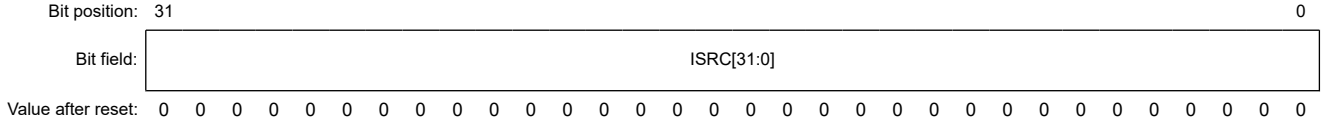
Bit position:	31																												3			0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	IMAP[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	IMAP[3:0]	Port Mirroring Ingress Port Definitions 1 bit per port. When this bit is 1 (enabled), frames from the port(s) are mirrored to the mirror port.	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.20 MIRROR_ISRC_0 : Ingress Source MAC Address for Mirror Filtering Register 0

Base address: ETHSW = 0x8012_0000

Offset address: 0x4C

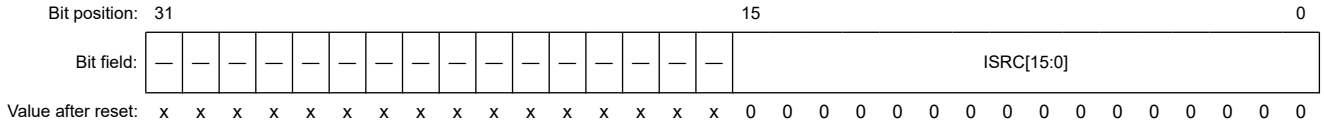


Bit	Symbol	Function	R/W
31:0	ISRC[31:0]	Ingress Source MAC Address for Mirror Filtering Lowest 32-bit of address.	R/W

29.3.1.21 MIRROR_ISRC_1 : Ingress Source MAC Address for Mirror Filtering Register 1

Base address: ETHSW = 0x8012_0000

Offset address: 0x50

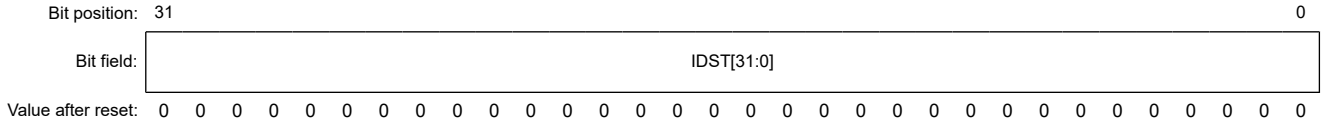


Bit	Symbol	Function	R/W
15:0	ISRC[15:0]	Ingress Source MAC Address for Mirror Filtering Upper 16-bit of address.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.22 MIRROR_IDST_0 : Ingress Destination MAC Address for Mirror Filtering Register 0

Base address: ETHSW = 0x8012_0000

Offset address: 0x54

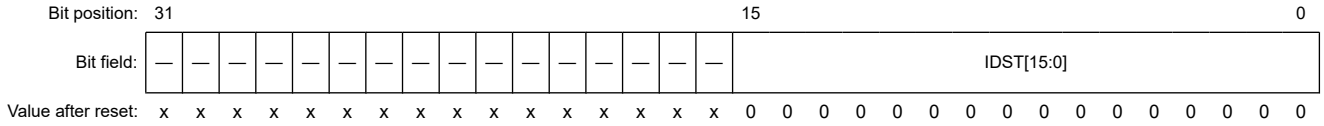


Bit	Symbol	Function	R/W
31:0	IDST[31:0]	Ingress Destination MAC Address for Mirror Filtering Lowest 32-bit of address.	R/W

29.3.1.23 MIRROR_IDST_1 : Ingress Destination MAC Address for Mirror Filtering Register 1

Base address: ETHSW = 0x8012_0000

Offset address: 0x58



Bit	Symbol	Function	R/W
15:0	IDST[15:0]	Ingress Destination MAC Address for Mirror Filtering Upper 16-bit of address.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.24 MIRROR_ESRC_0 : Egress Source MAC Address for Mirror Filtering Register 0

Base address: ETHSW = 0x8012_0000

Offset address: 0x5C

Bit position:	31																												0
Bit field:	ESRC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ESRC[31:0]	Egress Source MAC Address for Mirror Filtering Lowest 32-bit of address.	R/W

29.3.1.25 MIRROR_ESRC_1 : Egress Source MAC Address for Mirror Filtering Register 1

Base address: ETHSW = 0x8012_0000

Offset address: 0x60

Bit position:	31															15													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ESRC[15:0]													
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ESRC[15:0]	Egress Source MAC Address for Mirror Filtering Upper 16-bit of address.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.26 MIRROR_EDST_0 : Egress Destination MAC Address for Mirror Filtering Register 0

Base address: ETHSW = 0x8012_0000

Offset address: 0x64

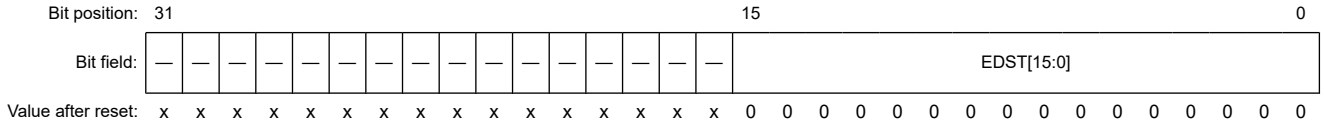
Bit position:	31																												0
Bit field:	EDST[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	EDST[31:0]	Egress Destination MAC Address for Mirror Filtering Lowest 32-bit of address.	R/W

29.3.1.27 MIRROR_EDST_1 : Egress Destination MAC Address for Mirror Filtering Register 1

Base address: ETHSW = 0x8012_0000

Offset address: 0x68

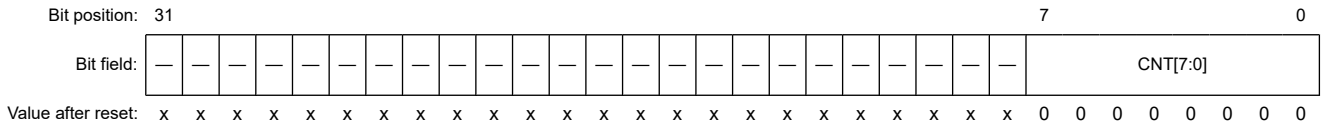


Bit	Symbol	Function	R/W
15:0	EDST[15:0]	Egress Destination MAC Address for Mirror Filtering Upper 16-bit of address.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.28 MIRROR_CNT : Mirror Filtering Count Value Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x6C

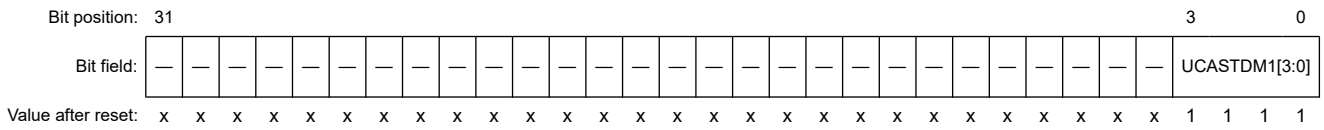


Bit	Symbol	Function	R/W
7:0	CNT[7:0]	Count Value for Mirror Filtering Every n-th frame is forwarded to the mirror port if enabled. A value of 1 or 0 means every frame.	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.29 UCAST_DEFAULT_MASK1 : Unicast Default Mask Register 1

Base address: ETHSW = 0x8012_0000

Offset address: 0x70



Bit	Symbol	Function	R/W
3:0	UCASTDM1[3:0]	Default Unicast Resolution Mask 1 1 bit per port. For unicast frame flooding resolution, the default output port list if the destination address is not found in the MAC lookup table.	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.30 BCAST_DEFAULT_MASK1 : Broadcast Default Mask Register 1

Base address: ETHSW = 0x8012_0000

Offset address: 0x74

Bit position:	31																											3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BCASTDM1[3:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	1	1	1	1

Bit	Symbol	Function	R/W
3:0	BCASTDM1[3:0]	Default Broadcast Resolution Mask 1 1 bit per port. For broadcast/flooding resolution, the default output port list.	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.31 MCAST_DEFAULT_MASK1 : Multicast Default Mask Register 1

Base address: ETHSW = 0x8012_0000

Offset address: 0x78

Bit position:	31																											3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCASTDM1[3:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	1	1	1	1

Bit	Symbol	Function	R/W
3:0	MCASTDM1[3:0]	Default Multicast Resolution Mask 1 1 bit per port. Used for broadcast/flooding resolution. The default output port list is used instead of the BCAST_DEFAULT_MASK1, when the received frame carries a multicast address.	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.32 PORT_XCAST_MASK_SEL : Port Mask Select Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x7C

Bit position:	31																											3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MSEL[3:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	MSEL[3:0]	Mask Select 1 bit per port that selects which UCAST, MCAST, and BCAST Default Mask register set to use for forwarding the respective frames. This facilitates separation of a bridge domain between various switch ports so that broadcast, multicast, or unknown destination addresses flooding do not cross over two networks when VLAN verification is not used. If VLAN verification is used, then it is better to use the VLAN identification function to separate traffic between networks. 0: XCAST_DEFAULT_MASK0 registers are selected 1: XCAST_DEFAULT_MASK1 registers are selected	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.33 QMGR_ST_MINCELLS : Minimum Memory Cell Statistics Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x88

Bit position:	31														10											0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STMINCELLS[10:0]				
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	STMINCELLS[10:0]	Minimum Free Cell Indication Statistic providing the lowest number of free cells reached in memory during operation since this statistic was last cleared. The value is reset to the maximum when a write to the register with any value is performed.	R/W
31:11	—	The read values are undefined. The write value should be 0.	R/W

The QMGR_ST_MINCELLS register is used to indicate the minimum number of free cells in the memory of the ethernet switch.

29.3.1.34 QMGR_RED_MIN4 : RED Minimum Threshold Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x94

Bit position:	31																									0
Bit field:	CFGRED_MINTH4[31:0]																									
Value after reset:	0	0	0	0	1	1	1	1	0	0	0	0	1	1	1	1	0	0	0	0	1	1	1	1	0	0	0	0	1	1	1	1

Bit	Symbol	Function	R/W
31:0	CFGRED_MINTH4[31:0]	Random Early Detection (RED) Minimum Threshold for Queues 0 to 3 An 8-bit value per queue, global for all ports: CFGRED_MINTH4[7:0]: Queue 0 CFGRED_MINTH4[15:8]: Queue 1 CFGRED_MINTH4[23:16]: Queue 2 CFGRED_MINTH4[31:24]: Queue 3	R/W

29.3.1.35 QMGR_RED_MAX4 : RED Maximum Threshold Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x98

Bit position:	31																									0
Bit field:	CFGRED_MAXTH4[31:0]																									
Value after reset:	0	0	1	0	1	1	1	1	0	0	1	0	1	1	1	1	0	0	1	0	1	1	1	1	0	0	1	0	1	1	1	1

Bit	Symbol	Function	R/W
31:0	CFGRED_MAXTH4[31:0]	Random Early Detection (RED) Maximum Threshold for Queues 0 to 3 An 8-bit value per queue, global for all ports: CFGRED_MAXTH4[7:0]: Queue 0 CFGRED_MAXTH4[15:8]: Queue 1 CFGRED_MAXTH4[23:16]: Queue 2 CFGRED_MAXTH4[31:24]: Queue 3	R/W

29.3.1.36 QMGR_RED_CONFIG : RED Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x9C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	GACTIVITY_EN	—	—	—	—	QUEUE_RED_EN[3:0]			
Value after reset:	x	x	x	x	x	x	x	0	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	QUEUE_RED_EN[3:0]	Enable Random Early Detection (RED) (when this bit is 1) or Tail Drop (when this bit is 0) congestion management for a queue. One bit per queue: bit 0 = queue 0, bit 1 = queue 1, and so on. Per queue setting, but global for all queues of all ports.	R/W
7:4	—	The read values are undefined. The write value should be 0.	R/W
8	GACTIVITY_EN	Enable Averaging on Global Switch Activity (when this bit is 1) or on port local activity (when this bit is 0) only.	R/W
31:9	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.37 IMC_STATUS : Input Memory Controller Status Register

Base address: ETHSW = 0x8012_0000

Offset address: 0xA0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	MEM_FULL	DE_INIT	DE_ERR	CF_ERR	CELLS_AVAILABLE[23:0]							
Value after reset:	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CELLS_AVAILABLE[23:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	CELLS_AVAILABLE[23:0]	Total number of memory cells (128-byte units) available in the shared memory (real time).	R
24	CF_ERR	Cell Factory Empty Error Indication that memory overflow occurred. There are more memory cells requested than available. This is a fatal error that must not occur during normal operation as it may indicate memory leakage. This bit is cleared by reading it.	R
25	DE_ERR	Deallocation Error Indication that memory cells cannot be deallocated and are lost for further usage. This is a fatal error that must not occur during normal operation as it may indicate memory leakage. This bit is cleared by reading it.	R
26	DE_INIT	Asserts during Memory Initialization (deallocation module) Asserts after reset as long as memory initialization is ongoing and then clears when the memory is ready for normal operation. The switch must not be enabled before the memory is ready for operation.	R

Bit	Symbol	Function	R/W
27	MEM_FULL	Latched Indication that Memory is or was Full Asserts when all cells of the memory have been allocated (memory congestion). As a result, frames are discarded. This is not an error. This bit is cleared by reading it.	R
31:28	—	The read values are undefined.	R

Input Memory Controller (IMC) status/debug information. The IMC controls the shared memory which stores all frames from all ports.

The reset value may not be read as initialization begins immediately after reset (changing this register's value depending on progress). Register reads 0x08000400 when memory initialization is completed.

29.3.1.38 IMC_ERR_FULL : Input Port Memory Full and Truncation Indicator Register

Base address: ETHSW = 0x8012_0000

Offset address: 0xA4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IPC_ERR_TRUNC[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IPC_ERR_FULL[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	IPC_ERR_FULL[3:0]	Memory was full at start of a frame reception. A frame has been discarded. Shows congestion occurred on an input to the shared memory. One bit per port (bit 0 = port 0, bit 1 = port 1, and so on). This bit is cleared by reading it.	R
15:4	—	The read values are undefined.	R
19:16	IPC_ERR_TRUNC[3:0]	Memory became full while a frame was received and was partly written into memory. A frame has been truncated and discarded. Shows congestion occurred on an input to the shared memory. One bit per port (bit 0 = port 0, bit 1= port 1, and so on). This bit is cleared by reading it.	R
31:20	—	The read values are undefined.	R

29.3.1.39 IMC_ERR_IFACE : Input Port Memory Error Indicator Register

Base address: ETHSW = 0x8012_0000

Offset address: 0xA8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	WBUF_OVF[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IPC_ERR_IFACE[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	IPC_ERR_IFACE[3:0]	Error indication on memory input (receive from MAC) that a frame has been truncated and discarded. This may occur during normal operation if, for example, input rules discard a frame after it is written into memory (destination portmask is all 0, or VLAN domain verification fails, or source address not found discard is enabled and source was not found). It also indicates internal (fatal) errors if the memory access failed. One bit per port (bit 0 = port 0, bit 1 = port 1, and so on). This bit is cleared by reading it.	R
15:4	—	The read values are undefined.	R
19:16	WBUF_OVF[3:0]	Error indicating an overflow in the input write buffer to the memory controller (a small decoupling FIFO at every MAC RX). This must not occur during normal operation. If it occurs, the received frame is corrupted and is marked as error to be discarded eventually by the memory controller. One bit per port (bit 0 = port 0, bit 1 = port 1, and so on). This bit is cleared by reading it.	R
31:20	—	The read values are undefined.	R

29.3.1.40 IMC_ERR_QOFLOW : Output Port Queue Overflow Indicator Register

Base address: ETHSW = 0x8012_0000

Offset address: 0xAC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OP_ERR[3:0]
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	OP_ERR[3:0]	A frame cannot be stored in an output queue of the port as the queue FIFO overflowed (write occurred into full fifo). The frame is ignored but stays stored in memory. This should not occur during normal operation. This is a fatal error as the memory allocated by that frame is not freed, and resulting in memory leakage. It indicates an error in the congestion function which must normally prevent writing a frame into a queue when the queue is not capable of accepting it. One bit per port (bit 0 = port 0, bit 1 = port 1, and so on). This bit is cleared by reading it.	R
31:4	—	The read values are undefined.	R

29.3.1.41 IMC_CONFIG : Input Memory Controller Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0xB0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	CTFL_EMPTY_MD	SPEED_HIPRI_THR[2:0]			RSV_ENA	WFQ_EN
Value after reset:	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	WFQ_EN	Enable weighted fair queuing (when this bit is 1) or strict priority (when this bit is 0, default) output queue scheduling. When this bit is set, the output queues are weighted with factors 1, 2, 4, and 8 for queues 0, 1, 2, and 3 respectively (queue 3 is highest priority). A higher weight causes the queue to be served with higher priority. This bit must be set to 0 when TDMA scheduling is used.	R/W
1	RSV_ENA	Enable Memory Reservations to Operate When set to 1, the per-pool memory allocations can be configured. When set to 0, all memory is shared by all ports and queues.	R/W
4:2	SPEED_HIPRI_THR[2:0]	High-Priority Speed Threshold This register defines which speed as a 3-bit value is considered a high speed port. Ports at or above this speed value are serviced faster by the output memory controller than other ports.	R/W
5	CTFL_EMPTY_MD	When this bit is set to 0, a frame received in Cut-Through mode that cannot allocate an entry in the CTFL is forwarded as store and forward. When this bit is set to 1, if an entry in the CTFL is not available, the frame length is reported as 0 bytes and on transmission, the frame is held until Cut-Through is enabled again.	R/W
31:6	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.42 IMC_ERR_ALLOC : Input Port Error Indicator Register

Base address: ETHSW = 0x8012_0000

Offset address: 0xB4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	DISC_LATE[3:0]				—	—	—	—	—	—	—	—	—	—	—	—	DISC_FULL[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	DISC_FULL[3:0]	Per port discard indication due to memory pool going empty. Per port indication that one of the queues was full and a frame was discarded. This bit is cleared by reading it.	R
15:4	—	The read values are undefined.	R
19:16	DISC_LATE[3:0]	Per port discard indication due to lateness in the priority resolution. The priority resolution can be delayed by the pattern matchers. If it arrives too late (after approximately 100 bytes into the frame), the frame is discarded. This bit is cleared by reading it.	R
31:20	—	The read values are undefined.	R

29.3.1.43 GPARSERn : [n + 1]th Parser of 1st Block (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x00C0 + 0x4 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	CMP_MASK_OR	OFFSET_PLUS2	CMP16	IPPROTOCOL	IPDATA	SKIPVLAN	VALID	OFFSET_DA	—	OFFSET[5:0]					
Value after reset:	x	0	0	0	0	0	0	0	0	x	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	COMPARE_VAL[7:0]								MASK_VAL2[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	MASK_VAL2[7:0]	Mask for single byte compares or 2nd compare value (if bit 30 = 1) or least significant bits of a 16-bit compare value (if bit 28 = 1). When used as a mask (bit 28, 30 = 0, 0), the data from the frame is ANDed with this mask, then compared to the compare value. All bits having a 1 in the mask will be compared with the data in the frame. All bits having a 0 will be 0 for the compare, however this requires the compare value to have those bits also set to 0.	R/W
15:8	COMPARE_VAL[7:0]	The value to compare the frame data with at the given offset.	R/W
21:16	OFFSET[5:0]	An offset in bytes where to find the data for comparison within the frame. The offset value starts at 0 to indicate the very first byte after offset start. The offset start can be either the type/length field of the frame, that is, 0 = first byte of type/length field) or the payload following an IP header (see IPDATA). Valid values range from 0 to 60.	R/W
22	—	The read value is undefined. The write value should be 0.	R/W
23	OFFSET_DA	When set, the offset starts counting from the first byte of the MAC destination address. The SKIPVLAN, IPDATA, and IPPROTOCOL bits must be 0 when this bit is set.	R/W
24	VALID	Indicate that this entry is valid (when this bit is 1) and should be used. When this bit is 0, the parser result always indicates "no match" and none of the other bits are relevant.	R/W
25	SKIPVLAN	When set, any optional VLAN tags found in the frame are skipped and the parser starts operating at the first byte following any VLAN tags. When cleared, the parser starts with the first byte following the source MAC address. If this bit is 0, this means the first byte of the Type/length field is the first data for any compares, allowing to check for ether Types.	R/W
26	IPDATA	When set, the offset starts with the first byte following an IP header if an IP frame is processed. The following fields are skipped: ● any VLAN tags if present (implicitly acts as SKIPVLAN = 1) ● for Ipv4 the header and any header options ● for Ipv6 only the base header. If the bit is set, it implicitly requires an IP frame. If the frame is not an IP frame, the parser will report "no match" and not continue to inspect the frame. When cleared, the offset starts with the first data following the MAC source address (skipping VLAN tags if allowed by "SKIPVLAN"). When this bit is set, the SKIPVLAN bit has no meaning and can be set to any value.	R/W
27	IPPROTOCOL	When set, the compare value is compared with the protocol field found within the IP header for both IPv4 and IPv6 frames. It implicitly acts as SKIPVLAN = 1 skipping any VLAN tags if present. The offset setting has no meaning and is ignored. If the bit is set, but the frame is not an IPv4/v6 frame the parser will report "no match" and not continue to inspect the frame. When cleared, the offset is used normally on all frames. When this bit is set, the bits 25, 26, 28, 29, 30 have no meaning and should be set to 0. MASK_VAL2[7:0] is applied and should be 0xFF to achieve an exact match.	R/W
28	CMP16	When set, MASK_VAL2[7:0] is used as a value to perform a 16-bit compare. COMPARE_VAL[7:0] represent the byte at the given offset and MASK_VAL2[7:0] represent the byte following at offset + 1 which matches the network byte order for 16-bit fields. For example, setting a compare value of 0x0800 and offset 0 matches IP frames. No mask is available in this mode. When cleared, only one byte of data is compared and the mask can be used to mask individual bits.	R/W
29	OFFSET_PLUS2	Repeats the comparison at offset + 2, if the comparison at offset failed. Only usable when CMP16 = 1. This can be used to create a comparison for UDP or TCP port numbers allowing checking if the port number exists in the source or in the destination port number field.	R/W
30	CMP_MASK_OR	Use the MASK_VAL2[7:0] bits as a 2nd compare value. When set, the parser reports a match if the byte at given offset matches COMPARE_VAL[7:0] or MASK_VAL2[7:0]. Only usable when CMP16 = 0.	R/W
31	—	The read value is undefined. The write value should be 0.	R/W

29.3.1.44 GARITHn : Snoop Configuration for Arithmetic [n + 1]th Stage of 1st Block (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x00D0 + 0x4 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	SNP_MD[1:0]		—	—	RESULT_INV	OP
Value after reset:	x	x	x	x	x	x	x	x	x	x	0	0	x	x	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	SEL_ARITH2	SEL_ARITH1	SEL_ARITH0	SEL_MATCH[3:0]				—	—	—	—	NOT_INP[3:0]			
Value after reset:	x	0	0	0	0	0	0	0	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	NOT_INP[3:0]	Not Input Define, which match result from a parser should be used inverted. One bit per parser. Bit 0 = parser 0, Bit 1 = parser 1, …, Bit 3 = parser 3 When a bit is 1, the match result of the corresponding parser is used inverted in this stage.	R/W
7:4	—	The read values are undefined. The write value should be 0.	R/W
11:8	SEL_MATCH[3:0]	Select Match Define, which parser result is relevant at this stage. One bit per parser. Bit 8 = parser 0, …, Bit 11 = parser 3 When a bit is 1, the match result of the corresponding parser is used in this stage, otherwise it is ignored.	R/W
12	SEL_ARITH0	Select Arithmetic Stage 0 Available only on stages 1 to 3. If set, the result from arithmetic stage 0 is selected in addition to any of the parser results.	R/W
13	SEL_ARITH1	Select Arithmetic Stage 1 Available only on stages 2 and 3. If set, the result from arithmetic stage 1 is selected in addition to any of the parser results.	R/W
14	SEL_ARITH2	Select Arithmetic Stage 2 Available only on stage 3. If set, the result from arithmetic stage 2 is selected in addition to any of the parser results.	R/W
15	—	The read value is undefined. The write value should be 0.	R/W
16	OP	Operation 0: AND all selected inputs 1: OR all selected inputs	R/W
17	RESULT_INV	Result Invert 0: The output is used directly. 1: The output of this stage is inverted.	R/W
19:18	—	The read values are undefined. The write value should be 0.	R/W
21:20	SNP_MD[1:0]	Snoop Mode The last stage of the arithmetic (GARITH3) defines which snooping function should be performed if the result of the arithmetic evaluates to a match result. If both arithmetic blocks (arithmetic 0 and 1) match at the same time and have different mode settings, the lower mode is chosen (for example, if one function is programmed to 01b and the other to 11b, then mode 01b is executed). These bits exist only in the GARITH3 register. The bits are not writable in all others. 0 0: Disabled, no snooping occurs (forward normally) 0 1: Forward to designated management port only 1 0: Forward normally and copy to management port 1 1: Discard the frame	R/W
31:22	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.45 GPARSERn : [n - 3]th Parser of 2nd Block (n = 4 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x00E0 + 0x4 × (n - 4)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	CMP_MASK_OR	OFFSET_PLUS2	CMP16	IPPROTOCOL	IPDATA	SKIPVLAN	VALID	OFFSET_DA	—	OFFSET[5:0]					
Value after reset:	x	0	0	0	0	0	0	0	0	x	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	COMPARE_VAL[7:0]								MASK_VAL2[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	MASK_VAL2[7:0]	Mask for single byte compares or 2nd compare value (if bit 30 = 1) or least significant bits of a 16-bit compare value (if bit 28 = 1). When used as a mask (bit 28, 30 = 0, 0), the data from the frame is ANDed with this mask, then compared to the compare value. All bits having a 1 in the mask are compared with the data in the frame. All bits having a 0 will be 0 for the compare, however this requires the compare value to have those bits also set to 0.	R/W
15:8	COMPARE_VAL[7:0]	The value to compare the frame data with at the given offset.	R/W
21:16	OFFSET[5:0]	An offset in bytes to locate the data for comparison within the frame. The offset value starts at 0 to indicate the very first byte after offset start. The offset start can be either the type or length field of the frame, for example 0 = first byte of type/length field) or the payload following an IP header (see bit 26). Valid values range from 0 to 60.	R/W
22	—	The read value is undefined. The write value should be 0.	R/W
23	OFFSET_DA	When set, the offset starts counting from the first byte of the MAC destination address. The SKIPVLAN, IPDATA, and IPPROTOCOL bits must be 0 when this bit is set.	R/W
24	VALID	Indicates that this entry is valid (when this bit is 1) and should be used. When this bit is 0, the parser result always indicates "no match" and none of the other bits are relevant.	R/W
25	SKIPVLAN	When set, any optional VLAN tags found in the frame are skipped and the parser starts operating at the first byte following any VLAN tags. When cleared, the parser starts with the first byte following the source MAC address. When this bit is 0, this means the first byte of the type/length field is the first data for any compare, allowing to check for either types.	R/W
26	IPDATA	When set, the offset starts with the first byte following an IP header if an IP frame is processed. The following fields are skipped: ● any VLAN tags if present (implicitly acts as SKIPVLAN = 1) ● for Ipv4 the header and any header options ● for Ipv6 only the base header If the bit is set, it implicitly requires an IP frame. If the frame is not an IP frame, the parser reports "no match" and does not continue to inspect the frame. When cleared, the offset starts with the first data following the MAC source address (skipping VLAN tags if allowed by the bit SKIPVLAN. When this bit is set, the SKIPVLAN bit has no meaning and can be set to any value.	R/W
27	IPPROTOCOL	When set, the compare value is compared with the protocol field located within the IP header for both IPv4 and IPv6 frames. It implicitly acts as SKIPVLAN = 1 skipping any VLAN tags if present. The offset setting has no meaning and is ignored. If the bit is set, but the frame is not an IPv4/v6 frame the parser reports a no match and does not continue to inspect the frame. When cleared, the offset is used normally on all frames. When this bit is set, bits 25, 26, 28, 29, and 30 have no meaning and should be set to 0. MASK_VAL2[7:0] is applied therefore should be 0xFF to achieve an exact match.	R/W
28	CMP16	When set, MASK_VAL2[7:0] is used as a value to perform a 16-bit compare. COMPARE_VAL[7:0] represents the byte at the given offset and MASK_VAL2[7:0] represents the byte following at offset + 1 which matches the network byte order for 16-bit fields, (for example setting a compare value of 0x0800 and offset 0 matches IP frames). No mask is available in this mode. When cleared, only one byte of data is compared and the mask can be used to mask individual bits.	R/W

Bit	Symbol	Function	R/W
29	OFFSET_PLUS2	Repeats the comparison at offset + 2, if the comparison at offset failed. Only usable when CMP16 = 1. This can be used to create a comparison for UDP or TCP port numbers allowing for checking if the port number exists in the source or in the destination port number field.	R/W
30	CMP_MASK_OR	Use MASK_VAL2[7:0] as a second compare value. When set, the parser reports a match if the byte at given offset matches COMPARE_VAL[7:0] or MASK_VAL2[7:0]. Only usable when CMP16 = 0.	R/W
31	—	The read value is undefined. The write value should be 0.	R/W

The GPARSERn register is used as a port snooping function parser configuration.

29.3.1.46 GARITHn : Snoop Configuration for Arithmetic [n − 3]th Stage of 2nd Block (n = 4 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x00F0 + 0x4 × (n - 4)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	SNP_MD[1:0]		—	—	RESULT_INV	OP
Value after reset:	x	x	x	x	x	x	x	x	x	x	0	0	x	x	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	SEL_ARITH2	SEL_ARITH1	SEL_ARITH0	SEL_MATCH[3:0]				—	—	—	—	NOT_INP[3:0]			
Value after reset:	x	0	0	0	0	0	0	0	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	NOT_INP[3:0]	Not Input Define, which match result from a parser should be used inverted. One bit per parser. Bit 0 = parser 4, Bit 1 = parser 5, …, Bit 3 = parser 7 When a bit is 1, the match result of the corresponding parser is used inverted in this stage.	R/W
7:4	—	The read values are undefined. The write value should be 0.	R/W
11:8	SEL_MATCH[3:0]	Select Match Define, which parser result is relevant at this stage. One bit per parser. Bit 8 = parser 4, …, Bit 11 = parser 7 When a bit is 1, the match result of the corresponding parser is used in this stage, otherwise it is ignored.	R/W
12	SEL_ARITH0	Select Arithmetic Stage 0 Available only in stages 1 to 3. If set, the result from arithmetic stage 0 is selected in addition to any of the parser results.	R/W
13	SEL_ARITH1	Select Arithmetic Stage 1 Available only in stages 2 and 3. If set, the result from arithmetic stage 1 is selected in addition to any of the parser results.	R/W
14	SEL_ARITH2	Select Arithmetic Stage 2 Available only in stage 3. If set, the result from arithmetic stage 2 is selected in addition to any of the parser results.	R/W
15	—	The read value is undefined. The write value should be 0.	R/W
16	OP	Operation 0: AND all selected inputs 1: OR all selected inputs	R/W
17	RESULT_INV	Result Invert 0: The output is used directly 1: The output of this stage is inverted	R/W
19:18	—	The read values are undefined. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
21:20	SNP_MD[1:0]	Snoop Mode The last stage of the arithmetic (GARITH7) defines which snooping function should be performed if the result of the arithmetic evaluates to a match result. If both arithmetic blocks (arithmetic 0 and 1) match at the same time and they have different mode settings, the lower mode is chosen. For example, if one function is programmed to 01b and the other to 11b, then mode 01b is executed. These bits exist only in the GARITH7 register. These bits are not writable in other registers. 0 0: Disabled, no snooping occurs (forward normally) 0 1: Forward to designated management port only 1 0: Forward normally and copy to management port 1 1: Discard the frame	R/W
31:22	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.47 VLAN_PRIORITYn : VLAN Priority Register n (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x0100 + 0x4 × n

Bit position:	31								23		21	20		18	17		15	14		12	11		9	8		6	5		3	2		0
Bit field:	—	—	—	—	—	—	—	—	PRIORITY 7[2:0]			PRIORITY 6[2:0]			PRIORITY 5[2:0]			PRIORITY 4[2:0]			PRIORITY 3[2:0]			PRIORITY 2[2:0]			PRIORITY 1[2:0]			PRIORITY 0[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	0	1	1	0	1	1	0	1	1	0	1	1	0	1	1	0	1	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
2:0	PRIORITY0[2:0]	Priority 0 Setting Priority for priority 0 of VLAN tag of input frames	R/W
5:3	PRIORITY1[2:0]	Priority 1 Setting Priority for priority 1 of VLAN tag of input frames	R/W
8:6	PRIORITY2[2:0]	Priority 2 Setting Priority for priority 2 of VLAN tag of input frames	R/W
11:9	PRIORITY3[2:0]	Priority 3 Setting Priority for priority 3 of VLAN tag of input frames	R/W
14:12	PRIORITY4[2:0]	Priority 4 Setting Priority for priority 4 of VLAN tag of input frames	R/W
17:15	PRIORITY5[2:0]	Priority 5 Setting Priority for priority 5 of VLAN tag of input frames	R/W
20:18	PRIORITY6[2:0]	Priority 6 Setting Priority for priority 6 of VLAN tag of input frames	R/W
23:21	PRIORITY7[2:0]	Priority 7 Setting Priority for priority 7 of VLAN tag of input frames	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

Note: n = 0: port 0, n = 1: port 1, n = 2: port 2, n = 3: port 3 (management port)

The VLAN_PRIORITYn registers are used to set the priority of the VLAN tag of the input frames.

The ethernet switch has an 8-entry programmable priority lookup table for each port. The priority included in the 3 higher-order bits of the first octet of the VLAN info is used as an index of the lookup table and can be remapped.

29.3.1.48 IP_PRIORITYn : IP Priority Register n (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x0140 + 0x4 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	READ	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	PRIORITY[2:0]			IPV6SELECT	ADDRESS[7:0]							
Value after reset:	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ADDRESS[7:0]	COS Table Address Specifying Specify an address for the index of the COS table. The IPv4 priority table is 6 bits (64 entries) and the IPv6 table is 8 bits (256 entries).	R/W
8	IPV6SELECT	IPv6 COS Table Selection Indicates the selection of the IPv6 COS table. 0: The IPv4 table is accessed. The valid range of the ADDRESS[7:0] bits is from 0 to 63. 1: The IPv6 table is accessed. The valid range of the ADDRESS[7:0] bits is from 0 to 255.	R/W
11:9	PRIORITY[2:0]	COS Table Priority When writing, set the priority information to be written to the COS table. When read, the priority information written to the COS table can be read. The address index of the COS table to be read is the address of the last write operation.	R/W
30:12	—	The read values are undefined. The write value should be 0.	R/W
31	READ	COS Table Operation Switching Switches write or read operation to the COS table. Read operation to the register: The priority information of the address of the last write operation is read from the table. Use the following procedure to read the priority information from the COS table: 1. Perform a write (that is, specification of the address to be read) while this bit is 1 and the IPV6SELECT and ADDRESS[7:0] bits are set to the target values. 2. Execute a read operation Write operation to the register: 0: Write the priority information to the COS table 1: Does not write the priority information to the COS table (unchanged)	R/W

Note: n = 0: port 0, n = 1: port 1, n = 2: port 2, n = 3: port 3 (management port)

The IP_PRIORITYn register is used to make and refer to the COS table settings by writing to the COS table or specifying the settings for reference to a priority level. Each port of the ethernet switch has class of services (COS) tables for IPv4 and IPv6. In the COS table entries for IPv4, the 6-bit DiffServ field of the frame is provided as an index to the Lookup table and a 3-bit priority can be set. In the COS table entries for IPv6, the 8-bit COS field of the frame is provided as an index to the Lookup table and a 3-bit priority can be set.

29.3.1.49 PRIORITY_CFGn : Priority Configuration Register n (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x0180 + 0x4 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PCP_REMAP[23:8]															
Value after reset:	1*1	1*1	1*1	1*1	1*1	0	1*1	0	1*1	1*1	0	0	0	1*1	1*1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PCP_REMAP[7:0]								PCP_REMAP_DIS	DEFAULTPRI[2:0]			TYPE_EN	MACEN	IPEN	VLANEN
Value after reset:	1*1	0	0	0	1*1	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	VLANEN	VLAN Priority Enable Enables VLAN priority for a frame received on port n. 0: VLAN priority is not used. The priority field of the VLAN tag of a frame is ignored. 1: Priority in the switch is determined using the priority field of the VLAN tag of a frame according to the VLAN_PRIORITYn setting for the port on which the frame was received.	R/W
1	IPEN	IP Priority Enable Enables IP priority for a frame received on port n. 0: IP priority is not used and IP DiffServ/COS fields of the frame are ignored 1: Priority in the switch is determined using the IP DiffServ/COS field according to the IP_PRIORITYn setting for the port on which the frame was received	R/W
2	MACEN	MAC Based Priority Enable 0: MAC priority is ignored 1: Priority information found within the MAC address table (for a static entry)	R/W
3	TYPE_EN	TYPE Based Priority Enable 0: Type fields are ignored 1: The type/length field of the frame (following any VLAN tags) is compared to all PRIORITY_TYPE configured values. If any of the values matches, the priority information from that matching type is used.	R/W
6:4	DEFAULTPRI[2:0]	Default Priority Enable Setting Set the default priority of a frame received on port n. When neither of the priorities is used, this priority is applied. The valid range is from 0 to 7.	R/W
7	PCP_REMAP_DIS	Disables PCP remapping when set to 1. See PCP_REMAP[23:0] field.	R/W
31:8	PCP_REMAP[23:0]	PCP Remapping function On ingress frame's VLAN.PCP is remapped according to this function and the frame's VLAN tag is modified accordingly (section 29.4.3.2. VLAN Input Processing Function (5) VLAN PCP remap). Default value keeps the same PCP value. The function is only present for line ports. PCP_REMAP[2:0]: Remap value for PCP 0 PCP_REMAP[5:3]: Remap value for PCP 1 PCP_REMAP[8:6]: Remap value for PCP 2 PCP_REMAP[11:9]: Remap value for PCP 3 PCP_REMAP[14:12]: Remap value for PCP 4 PCP_REMAP[17:15]: Remap value for PCP 5 PCP_REMAP[20:18]: Remap value for PCP 6 PCP_REMAP[23:21]: Remap value for PCP 7	R/W

Note: n = 0: port 0, n = 1: port 1, n = 2: port 2, n = 3: port 3 (management port)

Note 1. The initial value of the PRIORITY_CFG3 register for management port (Port 3) is 0x00000000. Others are 0xFAC68800.

The PRIORITY_CFGn register is used to set each port for how received frames are assigned according to the priority of the queues in the switch using the priority in the frames, and VLAN PCP remapping function.

When several types of the priority fields are enabled, priority reassignment is executed according to the higher priority (IP priority (DiffServ/COS), VLAN priority, and default priority).

29.3.1.50 PRIORITY_TYPE1 : Priority Type Register 1

Base address: ETHSW = 0x8012_0000

Offset address: 0x01B8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	PRIORITY[2:0]			VALID
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TYPEVAL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TYPEVAL[15:0]	Type Priority A 16-bit value to be compared against the type/length field of the frame at receive. For example, a value of 0x88F7 would match IEEE 1588 frames. All such PRIORITY_TYPE registers are simultaneously searched and a type match occurs if a compare is successful. The value is relevant (and used for comparison) only if the valid bit is set. This value is always compared against the type/length field of the frame following any VLAN tags. Up to two VLAN tags can be present in the frame. When used with the management port special frame tagging (see section 29.3.1.91. MGMT_TAG_CONFIG : Management Tag Configuration Register), no VLAN tags can be supported for the tag insertion selection. That is, the management tag is inserted only if this is the first tag found in the frame. At the same time, for priority definition, VLAN tags are supported.	R/W
16	VALID	If set indicates, this register contains valid data. If cleared (default), the data from this register is ignored. When using with the management port special frame tagging, the valid bit has no relevance. The type is compared if enabled in the section 29.3.1.91. MGMT_TAG_CONFIG : Management Tag Configuration Register. This allows for using the type for the management tag only, or at the same time for priority resolution (useful for 1588 frames).	R/W
19:17	PRIORITY[2:0]	The priority value to use if a match occurs. PRIORITY_CFGn.TYPE_EN bit of a port controls the use of this priority.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The PRIORITY_TYPE1 register is used to compare value for prioritizing frames with a specific type field.

29.3.1.51 PRIORITY_TYPE2 : Priority Type Register 2

Base address: ETHSW = 0x8012_0000

Offset address: 0x01BC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	PRIORITY[2:0]			VALID
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TYPEVAL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

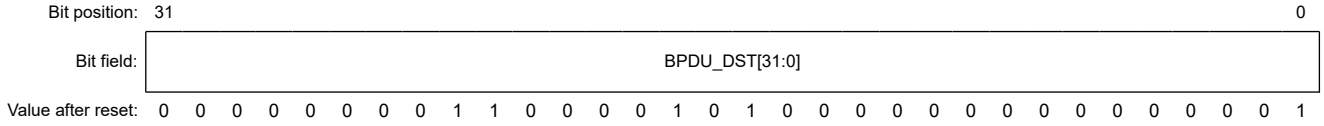
Bit	Symbol	Function	R/W
15:0	TYPEVAL[15:0]	Type Priority A 16-bit value to be compared against the type/length field of the frame at receive. For example, a value of 0x88F7 would match IEEE 1588 frames. All such PRIORITY_TYPE registers are simultaneously searched and a type match occurs if a compare is successful. The value is relevant (and used for comparison) only if the valid bit is set. This value is always compared against the type/length field of the frame following any VLAN tags. Up to two VLAN tags can be present in the frame. When used with the management port special frame tagging (see section 29.3.1.91. MGMT_TAG_CONFIG : Management Tag Configuration Register), no VLAN tags can be supported for the tag insertion selection. That is, the management tag is inserted only if this is the first tag found in the frame. At the same time, for priority definition, VLAN tags are supported.	R/W
16	VALID	If set indicates, this register contains valid data. If cleared (default), the data from this register is ignored. When using with the management port special frame tagging, the valid bit has no relevance. The type is compared if enabled in the section 29.3.1.91. MGMT_TAG_CONFIG : Management Tag Configuration Register. This allows for using the type for the management tag only, or at the same time for priority resolution (useful for 1588 frames).	R/W
19:17	PRIORITY[2:0]	The priority value to use if a match occurs. PRIORITY_CFGn.TYPE_EN bit of a port controls the use of this priority.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The PRIORITY_TYPE2 register is used to compare value for prioritizing frames with a specific type field.

29.3.1.52 MGMT_ADDR0_lo : Lower MAC Address 0 for Bridge Protocol Frame Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01C0

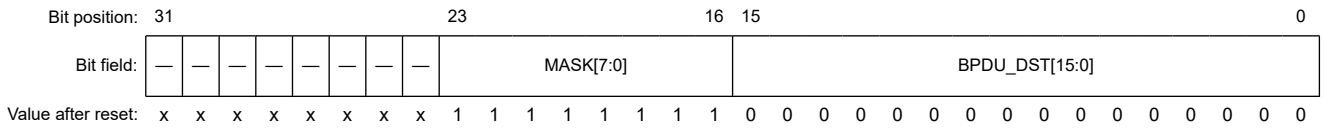


Bit	Symbol	Function	R/W
31:0	BPDU_DST[31:0]	Additional MAC address defining a Bridge Protocol Frame (BPDU) in addition to the commonly-known addresses First 4 bytes of MAC address: Bits [7:0] = 1st, bits [15:8] = 2nd, bits [23:16] = 3rd, bits [31:24] = 4th.	R/W

29.3.1.53 MGMT_ADDR0_hi : Higher MAC Address 0 for Bridge Protocol Frame Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01C4



Bit	Symbol	Function	R/W
15:0	BPDU_DST[15:0]	Bits [7:0] is 5th byte, bits [15:8] is 6th (last) byte	R/W
23:16	MASK[7:0]	8-bit mask for comparing the last byte of the MAC address. Each bit that is 1 in the mask is compared. The mask is ANDed with the last byte of the MAC address (6th byte in frame) before comparison. Setting the mask to 0xFF compares all bits. A mask of 0x00 ignores the last byte of the MAC address and a match occurs on any value. All mask bits with 0 must also have 0 in the corresponding MAC address bit (bits [15:8] in this register).	R/W

Bit	Symbol	Function	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

The MGMT_ADDR0_hi register specifies the last 2 octets of the MAC address and the mask/valid bits.

Note: The compare is always active. To disable it, set a default value. Reset defaults to 01-80-c2-00-00-00 mask 0xFF.

29.3.1.54 MGMT_ADDR1_lo : Lower MAC Address 1 for Bridge Protocol Frame Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01C8

Bit position:	31																												0
Bit field:	BPDU_DST[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	1	1	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
31:0	BPDU_DST[31:0]	Additional MAC address defining a Bridge Protocol Frame (BPDU) in addition to the commonly-known addresses First 4 bytes of MAC address: Bits [7:0] = 1st, bits [15:8] = 2nd, bits [23:16] = 3rd, bits [31:24] = 4th.	R/W

29.3.1.55 MGMT_ADDR1_hi : Higher MAC Address 1 for Bridge Protocol Frame Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01CC

Bit position:	31								23							16	15													0
Bit field:	—	—	—	—	—	—	—	—	MASK[7:0]								BPDU_DST[15:0]														
Value after reset:	x	x	x	x	x	x	x	x	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	BPDU_DST[15:0]	Bits [7:0] is 5th byte, bits [15:8] is 6th (last) byte.	R/W
23:16	MASK[7:0]	8-bit mask for comparing the last byte of the MAC address. Each bit that is 1 in the mask is compared. The mask is ANDed with the last byte of the MAC address (6th byte in frame) before comparison. Setting the mask to 0xFF compares all bits. A mask of 0x00 ignores the last byte of the MAC address and a match occurs on any value. All mask bits with 0 must also have 0 in the corresponding MAC address bit (bits [15:8] in this register).	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

The MGMT_ADDR1_hi register specifies the last 2 octets of the MAC address and the mask/valid bits.

Note: The compare is always active. To disable it, set a default value. Reset defaults to 01-80-c2-00-00-00 mask 0xFF.

29.3.1.56 MGMT_ADDR2_lo : Lower MAC Address 2 for Bridge Protocol Frame Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01D0

Bit position:	31																												0
Bit field:	BPDU_DST[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	1	1	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
31:0	BPDU_DST[31:0]	Additional MAC address defining a Bridge Protocol Frame (BPDU) in addition to the commonly-known addresses. First 4 bytes of MAC address: Bits [7:0] = 1st, bits [15:8] = 2nd, bits [23:16] = 3rd, bits [31:24] = 4th.	R/W

29.3.1.57 MGMT_ADDR2_hi : Higher MAC Address 2 for Bridge Protocol Frame Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01D4

Bit position:	31								23								16	15													0
Bit field:	—	—	—	—	—	—	—	—	MASK[7:0]								BPDU_DST[15:0]															
Value after reset:	x	x	x	x	x	x	x	x	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	BPDU_DST[15:0]	Bits [7:0] is 5th byte, bits [15:8] is 6th (last) byte.	R/W
23:16	MASK[7:0]	8-bit mask for comparing the last byte of the MAC address. Each bit that is 1 in the mask is compared. The mask is ANDed with the last byte of the MAC address (6th byte in frame) before comparison. Setting the mask to 0xFF compares all bits. A mask of 0x00 ignores the last byte of the MAC address and a match occurs on any value. All mask bits with 0 must also have 0 in the corresponding MAC address bit (bits [15:8] in this register).	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

The MGMT_ADDR2_hi register specifies the last 2 octets of the MAC address and the mask/valid bits.

Note: The compare is always active. To disable it, set a default value. Reset defaults to 01-80-c2-00-00-00 mask 0xFF.

29.3.1.58 MGMT_ADDR3_lo : Lower MAC Address 3 for Bridge Protocol Frame Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01D8

Bit position:	31																														0
Bit field:	BPDU_DST[31:0]																														
Value after reset:	0	0	0	0	0	0	0	0	1	1	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
31:0	BPDU_DST[31:0]	Additional MAC address defining a Bridge Protocol Frame (BPDU) in addition to the commonly-known addresses. First 4 bytes of MAC address: Bits [7:0] = 1st, bits [15:8] = 2nd, bits [23:16] = 3rd, bits [31:24] = 4th.	R/W

29.3.1.59 MGMT_ADDR3_hi : Higher MAC Address 3 for Bridge Protocol Frame Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01DC

Bit position:	31								23								16	15													0
Bit field:	—	—	—	—	—	—	—	—	MASK[7:0]								BPDU_DST[15:0]															
Value after reset:	x	x	x	x	x	x	x	x	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	BPDU_DST[15:0]	Bits [7:0] is 5th byte, bits [15:8] is 6th (last) byte.	R/W
23:16	MASK[7:0]	8-bit mask for comparing the last byte of the MAC address. Each bit that is 1 in the mask is compared. The mask is ANDed with the last byte of the MAC address (6th byte in frame) before comparison. Setting the mask to 0xFF compares all bits. A mask of 0x00 ignores the last byte of the MAC address and a match occurs on any value. All mask bits with 0 must also have 0 in the corresponding MAC address bit (bits [15:8] in this register).	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

The MGMT_ADDR3_hi register specifies the last 2 octets of the MAC address and the mask/valid bits.

Note: The compare is always active. To disable it, set a default value. Reset defaults to 01-80-c2-00-00-00 mask 0xFF.

29.3.1.60 SRCFLT_ENA : MAC Source Address Filtering Enable Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01E0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	DSTENA[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	SRCENA[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	SRCENA[2:0]	Per-Source Port Enable Enables for which ports the MAC source address filtering check is enabled when frames are received by the enabled port.	R/W
15:3	—	The read values are undefined. The write value should be 0.	R/W
19:16	DSTENA[3:0]	Per-Destination Port Enable Enables for which destination ports the source filtering is applied. When a frame is subject to filtering check and the MAC address is different, the ports enabled in DSTENA are filtered out from the final forwarding mask.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The SRCFLT_ENA register is used for the per-port MAC address source filtering enable.

29.3.1.61 SRCFLT_CONTROL : MAC Source Address Filtering Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01E4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	WATCHDOG_TIME[15:0]															
Value after reset:	0	0	0	0	0	1	1	1	1	1	0	1	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WATCHDOG_ENA	MGMT_FWD
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
0	MGMT_FWD	Management Forward Enable When this bit is set to 1 and a MAC source address filter check results in a port being removed from the destination port mask, the frame is then copied to the management port.	R/W
1	WATCHDOG_ENA	When set to 1, a watchdog is enabled. The watchdog is used to trigger the interrupt SRCFLT_WD_INT when the time in WATCHDOG_TIME expires. The watchdog starts to operate immediately when this bit is 1. It resets every time a frame is received in a port with SRCENA set to 1 and the source address of the frame matches SRCFLT_MACADDR.	R/W
15:2	—	The read values are undefined. The write value should be 0.	R/W
31:16	WATCHDOG_TIME[15:0]	Defines the watchdog expire time in milliseconds. The default is 2000 milliseconds.	R/W

29.3.1.62 SRCFLT_MACADDR_LO : Lower MAC Filtering Address Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01E8

Bit position:	31																												0
Bit field:	SRCFLT_MACADDR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SRCFLT_MACADDR[31:0]	MAC address to use in source filtering The mapping to the first 32 bits of the MAC source address MACSA[31:0] to be matched against.	R/W

29.3.1.63 SRCFLT_MACADDR_HI : Higher MAC Filtering Address Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01EC

Bit position:	31															16	15													0
Bit field:	MASK[15:0]																SRCFLT_MACADDR[15:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SRCFLT_MACADDR[15:0]	MAC address to use in source filtering The mapping to the last 16 bits of the MAC source address MACSA[47:32] to be matched against.	R/W
31:16	MASK[15:0]	The mask to apply to the last 16 bits of the MAC address When set to 0, the corresponding bit in MACSA[47:32] is ignored. For the mask to work correctly, the corresponding bit in MACSA[47:32] must also be set to 0.	R/W

29.3.1.64 PHY_FILTER_CFG : Debounce Filter Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x01FC

Bit position:	31													18	16								8							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	FLT_EN[2:0]		—	—	—	—	—	—	—	FILTER_DURATION[8:0]							
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	x	x	x	x	x	x	x	0	0	0	0	1	0	1	1	1

Bit	Symbol	Function	R/W
8:0	FILTER_DURATION[8:0]	This is the amount of time to wait after the last phy_link (ETHSW_PHYLINKn: n = port) transition from 0 to 1 to acknowledge the link-up condition. Each unit corresponds to 2^{16} switch clock periods. At 200 MHz each unit is 0.328 ms. The default value sets a debounce time of approximately 7.5 ms.	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
18:16	FLT_EN[2:0]	Per-port Enable Mask Set to 1 to enable the link-up debounce filter on each port.	R/W
31:19	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.65 SYSTEM_TAGINFOn : One VLAN ID Field n for VLAN Input Manipulation (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x0200 + 0x4 × n

Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SYSVLANINFO[15:0]														
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SYSVLANINFO[15:0]	System VLAN Info (prio/cfi/vid) for Port n	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.66 AUTH_PORTn : Port n Authentication Control and Configuration (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x0240 + 0x4 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	GUEST_MASK[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EAPOL_PNUM[3:0]				ACHG_UNAUTH	—	—	—	—	—	EAPOL_UC_EN	BPDU_EN	GUEST_EN	EAPOL_EN	CTRL_BOTH	AUTH
Value after reset:	0	0	1	1	0	x	x	x	x	x	0	0	0	0	0	x

Bit	Symbol	Function	R/W
0	AUTH	Authorized 0: The port is unauthorized restricting forwarding according to the rules configured in this register 1: The port is in the authorized state and operates normally without restrictions. The other bits of this register, except for bits [15:12] and bit [2], are not relevant.	R/W
1	CTRL_BOTH	Controlled Both 0: The port operates in Controlled Directions (mode in). This allows frames from other ports to be forwarded to this port for transmission, but reception is still restricted. 1: The port operates in Controlled Directions (mode both). This means other ports cannot transmit any traffic on this port, except the port specified in the EAPOL destination port.	R/W

Bit	Symbol	Function	R/W
2	EAPOL_EN	EAPOL Enable Enable (when this bit is 1) / Disable (when this bit is 0) Reception of EAPOL Frames. When enabled, EAPOL frames are forwarded to the port given in EAPOL destination port number set in EAPOL_PNUM[3:0]. This is independent from the authorized state. If disabled and the port is: ● Unauthorized — EAPOL frames are discarded ● Authorized — EAPOL frames are treated as BPDU frames and forwarded to the management port This bit is disabled if implementing the HELD state of the authentication state machine where a port is unauthorized and is not allowed to accept EAPOL frames.	R/W
3	GUEST_EN	Guest Enable Enable (when this bit is 1) / Disable (when this bit is 0) Reception of non EAPOL Frames. When enabled and the port is unauthorized, such frames are forwarded only to the given guest port mask set in GUEST_MASK[3:0]. When this bit is enabled, the normal VLAN manipulation function (VLAN insertion) can be used if required.	R/W
4	BPDU_EN	BPDU Enable Enable (when this bit is 1) / Disable (when this bit is 0) Reception of BPDU Frames. When enabled and the port is unauthorized, BPDU frames are forwarded to the management port normally. Otherwise, BPDU frames are discarded. Although EAPOL frames use BPDU multicast addresses, they are not discarded by setting this bit to 0.	R/W
5	EAPOL_UC_EN	EAPOL Unicast Enable Normally EAPOL frames must use the dedicated PAE multicast destination address. However, if this bit is set and a unicast destination address is found, the frame is accepted if it matches the MAC address of the port as configured in the ADDR registers of the MAC. The frame is then forwarded to the EAPOL destination port number given in bits [15:12].	R/W
10:6	—	The read values are undefined. The write value should be 0.	R/W
11	ACHG_UNAUTH	Automatic Port Change to Unauthorized Enables automatic port change to unauthorized. When this bit is set to 1 (enabled) and a frame of unknown source is received at the port, the authorized (AUTH) bit of this register is cleared. The port changes into an unauthorized state and it is up to the application to re-authenticate the port and eventually set the authorized bit again. This bit is valid only if the port has learning disabled (see section 29.3.1.8. INPUT_LEARN_BLOCK : Input Learning Block Register) and is configured to discard frames of unknown source (see section 29.3.1.83. LK_CTRL : Learning/Lookup Function Global Configuration Register). The interrupt (INT_CONFIG.LK_NEW_SRC) can be used to notify the application of this event.	R/W
15:12	EAPOL_PNUM[3:0]	EAPOL Port Number 4 bits port number where to send EAPOL frames. Typically it is the management port (port number = 3), but can be an external port if desired (with limitations). The setting must be identical for all ports. It is not recommended to change this setting. If it is modified and a port changes to authorized without keeping the EAPOL enable bit [2] set, then EAPOL frames are treated as normal BPDU frames. Therefore, an EAPOL log off message does not reach the configured port but is forwarded to the management port instead. The setting is also valid when a port is authorized and matches this number. If this port receives frames, it can always forward to unauthorized ports, even when controlled both is set.	R/W
19:16	GUEST_MASK[3:0]	Destination port mask with all ports that are allowed to receive non-EAPOL frames from this port while it is unauthorized and guest (GUEST_EN) is enabled. Bit 16 = port 0, Bit 17 = port 1, and so on. ● If all 0, frames are discarded even if guest is enabled ● If a destination port in this list is unauthorized and has its CTRL_BOTH bit set, it is removed from this list automatically during forwarding ● If a destination port in this list is authorized, it is not removed from this list. This allows forwarding of a frame from an unauthorized to an authorized port. This can be intentional, for example to implement DHCP with an external server connected at an authorized port. It is the responsibility of the application to ensure the update of all guest masks of all ports when a port changes to authorized, without receiving frames forwarded to it from unauthorized ports.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The AUTH bit reset defaults are controlled by the STRAP_SX_ENB bit and STRAP_HUB_ENB bit of SWCTRL register.

29.3.1.67 VLAN_RES_TABLEn : 32 VLAN Domain Entries (n = 0 to 31)

Base address: ETHSW = 0x8012_0000

Offset address: 0x0280 + 0x4 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	WT_PRTMSK	WT_TAGMSK	RD_TAGMSK	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	0	0	0	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	VLANID[11:0]												PORTMASK[3:0]			
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
3:0	PORTMASK[3:0]	When this bit is set to 1, it defines a port as a member of the VLAN. When bit [28] or bit [29] is set, the tagged bit mask is read/written instead of port mask.	R/W
15:4	VLANID[11:0]	The 12-bit VLAN identifier (VLAN ID) of the entry.	R/W
27:16	—	The read values are undefined. The write value should be 0.	R/W
28	RD_TAGMSK	Read TAG Mask Selects contents of PORTMASK[3:0] when reading the register. If this bit is set during a write into the register, all other bits of the write are ignored (for example bit [30], bit [29], bits [15:0]) and bit [28] of the register toggles (from 1 to 0 or 0 to 1). This is only used to allow changing bit [28] without changing any table contents. When the register is read, the bit indicates the contents of bits [3:0]. This bit is cleared when the register is written with bit [28] = 0. 0: The port mask is returned 1: The tagged bit mask is returned	R/W
29	WT_TAGMSK	Write TAG Mask When this bit is set while writing into the register, bits [3:0] are stored in the tagged bit mask for the domain only. The port mask is left unchanged and the VLAN ID must be set accordingly during the write. The tagged bit mask is allowed to specify for each port if the frames leaving the port should be tagged (when this bit is 1) or untagged (when this bit is 0). If a port is untagged, frames that leave that port have the VLAN tag removed. This tagged bit mask is interpreted by the output manipulation function on all ports that operate in output manipulation mode 3. When bits [30:29] are both 0 or both 1 during a write, bits [3:0] are always written into both the port mask and the tagged bit mask.	R/W
30	WT_PRTMSK	Write Port Mask When this bit is set when writing into the register, bits [3:0] are stored in the port mask for the domain only. The tagged bit mask is left unchanged. The VLAN ID must be set accordingly during the write. When bits [30:29] are both 0 or both 1 during a write, bits [3:0] are always written into both the port mask and the tagged bit mask.	R/W
31	—	The read value is undefined. The write value should be 0.	R/W

29.3.1.68 TOTAL_DISC : Discarded Frame Total Number Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0300

Bit position:	31	0
Bit field:	TOTAL_DISC[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	TOTAL_DISC[31:0]	Total number of incoming frames accepted by MAC RX but discarded in the switch	R

29.3.1.69 TOTAL_BYT_DISC : Discarded Frame Total Bytes Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0304

Bit position:	31																												0
Bit field:	TOTAL_BYT_DISC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TOTAL_BYT_DISC[31:0]	Sum of bytes of frames counted in TOTAL_DISC	R

29.3.1.70 TOTAL_FRM : Processed Frame Total Number Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0308

Bit position:	31																												0
Bit field:	TOTAL_FRM[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TOTAL_FRM[31:0]	Total number of incoming frames processed by the switch	R

Note: The number of incoming frames is also incremented when cut through forwarding is used and a frame with invalid CRC was received, as it has been forwarded. The IfOutErrors of the MAC however, will indicate erroneous frames forwarded.

29.3.1.71 TOTAL_BYT_FRM : Processed Frame Total Bytes Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x030C

Bit position:	31																												0
Bit field:	TOTAL_BYT_FRM[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TOTAL_BYT_FRM[31:0]	Sum of bytes of frames counted in TOTAL_FRM	R

29.3.1.72 IALK_CONTROL : IA Lookup Function Enable Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0340

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CT_ENA[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IA_LKUP_ENA[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	IA_LKUP_ENA[3:0]	Per-port Enable to the IA Lookup Table When enabled on a port, the L2 MAC destination address is sent to the IA database.	R/W
15:4	—	The read values are undefined. The write value should be 0.	R/W
19:16	CT_ENA[3:0]	Per-port Cut-Through Mode Enable When set to 0 and a lookup to the IA database results in a found result, the frame is not forwarded cut-through. When set to 1, the frame can be forwarded cut-through if all the other conditions are met.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The IALK_CONTROL register is used as the IA Lookup function per-port enable register.

29.3.1.73 IALK_OUI : IA Frames MAC Address OUI Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0344

Bit position:	31							23								0
Bit field:	—	—	—	—	—	—	—	—	IALK_OUI[23:0]							
Value after reset:	x	x	x	x	x	x	x	x	1	1	0	0	1	1	1	1	0	0	0	0	1	1	1	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
23:0	IALK_OUI[23:0]	IA Frames MAC Address OUI Configures the 24-bit OUI used to compare against the OUI of the receive frame.	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.74 IALK_ID_MIN : Minimum Value ID MAC Address Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0348

Bit position:	31							23								0
Bit field:	—	—	—	—	—	—	—	—	IALK_ID_MIN[23:0]							
Value after reset:	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	IALK_ID_MIN[23:0]	Minimum value for the 24-bit ID in the MAC address Frames below this minimum are not looked up in the IA table.	R/W

Bit	Symbol	Function	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.75 IALK_ID_MAX : Maximum Value ID MAC Address Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x034C

Bit position:	31								23																				0
Bit field:	—	—	—	—	—	—	—	—	IALK_ID_MAX[23:0]																				
Value after reset:	x	x	x	x	x	x	x	x	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
23:0	IALK_ID_MAX[23:0]	Maximum value for the 24-bit ID in the MAC address Frames above this minimum are not looked up in the IA table.	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.76 IALK_ID_SUB : Offset Value ID MAC Address Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0350

Bit position:	31								23																				0
Bit field:	—	—	—	—	—	—	—	—	IALK_ID_SUB[23:0]																				
Value after reset:	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	IALK_ID_SUB[23:0]	Offset value to subtract from the 24-bit ID in the MAC address	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.77 IALK_ID_CONFIG : Configures Lookup Response Unknown IDs Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0354

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	INVLD_ID_FLOOD_MASK[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	INVLD_ID_PRIO_VLD	INVLD_ID_PRIO[2:0]			—	—	INVLD_ID_LRN_ENA	INVLD_ID_FLOOD
Value after reset:	x	x	x	x	x	x	x	x	0	0	0	0	x	x	0	0

Bit	Symbol	Function	R/W
0	INVLD_ID_FLOOD	Setting this bit to 1 causes the IA table to return a found response for frames whose ID lies outside the ID range defined by [IA_LK_MAX:IA_LK_MIN] using INVLD_ID_FLOOD_MASK[3:0] bits. When set to 0, an unknown ID returns a not-found response and the switch uses the result from the L2 FDB instead.	R/W

Bit	Symbol	Function	R/W
1	INVLD_ID_LRN_ENA	Setting this bit to 1 allows automatic learning into the L2 FDB for frames with unknown IDs. When 0, learning is inhibited. This bit is only valid when INVLD_ID_FLOOD bit is set to 1.	R/W
3:2	—	The read values are undefined. The write value should be 0.	R/W
6:4	INVLD_ID_PRIO[2:0]	Priority to use for found responses of an invalid ID. This bit is only valid when INVLD_ID_FLOOD bit is set to 1.	R/W
7	INVLD_ID_PRIO_VLD	Indicates if the priority in INVLD_ID_PRIO is valid. This bit is valid only when INVLD_ID_FLOOD bit is set to 1.	R/W
15:8	—	The read values are undefined. The write value should be 0.	R/W
19:16	INVLD_ID_FLOOD_MASK[3:0]	Forwarding mask used for frames whose ID is invalid. This bit is only valid when INVLD_ID_FLOOD bit is set to 1. Setting this mask to 0 causes the frame to be dropped.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The IALK_ID_CONFIG register configures lookup response for unknown IDs (IDs that fall beyond the range of IALK_ID_MAX to IALK_ID_MIN).

29.3.1.78 IALK_VLAN_CONFIG : Configure Lookup Response Unknown VLAN Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0358

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	UNKWN_VLAN_FLOOD_MASK[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	VLANS_ENABLED[2:0]			UNKWN_VLAN_PRIO_VLD	UNKWN_VLAN_PRIO[2:0]			—	—	UNKWN_VLAN_LRN_ENA	UNKWN_VLAN_FLOOD
Value after reset:	x	x	x	x	x	0	0	0	0	0	0	0	x	x	0	0

Bit	Symbol	Function	R/W
0	UNKWN_VLAN_FLOOD	When this bit is set to 1, a frame matching the OUI and with a valid ID but having a VLAN ID not matching any of the enabled values in IALK_VLANIDn causes the IA table to return a found response using the forwarding mask in UNKWN_VLAN_FLOOD_MASK[3:0]. When this bit is set to 0, an unknown VLAN causes the IA table to return a not-found response and the switch uses the result from the L2 FDB instead. This bit is only valid when VLANS_ENABLED[2:0] is greater than 0.	R/W
1	UNKWN_VLAN_LRN_ENA	Setting this bit to 1 allows automatic learning into the L2 FDB for frames with unknown VLANs. When 0, learning is inhibited. This bit is only valid when UNKWN_VLAN_FLOOD bit is set to 1.	R/W
3:2	—	The read values are undefined. The write value should be 0.	R/W
6:4	UNKWN_VLAN_PRIO[2:0]	Priority to use for found responses for an unknown VLAN. This bit is only valid when UNKWN_VLAN_FLOOD bit is set to 1.	R/W
7	UNKWN_VLAN_PRIO_VLD	Indicates if the priority in UNKWN_VLAN_PRIO[2:0] is valid. This bit is only valid when UNKWN_VLAN_FLOOD bit is set to 1.	R/W
10:8	VLANS_ENABLED[2:0]	Configures the logical geometry of the IA table by specifying the number of distinct VLAN IDs enabled. When set to 0, no VLANs are supported and the VLAN ID for the frames is ignored. Valid values must be powers of 2 such as 0, 1, 2, or 4.	R/W
15:11	—	The read values are undefined. The write value should be 0.	R/W

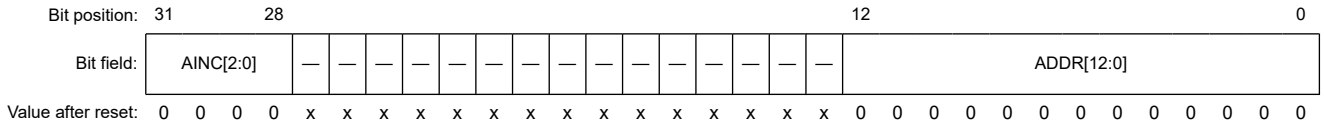
Bit	Symbol	Function	R/W
19:16	UNKWN_VLAN_FLOOD_MASK[3:0]	Forwarding mask used for frames with an unknown VLAN ID. One bit per port (bit 0 = port 0, bit 1 = port 1, and so on). This bit is only valid when UNKWN_VLAN_FLOOD bit is set to 1. Setting this bit to 0 causes the frame to be dropped.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The IALK_VLAN_CONFIG register configures lookup response for unknown VLANs and the logical geometry of the IA lookup database.

29.3.1.79 IALK_TBL_ADDR : IA Lookup Database Address Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x035C



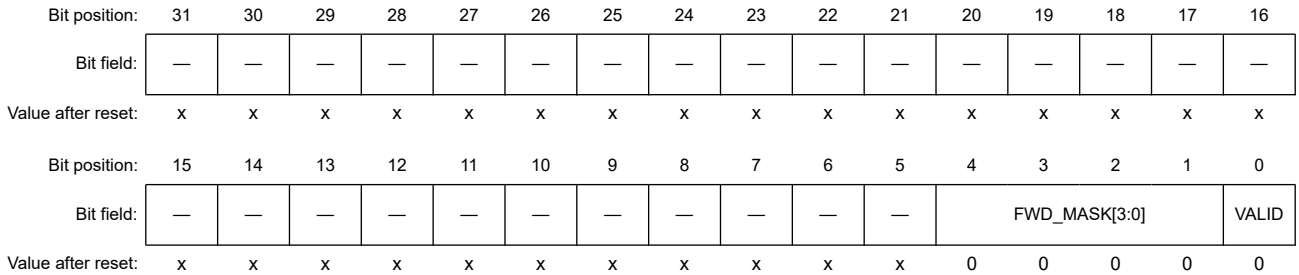
Bit	Symbol	Function	R/W
12:0	ADDR[12:0]	Defines the address to write to or read from the IA Lookup table This is the logical entry address where the LSBits specify the VLAN (based on $\log_2$(VLANS_ENABLED)) and the MSBits the ID. To this address, the value in IALK_ID_SUB is not applied.	R/W
27:13	—	The read values are undefined. The write value should be 0.	R/W
31:28	AINC[2:0]	Auto-Increment Control When set to a value other than 0, the value in ADDR is auto-incremented with each access to IALK_TBL_DATA by this amount. The address rolls over at the maximum address.	R/W

The IALK_TBL_ADDR register configures the address to access and whether to auto-increment with each read or write operation. The data to be written or to be read is accessed using the IALK_TBL_DATA register.

29.3.1.80 IALK_TBL_DATA : IA Lookup Database Data Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0360



Bit	Symbol	Function	R/W
0	VALID	Indicates whether the entry indicated by ADDR is valid or not. When set to 1, the IA Lookup table responds with found and the forwarding mask used is the value in FWD_MASK[3:0]. When set to 0, the response is the flooding mask of VLAN (IALK_VLANIDn.VLANID_FLOOD_MASK[3:0]). If VLAN is not enabled (VLANS_ENABLED is 0) then the response is not-found and the switch uses the response from the L2 FDB.	R/W
4:1	FWD_MASK[3:0]	Forwarding mask used for lookups that hit the entry and when VALID is set to 1. One bit per port (bit 0 = port 0, bit 1 = port 1, and so on).	R/W

Bit	Symbol	Function	R/W
31:5	—	The read values are undefined. The write value should be 0.	R/W

When reading from the IALK_TBL_DATA register, the entry indicated in IALK_TBL_ADDR is returned. When writing to this register, the entry indicated in IALK_TBL_ADDR is written to.

29.3.1.81 IALK_VLANIDn : IA Lookup VLANIDn Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x0380 + 0x4 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	VLANID_PRIO_VLD	VLANID_PRIO[2:0]			—	—	—	—	—	—	—	—	VLANID_FLOOD_MASK[3:0]			
Value after reset:	0	0	0	0	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	VLANID_LRN_ENA	VLANID_ENA	VLANID[11:0]											
Value after reset:	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	VLANID[11:0]	Configure the VLAN ID to be used for VLAN n (n: IALK_VLAN_CONFIG.VLANS_ENABLED). This bit is only valid when VLANID_ENA bit is set to 1. A value of 0 matches any VLAN ID.	R/W
12	VLANID_ENA	Enables this VLAN ID. When set to 1, the VLAN ID of the frame is compared against VLANID[11:0]. If a match is found, the lowest IALK_VLANIDn register selects the VLAN column to look for in the IA table.	R/W
13	VLANID_LRN_ENA	Configures whether automatic learning in the L2 FDB is allowed for frames matching VLAN ID. This also includes frames that match the VLAN ID and that the entry in the IA table is invalid.	R/W
15:14	—	The read values are undefined. The write value should be 0.	R/W
19:16	VLANID_FLOOD_MASK[3:0]	Flooding mask to be used for frames matching this VLAN ID but with an invalid entry in the IA table. One bit per port (bit 0 = port 0, bit 1 = port 1, and so on).	R/W
27:20	—	The read values are undefined. The write value should be 0.	R/W
30:28	VLANID_PRIO[2:0]	Priority to use for found responses.	R/W
31	VLANID_PRIO_VLD	Indicates if the priority in VLANID_PRIO[2:0] is valid.	R/W

The IALK_VLANIDn register is used to configure for each supported and enabled VLAN the ID and the flooding mask.

29.3.1.82 IMC_QLEVEL_Pn : Port n Queued Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x03C0 + 0x4 × n

Bit position:	31 28	27 24	23 20	19 16	15 12	11 8	7 4	3 0
Bit field:	QUEUE7[3:0]	QUEUE6[3:0]	QUEUE5[3:0]	QUEUE4[3:0]	QUEUE3[3:0]	QUEUE2[3:0]	QUEUE1[3:0]	QUEUE0[3:0]
Value after reset:	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0

Bit	Symbol	Function	R/W
3:0	QUEUE0[3:0]	A 4-bit value per queue indicating the number of frames stored in queue 0 Saturates at 15 if more than 15 frames are stored in the queue.	R
7:4	QUEUE1[3:0]	A 4-bit value per queue indicating the number of frames stored in queue 1 Saturates at 15 if more than 15 frames are stored in the queue.	R
11:8	QUEUE2[3:0]	A 4-bit value per queue indicating the number of frames stored in queue 2 Saturates at 15 if more than 15 frames are stored in the queue.	R
15:12	QUEUE3[3:0]	A 4-bit value per queue indicating the number of frames stored in queue 3 Saturates at 15 if more than 15 frames are stored in the queue.	R
19:16	QUEUE4[3:0]	A 4-bit value per queue indicating the number of frames stored in queue 4 Saturates at 15 if more than 15 frames are stored in the queue.	R
23:20	QUEUE5[3:0]	A 4-bit value per queue indicating the number of frames stored in queue 5 Saturates at 15 if more than 15 frames are stored in the queue.	R
27:24	QUEUE6[3:0]	A 4-bit value per queue indicating the number of frames stored in queue 6 Saturates at 15 if more than 15 frames are stored in the queue.	R
31:28	QUEUE7[3:0]	A 4-bit value per queue indicating the number of frames stored in queue 7 Saturates at 15 if more than 15 frames are stored in the queue.	R

The IMC_QLEVEL_Pn register indicates the port n status (real-time) of the number of frames stored in each of the output queues of the port.

29.3.1.83 LK_CTRL : Learning/Lookup Function Global Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0400

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	DISC_UNK_SRC[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	IND_VLAN	CLRTBL	—	DISC_UNK_DEST	ALW_MGRT	AGING_EN	LEARN_EN	LKUP_EN
Value after reset:	x	x	x	x	x	x	x	x	0	1	x	0	1	1	1	1

Bit	Symbol	Function	R/W
0	LKUP_EN	Lookup Controller Enable The Lookup controller can be enabled or disabled. When disabled, the switch forwarding engine skips the lookup and floods all incoming frames as if no address was found.	R/W
1	LEARN_EN	Learning Enable When set to 1 (enabled), a frame source address if not found in the lookup memory is added automatically by the hardware. The source lookup is followed by a store operation, storing the MAC address in the next free address of the lookup memory. When set to 0 (disabled), unknown source addresses is not added to the memory automatically and it is up to the software to maintain the table entries.	R/W
2	AGING_EN	Aging Enable When set to 1 (enabled), the aging process continuously scans the table for outdated entries and removes them. When set to 0 (disabled), no aging occurs.	R/W
3	ALW_MGRT	Allow Migration When set to 1 (enabled), existing dynamic entries in the Lookup table are updated if the source port of the entry changed. This requires LEARN_EN bit to be enabled. When set to 0 (disabled), no update occurs on dynamic entries when the incoming port number changes.	R/W

Bit	Symbol	Function	R/W
4	DISC_UNK_DEST	Discard Unknown Destination When set to 1 (enabled) and the destination address is not found, the frame is discarded. This setting does not affect BPDU frames, which are always accepted. When set to 0 (disabled), frames are flooded normally.	R/W
5	—	The read value is undefined. The write value should be 0.	R/W
6	CLRTBL	Clear Table Writes all table entries with 0. When this bit is set to 1, the bit remains 1 until the function has completed. Lookup is disabled during this time and the switch floods all frames. The BUSY bit within register LK_ADDR_CTRL is also set until the function has completed. This bit is set after reset to flush the table. Software might read the bit as 1 if the flushing is not completed and software should not enable the switch until the bit changes to 0.	R/W
7	IND_VLAN	Enable Independent VLAN Learning When enabled, the VLAN ID is stored together with the MAC address in the Lookup table to allow the same MAC address within different VLANs.	R/W
15:8	—	The read values are undefined. The write value should be 0.	R/W
19:16	DISC_UNK_SRC[3:0]	Discard Unknown Source Per port discard if source address not found. Bit 16 = port 0, bit 17 = port 1, and so on. When set to 1 (enabled) and the source address of an incoming frame is not found, the frame is discarded. The source is not learned, even if learning is allowed (INPUT_LEARN_BLOCK). Such discard events are counted in the switch per port input statistics IDISC_BLOCKEDn. When set to 0 (disabled), frames are accepted normally. This setting does not affect BPDU frames, which are always accepted. Independently from this setting, the unknown source interrupt is triggered and the new address is stored internally for retrieval with the LK_ADDR_CTRL.GETLASTNEW command.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

Note: For a normal switch operation, set bits [3:0] to all 1s.

29.3.1.84 LK_STATUS : Status Bits and Table Overflow Counter Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0404

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	LRNEVNT	—	OVERFLOW[13:0]													
Value after reset:	0	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	AGEADDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
15:0	AGEADDR[15:0]	Address the aging process will inspect when the aging timer expires next time.	R
29:16	OVERFLOW[13:0]	Counts number of table overflows that occurred (a new address was learned but the table had no storage and an older entry was deleted). The counter is cleared by writing into the register and having bit 16 set to 1.	R/W
30	—	The read value is undefined. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
31	LRNEVNT	Learn Event Indicates a new source address was detected. The bit is set whenever the lookup task cannot find the source address from a received frame in the MAC address table. This bit is cleared when writing 1 to it or when issuing the GETLASTNEW command in LK_ADDR_CTRL to retrieve the latest entry. The bit asserts for every newly learned source address, independent from automatic learning or any discard options that are configured. If the bit is already set from a previous event, it remains set.	R/W

29.3.1.85 LK_ADDR_CTRL : Address Table Transaction Control and Read/Write Address

Base address: ETHSW = 0x8012_0000

Offset address: 0x0408

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BUSY	DEL_PORT	CLEAR	LOOKUP	WAIT_COMP	READ	WRITE	GETLASTNEW	CLR_STATIC	CLR_DYNAMIC	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	ADDR_MSK[11:0]											
Value after reset:	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0

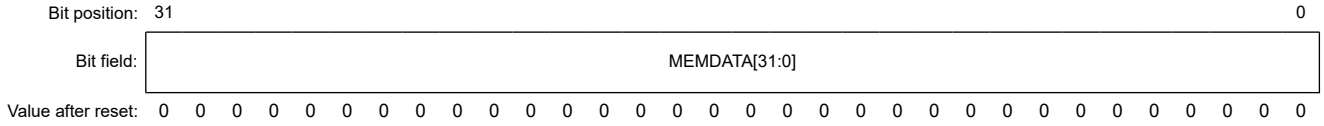
Bit	Symbol	Function	R/W
11:0	ADDR_MSK[11:0]	Memory address for read and write transactions. This is the address of a 69-bit entry. For the DEL_PORT bit, a port mask can be provided in these bits instead of the address. Bit 0 represents port 0, bit 1 port 1, and so on. When a LOOKUP function is executed and the address (LK_DATA_HI[16] = 1) is found, the memory address of the entry is returned. When a LOOKUP function is executed and the address (LK_DATA_HI[16] = 0) is not found, it returns the valid memory address of an empty entry which can be used to store the new data if required (for a 4096-size table, bits [11:3] contain the calculated hash value, bits [2:0] the offset within the 8 entries block).	R/W
21:12	—	The read values are undefined. The write value should be 0.	R/W
22	CLR_DYNAMIC	When set to 1, scans the complete table for valid dynamic entries and deletes them (writes entry with all 0s). This bit is cleared when the function has completed.	R/W
23	CLR_STATIC	When set to 1, scans the complete table for valid static entries and deletes them (writes entry with all 0s). This bit is cleared when the function has completed.	R/W
24	GETLASTNEW	When set to 1, retrieves the last source address that was not found in the table and places it into LK_DATA_LO/HI/HI2. The valid bit of the entry (bit LK_DATA_HI[16]) indicates if the address is new (when valid bit is 1) or not (when valid bit is 0) since the command was last issued. The port mask (LK_DATA_HI[24:21]) indicates at which port the new address was received. Whenever the learning task detects an unknown source address, it stores it into an internal storage that can be retrieved by this command. This occurs for each new source address, no matter if learning is enabled or not. It also stores the address when the no source discard feature is enabled. Only one entry is stored, if another new address is found before the data is read, it overwrites any existing data.	R/W
25	WRITE	When set to 1, perform a single write transaction. LK_DATA_LO/HI/HI2 must be set prior to starting the transactions.	R/W
26	READ	When set to 1, perform a single read transaction. Data is returned in LK_DATA_LO/HI/HI2.	R/W
27	WAIT_COMP	When set to 1, instructs to stall the processor bus until the transaction is completed. This allows performing of consecutive writes into this register with varying commands without the need for polling the BUSY bit.	R/W

Bit	Symbol	Function	R/W
28	LOOKUP	When set to 1, perform a lookup of the MAC address given in LK_DATA_LO/HI/HI2. When the lookup completed, the LK_DATA_HI upper 16-bit are updated with the corresponding bits read from the found entry. The ADDR_MSK field in this register shows the address where the entry is found. If the MAC address was not found, LK_DATA_HI valid bit [16] is 0 and bits [31:17] are arbitrary. The address field of this register is changed to the correct memory address that is empty and can be used to write the new entry. For example, it returns the hash calculated for the MAC address plus an offset to the empty entry within the 8 entries block. When LK_DATA_HI indicates a valid entry, LK_DATA_HI2 is valid too. This bit remains 1 together with the BUSY indication until the function completed.	R
29	CLEAR	When set to 1, writes all 0s to the entry selected by the given address set in ADDR_MSK[11:0]. If this bit is set together with the LOOKUP bit, first a lookup is performed and if the lookup succeeds, the entry is then deleted. The registers LK_DATA_LO/HI/HI2 are also cleared. The memory address in this register is set from the lookup result. If the lookup failed, the clear command is ignored and memory address is arbitrary.	R/W
30	DEL_PORT	When set to 1, scans the complete table for valid dynamic entries that contain the given ports in their destination port mask and deletes the ports or the complete entry. The port mask is provided in the ADDR_MSK[3:0] when writing this register (1 bit per port, bit 0 = port 0, bit 1 = port 1, and so on). The given port mask is ANDed with the port mask of each entry. When the result is non-zero, the entry is processed. Otherwise, it is ignored. When an entry is processed, the bits given in the mask are cleared in the port mask of the entry. If the resulting port mask is all 0s, the entry is deleted from the table (valid bit = 0). The function operates on dynamic entries only and does not affect static entries. This bit remains 1 together with the BUSY indication until the table is completely scanned.	R/W
31	BUSY	Transaction Busy Indication If this bit is 1, controller is busy. As long as the controller is busy, the corresponding command bit is set. When the controller becomes non-busy again, all command bits are cleared.	R

29.3.1.86 LK_DATA_LO : Lower 32-Bit Data of Lookup Memory Entry

Base address: ETHSW = 0x8012_0000

Offset address: 0x040C

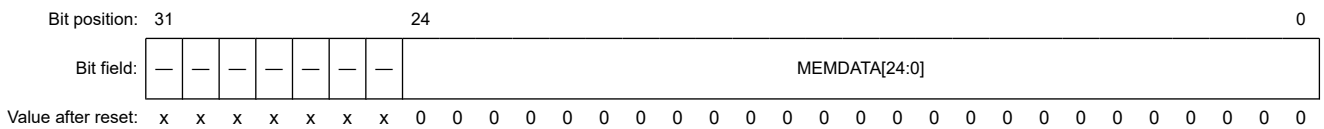


Bit	Symbol	Function	R/W
31:0	MEMDATA[31:0]	Memory Data [31:0] The lower 32-bit data of a memory entry. When writing MAC addresses, the first byte is [7:0] and the 4th byte is [31:24]. When reading, the data returned is the captured data of the last read transaction.	R/W

29.3.1.87 LK_DATA_HI : Higher 25-Bit Data of Lookup Memory Entry

Base address: ETHSW = 0x8012_0000

Offset address: 0x0410

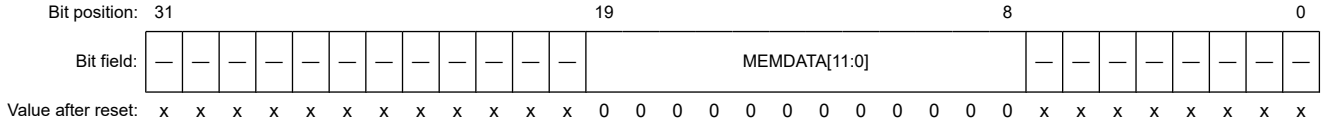


Bit	Symbol	Function	R/W
24:0	MEMDATA[24:0]	Memory Data [56:32] The next 25-bit data of a memory entry. When writing MAC addresses, the 5th byte is [7:0] and the 6th byte is [15:8]. The upper 9-bit are bits [56:48] of the memory.	R/W
31:25	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.88 LK_DATA_HI2 : Higher2 12-Bit Data of Lookup Memory Entry

Base address: ETHSW = 0x8012_0000

Offset address: 0x0414

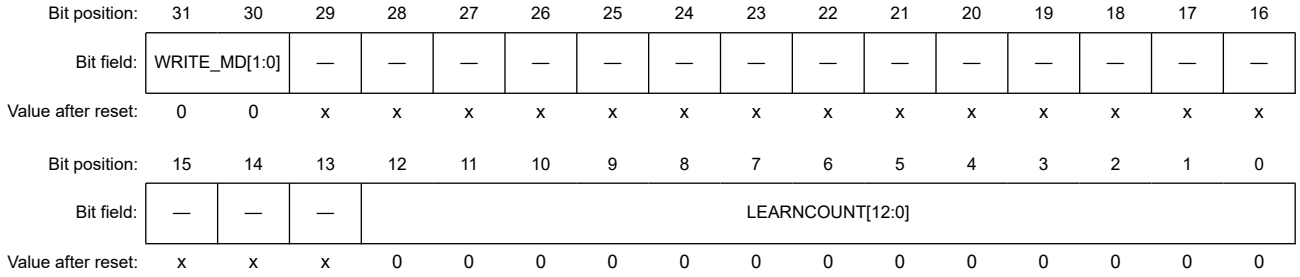


Bit	Symbol	Function	R/W
7:0	—	The read values are undefined. The write value should be 0.	R/W
19:8	MEMDATA[11:0]	Memory Data [68:57] The 12-bit VLAN ID of the entry, if VLAN IDs are stored in the address table.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

29.3.1.89 LK_LEARNCOUNT : Learned Address Count Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0418



Bit	Symbol	Function	R/W
12:0	LEARNCOUNT[12:0]	Number of Learned Addresses	R/W
29:13	—	The read values are undefined. The write value should be 0.	R/W
31:30	WRITE_MD[1:0]	These bits define how the LEARNCOUNT value is modified when writing into the register: 0 0: Sets LEARNCOUNT to given value 0 1: Increments the LEARNCOUNT value by 1 (atomic) 1 0: Decrements the LEARNCOUNT value by 1 (atomic) 1 1: Reserved, write has no effect on LEARNCOUNT	R/W

Software can increment the value LEARNCOUNT when it has added a MAC address into the memory. Software can decrement the value if an entry has been removed.

The value set in the LEARNCOUNT[12:0] is ignored when writing WRITE_MD[1:0] bit to 01b or 10b so that the hardware can change the value in parallel.

29.3.1.90 LK_AGETIME : Period of the Aging Timer

Base address: ETHSW = 0x8012_0000

Offset address: 0x041C

Bit position:	31								23																			0
Bit field:	—	—	—	—	—	—	—	—	AGETIME[23:0]																			
Value after reset:	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	AGETIME[23:0]	24-bit Timer Value	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

The timer is decremented once every 1024 switch operating clock cycles and reloaded with this value when it reaches 0. One table entry is inspected whenever the age-timer expires.

Therefore, a full aging timeout is the amount of time given in this register multiplied by the size of the lookup memory (number of entries).

Initial value: 16384 (for example, at 200 MHz switch operating clock, it is up to 5.7 minutes for 4096 entries table: n × 1024 × period × table-size = 16384 × 1024 × 5 ns × 4096)

29.3.1.91 MGMT_TAG_CONFIG : Management Tag Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x0480

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TAGFIELD[15:0]															
Value after reset:	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TYPE2_EN	TYPE1_EN	—	—	AL_FRAMES	ENABLE
Value after reset:	x	x	x	x	x	x	x	x	x	x	0	0	x	x	0	0

Bit	Symbol	Function	R/W
0	ENABLE	Enable Management Tag Insertion Module If set, the function adds tags to outgoing frames and removes tags from incoming frames at the management port. If this bit is 0 (reset default), no frame manipulation occurs.	R/W
1	AL_FRAMES	Enable Tag Insertion for All Frames If set, the function inserts the management tag into all transmitted frames at the management port. This requires that the CPU must be capable of receiving frames of at least 1526 bytes (1518 + 8) for normal frames and 1530 bytes for VLAN tagged frames. If this bit is 0 (reset default), only frames marked as management frames (BPDU frames) are tagged with extra control information. Other frames are not manipulated. The input processing (receive CPU to switch) always operates when ENABLE (bit [0]) = 1, independent from this setting.	R/W
3:2	—	The read values are undefined. The write value should be 0.	R/W
4	TYPE1_EN	When set, frames with a Type field that match the value in PRIORITY_TYPE1.TYPEVAL[15:0] have management tag inserted. This is in addition to BPDU frames which always have tag inserted. The valid bit [16] in PRIORITY_TYPE1 register has no effect for this Type field check. Validity is indicated when this bit is set.	R/W

Bit	Symbol	Function	R/W
5	TYPE2_EN	When set, frames with a Type field that match the value in PRIORITY_TYPE2.TYPEVAL[15:0] have management tag inserted. This is in addition to BPDU frames which always have tag inserted. The valid bit [16] in PRIORITY_TYPE2 register has no effect for this Type field check. Validity is indicated when this bit is set.	R/W
15:6	—	The read values are undefined. The write value should be 0.	R/W
31:16	TAGFIELD[15:0]	The value of the tag that is found in the first Type/Length field of the frame to identify that the control information is present within a frame. For example, [31:24] = first octet, [23:16] = 2nd octet.	R/W

29.3.2 1588 Timestamping Control Module Registers

29.3.2.1 TSM_CONFIG : Timestamping Control Module Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x504

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IRQ_TX_EN[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	IRQ_ATIME_OVER[1:0]		—	—	IRQ_EVT_PERIOD[1:0]		—	—	IRQ_EVT_OFFSET[1:0]		—	IRQ_TSFIFO_OVR	IRQ_TEST	IRQ_EN
Value after reset:	x	x	0	0	x	x	0	0	x	x	0	0	x	0	0	0

Bit	Symbol	Function	R/W
0	IRQ_EN	Final Interrupt enable Interrupts are possible only when this bit is set to 1.	R/W
1	IRQ_TEST	Software controlled interrupt for testing purposes When set, an interrupt is triggered immediately. Can be used to cause a software controlled interrupt for testing purposes. Self-clearing, always reads back 0.	R/W
2	IRQ_TSFIFO_OVR	Trigger interrupt enable for Transmit Timestamp Capture Overflow event When set to 1, the interrupt is enabled.	R/W
3	—	The read value is undefined. The write value should be 0.	R/W
5:4	IRQ_EVT_OFFSET[1:0]	Per-timer Trigger interrupt enable for the timer offset event When set to 1, the interrupt is enabled.	R/W
7:6	—	The read values are undefined. The write value should be 0.	R/W
9:8	IRQ_EVT_PERIOD[1:0]	Per-timer Trigger interrupt enable for the timer periodical event When set to 1, the interrupt is enabled.	R/W
11:10	—	The read values are undefined. The write value should be 0.	R/W
13:12	IRQ_ATIME_OVER[1:0]	Per-timer Trigger interrupt enable for the timer wrap (reached its maximum) When set to 1, the interrupt is enabled.	R/W
15:14	—	The read values are undefined. The write value should be 0.	R/W
19:16	IRQ_TX_EN[3:0]	Per Port Transmit Timestamp Capture Interrupt Enable One bit for each port: Bit 16 = Port 0 Bit 17 = Port 1 Bit 18 = Port 2 Bit 19 = Port 3 When set, an interrupt is generated when the transmit timestamp register of the port has stored a new timestamp.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The TSM_CONFIG register is used for module configuration and interrupt enable mask.

29.3.2.2 TSM_IRQ_STAT_ACK : Interrupt Status/Acknowledge Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x508

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IRQ_TX[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	IRQ_ATIME_OVER[1:0]		—	—	IRQ_EVT_PERIOD[1:0]		—	—	IRQ_EVT_OFFSET[1:0]		—	IRQ_TSFIFO_OVR	IRQ_TEST	IRQ_STAT
Value after reset:	x	x	0	0	x	x	0	0	x	x	0	0	x	0	0	0

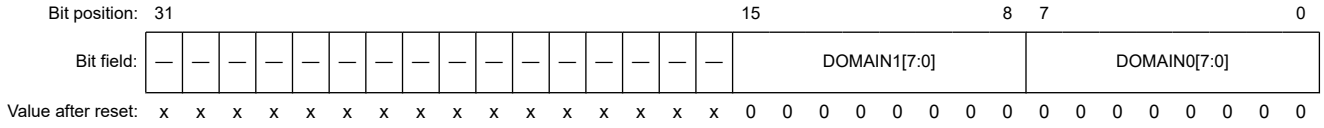
Bit	Symbol	Function	R/W
0	IRQ_STAT	Interrupt Pending Status Asserted as long as the interrupt is active.	R
1	IRQ_TEST	Test Interrupt Pending Status If an event occurs, the corresponding bit is latched high. Writing the bit with 1 clears the interrupt.	R/W
2	IRQ_TSFIFO_OVR	Transmit Timestamp Capture Overflow Interrupt Pending Status If an event occurs, the corresponding bit is latched high. Indicates that an overflow has occurred for a timestamp FIFO. The actual port where the event occurred can be determined by reading the register TS_FIFO_STATUS. The interrupt is cleared in the TS_FIFO_STATUS register by clearing the overflow latched event.	R
3	—	The read value is undefined. The write value should be 0.	R/W
5:4	IRQ_EVT_OFFSET[1:0]	Per-timer Offset Interrupt Pending Status If an event occurs, the corresponding bit is latched high. Writing the bit with 1 clears the interrupt. One bit for a timer.	R/W
7:6	—	The read values are undefined. The write value should be 0.	R/W
9:8	IRQ_EVT_PERIOD[1:0]	Per-timer Periodical Interrupt Pending Status If an event occurs, the corresponding bit is latched high. Writing the bit with 1 clears the interrupt. One bit for a timer.	R/W
11:10	—	The read values are undefined. The write value should be 0.	R/W
13:12	IRQ_ATIME_OVER[1:0]	Per-timer Overflow Interrupt Pending Status If an event occurs, the corresponding bit is latched high. Writing the bit with 1 clears the interrupt. One bit for a timer.	R/W
15:14	—	The read values are undefined. The write value should be 0.	R/W
19:16	IRQ_TX[3:0]	Per Port Transmit Timestamp Capture Interrupt One bit for each port: Bit 16 = Port 0 Bit 17 = Port 1 Bit 18 = Port 2 Bit 19 = Port 3 If the port's transmit timestamp register has stored a new timestamp, the corresponding bit is latched high. Writing a bit with 1 clears the interrupt.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The TSM_IRQ_STAT_ACK register indicates the interrupt status and acknowledge for timestamping control module.

29.3.2.3 PTP_DOMAIN : Domain Number of PTP Frame

Base address: ETHSW = 0x8012_0000

Offset address: 0x50C



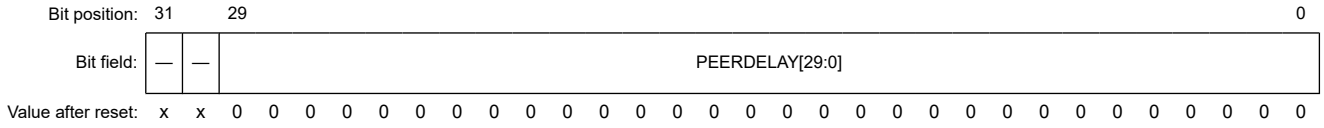
Bit	Symbol	Function	R/W
7:0	DOMAIN0[7:0]	DomainNumber to Match Against for Timer 0 When the PTP domainNumber field matches this value, the hardware timer 0 is used for timestamping the frame on receive and on transmit.	R/W
15:8	DOMAIN1[7:0]	DomainNumber to Match Against for Timer 1 When the PTP domainNumber field matches this value, the hardware timer 1 is used for timestamping the frame on receive and on transmit.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

Sets the default hardware timer to use for timestamping frames when PTPAUTORESPONSE_Pn is enabled based on the domainNumber of the PTP frame.

29.3.2.4 PEERDELAY_Pn_T0 : Port n Peer Delay Value for Timer 0 (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x540 + 0x10 × n

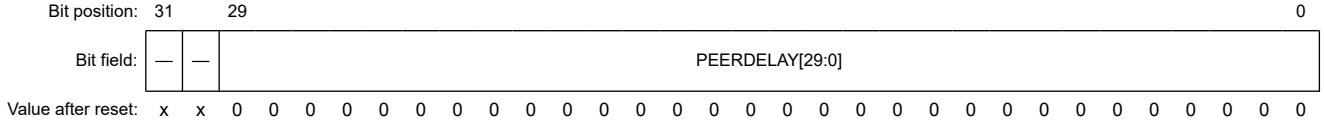


Bit	Symbol	Function	R/W
29:0	PEERDELAY[29:0]	Peer Delay Value Determined at the Port n for Timer 0 The value is added to the correction field of the received frame when a transient time correction is performed. This time value is set by the application after performing peer delay measurement on the port. Required only when the network uses peer-to-peer transparent clocks. A value of 0 is necessary to implement an end-to-end transparent clock. Value is in nanoseconds and must be less than 10^9. It must be set by the application after measuring the latency at the port where it receives SYNC messages.	R/W
31:30	—	The read values are undefined. The write value should be 0.	R/W

29.3.2.5 PEERDELAY_Pn_T1 : Port n Peer Delay Value for Timer 1 (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x544 + 0x10 × n



Bit	Symbol	Function	R/W
29:0	PEERDELAY[29:0]	Peer Delay Value Determined at the Port n for Timer 1 The value is added to the correction field of the received frame when a transient time correction is performed. This time value is set by the application after performing peer delay measurement on the port. Required only when the network uses peer-to-peer transparent clocks. A value of 0 is necessary to implement an end-to-end transparent clock. Value is in nanoseconds and must be less than 10^9. It must be set by the application after measuring the latency at the port where it receives SYNC messages.	R/W
31:30	—	The read values are undefined. The write value should be 0.	R/W

29.3.2.6 TS_FIFO_STATUS : Transmit Timestamp FIFO Status Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x5C0

Bit position:	31											19		16											3		0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	FF_OVR[3:0]				—	—	—	—	—	—	—	—	—	—	—	—	FF_VALID[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	FF_VALID[3:0]	Per-port indication that a valid timestamp is available in the corresponding FIFO of the port	R
15:4	—	The read values are undefined. The write value should be 0.	R/W
19:16	FF_OVR[3:0]	Per-port indication that a timestamp cannot be written to the FIFO because of the FIFO being full. This indicates that at least one timestamp information was lost. Writing a 1 to the corresponding bit clears the value.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The TS_FIFO_STATUS register indicates the transmit timestamp FIFO status, per-port indication of valid data in the FIFO, and whether an overrun has occurred.

29.3.2.7 TS_FIFO_READ_CTRL : Transmit Timestamp FIFO Read Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x5C4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	TS_ID[6:0]							—	TS_SEL	—	TS_VALID	—	—	PORT_NUM[1:0]	
Value after reset:	x	0	0	0	0	0	0	0	x	0	x	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PORT_NUM[1:0]	Port Number to Read from Write to this register to select the port number to read from. Writing to this register invalidates any previously read value (TS_VALID is set to 0).	R/W
3:2	—	This bit is read as 0. The write value should be 0.	R/W
4	TS_VALID	When reading from this register, this bit is 1 if the FIFO indicated by PORT_NUM contained valid data.	R

Bit	Symbol	Function	R/W
5	—	The read value is undefined. The write value should be 0.	R/W
6	TS_SEL	When TS_VALID is 1, TS_SEL indicates the timer used for the read timestamp.	R
7	—	The read value is undefined. The write value should be 0.	R/W
14:8	TS_ID[6:0]	When TS_VALID is 1, TS_ID indicates the ID specified by the application through the management tag control information, if present.	R
31:15	—	The read values are undefined. The write value should be 0.	R/W

The TS_FIFO_READ_CTRL register is used to control transmit timestamp FIFO read control. Selects the FIFO (port) to read from and returns the metadata such as valid indication, timer used for the timestamp, and timestamp ID. On write, the port number is written to select the FIFO (port) to read from. On read, the corresponding FIFO is read if not empty. Every read on this register generates a new read from the FIFO as long as the FIFO has data. Whether the read was successful can be determined by the TS_VALID field.

29.3.2.8 TS_FIFO_READ_TIMESTAMP : 32-bit Timestamp Value Read from FIFO

Base address: ETHSW = 0x8012_0000

Offset address: 0x5C8

Bit position:	31																												0
Bit field:	TIMESTAMP[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TIMESTAMP[31:0]	32-bit timestamp value read from the FIFO When TS_FIFO_READ_CTRL is read and TS_VALID is 1, this register must be read next to read the corresponding 32-bit timestamp value.	R

29.3.3 Interrupt Control Registers

29.3.3.1 INT_CONFIG : Interrupt Enable Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x600

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PATTERN_INT	TDMA_INT	TSM_INT	SRCFLT_WD_INT	EFP_INT	—	—	—	—	—	—	—	—	IRQ_MAC_EEE[2:0]		
Value after reset:	0	0	0	0	0	x	x	x	x	x	x	x	x	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	IRQ_LINK[2:0]			HUB_INT	PRP_INT	DLR_INT	IRQ_TEST	LK_NEW_SRC	—	MDIO1	IRQ_EN
Value after reset:	x	x	x	x	x	0	0	0	0	0	0	0	0	x	0	0

Bit	Symbol	Function	R/W
0	IRQ_EN	Interrupt Global Enable When set and if any of the interrupt events occurs and is enabled, the interrupt signal is asserted 1.	R/W
1	MDIO1	Enable Interrupt on Transaction Complete from MDIO Controller When set to 1, the interrupt is enabled.	R/W
2	—	The read value is undefined. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
3	LK_NEW_SRC	Enable Interrupt for New Source Address When set, an interrupt is triggered when the lookup process detects a new (unknown) source address on a port. The interrupt triggers on every unknown source detected, independent of learning (INPUT_LEARN_BLOCK) or whether source discard (LK_CTRL) was enabled or not.	R/W
4	IRQ_TEST	When set, an interrupt is triggered immediately. Can be used to cause a software controlled interrupt for testing purposes.	R/W
5	DLR_INT	Enable Interrupt for DLR When set to 1, the interrupt is enabled. This interrupt event is controlled by the DLR_IRQ_CONTROL register. The interrupt signal (ETHSW_DLR) is not affected by the setting of this bit. See section 29.3.11.4. DLR_IRQ_CONTROL : DLR Interrupt Control Register.	R/W
6	PRP_INT	Enable Interrupt for PRP When set to 1, the interrupt is enabled. This interrupt event is controlled by the PRP_IRQ_CONTROL register. The interrupt signal (ETHSW_PRP) is not affected by the setting of this bit. See section 29.3.12.7. PRP_IRQ_CONTROL : PRP Interrupt Control Register.	R/W
7	HUB_INT	Enable Interrupt for HUB When set to 1, the interrupt is enabled. This interrupt event is controlled by the HUB_IRQ_CONTROL register. The interrupt signal (ETHSW_HUB) is not affected by the setting of this bit. See section 29.3.13.7. HUB_IRQ_CONTROL : HUB Interrupt Control Register.	R/W
10:8	IRQ_LINK[2:0]	Per Line Port Phy Link Change Interrupt Enable When set, an interrupt is generated when the Link status input from PHY of a port changes. One bit for each line port: Bit 8 = Port 0, Bit 9 = Port 1, Bit 10 = Port 2.	R/W
15:11	—	The read values are undefined. The write value should be 0.	R/W
18:16	IRQ_MAC_EEE[2:0]	Per Line Port MAC interrupt When set, an interrupt is generated when the EEE function of the port changed state. Bit 16 = Port 0, Bit 17 = Port 1, Bit 18 = Port 2	R/W
26:19	—	The read values are undefined. The write value should be 0.	R/W
27	EFP_INT	Enable Interrupt for Extended Frame Parser When set to 1, the interrupt is enabled. This interrupt event is controlled by registers in Extended Frame Parser. See section 29.4.19.11. Interrupt Source.	R/W
28	SRCFLT_WD_INT	MAC Address Source Filtering Watchdog Asserts when the source filtering watchdog triggers.	R/W
29	TSM_INT	Enable Interrupt for TSM (Timer, Timestamping) When set to 1, the interrupt is enabled. This interrupt event is controlled by the TSM_CONFIG register. See section 29.3.2.1. TSM_CONFIG : Timestamping Control Module Configuration Register.	R/W
30	TDMA_INT	Enable Interrupt for TDMA scheduler When set to 1, the interrupt is enabled. This interrupt event is controlled by the TDMA_IRQ_CONTROL register. See section 29.3.14.16. TDMA_IRQ_CONTROL : TDMA IRQ Control Register.	R/W
31	PATTERN_INT	Enable Interrupt for RX Pattern Matcher When set to 1, the interrupt is enabled. This interrupt event is controlled by the PATTERN_IRQ_CONTROL register. The interrupt signal (ETHSW_PTRNn, n = 0 to 11) is not affected by the setting of this bit. See section 29.3.15.3. PATTERN_IRQ_CONTROL : RX Pattern Matcher Interrupt Control Register.	R/W

29.3.3.2 INT_STAT_ACK : Interrupt Status/ACK Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x604

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PATTERN_INT	TDMA_INT	TSM_INT	SRCFLT_WD_INT	EFP_INT	—	—	—	—	—	—	—	—	IRQ_MAC_EEE[2:0]		
Value after reset:	0	0	0	0	0	x	x	x	x	x	x	x	x	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	IRQ_LINK[2:0]			HUB_INT	PRP_INT	DLR_INT	IRQ_TEST	LK_NEW_SRC	—	MDIO1	IRQ_PEND
Value after reset:	x	x	x	x	x	0	0	0	0	0	0	0	0	x	0	0

Bit	Symbol	Function	R/W
0	IRQ_PEND	Interrupt Pending Status Asserted as long as any pending and enabled interrupt exists. Each interrupt latch bit in this register asserts when the interrupt event occurred, independent of the enable setting in INT_CONFIG. However, the IRQ_PEND asserts only if a latch bit and its corresponding enable bit are both set for any of the events. When set, the signal (ETHSW_INTR) asserts if the global enable bit INT_CONFIG.IRQ_EN is set.	R
1	MDIO1	Latched Interrupt Status for MDIO1 If an event occurs, the corresponding bit is latched high. Writing the bit with 1 clears the latch.	R/W
2	—	The read value is undefined. The write value should be 0.	R/W
3	LK_NEW_SRC	Latched Interrupt Status for LK_NEW_SRC If an event occurs, the corresponding bit is latched high. Writing the bit with 1 clears the latch.	R/W
4	IRQ_TEST	Interrupt Status for IRQ_TEST This bit is set as long as INT_CONFIG.IRQ_TEST is 1. To clear the interrupt, the INT_CONFIG.IRQ_TEST must be cleared.	R
5	DLR_INT	Interrupt Pending Status from DLR Module Asserted as long as the interrupt register of the DLR module has pending interrupts (represents the status of signal ETHSW_DLR). To clear the interrupt, the status/acknowledge register of the DLR module must be written. Writing this bit has no effect. See section 29.3.11.5. DLR_IRQ_STAT_ACK : DLR Interrupt Status/ACK Register.	R
6	PRP_INT	Interrupt Pending Status from PRP Module Asserted as long as the interrupt register of the PRP module has pending interrupts (represents status of the ETHSW_PRP signal). To clear the interrupt, the status/acknowledge register of the PRP module must be written. Writing this bit has no effect. See section 29.3.12.8. PRP_IRQ_STAT_ACK : PRP Interrupt Status/ACK Register.	R
7	HUB_INT	Interrupt Pending Status from Hub Module Asserted as long as the interrupt register of the Hub module has pending interrupts (represents status of the ETHSW_HUB signal). To clear the interrupt, the status/acknowledge register of the Hub module must be written. Writing this bit has no effect. See section 29.3.13.8. HUB_IRQ_STAT_ACK : HUB Interrupt Status/ACK Register.	R
10:8	IRQ_LINK[2:0]	Interrupt Pending per Line Port Phy Link Change Interrupt When set, the corresponding port link state changes. Writing a bit with 1 clears the interrupt.	R/W
15:11	—	The read values are undefined. The write value should be 0.	R/W
18:16	IRQ_MAC_EEE[2:0]	Interrupt Pending Status per Line Port MAC Interrupt When set, an interrupt is generated when the EEE function of the port changed state. Writing a bit with 1 clears the interrupt.	R/W
26:19	—	The read values are undefined. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
27	EFP_INT	Interrupt from Extended Frame Parser If an event occurs, the corresponding bit is latched high. To clear the interrupt the registers in Extended Frame Parser must be written. Writing this bit has no effect. See section 29.4.19.11. Interrupt Source.	R/W
28	SRCFLT_WD_INT	Interrupt Pending Status for MAC Source Filtering Watchdog If an event occurs, the corresponding bit is latched high. Writing a bit with 1 clears the interrupt.	R/W
29	TSM_INT	Interrupt Pending Interrupt Indication from TSM (Timestamping) module If an event occurs, the corresponding bit is latched high. To clear the interrupt the TSM_IRQ_STAT_ACK register must be written. Writing this bit has no effect.	R
30	TDMA_INT	Interrupt Pending Status from TDMA Scheduler Asserted as long as any TDMA interrupt is enabled and is pending. To clear the interrupt, the TDMA_IRQ_STAT_ACK register must be used. Writing this bit has no effect.	R
31	PATTERN_INT	Interrupt Pending Status from RX Pattern Matcher Module Asserted as long as the interrupt register of the module has pending interrupts (represents OR of all the module interrupt output of the RX Pattern Matcher). To clear the interrupt, the status/acknowledge register of the pattern module must be written. Writing this bit has no effect. See section 29.3.15.4. PATTERN_IRQ_STAT_ACK : RX Pattern Matcher Interrupt Status/ACK Register.	R

29.3.4 Hardware Timers Registers

29.3.4.1 ATIME_CTRLn : Timer n Control Register (n = 0, 1)

Base address: ETHSW = 0x8012_0000

Offset address: 0x680 + 0x20 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CAPTURE_ALL	CAPTURE	—	RESTART	—	—	—	EVT_PERIOD_RST	EVT_PERIOD_ENA	—	EVT_OFFSET_ENA	ONE_SHOT	ENABLE
Value after reset:	x	x	x	0	0	x	0	x	x	x	0	0	x	0	0	0

Bit	Symbol	Function	R/W
0	ENABLE	When set to 1, the timer starts incrementing. When set to 0, the timer stops at the current value.	R/W
1	ONE_SHOT	Avoid timer wrap around. If set, the timer stops at maximum. An overflow interrupt (TSM_CONFIG.IRQ_ATIME_OVER) occurs (if enabled) when the maximum is reached. When cleared (default), the timer operates continuously.	R/W
2	EVT_OFFSET_ENA	Enable Offset Event When set to 1, an offset-event interrupt can be generated (if enabled) when the offset correction has completed. The bit is cleared when the offset event is reached so no further event is created until the bit is set again. The timer offset value should be set before.	R/W
3	—	The read value is undefined. The write value should be 0.	R/W
4	EVT_PERIOD_ENA	Enable Periodical Event When set to 1, a period event interrupt can be generated (if enabled). The timer period value should be set before.	R/W

Bit	Symbol	Function	R/W
5	EVT_PERIOD_RST	Reset Timer on Periodical Event When set to 1, the timer is reset to 0 when the period setting is reached (causing an periodical event). If cleared, the counter increments continuously unit it wraps around.	R/W
8:6	—	The read values are undefined. The write value should be 0.	R/W
9	RESTART	Resets the Timer to Zero (Command Bit) This has no effect on the counter enable. If the counter is enabled while the command is triggered, the timer is reset to 0 and starts counting from there. When set, all other bits of this register are ignored.	R/W
10	—	The read value is undefined. The write value should be 0.	R/W
11	CAPTURE	Capture Time Value (Command Bit) When set, the current time is captured and can be read from the ATIMEn and ATIME_SECn registers. The bit is cleared when the capture has completed and the time value can be read from the timer register.	R/W
12	CAPTURE_ALL	Capture All Timers Value (Command Bit) This bit is the same as the CAPTURE bit but causes all timers in the system to capture the current time simultaneously. Can be used to validate drifting of the clocks. The bit is cleared when the capture has completed, and the time value can be read from the timer register.	R/W
31:13	—	The read values are undefined. The write value should be 0.	R/W

Note: The command bits can be used to trigger the corresponding events directly. When command bit is set to 1, the write values of all other bits are ignored.

29.3.4.2 ATIMEn : Timer n Count Register (n = 0, 1)

Base address: ETHSW = 0x8012_0000

Offset address: 0x684 + 0x20 × n

Bit position:	31																												0
Bit field:	TIMER_VAL[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TIMER_VAL[31:0]	Timer Value A write sets the timer. A read returns the last capture value. To read the current value, a capture command must be issued in the ATIME_CTRLn register. The value represents true nanoseconds (ns). The seconds value, see section 29.3.4.7. ATIME_SECn : Timer n Seconds Time Register (n = 0, 1), must be programmed before writing to this register.	R/W

29.3.4.3 ATIME_OFFSETn : Timer n Offset Register (n = 0, 1)

Base address: ETHSW = 0x8012_0000

Offset address: 0x688 + 0x20 × n

Bit position:	31																												0
Bit field:	OFFSET[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	OFFSET[31:0]	Value used for performing offset corrections without changing the drift correction The value is used in two different ways: ● If ATIME_OFFS_CORRn is 0, the value is immediately added to the current timer value when this register is written. The value must be given in true nanoseconds. When a negative value is given, the value is effectively subtracted. The actual correction value has an error of 2 timer clock periods, therefore to the desired correction value a correction factor of 2 × ts_cyc (timer clock cycle period) must be added. The rate for ATIME_OFFSETn must be [- (PERIOD - 2 × ATIME_INCn), + (PERIOD - 2 × ATIME_INCn)], where period is the value in ATIME_EVT_PERIODn. This function must not be used when the timer is being used by the TDMA. ● If ATIME_OFFS_CORRn is not 0, the value defines how many offset corrections to be performed. After each correction, the value is decremented by 1 until it reaches 0. When it has reached 0, no more offset corrections are performed. The register is then also reset to 0 and if enabled (EVT_OFFSET_ENA in ATIME_CTRLn register), an offset event interrupt is generated. ATIME_OFFS_CORRn must be written prior to writing this register to define the intended function.	R/W

29.3.4.4 ATIME_EVT_PERIODn : Timer n Periodic Event Register (n = 0, 1)

Base address: ETHSW = 0x8012_0000

Offset address: 0x68C + 0x20 × n

Bit position:	31																												0
Bit field:	PERIOD[31:0]																												
Value after reset:	0	0	1	1	1	0	1	1	1	0	0	1	1	0	1	0	1	1	0	0	1	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PERIOD[31:0]	Value for generating periodic events Each time the nanoseconds timer has reached this time, the period event occurs and the nanoseconds timer restarts. If enabled (EVT_PERIOD_ENA in ATIME_CTRLn register), the period event interrupt is generated. The value represents true nanoseconds (ns). Defaults to 1×10^9 representing one second. Allowable value is 10^9 or 0 only.	R/W

29.3.4.5 ATIME_CORRn : Timer n Correction Period Register (n = 0, 1)

Base address: ETHSW = 0x8012_0000

Offset address: 0x690 + 0x20 × n

Bit position:	31	30																											0
Bit field:	—	CORR_PERIOD[30:0]																											
Value after reset:	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
30:0	CORR_PERIOD[30:0]	Correction Period Defines after how many clock cycles (125 MHz) the timer should be corrected once. Bit 31 is unused and is always 0. The amount of correction is defined in ATIME_INCn.CORR_INC[6:0]. Setting the increment amount to 0 stops the timer for one clock cycle, slowing it down. Larger values can be used to speed up the timer. The correction value is the reciprocal of the ppm deviation between the master and slave oscillators. This value is given in clock cycles, not in nanoseconds as other values.	R/W

Bit	Symbol	Function	R/W
31	—	The read value is undefined. The write value should be 0.	R/W

29.3.4.6 ATIME_INCn : Timer n Increment Register (n = 0, 1)

Base address: ETHSW = 0x8012_0000

Offset address: 0x694 + 0x20 × n

Bit position:	31									22						16	14							8	6						0
Bit field:	—	—	—	—	—	—	—	—	—	OFFS_CORR_INC[6:0]							—	CORR_INC[6:0]							—	CLK_PERIOD[6:0]						
Value after reset:	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	x	0	0	0	0	0	0	0	x	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	CLK_PERIOD[6:0]	Clock Period of the Timestamping Clock (125 MHz) in nanoseconds The timer increments by this amount with every clock cycle. The value must be set to 0x08 in this LSI. The ATIME_EVT_PERIODn must be an integer multiple of this value.	R/W
7	—	The read value is undefined. The write value should be 0.	R/W
14:8	CORR_INC[6:0]	Correction Increment Value This value is added once every time the correction timer has advanced the number of clock cycles given in ATIME_CORRn. A value smaller than in bits CLK_PERIOD[6:0] slows down the timer. A value larger than in bits CLK_PERIOD[6:0] speeds up the timer.	R/W
15	—	The read value is undefined. The write value should be 0.	R/W
22:16	OFFS_CORR_INC[6:0]	Offset Correction Increment Value This value is added once every time the offset correction counter has advanced the number of clock cycles given in ATIME_OFFS_CORRn.	R/W
31:23	—	The read values are undefined. The write value should be 0.	R/W

29.3.4.7 ATIME_SECn : Timer n Seconds Time Register (n = 0, 1)

Base address: ETHSW = 0x8012_0000

Offset address: 0x698 + 0x20 × n

Bit position:	31																														0
Bit field:	SEC_TIME[31:0]																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SEC_TIME[31:0]	Seconds Time Value The seconds timer is incremented when the nanoseconds timer has reached its period setting. When written, the value is stored in a local register only. It is then loaded into the seconds timer when the ATIMEn register is written. On a read, it returns the last captured value (after read command was issued in ATIME_CTRLn).	R/W

29.3.4.8 ATIME_OFFS_CORRn : Timer n Offset Correction Counter Register (n = 0, 1)

Base address: ETHSW = 0x8012_0000

Offset address: 0x69C + 0x20 × n

Bit position:	31																												0
Bit field:	OFFS_CORR_CNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	OFFS_CORR_CNT[31:0]	Offset Correction Counter Defines, after how many clock cycles (125 MHz) the timer should be incremented once by the amount given in ATIME_INCn.OFFS_CORR_INC[6:0]. These bits are used in combination with the ATIME_OFFSETn value to distribute the time change over a longer time. This avoids jumps in time and causes only low jitter during offset corrections.	R/W

29.3.5 MDIO Master Registers

29.3.5.1 MDIO_CFG_STATUS : MDIO Configuration and Status Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x700

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CLKDIV[8:0]									—	DISPREAM	HOLD[2:0]			READERR	BUSY
Value after reset:	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BUSY	MDIO Busy If set, a MDIO transaction is currently ongoing. If cleared, the application can access other registers.	R
1	READERR	MDIO Read Error If set, the last read transaction had no response from a PHY and the data read could be invalid. This can happen, if the PHY address does not match any PHY that is available on the MDIO bus.	R
4:2	HOLD[2:0]	MDIO Hold Time Setting The output timing is based on the rising edge of MDC. 0 0 0: 1 PCLKM clock cycle (default) 0 0 1: 3 PCLKM clock cycles 0 1 0: 5 PCLKM clock cycles 0 1 1: 7 PCLKM clock cycles 1 0 0: 9 PCLKM clock cycles 1 0 1: 11 PCLKM clock cycles 1 1 0: 13 PCLKM clock cycles 1 1 1: 15 PCLKM clock cycles	R/W
5	DISPREAM	Disable Preamble 0: Enable Preamble 1: Disable Preamble	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:7	CLKDIV[8:0]	MDIO Clock Divisor A value of 5 to 511 can be set. The frequency is (PCLKM clock freq.) / (2 × divisor + 1). The reset default is 40. Setting the divisor to 0 disables MDC.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.5.2 MDIO_COMMAND : MDIO PHY Command Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x704

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TRANINIT	—	—	—	—	—	PHYADDR[4:0]					REGADDR[4:0]				
Value after reset:	0	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	REGADDR[4:0]	Register Address	R/W
9:5	PHYADDR[4:0]	PHY Address	R/W
14:10	—	The read values are undefined. The write value should be 0.	R/W
15	TRANINIT	If set to 1, a read transaction is initiated.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.5.3 MDIO_DATA : MDIO Data Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x708

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MDIO_DATA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MDIO_DATA[15:0]	• When written: Initiates a write transaction to the PHY. The MDIO_COMMAND register must be initialized. The busy status bit (MDIO_CFG_STATUS.BUSY) is set immediately and cleared when the write transaction has finished. • When read: Returns the data read from the PHY register after a read transaction has completed (initiated by writing the MDIO_COMMAND register).	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.6 MAC Control/Status Registers

Every MAC provides an individual set of registers are listed in following tables.

29.3.6.1 REV_Pn : Port n MAC Core Revision (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x800 + 0x400 × n

Bit position:	31																												0
Bit field:	REV[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	x	1	x

Bit	Symbol	Function	R/W
31:0	REV[31:0]	MAC Core Revision n = 0 to 2: 0x00010006 n = 3: 0x00010003	R

29.3.6.2 COMMAND_CONFIG_Pn : Port n Command Configuration Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x808 + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	TIMER_SEL	—	—	TX_TRUNCATE	EFPI_SELECT	ENA_10	NO_LGTH_CHK	CNTL_FRM_ENA	—	—	—	—	—	—	—
Value after reset:	x	0	x	x	0	0	0	1	0	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	SW_RESET	—	TX_CRC_APPEND	HD_ENA	TX_ADDR_INS	PAUSE_IGNORE	PAUSE_FWD	—	PAD_EN	PROMIS_EN	ETH_SPEED	TDMA_PREBUF_DIS	RX_ENA	TX_ENA
Value after reset:	x	x	0	0	1	0	0	0	0	0	0	1	0	0	1	1

Bit	Symbol	Function	R/W
0	TX_ENA	Enable/Disable MAC Transmit Path When set to 0, the MAC transmit function is disabled. When set to 1, the MAC transmit function is enabled. Do not change this value to 0. See section 29.4.23.1. Restriction.	R/W
1	RX_ENA	Enable/Disable MAC Receive Path When set to 0, the MAC receive function is disabled. When set to 1, the MAC receive function is enabled.	R/W
2	TDMA_PREBUF_DIS	Disables pre-buffering of frames in the transmit MAC when TDMA is enabled. When set to 1, the MAC does not request a new frame from the IMC until the current frame is completed. This can cause the IPG between frames to be more than the value in TX_IPG_LENGTH. When set to 0, a small buffer in the MAC affects the precision of the TDMA for stopping the port (gating queues) so a bigger time guard band must be used when programming the TCVs.	R/W
3	ETH_SPEED	Operation Mode Definition 0: 10/100 Megabit mode 1: 1 Gigabit mode	R/W
4	PROMIS_EN	Enable/Disable MAC Promiscuous Operation When asserted (set to 1), all frames are received without Unicast address filtering. This bit is always fixed to 1.	R
5	PAD_EN	Enable/Disable Frame Padding Remove on Receive If enabled (set to 1), padding is removed from received frames before they are given to the user application. If disabled (reset to a value 0), no padding is removed on receive by the MAC. This bit is always fixed to 0.	R

Bit	Symbol	Function	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	PAUSE_FWD	Terminate/Forward Pause Frames If enabled (set to 1), pause frames are forwarded to the user application. In normal mode (reset to a value 0), pause frames are terminated and discarded in the MAC. This bit is always fixed to 0.	R
8	PAUSE_IGNORE	Ignore Pause Frame Quanta If enabled (set to 1), received pause frames are ignored by the MAC. When disabled (reset to a value 0), the transmit process is stopped for the amount of time specified in the pause quanta received within the pause frame.	R/W
9	TX_ADDR_INS	Non writable bit, fixed to 0 always.	R
10	HD_ENA	Enable auto full/half-duplex operation (set to 1) or full-duplex only (set to 0). To set half-duplex, set this bit to 1 and PHY_DUPLEX[2:0] bits of Switch Core Duplex Mode Register (SWDUPC) to 0. Otherwise, full-duplex is selected.	R/W
11	TX_CRC_APPEND	Enable CRC Append on Transmit If set to 1, the TX appends a CRC to all outgoing frames. If frame manipulation operations are activated within the switch, all MACs should be appended CRC on transmit. If no frame manipulation is configured within the switch, the CRC may be forwarded together with the frame throughout the switch.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	SW_RESET	Self Clearing Reset Command Bit When set to 1, it clears the statistics registers and disables the MAC transmit and receive data path. Only when this bit is written in the MAC Port 0 register that the statistics of all ports are cleared. Writing this bit on any other register of the port has no effect on the statistics counters. This bit is automatically cleared when the reset is complete.	R/W
22:14	—	The read values are undefined. The write value should be 0.	R/W
23	CNTL_FRM_ENA	MAC Control Frame Enable When set to 0, MAC Control frames (type = 0x8808: Pause frame) with any opcode other than 0x0001 are silently discarded. When set to 1, MAC control frames with any opcode other than 0x0001 are accepted and forwarded to the Client interface.	R/W
24	NO_LGTH_CHK	Payload Length Check Disable When set to 0, the Core checks the payload length of the frame with the Frame Length/Type field. When set to 1, the payload length check is disabled.	R/W
25	ENA_10	This bit has no effect except PHYSPEED bit of STATUS_Pn register.	R/W
26	EFPI_SELECT	Extended Frame Parser (EFP) Enable 0: EFP disable 1: EFP enable	R/W
27	TX_TRUNCATE	Selects whether to truncate the transmitted frames when the frame is received with an error. In cut-through mode, the frame may have commenced transmission before the CRC is checked. Setting this bit to 1 causes the switch to shorten the frame by 8 to 12 bytes when the frame is marked as an errored frame by the switch. When set to 0 the frame length is not modified.	R/W
29:28	—	The read values are undefined. The write value should be 0.	R/W
30	TIMER_SEL	Selects the default timer to use for timestamping operations on transmit and on receive. The value is used when not overridden by the PTP auto-response function, pattern matchers or force forwarding information in a management tag. 0: Use timer 0 1: Use timer 1	R/W
31	—	The read value is undefined. The write value should be 0.	R/W

29.3.6.3 MAC_ADDR_0_Pn : Port n MAC Address Register 0 (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x80C + 0x400 × n

Bit position:	31																												0
Bit field:	MAC_ADDR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	MAC_ADDR[31:0]	The first 4 bytes of the MAC address of the port. First byte is bits [7:0]. The MAC address is used on locally generated frames such as pause frames, peer-delay response.	R/W

29.3.6.4 MAC_ADDR_1_Pn : Port n MAC Address Register 1 (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x810 + 0x400 × n

Bit position:	31																15												0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MAC_ADDR[15:0]												
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MAC_ADDR[15:0]	The last 2 bytes of the MAC address of the port. Bits [7:0] is the 5th byte and bits [15:8] is the 6th byte.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.6.5 FRM_LENGTH_Pn : Port n Maximum Frame Length Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x814 + 0x400 × n

Bit position:	31																	13												0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FRM_LENGTH[13:0]											
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	1	0	1	1	1	1	1	1	0

Bit	Symbol	Function	R/W
13:0	FRM_LENGTH[13:0]	Maximum Frame Length Defines a 14-bit maximum frame length used by the MAC receive logic to check frames. This is the maximum total length of a frame allowed. Therefore, if VLAN frames must be supported, the value should be adjusted to 1522 or 1526 for single or double tagged VLAN support respectively.	R/W
31:14	—	The read values are undefined. The write value should be 0.	R/W

To allow the management port to accept a frame with the special management tag, the allowed length must be increased by 8 for this port. As typical setting (support double VLAN), 1534 on the management port and 1526 on all other ports.

29.3.6.6 PAUSE_QUANT_Pn : Port n MAC Pause Quanta (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x818 + 0x400 × n

Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PAUSE_QUANT[15:0]														
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	PAUSE_QUANT[15:0]	Pause Quanta A 16-bit value and when set, in increment of 512 Ethernet bit times, the pause quanta used in each pause frame is sent to the remote Ethernet device.	R
31:16	—	The read values are undefined.	R

29.3.6.7 MAC_LINK_QTRIG_Pn : Port n Trigger Event Configuration Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x81C + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ENABLE	MODE	DLR_MODE	TRIGGERED	—	—	—	—	QUEUE_MASK[7:0]							
Value after reset:	0	0	0	0	x	x	x	x	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	PORT_MASK[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	PORT_MASK[3:0]	Per-port Bit Mask When set to 1 for a port, a frame is triggered from the closed queues indicated by QUEUE_MASK.	R/W
15:4	—	The read values are undefined. The write value should be 0.	R/W
23:16	QUEUE_MASK[7:0]	1-bit per queue indicating from which queues a frame is transmitted from the ports indicated by PORT_MASK. A single frame is transmitted per indicated port in PORT_MASK among the queues indicated by QUEUE_MASK.	R/W
27:24	—	The read values are undefined. The write value should be 0.	R/W
28	TRIGGERED	When MODE is set to 1, TRIGGERED indicates whether a frame was transmitted. When MODE is set to 0, TRIGGERED is always 0. This flag clears when the register is written.	R/W
29	DLR_MODE	When set to 0, the DLR state machine is ignored. When set to 1, the Link Queue Trigger occurs only if the DLR state machine is in the NORMAL or FAULT state.	R/W
30	MODE	When set to 0, only a single Link_Status frame is generated. This is to prevent sending multiple frames due to link flapping. When set to 1, a Link_Status frame is generated for every 1 → 0 transition in the link status.	R/W
31	ENABLE	Write to 1 to enable the Link Queue Trigger feature. When the link status (phy_link) transitions from 1 → 0, a trigger event is generated to the memory controller for the ports and queues indicated in PORT_MASK and QUEUE_MASK.	R/W

The MAC_LINK_QTRIG_Pn register enables and configures a trigger event when the link changes from active to lost.

29.3.6.8 PTPCLOCKIDENTITY1_Pn : Port n PTP Clock Identity 1 Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x830 + 0x400 × n

Bit position:	31							24	23							16	15							8	7							0
Bit field:	CLK_IDENTITY3[7:0]								CLK_IDENTITY2[7:0]								CLK_IDENTITY1[7:0]								CLK_IDENTITY0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CLK_IDENTITY0[7:0]	20, portIdentity.ClockIdentity[0]	R/W
15:8	CLK_IDENTITY1[7:0]	21, portIdentity.ClockIdentity[1]	R/W
23:16	CLK_IDENTITY2[7:0]	22, portIdentity.ClockIdentity[2]	R/W
31:24	CLK_IDENTITY3[7:0]	23, portIdentity.ClockIdentity[3]	R/W

The PTPCLOCKIDENTITY1_Pn register sets the first 4 octets of the 8-byte PTP ClockIdentity used for automatic PDELAY_RESP generation.

29.3.6.9 PTPCLOCKIDENTITY2_Pn : Port n PTP Clock Identity 2 Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x834 + 0x400 × n

Bit position:	31							24	23							16	15							8	7							0
Bit field:	CLK_IDENTITY7[7:0]								CLK_IDENTITY6[7:0]								CLK_IDENTITY5[7:0]								CLK_IDENTITY4[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CLK_IDENTITY4[7:0]	24, portIdentity.ClockIdentity[4]	R/W
15:8	CLK_IDENTITY5[7:0]	25, portIdentity.ClockIdentity[5]	R/W
23:16	CLK_IDENTITY6[7:0]	26, portIdentity.ClockIdentity[6]	R/W
31:24	CLK_IDENTITY7[7:0]	27, portIdentity.ClockIdentity[7]	R/W

The PTPCLOCKIDENTITY2_Pn register sets the last 4 octets of the 8-byte PTP ClockIdentity used for automatic PDELAY_RESP generation.

29.3.6.10 PTPAUTORESPONSE_Pn : Port n PTP Auto Response Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x838 + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PORTNUM0[7:0]								PORTNUM1[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	D_TIMER	ARSP_EN
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
0	ARSP_EN	Auto Response Enable Enable automatic generation of IEEE 1588v2 Layer2 peer delay response (PDELAY_RESP) messages. When this bit is 1, the MAC detects PDELAY_REQ messages causing an automatic reply with PDELAY_RESP. When this bit is 0, the MAC does not cause automatic response generation. The PRIORITY_TYPE registers can be used to define the priority for the response frames.	R/W
1	D_TIMER	Default timer to use for auto-response generation 0: Use timer 0 1: Use timer 1	R/W
15:2	—	The read values are undefined. The write value should be 0.	R/W
23:16	PORTNUM1[7:0]	29, portIdentity.PortNumber[1] (lsb)	R/W
31:24	PORTNUM0[7:0]	28, portIdentity.PortNumber[0] (msb)	R/W

The PTPAUTORESPONSE_Pn register enables automatic PDELAY_RESP message generation and defines the PTP PortNumber.

29.3.6.11 STATUS_Pn : Port n Status Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x840 + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BR_VERIF_ST[2:0]			LK_DST_ERR	TX_UNDFLW	PHYDUPLEX	PHYLINK	PHYSPEED[1:0]	
Value after reset:	x	x	x	x	x	x	x	0	0	0	0	0	1	0	x	x

Bit	Symbol	Function	R/W
1:0	PHYSPEED[1:0]	Currently Active PHY Interface Speed The information is valid only if the link is up (PHYLINK = 1). Otherwise, it can be arbitrary. Fixed to 10b for port 3 (management port) 0 0: 10 Mbps 0 1: 100 Mbps 1 0: 1 Gbps 1 1: Reserved	R

Bit	Symbol	Function	R/W
2	PHYLINK	Link status from PHY interface This is a direct representation of Link status input (ETHSW_PHYLINKn, n: 0 to 2) from PHY. Fixed to 1 for port 3 (management port) 0: link down 1: link up	R
3	PHYDUPLEX	Duplex status from PHY interface The information is valid only if the PHYLINK = 1. Otherwise, it can be arbitrary. This is a direct representation of PHY_DUPLEX[2:0] bits of Switch Core Duplex Mode Register (SWDUPC). Therefore, the actual PHY status may differ from this. Fixed to 1 for port 3 (management port) 0: half-duplex 1: full-duplex	R
4	TX_UNDFLW	Indicates that the transmit MAC underflow. This shall never occur during normal operation. Cleared when writing to 1.	R/W
5	LK_DST_ERR	Indicates that the L2 destination lookup process failed to complete in time before the next frame was received at the port. This should never occur under normal operation. The cause could be from IPG violations in the received frames. Cleared when writing to 1.	R/W
8:6	BR_VERIF_ST[2:0]	Indicates the current status of the verification according to clause 30.14.1.2 of the 802.3br specification Fixed to 000b for port 3 (management port) 0 0 0: Unknown (during reset) 0 0 1: Initial (when preemption is disabled) 0 1 0: Verifying 0 1 1: Succeeded 1 0 0: Failed 1 0 1: Disabled (if preempt verification is disabled)	R
31:9	—	The read values are undefined. The write value should be 0.	R/W

The STATUS_Pn register is a read-only register that contains information of the current speed of the port, link and duplex status as communicated by the PHY interface to the MAC.

29.3.6.12 TX_IPG_LENGTH_Pn : Port n Transmit IPG Length Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x844 + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	MINRTC3GAP[4:0]				
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	0	1/0*1	1/0*1	1/0*1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	TX_IPG_LENGTH[4:0]				
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	0	1	1	0	0

Bit	Symbol	Function	R/W
4:0	TX_IPG_LENGTH[4:0]	Define transmit interpacket gap in octets. Allowed values are in the range of 8 to 31.	R/W
15:5	—	The read values are undefined. The write value should be 0.	R/W
20:16	MINRTC3GAP[4:0]	Set the MinRTC3Gap parameter which defines the IPG to use when in RED period (as indicated by the TDMA scheduler). This is for use with Profinet IRT. Default is 14 bytes. The management port (Port 3) does not support this field, and bits [20:16] are not writable. Read back always return 0. If a port is not operating in Profinet IRT, bits [20:16] must be written with the same value as bits [4:0].	R/W
31:21	—	The read values are undefined. The write value should be 0.	R/W

Note 1. Initial value of MINRTC3GAP for the management port (Port 3) is 0x00. Others are 0x0E.

29.3.6.13 EEE_CTL_STAT_Pn : Port n MAC EEE Functions Control and Status (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x848 + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	STLH_LPI_IND	—	STLH_TXBUSY	STLH_LPI_TXHOLD	STLH_LPI_REQ
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	0	x	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	ST_LPI_IND	ST_TXAVAIL	ST_TXBUSY	ST_LPI_TXHOLD	ST_LPI_REQ	—	—	—	—	—	LPI_TXHOLD	LPI_REQ	EEE_AUTO
Value after reset:	x	x	x	0	0	0	0	0	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
0	EEE_AUTO	EEE Automatic Mode of Operation When this bit is 1, the MAC begins transmitting LPI sequences as soon as it is in idle for the duration configured in register EEE_IDLE_TIME_Pn. The bit should be set to 1 only following initialization of the timer registers (EEE_IDLE_TIME_Pn, EEE_TWSYS_TIME_Pn). When this bit is 0, the MAC does not perform automatic LPI transmission.	R/W
1	LPI_REQ	Request LPI Transmission when MAC Becomes Idle When this bit is 1, the MAC continues to transmit any available frames in its output queues and then transmit LPI sequences. When it transitioned into LPI, the ST_LPI_REQ status bit asserts. As long as in LPI state, the MAC does not serve new frames arriving in its output queues. Writing LPI_REQ = 1 and LPI_TXHOLD = 0 ensures all frames in the transmit queue are sent before entering LPI. If LPI_TXHOLD is set together with LPI_REQ, the MAC stops immediately after currently ongoing frame transmission completed and does not empty its output queue. Before clearing LPI_REQ, the LPI_TXHOLD bit should be set to prevent the MAC from immediately transmitting frames following LPI removal (for example, not respecting any wake time). A typical application controlled power down sequence is: LPI_REQ = 1 → wait until ST_LPI_REQ = 1 → LPI_TXHOLD = 1 → wait quiet timeout or data available → LPI_REQ = 0 → wait wake timeout → LPI_TXHOLD = 0. This bit can be set at any time (even when EEE_AUTO = 1). Set this bit to 0 for normal operation.	R/W
2	LPI_TXHOLD	MAC Transmission Hold When this bit is 1, the MAC continues to transmit a currently ongoing frame, if any, and then stops reading any more frames from its transmit FIFO/Queue. This bit must be set before LPI_REQ is cleared to ensure the MAC transitions to idle after LPI. Then LPI_TXHOLD is cleared after the (application controlled) wake time expired, allowing the MAC to transmit frames normally again. Using LPI_REQ and LPI_TXHOLD controls requires the application to implement corresponding quiet and wake timers. Set this bit to 0 for normal operation or when EEE_AUTO is used.	R/W
7:3	—	The read values are undefined. The write value should be 0.	R/W
8	ST_LPI_REQ	Status (real time) of Internal LPI_REQ to the MAC Asserts either as a result of writing the LPI_REQ bit, or when the automatic mode is enabled and the idle time has expired.	R
9	ST_LPI_TXHOLD	Status (real time) of Internal LPI_TXHOLD to the MAC Indicates the MAC is stopped and no longer serving frames. It asserts either as a result of writing the LPI_REQ or LPI_TXHOLD bit, or when the automatic mode is enabled and the MAC is not yet allowed to transmit frames.	R
10	ST_TXBUSY	Status (real time) if the MAC is currently transmitting.	R
11	ST_TXAVAIL	Status (real time) if the MAC transmit FIFO has data available for transmission.	R

Bit	Symbol	Function	R/W
12	ST_LPI_IND	Status (real time) of Received LPI Asserts as long as the RS layer of the MAC detects LPI sequences at its receive interface.	R
15:13	—	The read values are undefined. The write value should be 0.	R/W
16	STLH_LPI_REQ	Status (latched high) of Internal LPI_REQ to the MAC Bit clears on register read.	R
17	STLH_LPI_TXHOLD	Status (latched high) of Internal LPI_TXHOLD to the MAC Bit clears on register read.	R
18	STLH_TXBUSY	Status (latched high) if the MAC is/was Transmitting Bit clears on register read.	R
19	—	The read value is undefined. The write value should be 0.	R/W
20	STLH_LPI_IND	Status (latched high) of Received LPI (ST_LPI_IND) Bit clears on register read.	R
31:21	—	The read values are undefined. The write value should be 0.	R/W

The EEE_CTL_STAT_Pn register controls MAC EEE and indicates the status.

29.3.6.14 EEE_IDLE_TIME_Pn : Port n EEE Idle Time Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x84C + 0x400 × n

Bit position:	31																													0
Bit field:	EEE_IDLE_TIME[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	EEE_IDLE_TIME[31:0]	Time (−1) the transmitter must be idle before transmission of LPI begins. A 32-bit value in steps of 32 switch operating clock cycles. A value of 0 disables the timer. The value must be set to 1 less count.	R/W

29.3.6.15 EEE_TWSYS_TIME_Pn : Port n EEE Wake Up Time Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x850 + 0x400 × n

Bit position:	31																													0
Bit field:	EEE_WKUP_TIME[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	EEE_WKUP_TIME[31:0]	Time (−1) after PHY wakeup until the MAC is allowed to begin transmitting the first frame again. A 32-bit value in steps of switch operating clock cycles. A value of 0 disables the timer. The value must be set to 1 less count.	R/W

29.3.6.16 IDLE_SLOPE_Pn : Port n MAC Traffic Shaper Bandwidth Control (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x854 + 0x400 × n

Bit position:	31																			10										0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	IDLE_SLOPE[10:0]										
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	IDLE_SLOPE[10:0]	Traffic Shaper Bandwidth Control When a non-zero value is set, the shaper is active and controls the bandwidth. When this bit is 0, the shaper is disabled. The valid value is 2 to 2046.	R/W
31:11	—	The read values are undefined. The write value should be 0.	R/W

29.3.6.17 CT_DELAY_Pn : Port n Cut-Through Delay Indication Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x858 + 0x400 × n

Bit position:	31																					8								0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CT_DELAY[8:0]								
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	CT_DELAY[8:0]	Delay Value in 400 ns / 40 ns / 8 ns increments (frequency of the MII PHY interface)	R/W
31:9	—	The read values are undefined. The write value should be 0.	R/W

The CT_DELAY_Pn register indicates Cut-Through delay. This is a programmable value in MII clock cycles that can delay the assertion of the cut-through flag to the forwarding engine in order to hide the variable latency of the forwarding decision. The default value is 0 unless required for specific protocols like Profinet IRT.

Recommended values are:

- 10 Mbit/s: 0 (400 ns increments)
- 100 Mbit/s: 32 (40 ns increments)
- 1 Gbit/s: 0 (8 ns increments)

29.3.6.18 BR_CONTROL_Pn : Port n 802.3br Frame Configuration Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x85C + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	RX_MCRC_INV	TX_MCRC_INV	RX_STRICT_BR_CTL	RX_BR_SMD_DIS	RX_STRICT_PRE
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	TX_VERIFY_TIME[6:0]							—	—	ADDFRAGSIZE[1:0]		—	RESPONSE_DIS	VERIFY_DIS	PREEMPT_ENA
Value after reset:	x	0	0	0	1	0	1	0	x	x	0	0	x	0	0	0

Bit	Symbol	Function	R/W
0	PREEMPT_ENA	When set to 1, enables 802.3br Frame Preemption. This bit must be set to 1 to allow 802.3br operation.	R/W
1	VERIFY_DIS	When set to 1, disables the verify process required for preemption operation. When PREEMPT_ENA is set to 1, preemption is not operational until the verify process validates that the peer port is also capable of performing frame preemption. Setting VERIFY_DIS disables this process and allows frame preemption without running the verify process.	R/W
2	RESPONSE_DIS	When set to 1 prevents the MAC from responding to "verify" frames. "verify" frames are always replied to unless PREEMPT_ENA is set to 0 and RESPONSE_DIS is set to 1. This bit must be kept at 0 to be compliant with 802.3br.	R/W
3	—	The read value is undefined. The write value should be 0.	R/W
5:4	ADDFRAGSIZE[1:0]	Minimum fragment size in increments of 64 bytes. Sets the minimum mPacket size when preempting a Preemptable frame. The default value of 0 corresponds to 64 bytes, a value of 1 corresponds to 128 bytes, and so on.	R/W
7:6	—	The read values are undefined. The write value should be 0.	R/W
14:8	TX_VERIFY_TIME[6:0]	Preemption verification timeout in milliseconds. When preemption is enabled and verification is running, this is the timeout to wait for a RESPONSE frame after sending a VERIFY frames +/− 1 ms. VERIFY frames are sent after the timeout up to two more times. Default value is 10 ms. When the value is set to less than 5 ms, it does not meet the 20% precision required by the 802.3br, so it is recommended to use larger times.	R/W
15	—	The read value is undefined. The write value should be 0.	R/W
16	RX_STRICT_PRE	When set to 1, the preamble is checked so all bytes except the SFD are 0x55. When set to 0, only the last 2 bytes of the preamble are checked (SFD/SMD and FRAG_COUNT). It is recommended to set this bit to 1 to comply with the 802.3br specification. This bit must be set to 0 if only non-802.3br traffic is expected (for example, normal Ethernet traffic) and if custom preamble is used.	R/W
17	RX_BR_SMD_DIS	When set to 1, the receiver does not decode the 802.3br SMDs and assumes all frames are express frames. This bit must be set to 0 for correct operation with 802.3br, and can be set to 1 when 802.3br is not enabled to avoid false detection of SMDs. Setting this bit to 1 also causes any preempted frame to be aborted, bringing the re-assembly state machine to IDLE.	R/W
18	RX_STRICT_BR_CTL	When set to 1, strict checking of VERIFY and RESPONSE frames is enabled. When set to 1, the frame contents and frame length checks are also performed on these frames. The mCRC is always checked regardless of the value of this register. This bit must be set to 0 to be compliant with the functionality described in IEEE 802.3br.	R/W
19	TX_MCRC_INV	When set to 1, the 32-bit XOR mask used to calculate the mCRC for transmitted frames is inverted. This bit must always be written to 0 and only used for debugging.	R/W
20	RX_MCRC_INV	When set to 1, the 32-bit XOR mask used to calculate the mCRC for received frames is inverted. This bit must always be written to 0 and only used for debugging.	R/W
31:21	—	The read values are undefined. The write value should be 0.	R/W

The BR_CONTROL_Pn register is a configuration register for the 802.3br frame preemption.

29.3.7 MAC Statistics Registers

Every MAC provides an individual set of statistics as listed in following tables.

The counters are 64-bit wide. To read a 64-bit value, first, the counter as given in table below must be read. The returned value is the lower 32 bits of the counter. At the same time, the upper 32 bits are latched into register STATS_HIWORD. The STATS_HIWORD is a single global register that stores only the higher counter bits for the most recently read statistics counter. If it is not read before another counter (in any MAC page) is accessed the value is overridden with upper data from the newly read counter. Global means although it can be read from within a MAC page, it exists only once in hardware and the very same register is read independently of which MAC page is used.

The counters can be cleared by two possible commands:

1. Issuing a soft-reset (SW_RESET) to the Port 0 MAC (COMMAND_CONFIG_P0). This also clears the test registers STATS_CLEAR_VALUELO/HI and all counters will be initialized to 0.

2. Writing register STATS_CTRL with bit 0 = 1 (CLRALL). Sets all counters to the value given in registers STATS_CLEAR_VALUELO/HI. Setting a non-zero value can be used for testing purposes. Typically an all zero value should be set for normal operation.

As the counter clearing requires many clock cycles (~ 30 × 4 ports) to sequentially update all counter memory locations a read to any statistics counter should be avoided until the clear is completed. This is indicated by register bit STATS_CTRL.CLRBUSY.

An individual per port clearing of the statistics is not available.

29.3.7.1 AFRAMESTRANSMITTEDOK_Pn : Port n MAC Transmitted Valid Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x868 + 0x400 × n

Bit position:	31																												0
Bit field:	TXVALIDCOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TXVALIDCOUNT[31:0]	PORT n, this field indicates the number of MAC Valid Transmitted, including pause.	R

29.3.7.2 AFRAMESRECEIVEDOK_Pn : Port n MAC Received Valid Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x86C + 0x400 × n

Bit position:	31																												0
Bit field:	RXVALIDCOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXVALIDCOUNT[31:0]	PORT n, this field indicates the number of MAC Valid Received, including pause.	R

29.3.7.3 AFRAMECHECKSEQUENCEERRORS_Pn : Port n MAC FCS Error Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x870 + 0x400 × n

Bit position:	31																												0
Bit field:	FCSERRCOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FCSERRCOUNT[31:0]	PORT n, this field indicates the number of MAC Valid Length but CRC error.	R

29.3.7.4 AALIGNMENTERRORS_Pn : Port n MAC Alignment Error Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x874 + 0x400 × n

Bit position:	31																												0
Bit field:	ALGNERRCOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ALGNERRCOUNT[31:0]	PORT n, this field indicates the number of MAC Odd Number of Nibbles (MII) Received.	R

29.3.7.5 AOCTETSTRANSMITTEDOK_Pn : Port n MAC Transmitted Valid Frame Octets Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x878 + 0x400 × n

Bit position:	31																												0
Bit field:	TXVALIDOCTETS[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TXVALIDOCTETS[31:0]	PORT n, this field indicates the octets (the payload only) of MAC Valid Transmitted.	R

29.3.7.6 AOCTETSRECEIVEDOK_Pn : Port n MAC Received Valid Frame Octets Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x87C + 0x400 × n

Bit position:	31																												0
Bit field:	RXVALIDOCTETS[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXVALIDOCTETS[31:0]	PORT n, this field indicates the octets (the payload only) of MAC Valid Received.	R

29.3.7.7 ATXPAUSEMACCTRLFRAMES_Pn : Port n MAC Transmitted Pause Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x880 + 0x400 × n

Bit position:	31																												0
Bit field:	TXPAUSECOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TXPAUSECOUNT[31:0]	PORT n, this field indicates the number of MAC Valid Pause Transmitted.	R

29.3.7.8 ARXPAUSEMACCTRLFRAMES_Pn : Port n MAC Received Pause Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x884 + 0x400 × n

Bit position:	31																												0
Bit field:	RXPAUSECOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RXPAUSECOUNT[31:0]	PORT n, this field indicates the number of MAC Valid Pause Received.	R

29.3.7.9 IFINERRORS_Pn : Port n MAC Input Error Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x888 + 0x400 × n

Bit position:	31																												0
Bit field:	INERRCOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	INERRCOUNT[31:0]	PORT n, this field indicates the number of MAC Any Error During Reception such as CRC, Length, PHY Error, RX FIFO Overflow.	R

29.3.7.10 IFOUTERRORS_Pn : Port n MAC Output Error Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x88C + 0x400 × n

Bit position:	31																												0
Bit field:	OUTERRCOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	OUTERRCOUNT[31:0]	PORT n, this field indicates the number of MAC Frame Transmitted with PHY error.	R

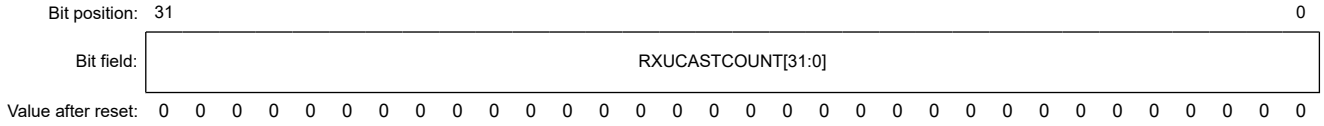
Increments on internal errors (for example, TX FIFO underflow) or when cut-through forwarding was used and a frame with error was received.

This register does not count aborted frames (half-duplex collisions).

29.3.7.11 IFINUCASTPKTS_Pn : Port n MAC Received Unicast Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x890 + 0x400 × n

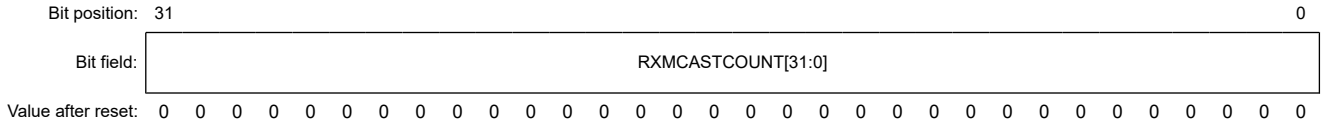


Bit	Symbol	Function	R/W
31:0	RXUCASTCOUNT[31:0]	PORT n, this field indicates the number of MAC Unicast Frame Valid Received.	R

29.3.7.12 IFINMULTICASTPKTS_Pn : Port n MAC Received Multicast Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x894 + 0x400 × n

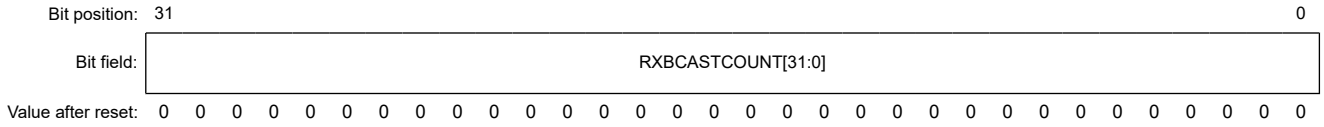


Bit	Symbol	Function	R/W
31:0	RXMCASTCOUNT[31:0]	PORT n, this field indicates the number of MAC Multicast Frame Valid Received.	R

29.3.7.13 IFINBROADCASTPKTS_Pn : Port n MAC Received Broadcast Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x898 + 0x400 × n

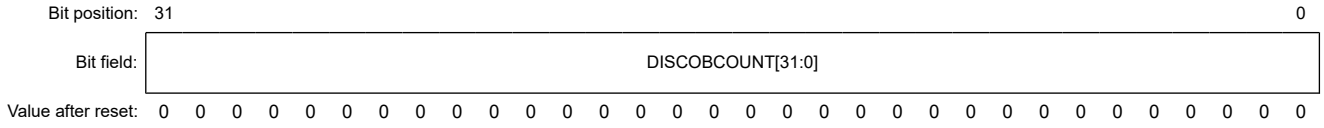


Bit	Symbol	Function	R/W
31:0	RXBCASTCOUNT[31:0]	PORT n, this field indicates the number of MAC Broadcast Frame Valid Received.	R

29.3.7.14 IFOUTDISCARDS_Pn : Port n MAC Discarded Outbound Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x89C + 0x400 × n

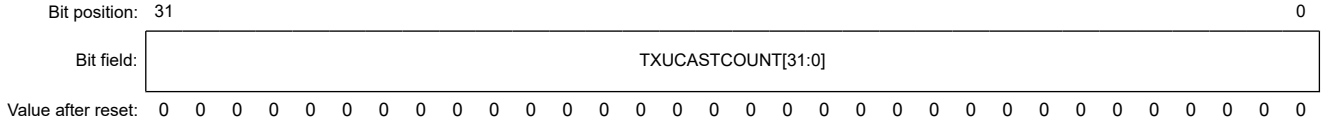


Bit	Symbol	Function	R/W
31:0	DISCOBCOUNT[31:0]	Not Applicable	R

29.3.7.15 IFOUTUCASTPKTS_Pn : Port n MAC Transmitted Unicast Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8A0 + 0x400 × n

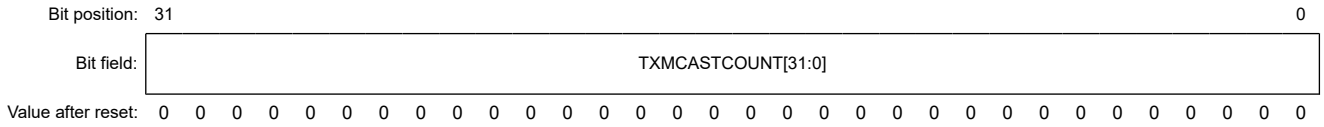


Bit	Symbol	Function	R/W
31:0	TXUCASTCOUNT[31:0]	PORT n, this field indicates the number of MAC Unicast Frame Valid Transmitted.	R

29.3.7.16 IFOUTMULTICASTPKTS_Pn : Port n MAC Transmitted Multicast Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8A4 + 0x400 × n

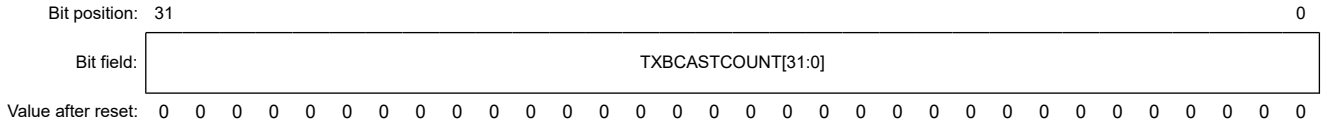


Bit	Symbol	Function	R/W
31:0	TXMCASTCOUNT[31:0]	PORT n, this field indicates the number of MAC Multicast Frame Valid Transmitted.	R

29.3.7.17 IFOUTBROADCASTPKTS_Pn : Port n MAC Transmitted Broadcast Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8A8 + 0x400 × n

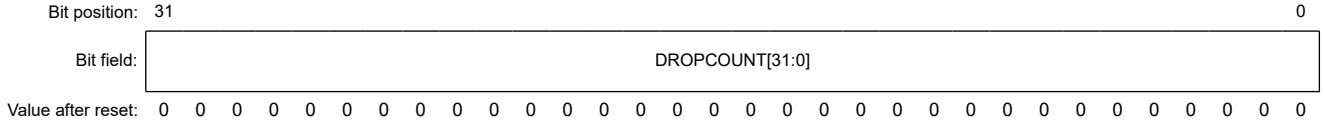


Bit	Symbol	Function	R/W
31:0	TXBCASTCOUNT[31:0]	PORT n, this field indicates the number of MAC Broadcast Frame Valid Transmitted.	R

29.3.7.18 ETHERSTATSDROPEVENTS_Pn : Port n MAC Dropped Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8AC + 0x400 × n

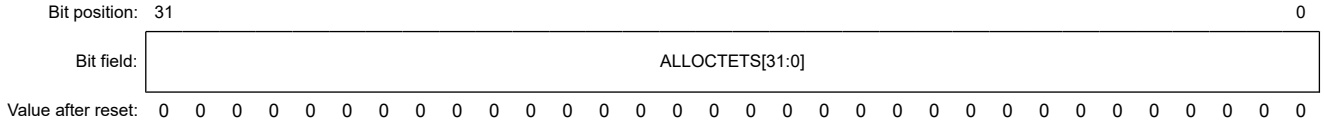


Bit	Symbol	Function	R/W
31:0	DROPCOUNT[31:0]	PORT n, this field indicates the number of MAC RX FIFO Full at frame start.	R

29.3.7.19 ETHERSTATSOCTETS_Pn : Port n MAC All Frame Octets Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8B0 + 0x400 × n

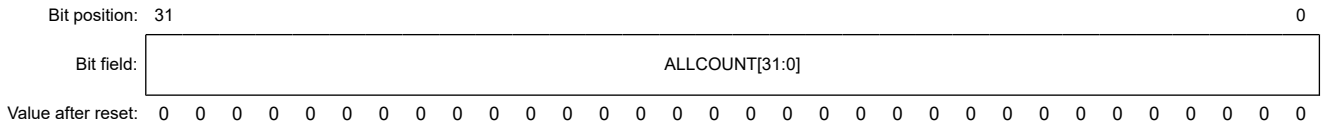


Bit	Symbol	Function	R/W
31:0	ALLOCTETS[31:0]	PORT n, this field indicates the octets of MAC All Frames, Good and Bad, including too long/short.	R

29.3.7.20 ETHERSTATSPKTS_Pn : Port n MAC All Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8B4 + 0x400 × n



Bit	Symbol	Function	R/W
31:0	ALLCOUNT[31:0]	PORT n, this field indicates the number of MAC All Frames, Good and Bad, including too long/short.	R

29.3.7.21 ETHERSTATSUNDERSIZEPKTS_Pn : Port n MAC Too Short Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8B8 + 0x400 × n

Bit position:	31																												0
Bit field:	TOOSHRTCOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TOOSHRTCOUNT[31:0]	PORT n, this field indicates the number of MAC too Short, Good CRC.	R

29.3.7.22 ETHERSTATSOVERSIZEPKTS_Pn : Port n MAC Too Long Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8BC + 0x400 × n

Bit position:	31																												0
Bit field:	TOOLONGCOUNT[31:0]

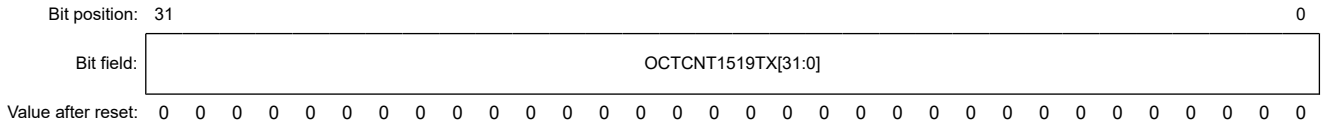
29.3.7.29 ETHERSTATSPKTS1519TOXOCTETS_Pn : Port n MAC Over 1519 Octets Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8D8 + 0x400 × n

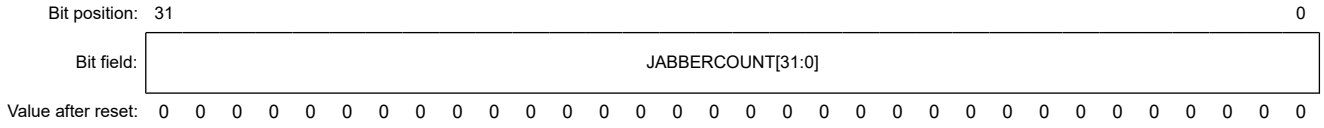


Bit	Symbol	Function	R/W
31:0	OCTCNT1519TX[31:0]	PORT n, this field indicates the number of MAC all Frames, Good and Bad (Packet Size: over 1519 bytes).	R

29.3.7.30 ETHERSTATSJABBERS_Pn : Port n MAC Jabbers Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8DC + 0x400 × n

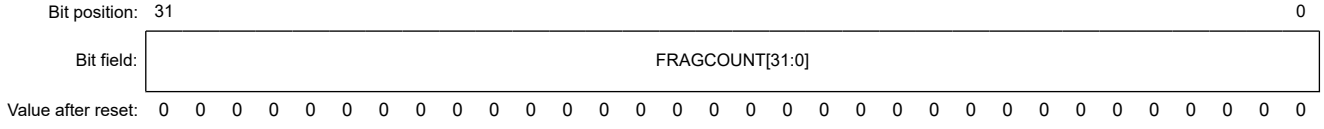


Bit	Symbol	Function	R/W
31:0	JABBERCOUNT[31:0]	PORT n, this field indicates the number of MAC too Long, Bad CRC.	R

29.3.7.31 ETHERSTATSFRAGMENTS_Pn : Port n MAC Fragment Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8E0 + 0x400 × n

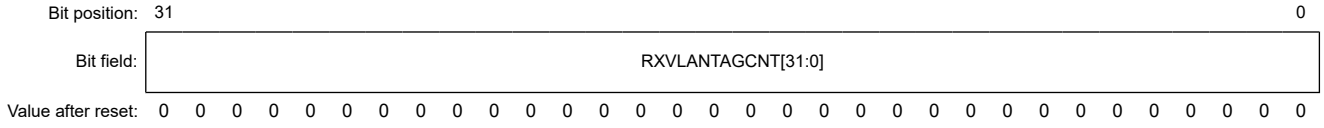


Bit	Symbol	Function	R/W
31:0	FRAGCOUNT[31:0]	PORT n, this field indicates the number of MAC too Short, Bad CRC.	R

29.3.7.32 VLANRECEIVEDOK_Pn : Port n MAC Received VLAN Tagged Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8E8 + 0x400 × n

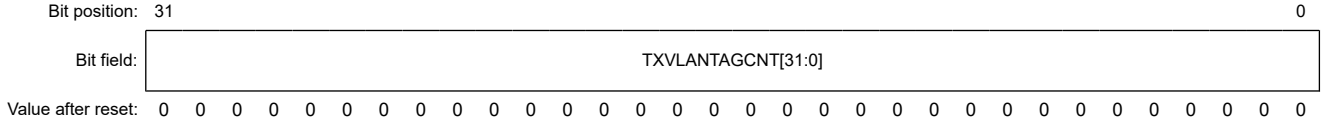


Bit	Symbol	Function	R/W
31:0	RXVLANTAGCNT[31:0]	PORT n, this field indicates the number of Good Frames with VLAN Tag Received.	R

29.3.7.33 VLANTRANSMITTEDOK_Pn : Port n MAC Transmitted VLAN Tagged Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8F4 + 0x400 × n



Bit	Symbol	Function	R/W
31:0	TXVLANTAGCNT[31:0]	PORT n, this field indicates the number of Good Frames with VLAN Tag Transmitted.	R

29.3.7.34 FRAMESRETRANSMITTED_Pn : Port n MAC Retransmitted Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x8F8 + 0x400 × n

Bit position:	31																												0
Bit field:	RETXCOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RETXCOUNT[31:0]	PORT n, this field indicates the number of Transmitted Frames that experienced a collision and were retransmitted. Increments once per frame, independent of number of retransmit attempts (increment even if a frame was discarded after 16 attempts). The counter does not increment for late collisions.	R

If the Hub mode retransmit is disabled (see section 29.3.13.1. HUB_CONFIG : HUB Configuration Register), the counter increments when a collision occurred that normally would cause a retransmit, although the frame was discarded.

The counter increments with the next frame transmitted, in case the frame was discarded due to too many retransmits or hub retransmit disabled.

29.3.7.35 STATS_HIWORD_Pn : Port n MAC Statistics Counter High Word Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x900 + 0x400 × n

Bit position:	31																												0
Bit field:	STATS_HIWORD[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	STATS_HIWORD[31:0]	The latched upper 32-bit of the 64 bits MAC Statistics Counter Last Read Returns latched bits [63:32] of the last accessed counter of any MAC page.	R

This register exists once only and is global. Accessing it in any of the MAC pages reads from this same global register. It also means that it is latching for every statistics counter read in any of the MAC pages.

29.3.7.36 STATS_CTRL_Pn : Port n MAC Statistics Control Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x904 + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLRBUSY	CLRALL
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
0	CLRALL	Self Clearing Counter Initialize Command The bit resets itself immediately, therefore always reads back as 0. When written with 1, all statistics counters of all MACs are initialized to the value given in STATS_CLEAR_VALUELO/HI. For test purposes, the clear value is programmable to perform counter wrap around or other memory tests for the counters. STATS_CLEAR_VALUELO/HI should be set to all 0s during normal operation. A clear takes many switch operating clock cycles (up to 30 × 4 ports).	R/W
1	CLRBUSY	Clear in Progress Indication The bit is set when a clear command is triggered (either by CLRALL control bit write, or soft reset (SW_RESET bit) write to Port 0 COMMAND_CONFIG_P0 register. The bit clears when all counters are initialized.	R
31:2	—	The read values are undefined. The write value should be 0.	R/W

This register exists once only and is global.

29.3.7.37 STATS_CLEAR_VALUELO_Pn : Port n MAC Statistics Clear Value Lower Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x908 + 0x400 × n

Bit position:	31	0
Bit field:	STATS_CLEAR_VALUELO[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	STATS_CLEAR_VALUELO[31:0]	PORT n, lower 32-bit of 64 bits value loaded into all counters when clearing all counters with STATS_CTRL_Pn.CLRALL command for test purposes. These bits should be set to 0 normally.	R/W

This register exists once only and is global. Clear value cannot be set for each MAC page.

29.3.7.38 STATS_CLEAR_VALUEHI_Pn : Port n MAC Statistics Clear Value Higher Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x90C + 0x400 × n

Bit position:	31																												0
Bit field:	STATS_CLEAR_VALUEHI[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	STATS_CLEAR_VALUEHI[31:0]	PORT n, upper 32-bit of 64 bits value loaded into all counters when clearing all counters with STATS_CTRL_Pn.CLRALL command for test purposes. These bits should be set to 0 normally.	R/W

This register exists once only and is global. Clear value cannot be set for each MAC page.

29.3.7.39 ADEFERRED_Pn : Port n MAC Deferred Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x910 + 0x400 × n

Bit position:	31																												0
Bit field:	DEFERCOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DEFERCOUNT[31:0]	PORT n, this field indicates the number of Frame Transmitted without collision but was deferred at begin.	R

29.3.7.40 AMULTIPLECOLLISIONS_Pn : Port n MAC Multiple Collision Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x914 + 0x400 × n

Bit position:	31																												0
Bit field:	COUNTAFTMLTCOLL[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	COUNTAFTMLTCOLL[31:0]	PORT n, this field indicates the number of Good Frame Transmit after multiple collisions.	R

29.3.7.41 ASINGLECOLLISIONS_Pn : Port n MAC Single Collision Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x918 + 0x400 × n

Bit position:	31																												0
Bit field:	COUNTAFTSNGLCOLL[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	COUNTAFTSNGLCOLL[31:0]	PORT n, this field indicates the number of Good Frame Transmit after single collision.	R

29.3.7.42 ALATECOLLISIONS_Pn : Port n MAC Late Collision Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x91C + 0x400 × n

Bit position:	31																												0
Bit field:	LATECOLLCOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	LATECOLLCOUNT[31:0]	PORT n, this field indicates the number of too Late Collision. Frame was aborted and not retransmitted. When this counter increments, the ifOutErrors counter also increments.	R

29.3.7.43 AEXCESSIVECOLLISIONS_Pn : Port n MAC Excessive Collision Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x920 + 0x400 × n

Bit position:	31																												0
Bit field:	EXCCOLLCOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	EXCCOLLCOUNT[31:0]	PORT n, this field indicates the number of Frames Discarded due to 16 consecutive collisions. When this counter increments, the ifOutErrors counter also increments.	R

29.3.7.44 ACARRIERSENSEERRORS_Pn : Port n MAC Carrier Sense Error Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x924 + 0x400 × n

Bit position:	31																												0
Bit field:	CSERRCOUNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CSERRCOUNT[31:0]	PORT n, increments during Transmission without Collisions the PHY Carrier Sense Signal (RX_CRS) dropped or never asserted.	R

29.3.8 Extended Frame Parser Registers

29.3.8.1 Pn_QSTMACUs : Qci Stream Filter Table MAC Address Upper Part (n = 0 to 2, s = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2000 + 0x400 × n + 0x028 × s

Bit position:	31															16	15												0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DASA	MACA[15:0]												
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MACA[15:0]	Qci stream filter table MAC address[47:32]	R/W
16	DASA	MAC address (MACA) select 0: MACA is a source address 1: MACA is a destination address	R/W
31:17	—	The read values are undefined. The write value should be 0.	R/W

For details of the write access procedure, see Figure 29.61.

29.3.8.2 Pn_QSTMACDs : Qci Stream Filter Table MAC Address Downer Part (n = 0 to 2, s = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2004 + 0x400 × n + 0x028 × s

Bit position:	31																												0
Bit field:	MACA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	MACA[31:0]	Qci stream filter table MAC address[31:0]	R/W

For details of the write access procedure, see Figure 29.61.

29.3.8.3 Pn_QSTMAMUs : Qci Stream Filter Table MAC Address Mask Upper Part (n = 0 to 2, s = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2008 + 0x400 × n + 0x028 × s

Bit position:	31															15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MACAM[15:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MACAM[15:0]	Qci stream filter table MAC address bit mask[47:32] 0: No bit mask 1: Bit mask (the bit value of the MAC address is ignored, any value matches)	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

For details of the write access procedure, see Figure 29.61.

29.3.8.4 Pn_QSTMAMDs : Qci Stream Filter Table MAC Address Mask Downer Part (n = 0 to 2, s = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x200C + 0x400 × n + 0x028 × s

Bit position:	31																														0
Bit field:	MACAM[31:0]																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	MACAM[31:0]	Qci stream filter table MAC address bit mask[31:0] 0: No bit mask 1: Bit mask (the bit value of the MAC address is ignored, any value matches)	R/W

For details of the write access procedure, see Figure 29.61.

29.3.8.5 Pn_QSFTVLs : Qci Stream Filter Table VLAN (n = 0 to 2, s = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2010 + 0x400 × n + 0x028 × s

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

26:16	MSDU[10:0]	Qci stream filter table max SDU size Byte unit, Include FCS	R/W
27	MSDUE	Qci stream filter table max SDU size Check enable 0: Check disable 1: Check enable	R/W
28	QSMSM	Qci stream MSDU mode 0: No effect 1: When a frame is discard by MSDU over, all frames are dropped until software clears Pn_QSEIS.QSMOIS[s].	R/W
31:29	—	The read values are undefined. The write value should be 0.	R/W

For details of the write access procedure, see Figure 29.61.

29.3.8.8 Pn_QSMFCs : Qci Stream Match Packet Count (n = 0 to 2, s = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x201C + 0x400 × n + 0x028 × s

Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	QSMFC[15:0]														
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	QSMFC[15:0]	Qci stream match packet count These bits are cleared by reading it.	R
31:16	—	The read values are undefined.	R

29.3.8.9 Pn_QMSPPCs : Qci MSDU Passed Packet Count (n = 0 to 2, s = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2020 + 0x400 × n + 0x028 × s

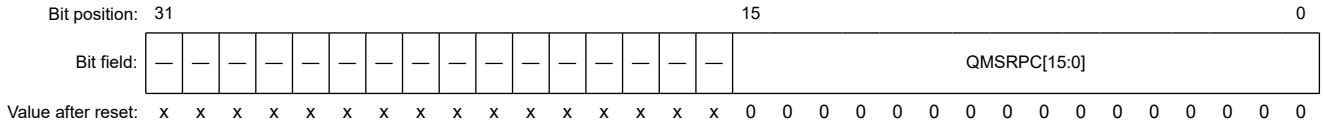
Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	QMSPPC[15:0]														
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	QMSPPC[15:0]	Qci msdu passed packet count These bits are cleared by reading it.	R
31:16	—	The read values are undefined.	R

29.3.8.10 Pn_QMSRPCs : Qci MSDU Reject Packet Count (n = 0 to 2, s = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2024 + 0x400 × n + 0x028 × s

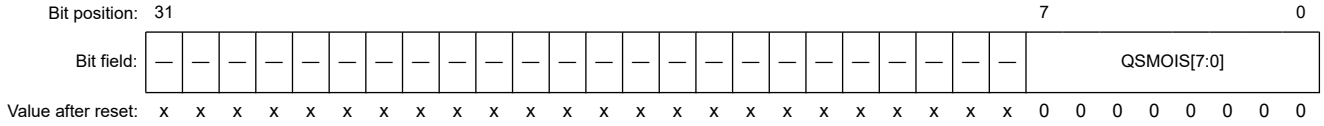


Bit	Symbol	Function	R/W
15:0	QMSRPC[15:0]	Qci MSDU rejected packet count These bits are cleared by reading it.	R
31:16	—	The read values are undefined.	R

29.3.8.11 Pn_QSEIS : Qci Stream Filter Error Interrupt Status (SDU Oversize) (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x21E8 + 0x400 × n

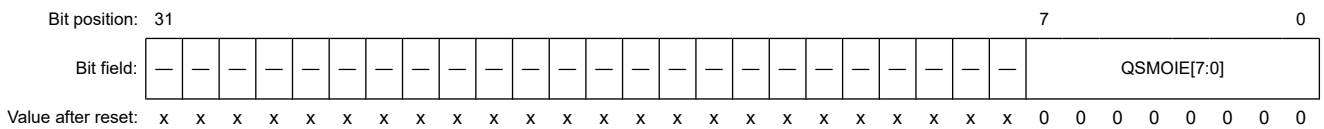


Bit	Symbol	Function	R/W
7:0	QSMOIS[7:0]	MSDU oversize frames Interrupt status[s] s: Stream ID (0 to 7) Writing 1 to this bit will clear it. Writing 0 to this bit has not effect.	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.12 Pn_QSEIE : Qci Stream Filter Error Interrupt Enable (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x21EC + 0x400 × n



Bit	Symbol	Function	R/W
7:0	QSMOIE[7:0]	MSDU oversize frames Interrupt Enable[s] s: Stream ID (0 to 7) Write 0 has no effect. 0: Interrupt which is occurred by Pn_QSEIS.QSMOIS is not appeared the interrupt output pin 1: Interrupt which is occurred by Pn_QSEIS.QSMOIS is appeared the interrupt output pin	R/W

Bit	Symbol	Function	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.13 Pn_QSEID : Qci Stream Filter Error Interrupt Disable (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x21F0 + 0x400 × n

Bit position:	31																						7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	QSMOID[7:0]							
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	QSMOID[7:0]	MSDU oversize frames Interrupt Disable[s] s: Stream ID (0 to 7) Write 1 will disable Pn_QSEIE.QSMOIE, write 0 has no effect. 0: No change of Pn_QSEIE.QSMOIE 1: Set Pn_QSEIE.QSMOIE to 0	W
31:8	—	The write value should be 0.	W

Read value of this register is 0x00000000.

29.3.8.14 Pn_QGMOD : Qci Gate Mode Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2200 + 0x400 × n

Bit position:	31																						7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	QGMOD[7:0]							
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	QGMOD[7:0]	Flow gate mode[g] QGMOD is used to select mode. g: Gate ID (0 to 7) 0: No effect 1: When the gate discards a frame due to a closed gate, all frames are dropped until software clears Pn_QGEIS.QGMOIS[g].	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.15 Pn_QGPPC : Qci Gate (All) Passed Packet Count Port n (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2204 + 0x400 × n

Bit position:	31																15													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	QGPPC[15:0]													
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0

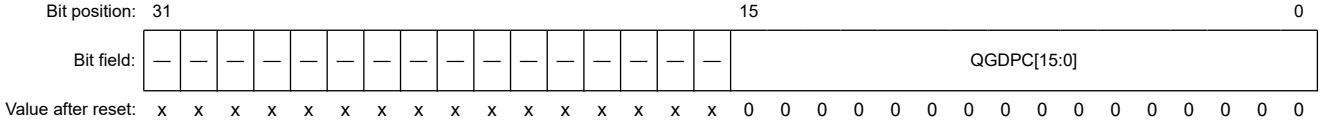
Bit	Symbol	Function	R/W
15:0	QGPPC[15:0]	Qci gate passed packet count These bits are cleared by reading it.	R

Bit	Symbol	Function	R/W
31:16	—	The read values are undefined.	R

29.3.8.16 Pn_QGDPCg : Qci Gate g Dropped Packet Count Port n (n = 0 to 2, g = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2208 + 0x400 × n + 0x008 × g

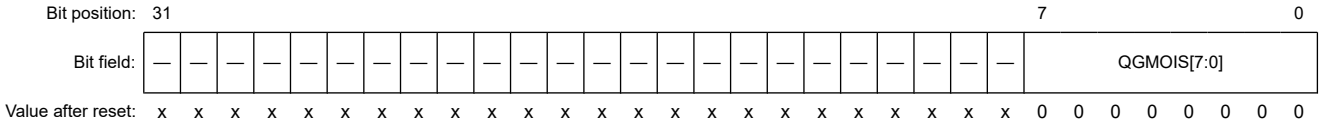


Bit	Symbol	Function	R/W
15:0	QGDPC[15:0]	Qci gate dropped packet count These bits are cleared by reading it.	R
31:16	—	The read values are undefined.	R

29.3.8.17 Pn_QGEIS : Qci Gate Error Interrupt Status (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2244 + 0x400 × n

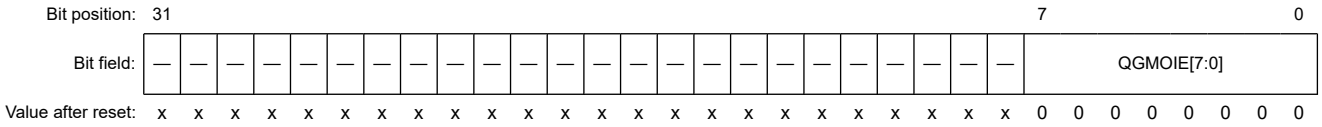


Bit	Symbol	Function	R/W
7:0	QGMOIS[7:0]	Gating error Interrupt status[g] g: Gate ID (0 to 7) Writing 1 to this bit will clear it. Writing 0 to this bit has not effect.	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.18 Pn_QGEIE : Qci Gate Error Interrupt Enable (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2248 + 0x400 × n

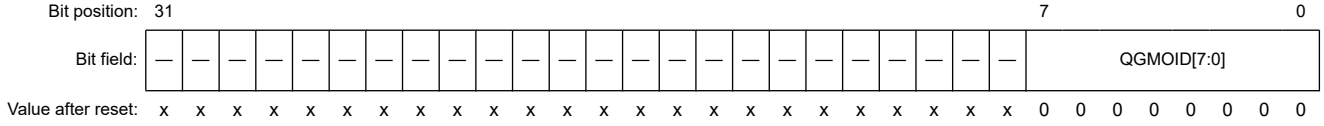


Bit	Symbol	Function	R/W
7:0	QGMOIE[7:0]	Gating error Interrupt Enable[g] g: Gate ID (0 to 7) Write 0 has no effect. 0: Interrupt which is occurred by Pn_QGEIS.QGMOIS is not appeared the interrupt output 1: Interrupt which is occurred by Pn_QGEIS.QGMOIS is appeared the interrupt output	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.19 Pn_QGEID : Qci Gate Error Interrupt Disable (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x224C + 0x400 × n



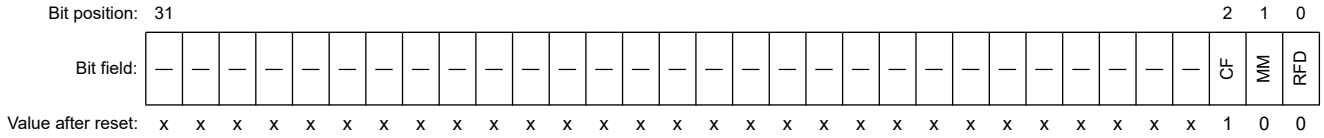
Bit	Symbol	Function	R/W
7:0	QGMOID[7:0]	Gating error Interrupt Disable[g] g: Gate ID (0 to 7) Write 1 will disable Pn_QGEIE.QGMOIE, write 0 has no effect. 0: No change of Pn_QGEIE.QGMOIE 1: Set Pn_QGEIE.QGMOIE to 0	W
31:8	—	The write value should be 0.	W

Read value of this register is 0x00000000.

29.3.8.20 Pn_QMDESCm : Qci Port n Flow Meter m Descriptor Register (n = 0 to 2, m = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2250 + 0x400 × n + 0x014 × m



Bit	Symbol	Function	R/W
0	RFD	Red frame drop RFD is used to drop red frame for meter 0: A red frame is not dropped. 1: A red frame is dropped.	R/W
1	MM	Flow meter mode MM is used to select mode for meter 0: No effect 1: When discard frame by Flow Meter, all frames are dropped until software clears Pn_QMEIS.QRFIS[m].	R/W
2	CF	Coupling flag Coupling flag for meter When coupling flag is 0, if the tokens overflow, these tokens will be added to the next bucket in the chain. When coupling flag is 1, overflow tokens are not added to the next meter.	R/W
31:3	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.21 Pn_QMCBSCm : Qci Meter CBS Configuration Port n, Meter m (n = 0 to 2, m = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2254 + 0x400 × n + 0x014 × m

Bit position:	31														17															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CBS[17:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
17:0	CBS[17:0]	CBS (Committed Burst Size) CBS value for counter Token maximum value	R/W
31:18	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.22 Pn_QMCIRCm : Qci Meter CIR Configuration n m (n = 0 to 2, m = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2258 + 0x400 × n + 0x014 × m

Bit position:	31															16															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CIR[16:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
16:0	CIR[16:0]	CIR (Committed Information Rate) CIR value for counter The token will be incremented depending on this value. CIR[16] is the token increment in byte per clock. CIR[15:0] is the token increment in sub-byte per clock.	R/W
31:17	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.23 Pn_QMGPCm : Qci Meter Green Packet Count (n = 0 to 2, m = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x225C + 0x400 × n + 0x014 × m

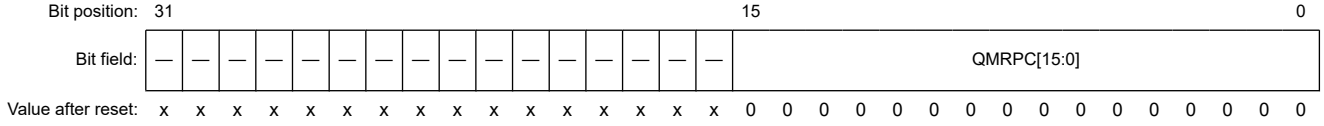
Bit position:	31																15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	QMGPC[15:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	QMGPC[15:0]	Qci meter green packet count These bits are cleared by reading it.	R
31:16	—	The read values are undefined.	R

29.3.8.24 Pn_QMRPCm : Qci Meter Red Packet Count (n = 0 to 2, m = 0 to 7)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2260 + 0x400 × n + 0x014 × m

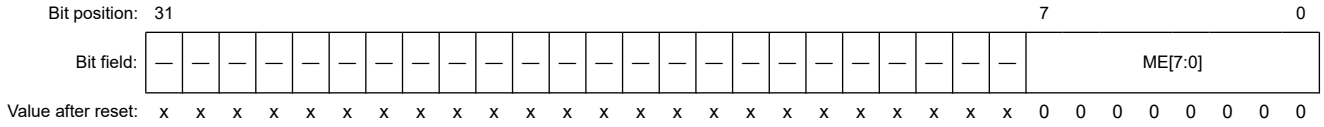


Bit	Symbol	Function	R/W
15:0	QMRPC[15:0]	Qci meter red packet count These bits are cleared by reading it.	R
31:16	—	The read values are undefined.	R

29.3.8.25 Pn_QMEC : Qci Meter Enable Configuration (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x22F0 + 0x400 × n

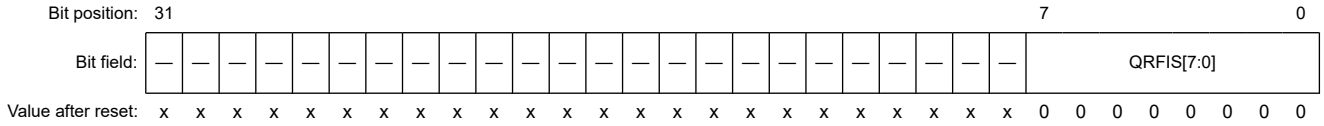


Bit	Symbol	Function	R/W
7:0	ME[7:0]	Enable meter[m] m: Meter ID (0 to 7) If Pn_QSFTBLs.MEIDV = 1 and Pn_QMEC.ME[m] = 0, those settings are invalid and the received packet is discard as Red-Frame.	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.26 Pn_QMEIS : Qci Meter Error Interrupt Status (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x22F4 + 0x400 × n



Bit	Symbol	Function	R/W
7:0	QRFIS[7:0]	Red frames Interrupt status[m] Indicate the status of frame discard by Flow Meter m: Meter ID (0 to 7) Writing 1 to this bit will clear it. Writing 0 to this bit has not effect.	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.27 Pn_QMEIE : Qci Meter Error Interrupt Enable (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x22F8 + 0x400 × n

Bit position:	31																						7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	QRFIE[7:0]							
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	QRFIE[7:0]	Red frames Interrupt Enable[m] m: Meter ID (0 to 7) Write 0 has no effect. 0: Interrupt which is occurred by Pn_QMEIS.QRFIS is not appeared the interrupt output pin 1: Interrupt which is occurred by Pn_QMEIS.QRFIS is appeared the interrupt output pin	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.28 Pn_QMEID : Qci Meter Error Interrupt Disable (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x22FC + 0x400 × n

Bit position:	31																						7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	QRFID[7:0]							
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	QRFID[7:0]	Red frames Interrupt Disable[m] m: Meter ID (0 to 7) Write 1 will disable Pn_QMEIE.QRFIE, write 0 has no effect. 0: No change of Pn_QMEIE.QRFIE 1: Set Pn_QMEIE.QRFIE to 0	W
31:8	—	The write value should be 0.	W

Read value of this register is 0x00000000.

29.3.8.29 Pn_PCP_REMAP : Port n VLAN Priority Code Point (PCP) Remap (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2300 + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	PCP_REMAP7[2:0]			PCP_REMAP6[2:0]			PCP_REMAP5[2:0]	
Value after reset:	x	x	x	x	x	x	x	x	1	1	1	1	1	0	1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PCP_REMAP5[2:0]	PCP_REMAP4[2:0]			PCP_REMAP3[2:0]			PCP_REMAP2[2:0]			PCP_REMAP1[2:0]			PCP_REMAP0[2:0]		
Value after reset:	1	1	0	0	0	1	1	0	1	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
2:0	PCP_REMAP0[2:0]	Source PCP = 0 or untagged will be remapped to this value.	R/W
5:3	PCP_REMAP1[2:0]	Source PCP = 1 will be remapped to this value.	R/W
8:6	PCP_REMAP2[2:0]	Source PCP = 2 will be remapped to this value.	R/W
11:9	PCP_REMAP3[2:0]	Source PCP = 3 will be remapped to this value.	R/W
14:12	PCP_REMAP4[2:0]	Source PCP = 4 will be remapped to this value.	R/W
17:15	PCP_REMAP5[2:0]	Source PCP = 5 will be remapped to this value.	R/W
20:18	PCP_REMAP6[2:0]	Source PCP = 6 will be remapped to this value.	R/W
23:21	PCP_REMAP7[2:0]	Source PCP = 7 will be remapped to this value.	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

Remaps TCI.PCP source to TCI.PCP destination.

29.3.8.30 Pn_VLAN_TAG : Port n VLAN TAG Information for Priority Regeneration (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2304 + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TPID[15:0]															
Value after reset:	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PCP[2:0]			DEI	VID[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	VID[11:0]	Port Domain VID	R/W
12	DEI	Port Drop Eligible Indicator	R/W
15:13	PCP[2:0]	Port Priority Code Point	R/W
31:16	TPID[15:0]	Port Tag Protocol Identifier	R/W

Untagged or Priority tagged frames will be tagged with the domain VID.

29.3.8.31 Pn_VLAN_MODE : Port n VLAN Mode (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2308 + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	VICM[1:0]		VITM[1:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

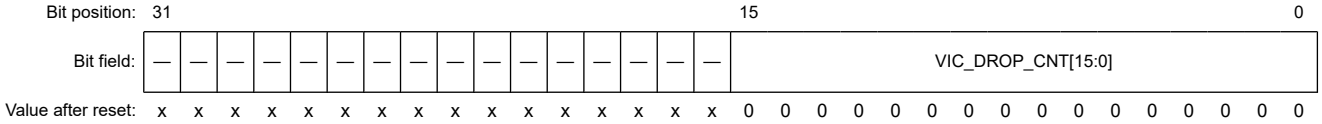
Bit	Symbol	Function	R/W
1:0	VITM[1:0]	VLAN input tagging mode See Table 29.42. 0 0: Disabled, VLAN tag is neither added nor overwritten 0 1: Single Tagging with Passthrough/ VLAN ID (VID) Overwrite 1 0: Single Tagging with Replace 1 1: Tag always	R/W
3:2	VICM[1:0]	VLAN input verification mode See Table 29.41. 0 0: Mode 0 0 1: Mode 1 1 0: Mode 2 1 1: Mode 3	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

Port n VLAN mode for ingress check and tagging.

29.3.8.32 Pn_VIC_DROP_CNT : Port n VLAN Ingress Check Drop Frame Counter (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x230C + 0x400 × n

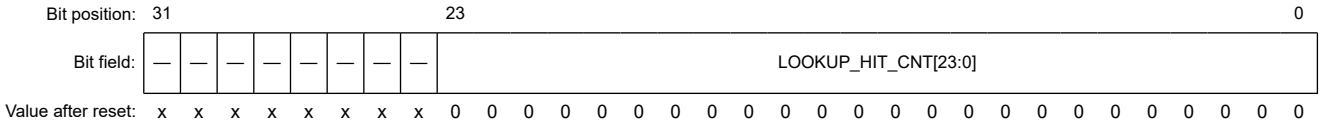


Bit	Symbol	Function	R/W
15:0	VIC_DROP_CNT[15:0]	Port n VLAN ingress check drop frame count Source counter will be reset on read.	R
31:16	—	The read values are undefined.	R

29.3.8.33 Pn_LOOKUP_HIT_CNT : Port n DST Address Lookup Hit Counter (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2328 + 0x400 × n



Bit	Symbol	Function	R/W
23:0	LOOKUP_HIT_CNT[23:0]	Port n Lookup hit count Source counter will be reset on read.	R
31:24	—	The read values are undefined.	R

29.3.8.34 Pn_ERROR_STATUS : Port n Frame Parser Runtime Error Status (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x232C + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	EOVRSZ	EUNDSZ	POVRSZ	PUNDSZ	SOPERR
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SOPERR	SOP error detected in frame parser If second (extra) SOP is received before receiving EOP, this error is asserted. Cleared by writing 1.	R/W
1	PUNDSZ	Preemptable frame under size error detected in frame parser If active frame size of preemptable frame < 64 bytes, this error is asserted. Cleared by writing 1.	R/W
2	POVRSZ	Preemptable frame over size error detected in frame parser If active frame size of preemptable frame > frm_max_length, this error is asserted. Cleared by writing 1.	R/W
3	EUNDSZ	Express frame under size error detected in frame parser If active frame size of express frame < 64 bytes, this error is asserted. Cleared by writing 1.	R/W
4	EOVRSZ	Express frame over size error detected in frame parser If active frame size of express frame > frm_max_length, this error is asserted. Cleared by writing 1.	R/W
31:5	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.35 Pn_ERROR_MASK : Port n Frame Parser Runtime Error Mask (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x2330 + 0x400 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	MEOVRSZ	MEUNDSZ	MPOVRSZ	MPUNDSZ	MSOPERR
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MSOPERR	Error mask of SOPERR (SOP error) Active 1	R/W
1	MPUNDSZ	Error mask of PUNDSZ (Preemptable frame under size error) Active 1	R/W
2	MPOVRSZ	Error mask of POVRSZ (Preemptable frame over size error) Active 1	R/W

Bit	Symbol	Function	R/W
3	MEUNDSZ	Error mask of EUNDSZ (Express frame under size error) Active 1	R/W
4	MEOVRSZ	Error mask of EOVRSZ (Express frame over size error) Active 1	R/W
31:5	—	The read values are undefined. The write value should be 0.	R/W

29.3.8.36 CHANNEL_STATE : Enable/Disable State of Ingress Channels

Base address: ETHSW = 0x8012_0000

Offset address: 0x23C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	CH2ACT	CH1ACT	CH0ACT
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
0	CH0ACT	State of Ingress channel port 0 0: Channel port 0 is in reset. No frames are forwarded. 1: Channel port 0 is enabled. Frames are forwarded and manipulated as configured.	R
1	CH1ACT	State of Ingress channel port 1 0: Channel port 1 is in reset. No frames are forwarded. 1: Channel port 1 is enabled. Frames are forwarded and manipulated as configured.	R
2	CH2ACT	State of Ingress channel port 2 0: Channel port 2 is in reset. No frames are forwarded. 1: Channel port 2 is enabled. Frames are forwarded and manipulated as configured.	R
31:3	—	The read values are undefined.	R

While deactivated (CHnACT = 0), all state machines of the respective channel n are in Reset state. The values of Extended Frame Parser registers are unchanged. Read/Write operation to Extended Frame Parser registers and to the Active Stream Identification table in memory are still possible.

29.3.8.37 CHANNEL_ENABLE : Enable Operation of Channel

Base address: ETHSW = 0x8012_0000

Offset address: 0x23C4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	CH2ENA	CH1ENA	CH0ENA
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
0	CH0ENA	Enable of Ingress channel port 0 0: Ignored 1: Enable Channel port 0	W
1	CH1ENA	Enable of Ingress channel port 1 0: Ignored 1: Enable Channel port 1	W
2	CH2ENA	Enable of Ingress channel port 2 0: Ignored 1: Enable Channel port 2	W
31:3	—	The write value should be 0.	W

29.3.8.38 CHANNEL_DISABLE : Disable and Reset Operation of Channel

Base address: ETHSW = 0x8012_0000

Offset address: 0x23C8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	CH2DIS	CH1DIS	CH0DIS
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
0	CH0DIS	Disable of Ingress channel port 0 0: Ignored 1: Disable and reset Channel port 0	W
1	CH1DIS	Disable of Ingress channel port 1 0: Ignored 1: Disable and reset Channel port 1	W
2	CH2DIS	Disable of Ingress channel port 2 0: Ignored 1: Disable and reset Channel port 2	W
31:3	—	The write value should be 0.	W

29.3.8.39 ASI_MEM_WDATAn : Memory Write Data Word n (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x23CC + 0x004 × n

Bit position:	31	0
Bit field:	WDATA[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	WDATA[31:0]	Destination MAC address regeneration write data Bit allocation of register ASI_MEM_WDATAn: ASI_MEM_WDATA0: WDATA[31:0] ASI_MEM_WDATA1: WDATA[63:32] ASI_MEM_WDATA2: WDATA[95:64] ASI_MEM_WDATA3: WDATA[127:96]	R/W

The Destination MAC address lookup table is accessed by an indirect addressing scheme. The data and control bits are spread over ASI_MEM_WDATAn (n = 0 to 3) registers. There is 1 lookup table per port with 128 entries each. See Table 29.43 and Table 29.44.

29.3.8.40 ASI_MEM_ADDR : Memory Address and R/W Control

Base address: ETHSW = 0x8012_0000

Offset address: 0x23DC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	MEM_REQ[2:0]			MEM_WEN	ADDR[6:0]						
Value after reset:	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	ADDR[6:0]	Memory access address The Address is a hash of lookup {DA, VID}: CRC-7 Polynomial (IEC 60870-5) 0x65 = $x^7 + x^6 + x^5 + x^2 + 1$	R/W
7	MEM_WEN	Read/Write enable 0: Read 1: Write	R/W
10:8	MEM_REQ[2:0]	Memory access request Write 1 to request access. Self clear after request complete. Port 0: MEM_REQ[0] Port 1: MEM_REQ[1] Port 2: MEM_REQ[2]	R/W
31:11	—	The read values are undefined. The write value should be 0.	R/W

Lookup table entry address: 0 to 127 entries. Each of the 128 entries corresponds to one table row of the Active Stream Identification table. See section 29.4.19.4. Active Stream Identification.

The request bits MEM_REQ will be self-cleared after a valid transaction. Only 1 request at a time is allowed. A request could be a write operation to one or multiple target channels or a read operation from one channel. All 128 bits of an entry are read or written in one access cycle. Access in byte or word granularity is not possible.

Setting multiple MEM_REQ bits for write operation (MEM_WEN = 1) will write the same memory content to the respective memories of selected channels (0 to 2).

Setting multiple MEM_REQ bits for read operation (MEM_WEN = 0) is prohibited. The result of such read operation is undefined.

29.3.8.41 ASI_MEM_RDATAn : Memory Read Data Word n (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x23E0 + 0x004 × n

Bit position:	31	0
Bit field:	RDATA[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	RDATA[31:0]	Destination MAC address regeneration read data Bit allocation of register ASI_MEM_RDATAn: ASI_MEM_RDATA0: RDATA[31:0] ASI_MEM_RDATA1: RDATA[63:32] ASI_MEM_RDATA2: RDATA[95:64] ASI_MEM_RDATA3: RDATA[127:96]	R

29.3.9 Global Discard and 802.3br Statistics Registers

This address space contains a per-port set of counters for discarded frames and 802.3br statistics. The counters are organized in pages, one page per port. The pages are the same size for all ports except for the management port which does not support 802.3br.

The counters operate in rollover where the counters will roll-over their maximum value. Also, counters can be cleared when read, configurable using the STATN_CONFIG register. Counters can also be cleared by writing to them.

29.3.9.1 STATN_STATUS : Statistics Status Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3404

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BUSY
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	BUSY	Statistics module is busy Informal busy indicators providing a real-time indication that there is ongoing activity in a module. When this bit is 0, no counting activities occur in that module. This bit may not necessarily assert for ongoing commands and should not be used to check for command completion.	R
31:1	—	The read values are undefined.	R

29.3.9.2 STATN_CONFIG : Statistics Configure Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3408

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RESET	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLEAR_ON_READ	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	x

Bit	Symbol	Function	R/W
0	—	The read value is undefined. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
1	CLEAR_ON_READ	When set to 1, a read to a counter resets it to 0. When set to 0 (default), counters are not affected by read.	R/W
30:2	—	The read values are undefined. The write value should be 0.	R/W
31	RESET	Perform a soft-reset on the module When set to 1, all internal functions are aborted and return to a stable state (flushes prescalers). It also triggers a clear of all counter memory (all ports are cleared) by setting STATN_CONTROL.CMD_CLEAR with all mask bits. Capture memory is not reset. Self-clearing bit, always reads 0.	R/W

The STATN_CONFIG register configures the statistics module functions with statistics counters wrap around.

29.3.9.3 STATN_CONTROL : Statistics Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x340C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CMD_CLEAR	—	CLEAR_PRE	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	x	0	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CHANMASK[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

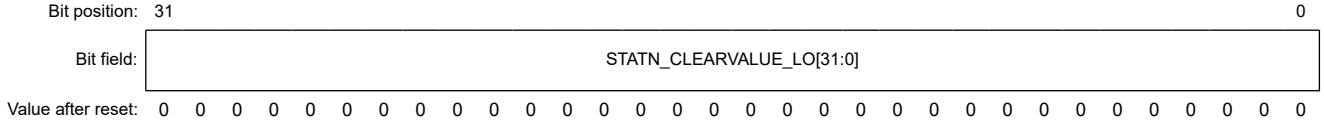
Bit	Symbol	Function	R/W
3:0	CHANMASK[3:0]	One bit per port. Bit 0 = port 0, bit 1 = port 1, and so on. Pages for ports set to 1 are cleared with the clear command. Setting multiple bits means all those ports are cleared. For self-clearing, when the command for a port begins (command is executed, but not necessarily completed yet), the corresponding bit clears itself to 0. A soft reset (STATN_CONFIG.RESET) sets all bits to 1 together with the clear command, causing all memories to be cleared.	R/W
28:4	—	The read values are undefined. The write value should be 0.	R/W
29	CLEAR_PRE	Clear the internal pre-scaler counters of ports when a clear occurs. This bit can be used together with the CMD_CLEAR command to clear the internal pre-scaler counters of the ports. When this bit is 1 and when any of the CMD_CLEAR commands is given, the memory and the prescaler values are cleared (flushes all storage). This is recommended for example, at the start of a port to ensure no pending false increments exist. When this bit is 0, only the memory stored counter values are cleared but the prescaler pending information is not modified and therefore, does not lose counts. This bit should be set to 0 for snapshot generation to avoid losing counts within the pre-scalers.	R/W
30	—	The read value is undefined. The write value should be 0.	R/W
31	CMD_CLEAR	Clear Channel Counters Command When set to 1, all counters of the channels as specified in the CHANMASK bits are cleared to 0. This can take a longer time because internal scheduling arbitration can take several 10s of cycles depending on the counters and the number of channels available and busy. For self resetting, this bit reads 0 when all channels are cleared. The soft reset from STATN_CONFIG also triggers the counter clear function.	R/W

The STATN_CONTROL register controls commands to the module for clearing and latching statistics.

29.3.9.4 STATN_CLEARVALUE_LO : Statistics Clear Value Lower Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3410

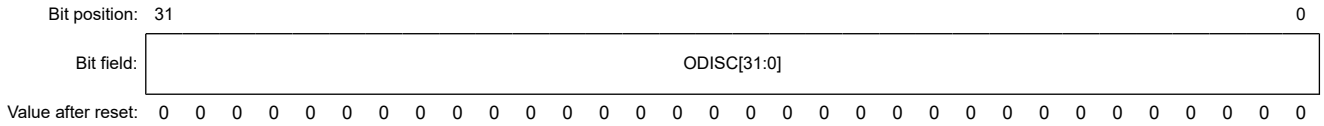


Bit	Symbol	Function	R/W
31:0	STATN_CLEARVALUE_LO[31:0]	32-bit value written into statistics memory when a clear command (STATN_CONTROL.CMD_CLEAR) is triggered (see section 29.3.9.2. STATN_CONFIG : Statistics Configure Register), or when a clear-after-read is used. Set these bits to 0 for a normal operation (intended for testing purposes to initialize the counters). The register clears to 0 when STATN_CONFIG.RESET is asserted.	R/W

29.3.9.5 ODISCn : Port n Discarded Outgoing Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3468 + 0x48 × n

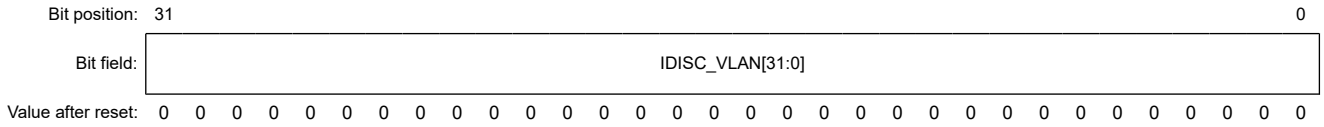


Bit	Symbol	Function	R/W
31:0	ODISC[31:0]	Port n outgoing frames discarded due to output queue congestion.	R

29.3.9.6 IDISC_VLANn : Port n Discarded Incoming VLAN Tagged Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x346C + 0x48 × n



Bit	Symbol	Function	R/W
31:0	IDISC_VLAN[31:0]	Port n incoming frames discarded due to mismatching or missing VLAN ID while VLAN verification was enabled.	R

29.3.9.7 IDISC_UNTAGGEDn : Port n Discarded Incoming VLAN Untagged Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3470 + 0x48 × n

Bit position:	31																												0
Bit field:	IDISC_UNTAGGED[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	IDISC_UNTAGGED[31:0]	Port n incoming frames discarded due to missing VLAN tag.	R

29.3.9.8 IDISC_BLOCKEDn : Port n Discarded Incoming Blocked Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3474 + 0x48 × n

Bit position:	31																												0
Bit field:	IDISC_BLOCKED[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	IDISC_BLOCKED[31:0]	Port n incoming frames discarded (after learning) as the port is configured in blocking mode.	R

29.3.9.9 IDISC_ANYn : Port n Discarded Any Frame Count Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3478 + 0x48 × n

Bit position:	31																												0
Bit field:	IDISC_ANY[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	IDISC_ANY[31:0]	Port n total incoming frames discarded. This includes IDISC_VLAN, IDSIC_UNTAGGED, IDISC_SRCFLT, and IDISC_BLOCKED. For port 3, this includes IDISC_VLAN, IDSIC_UNTAGGED, and IDISC_BLOCKED.	R

29.3.9.10 IDISC_SRCFLTn : Port n Discarded Address Source Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x347C + 0x48 × n

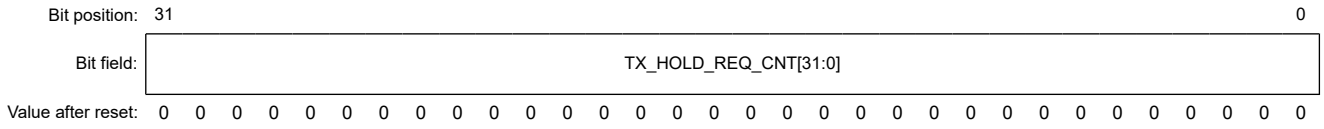
Bit position:	31																												0
Bit field:	IDISC_SRCFLT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	IDISC_SRCFLT[31:0]	Port n counts the number of incoming frames discarded due to the MAC address source filter.	R

29.3.9.11 TX_HOLD_REQ_CNTn : Port n TX Hold Request Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3480 + 0x48 × n

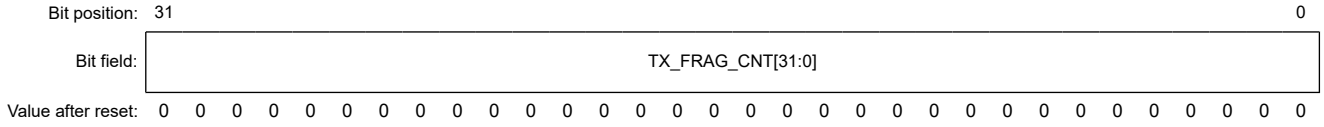


Bit	Symbol	Function	R/W
31:0	TX_HOLD_REQ_CNT[31:0]	Port n increments when MM_CTL.request (hold_req) transitions from FALSE to TRUE.	R

29.3.9.12 TX_FRAG_CNTn : Port n TX for Preemption Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3484 + 0x48 × n

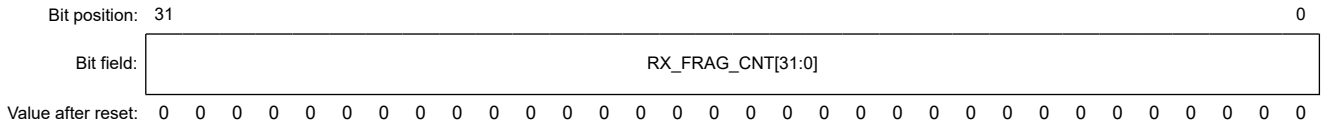


Bit	Symbol	Function	R/W
31:0	TX_FRAG_CNT[31:0]	Port n increments when an additional mPacket is transmitted due to preemption.	R

29.3.9.13 RX_FRAG_CNTn : Port n RX Continuation Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3488 + 0x48 × n



Bit	Symbol	Function	R/W
31:0	RX_FRAG_CNT[31:0]	Port n increments for every continuation mPacket received.	R

29.3.9.14 RX_ASSY_OK_CNTn : Port n RX Preempted Frame Success Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x348C + 0x48 × n

Bit position:	31																												0
Bit field:	RX_ASSY_OK_CNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RX_ASSY_OK_CNT[31:0]	Port n increments when a preempted frame is successfully assembled.	R

29.3.9.15 RX_ASSY_ERR_CNTn : Port n RX Preempted Frame Incorrect Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3490 + 0x48 × n

Bit position:	31																15												0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RX_ASSY_ERR_CNT[15:0]												
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RX_ASSY_ERR_CNT[15:0]	Port n increments when a preempted frame is incorrectly assembled.	R
31:16	—	The read values are undefined.	R

29.3.9.16 RX_SMD_ERR_CNTn : Port n RX SMD Frame Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3494 + 0x48 × n

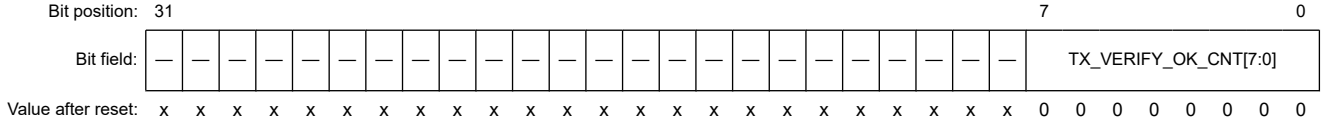
Bit position:	31																15												0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RX_SMD_ERR_CNT[15:0]												
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RX_SMD_ERR_CNT[15:0]	Port n increments when a frame with an SMD-Cx is received and no assembly is in progress.	R
31:16	—	The read values are undefined.	R

29.3.9.17 TX_VERIFY_OK_CNTn : Port n TX VERIFY Frame Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3498 + 0x48 × n

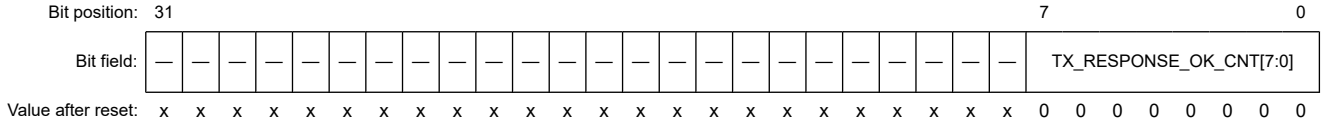


Bit	Symbol	Function	R/W
7:0	TX_VERIFY_OK_CNT[7:0]	Port n increments for every VERIFY frame transmitted.	R
31:8	—	The read values are undefined.	R

29.3.9.18 TX_RESPONSE_OK_CNTn : Port n TX RESPONSE Frame Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x349C + 0x48 × n

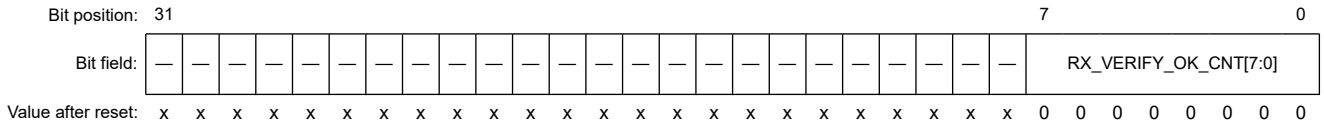


Bit	Symbol	Function	R/W
7:0	TX_RESPONSE_OK_CNT[7:0]	Port n increments for every RESPONSE frame transmitted.	R
31:8	—	The read values are undefined.	R

29.3.9.19 RX_VERIFY_OK_CNTn : Port n RX VERIFY Frame Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x34A0 + 0x48 × n

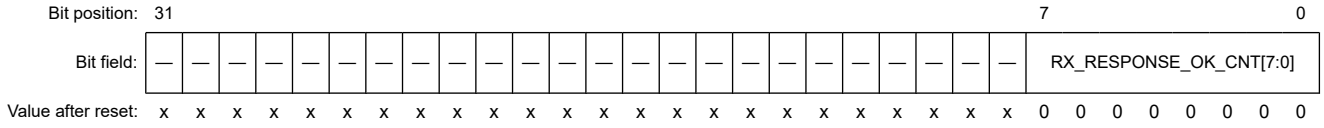


Bit	Symbol	Function	R/W
7:0	RX_VERIFY_OK_CNT[7:0]	Port n increments for every valid VERIFY frame received.	R
31:8	—	The read values are undefined.	R

29.3.9.20 RX_RESPONSE_OK_CNTn : Port n RX RESPONSE Frame Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x34A4 + 0x48 × n

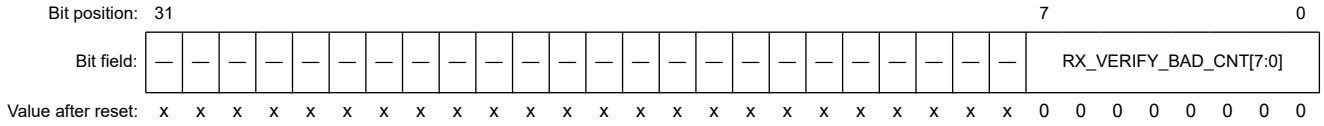


Bit	Symbol	Function	R/W
7:0	RX_RESPONSE_OK_CNT[7:0]	Port n increments for every valid RESPONSE frame received.	R
31:8	—	The read values are undefined.	R

29.3.9.21 RX_VERIFY_BAD_CNTn : Port n RX Error VERIFY Frame Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x34A8 + 0x48 × n

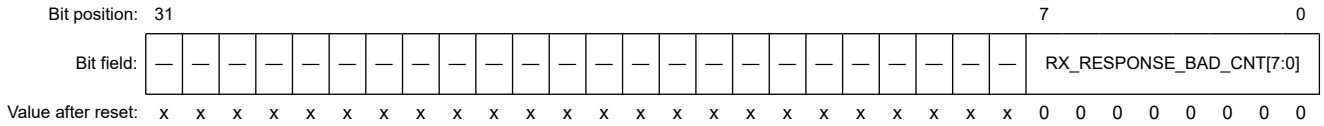


Bit	Symbol	Function	R/W
7:0	RX_VERIFY_BAD_CNT[7:0]	Port n increments for every errored VERIFY frame received.	R
31:8	—	The read values are undefined.	R

29.3.9.22 RX_RESPONSE_BAD_CNTn : Port n RX Error RESPONSE Frame Count Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x34AC + 0x48 × n



Bit	Symbol	Function	R/W
7:0	RX_RESPONSE_BAD_CNT[7:0]	Port n increments for every errored RESPONSE frame received.	R
31:8	—	The read values are undefined.	R

29.3.10 Memory Controller Extended Registers

29.3.10.1 MMCTL_OUT_CT : Cut-Through Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3B00

Bit position:	31													18	16													2	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	CT_OVR[2:0]		—	—	—	—	—	—	—	—	—	—	—	—	CT_OVR_ENA[2:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	CT_OVR_ENA[2:0]	Per-port bit mask to enable overriding the Cut-Through (CT) behavior of the output ports with CT_OVR. When set to 0, the frames are transmitted CT if the CT flag of the frame context is set.	R/W
15:3	—	The read values are undefined. The write value should be 0.	R/W
18:16	CT_OVR[2:0]	1 bit per-port value to set the Cut Through behavior of the output ports. When set to 0, all frames are sent as Store & Forward (SF) frames. When set to 1, frames with the CT flag set in the frame context are started as soon as the frame context information is available.	R/W
31:19	—	The read values are undefined. The write value should be 0.	R/W

The MMCTL_OUT_CT register allows overriding the output memory controller Cut-Through behavior. Only applicable to Ethernet ports.

29.3.10.2 MMCTL_CTFL_P0_3_ENA : Cut-Through Frame Length Enable Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3B04

Bit position:	31								23							16	15							8	7							0
Bit field:	—	—	—	—	—	—	—	—	CTFL_P2_ENA[7:0]								CTFL_P1_ENA[7:0]								CTFL_P0_ENA[7:0]							
Value after reset:	x	x	x	x	x	x	x	x	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	CTFL_P0_ENA[7:0]	Port 0 bit mask of n bits, where n is the number of queues per port indicating whether the CTFL is used for Cut-Through (CT) frames. When set to 1, a CT frame requires a CTFL entry to be written as a CT frame in the output memory.	R/W
15:8	CTFL_P1_ENA[7:0]	Port 1 bit mask of n bits, where n is the number of queues per port indicating whether the CTFL is used for Cut-Through (CT) frames. When set to 1, a CT frame requires a CTFL entry to be written as a CT frame in the output memory.	R/W
23:16	CTFL_P2_ENA[7:0]	Port 2 bit mask of n bits, where n is the number of queues per port indicating whether the CTFL is used for Cut-Through (CT) frames. When set to 1, a CT frame requires a CTFL entry to be written as a CT frame in the output memory.	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

Per-port/queue enable of the Cut-Through Frame Length table usage for ports 0 through 2. Only applicable to Ethernet ports.

29.3.10.3 MMCTL_YELLOW_BYTE_LENGTH_Pn : Port n Yellow Period Byte Length Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3B20 + 0x4 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	YLEN_EN
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	YELLOW_LEN[13:0]														—	—
Value after reset:	0	0	0	0	0	1	0	1	1	1	1	0	1	1	x	x

Bit	Symbol	Function	R/W
1:0	—	The read values are undefined. The write value should be 0.	R/W
15:2	YELLOW_LEN[13:0]	Length in bytes of the YELLOW period for port n. Determines whether a frame can be transmitted before the YELLOW period expires. The value is programmed in increments of 4 bytes excluding the MAC overhead (IPG, Preamble and FCS if appended) of the frame. Default value assumes a YELLOW period duration of 125 µs, which allows for 1562 bytes. Excluding the MAC maximum overhead of IPG (12 bytes), CRC (4 bytes), Preamble + SFD (8 bytes), and a safety margin (20 bytes). When OUT_CT_ENA transitions from 1 to 0, an internal counter is loaded with YELLOW_LEN and decrements at the port transmission rate. The length of every frame is compared against the value of this counter to determine if it can be transmitted without exceeding the remaining bytes.	R/W
16	YLEN_EN	When set to 1, enables transmission when OUT_CT_ENA is low only if the frame length is less than YELLOW_LEN. If cleared, YELLOW_LEN is ignored and frames are always transmitted in SF mode when OUT_CT_ENA is 0.	R/W
31:17	—	The read values are undefined. The write value should be 0.	R/W

Port n length in bytes of the YELLOW period, one register per port. Used for Profinet IRT when the output cut-through is switched from enabled to disabled. Only relevant for Ethernet ports.

29.3.10.4 MMCTL_POOLn_CTR : Memory Pool Counter (n = 0 to 1)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3B40 + 0x4 × n

Bit position:	31						25									16						9									0
Bit field:	—	—	—	—	—	—	USED[9:0]									—	—	—	—	—	—	CELLS[9:0]									
Value after reset:	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	CELLS[9:0]	Memory pool configuration for pool n. Configures, in cells, the size of each memory pool. The sum of all cells assigned among all pools including the global pool must be at most MEM_BLKS − IPORTS, where IPORTS is the number of input ports including the management port (when 802.3br is enabled in a port, two blocks must be reserved for it instead of one). Reading back this register returns the current pool utilization. The pools must be configured when there is no traffic and the memory is empty.	R/W
15:10	—	The read values are undefined. The write value should be 0.	R/W
25:16	USED[9:0]	Reports the current available number of used cells for this memory pool. The used number of free cells can be calculated as CELLS − USED.	R

Bit	Symbol	Function	R/W
31:26	—	The read values are undefined. The write value should be 0.	R/W

Pool n configuration, one register per counter. Write to define the number of memory cells assigned to pool n.

29.3.10.5 MMCTL_POOL_GLOBAL : Memory Pool Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3B60

Bit position:	31						25									16						9								0
Bit field:	—	—	—	—	—	—	USED[9:0]									—	—	—	—	—	—	CELLS[9:0]								
Value after reset:	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	x	x	x	x	x	x	1	1	1	1	1	1	1	0	0	1

Bit	Symbol	Function	R/W
9:0	CELLS[9:0]	Memory pool configuration for the global pool. Configures, in cells, the size of the global shared pool. The sum of all blocks assigned to all pools including the global pool must be at most MEM_BLKS − IPORTS, where IPORTS is the number of input ports including the management port (when 802.3br is enabled in a port, two blocks must be reserved for it instead of one). On initialization, all memory cells (MEM_BLKS) are assigned to the global pool minus one cell per input port (IPORTS). The minimum valid value for this field is 3.	R/W
15:10	—	The read values are undefined. The write value should be 0.	R/W
25:16	USED[9:0]	Reports the current number of used cells for the global shared pool. The used number of free cells can be calculated as CELLS − USED.	R
31:26	—	The read values are undefined. The write value should be 0.	R/W

The MMCTL_POOL_GLOBAL register is used for global pool configuration. Write to define the number of memory cells assigned to the global pool.

29.3.10.6 MMCTL_POOL_STATUS : Memory Pool Status Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3B64

Bit position:	31																							7						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	QUEUE_FULL[7:0]						
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	QUEUE_FULL[7:0]	Per-queue pool full indication. Indicates for each queue whether all the blocks in the corresponding pool and global pool are allocated. The value is reset to 0 after it is read.	R
31:8	—	The read values are undefined.	R

The MMCTL_POOL_STATUS register indicates pool full status and whether frames were discarded due to the pool filling up.

29.3.10.7 MMCTL_POOL_QMAP : Queue MAP Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3B68

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	Q7_ENA	—	—	Q7_MAP	Q6_ENA	—	—	Q6_MAP	Q5_ENA	—	—	Q5_MAP	Q4_ENA	—	—	Q4_MAP
Value after reset:	0	x	x	0	0	x	x	0	0	x	x	0	0	x	x	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	Q3_ENA	—	—	Q3_MAP	Q2_ENA	—	—	Q2_MAP	Q1_ENA	—	—	Q1_MAP	Q0_ENA	—	—	Q0_MAP
Value after reset:	0	x	x	0	0	x	x	0	0	x	x	0	0	x	x	0

Bit	Symbol	Function	R/W
0	Q0_MAP	Queue 0 Memory Pool Configures which memory pool is used for Queue 0 in all ports.	R/W
2:1	—	The read values are undefined. The write value should be 0.	R/W
3	Q0_ENA	Queue 0 Memory Pool Enabled 0: The queue only uses cells from the global pool 1: The queue uses the pool programmed in Q0_MAP	R/W
4	Q1_MAP	Queue 1 Memory Pool Configures which memory pool is used for Queue 1 in all ports.	R/W
6:5	—	The read values are undefined. The write value should be 0.	R/W
7	Q1_ENA	Queue 1 Memory Pool Enabled 0: The queue only uses cells from the global pool 1: The queue uses the pool programmed in Q1_MAP	R/W
8	Q2_MAP	Queue 2 Memory Pool Configures which memory pool is used for Queue 2 in all ports.	R/W
10:9	—	The read values are undefined. The write value should be 0.	R/W
11	Q2_ENA	Queue 2 Memory Pool Enabled 0: The queue only uses cells from the global pool 1: The queue uses the pool programmed in Q2_MAP	R/W
12	Q3_MAP	Queue 3 Memory Pool Configures which memory pool is used for Queue 3 in all ports.	R/W
14:13	—	The read values are undefined. The write value should be 0.	R/W
15	Q3_ENA	Queue 3 Memory Pool Enabled 0: The queue only uses cells from the global pool 1: The queue uses the pool programmed in Q3_MAP	R/W
16	Q4_MAP	Queue 4 Memory Pool Configures which memory pool is used for Queue 4 in all ports.	R/W
18:17	—	The read values are undefined. The write value should be 0.	R/W
19	Q4_ENA	Queue 4 Memory Pool Enabled 0: The queue only uses cells from the global pool 1: The queue uses the pool programmed in Q4_MAP	R/W
20	Q5_MAP	Queue 5 Memory Pool Configures which memory pool is used for Queue 5 in all ports.	R/W
22:21	—	The read values are undefined. The write value should be 0.	R/W
23	Q5_ENA	Queue 5 Memory Pool Enabled 0: The queue only uses cells from the global pool 1: The queue uses the pool programmed in Q5_MAP	R/W
24	Q6_MAP	Queue 6 Memory Pool Configures which memory pool is used for Queue 6 in all ports.	R/W

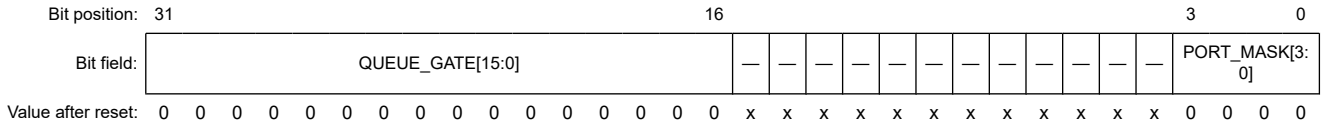
Bit	Symbol	Function	R/W
26:25	—	The read values are undefined. The write value should be 0.	R/W
27	Q6_ENA	Queue 6 Memory Pool Enabled 0: The queue only uses cells from the global pool 1: The queue uses the pool programmed in Q6_MAP	R/W
28	Q7_MAP	Queue 7 Memory Pool Configures which memory pool is used for Queue 7 in all ports.	R/W
30:29	—	The read values are undefined. The write value should be 0.	R/W
31	Q7_ENA	Queue 7 Memory Pool Enabled 0: The queue only uses cells from the global pool 1: The queue uses the pool programmed in Q7_MAP	R/W

The MMCTL_POOL_QMAP register maps each queue to a memory pool. By default, all queues are assigned to pool 0. All queues in the LSI use the same pool regardless of the port.

29.3.10.8 MMCTL_QGATE : Queue Gate State Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3B6C



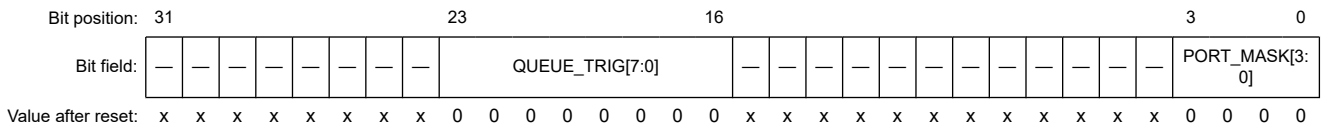
Bit	Symbol	Function	R/W
3:0	PORT_MASK[3:0]	Per-port bit mask. When set to 1 for a port, the queue gate state is changed for that port as indicated by QUEUE_GATE.	W
15:4	—	The write value should be 0.	W
31:16	QUEUE_GATE[15:0]	2-bit per queue indicating the action to be performed on each queue of the ports indicated by PORT_MASK. bits [1:0] = queue 0, bits [3:2] = queue 1, and so on. 0 0: Hold state, does not change the queue gate state 0 1: Toggle state, toggles the gate state 1 0: Gate queue, closes the queue 1 1: Open queue, enables the queue	W

The MMCTL_QGATE register is a write-only register and is used to change the gate state of queues. Writing to this register generates an action for the ports and queues indicating the changes to the gate state of the queues. Only relevant for Ethernet ports.

29.3.10.9 MMCTL_QTRIG : Queue Trigger Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3B70



Bit	Symbol	Function	R/W
3:0	PORT_MASK[3:0]	Per-port bit mask. When set to 1 for a port, a frame is triggered from the closed queues indicated by QUEUE_TRIG.	W
15:4	—	The write value should be 0.	W

Bit	Symbol	Function	R/W
23:16	QUEUE_TRIG[7:0]	1-bit per queue indicating from which queues a frame is to be transmitted from the ports indicated by PORT_MASK. When set to 1, a single frame is transmitted per indicated port in PORT_MASK among the queues indicated by QUEUE_TRIG.	W
31:24	—	The write value should be 0.	W

The MMCTL_QTRIG register is a write-only register and is used to trigger sending a frame from a set of queues in selected ports. The action is performed on a register write. The highest priority queue is selected from the enabled queues and a single frame is sent. The queue must be in a closed state. Only relevant for Ethernet ports.

29.3.10.10 MMCTL_QFLUSH : Flush Event Select Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3B74

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	ACTION[1:0]		QUEUE_MASK[7:0]							
Value after reset:	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	PORT_MASK[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	PORT_MASK[3:0]	Per-port bit mask. When set to 1 for a port, the queue flush status is changed for that port for the queues indicated in QUEUE_MASK.	W
15:4	—	The write value should be 0.	W
23:16	QUEUE_MASK[7:0]	1 bit per queue indicating for which queues of the ports indicated by PORT_MASK the flush state is changed as indicated in ACTION.	W
25:24	ACTION[1:0]	Selects the flush state for the queues indicated by QUEUE_MASK in the ports indicated by PORT_MASK. Possible actions are: 0 0: Disable flush 0 1: Flush when queue is closed, discarding any new frames 1 0: Flush on queue close until empty, then stops flushing 1 1: TRIGGER flush until empty, then return to current flush mode	W
31:26	—	The write value should be 0.	W

The MMCTL_QFLUSH register is a write-only register and is used to generate or stop flush events from selected ports and queues. The action is performed on a register write. Only relevant for Ethernet ports.

29.3.10.11 MMCTL_QCLOSED_STATUS_P0_3 : Queue Closed Status Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3B78

Bit position:	31								23								16	15							8	7							0
Bit field:	—	—	—	—	—	—	—	—	P2_STATUS[7:0]									P1_STATUS[7:0]								P0_STATUS[7:0]							
Value after reset:	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	P0_STATUS[7:0]	Per-queue closed status of Port 0 (1-bit per queue). A 0 indicates that the queue is open (enabled), and a 1 indicates that the queue is closed (disabled).	R

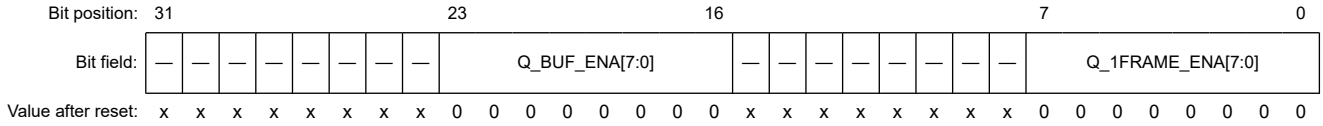
Bit	Symbol	Function	R/W
15:8	P1_STATUS[7:0]	Per-queue closed status of Port 1 (1-bit per queue). A 0 indicates that the queue is open (enabled), and a 1 indicates that the queue is closed (disabled).	R
23:16	P2_STATUS[7:0]	Per-queue closed status of Port 2 (1-bit per queue). A 0 indicates that the queue is open (enabled), and a 1 indicates that the queue is closed (disabled).	R
31:24	—	The read values are undefined.	R

The MMCTL_QCLOSED_STATUS_P0_3 register indicates the queue closed status. Reports whether each queue is open (enabled, 0) or closed (disabled, 1). Only relevant for Ethernet ports.

29.3.10.12 MMCTL_1FRAME_MODE_Pn : Port n 1-Frame Mode Configuration Register (n = 0 to 2)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3B80 + 0x4 × n



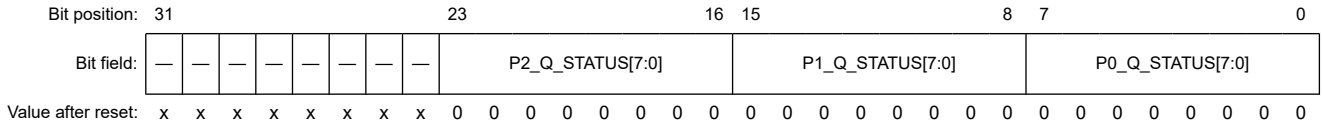
Bit	Symbol	Function	R/W
7:0	Q_1FRAME_ENA[7:0]	1 bit per queue. Setting a bit to 1 enables the 1-frame mode for that queue for port n. In this mode, only one frame is allowed in the queue. If a new frame is received, the old frame is discarded. This mode requires that the queue is in closed state, and frames are transmitted by a triggering action from the register, the pattern matchers, or the TDMA scheduler.	R/W
15:8	—	The read values are undefined. The write value should be 0.	R/W
23:16	Q_BUF_ENA[7:0]	1 bit per queue. Setting a bit to 1 enables the buffer mode behavior for that queue for port n. This mode requires also that Q_1FRAME_ENA is set to 1. When Q_BUF_ENA is set, a frame is always kept in the buffer after it is transmitted. If another frame is received in the queue, the old frame is discarded. This mode requires that the queue is in closed state, and frames are transmitted by a triggering action from the register, the pattern matchers, or the TDMA scheduler.	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

MMCTL_1FRAME_MODE_Pn register, one register per port. Per-queue control to enable 1-frame mode, where up to 1 frame is stored in the indicated queues, and whether the frame is discarded or kept after transmission. Only relevant for Ethernet ports.

29.3.10.13 MMCTL_P0_3_QUEUE_STATUS : Queue Status Indicator

Base address: ETHSW = 0x8012_0000

Offset address: 0x3BA0



Bit	Symbol	Function	R/W
7:0	P0_Q_STATUS[7:0]	Port 0 Per-Queue Bit Indication 0: Queue is empty 1: Queued frames	R

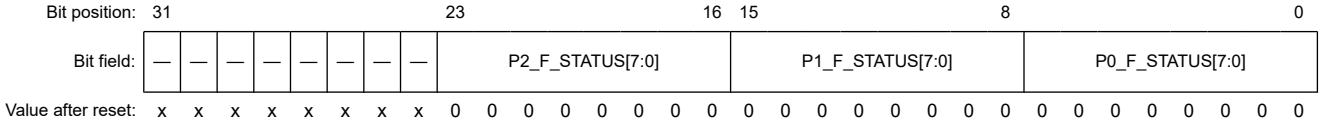
Bit	Symbol	Function	R/W
15:8	P1_Q_STATUS[7:0]	Port 1 Per-Queue Bit Indication 0: Queue is empty 1: Queued frames	R
23:16	P2_Q_STATUS[7:0]	Port 2 Per-Queue Bit Indication 0: Queue is empty 1: Queued frames	R
31:24	—	The read values are undefined.	R

The MMCTL_P0_3_QUEUE_STATUS register indicates per-port/queue status, whether the queue is empty (read 0) or not (read 1). Only relevant for Ethernet ports.

29.3.10.14 MMCTL_P0_3_FLUSH_STATUS : Queue Flush Status Indicator

Base address: ETHSW = 0x8012_0000

Offset address: 0x3BA8



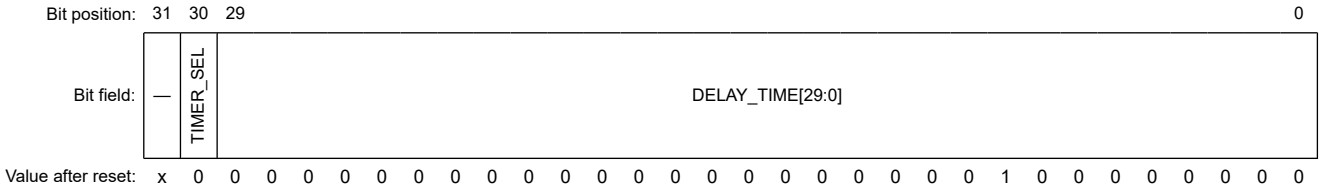
Bit	Symbol	Function	R/W
7:0	P0_F_STATUS[7:0]	Port 0 per-Queue Bit Indication on whether the queue is flushing frames (read 1) or not (read 0).	R
15:8	P1_F_STATUS[7:0]	Port 1 per-Queue Bit Indication on whether the queue is flushing frames (read 1) or not (read 0).	R
23:16	P2_F_STATUS[7:0]	Port 2 per-Queue Bit Indication on whether the queue is flushing frames (read 1) or not (read 0).	R
31:24	—	The read values are undefined.	R

The MMCTL_P0_3_FLUSH_STATUS register indicates per-port/queue status, whether the queue is flushing frames (read 1) or not (read 0). Only relevant for Ethernet ports.

29.3.10.15 MMCTL_DLY_QTRIGGER_CTRL : Delayed Queue Trigger Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3BB0



Bit	Symbol	Function	R/W
29:0	DELAY_TIME[29:0]	30-bit time in nanoseconds indicates the time after the trigger request from the pattern matchers to generate the event.	R/W
30	TIMER_SEL	Select the source timer to use for calculating the time. 0: Timer 0 1: Timer 1	R/W
31	—	The read value is undefined. The write value should be 0.	R/W

The MMCTL_DLY_QTRIGGER_CTRL register controls time for delayed queue triggering. Contains a timer select and a 30-bit time in nanoseconds for delayed queue triggering. When a pattern matcher generates a delay trigger event, this time is added to the current time in the selected timer to calculate the time for the trigger event to occur.

29.3.10.16 MMCTL_PREEMPT_QUEUES : Preemptable Queues Configures Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3BB4

Bit position:	31																15								8	7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PREEMPT_ON_QCLOSE[7:0]									PREEMPT_ENA[7:0]								
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0	

Bit	Symbol	Function	R/W
7:0	PREEMPT_ENA[7:0]	Per-queue enable bit to configure which queues are used for preemptable traffic. Set to 1 the corresponding bit to configure a queue to be preemptable. The express queues always have priority over preemptable queues.	R/W
15:8	PREEMPT_ON_QCLOSE[7:0]	Per-queue configuration bit to enable preempting a frame when the queue goes from OPEN to CLOSED. When the corresponding bit is set to 1 and the queue is configured as preemptable in PREEMPT_ENA, a queue close event causes the current frame to be preempted, if preemption is operational.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

The MMCTL_PREEMPT_QUEUES register configures which queues are preemptable queues when preemption is enabled and operational. Only relevant for Ethernet ports with 802.3br support.

29.3.10.17 MMCTL_HOLD_CONTROL : Request Preemption Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3BB8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	Q_HOLD_REQ_RELEASE[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	Q_HOLD_REQ_FORCE[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	Q_HOLD_REQ_FORCE[2:0]	A per-port bit that forces a preempt request using MM_CTL.request (hold_req). When this bit is set to 1, it overrides other sources of hold request, including the TDMA controller.	R/W
15:3	—	The read values are undefined. The write value should be 0.	R/W
18:16	Q_HOLD_REQ_RELEASE[2:0]	A per-port bit that forces a release of preemption request using MM_CTL.request (hold_req). When this bit is set to 1, it overrides other sources of hold request, including the TDMA controller and Q_HOLD_REQ_FORCE[2:0].	R/W
31:19	—	The read values are undefined. The write value should be 0.	R/W

Allows for the firmware to request a preemption when preemption is enabled and operational (MM_CTL.request (hold_req)). Only relevant for Ethernet ports with 802.3br support.

29.3.10.18 MMCTL_PREEMPT_STATUS : Preemption State Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3BBC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	HOLD_REQ_STATE[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	PREEMPT_STATE[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	PREEMPT_STATE[2:0]	A per-port bit that indicates if a port is in a preempted state. This is a real-time indication meant for debugging.	R
15:3	—	The read values are undefined.	R
18:16	HOLD_REQ_STATE[2:0]	A per-port bit that indicates if a port is preempted using MM_CTL.request (hold_req). This is a real-time indication meant for debugging.	R
31:19	—	The read values are undefined.	R

Per-port preemption state. Indicates if a port is preempting a frame and the state of MM_CTL.request (hold_req). Only relevant for Ethernet ports with 802.3br support.

29.3.10.19 MMCTL_CQF_CTRL_Pn : Port n Cyclic Queuing and Forwarding Control Register (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3BC0 + 0x4 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	REF_SEL0	USE_SOP0	GATE_SEL0[2:0]			QUEUE_SEL0[2:0]			PRIO_ENABLE0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

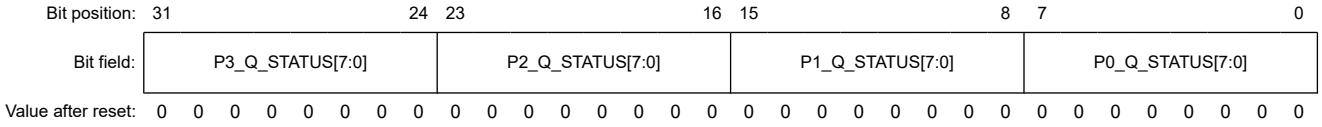
Bit	Symbol	Function	R/W
7:0	PRIO_ENABLE0[7:0]	A per-queue enable to select which ingress priorities are queued in the two CQF queues.	R/W
10:8	QUEUE_SEL0[2:0]	Select which two physical queues are used for CQF. The queues used are QUEUE_SEL0 and QUEUE_SEL0 + 1. Frames are written into QUEUE_SEL0 when the gate control selected with GATE_SEL0 is 0, and into QUEUE_SEL0 + 1 when the gate control is 1.	R/W
13:11	GATE_SEL0[2:0]	Select which gate control signal is used for selecting the output queue (these signals are the same as the ETHSW_TDMAOUT pins).	R/W
14	USE_SOP0	When set to 1, the CFQ queue is determined when the SOP is received at the frame writer in the memory controller. When set to 0, the queue is determined when the EOP is received at the frame writer.	R/W
15	REF_SEL0	Select whether the gate control signal used for the CQF group is based on the egress port when set to 0, or the ingress port when set to 1.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

Controls for configuring Cyclic Queuing and Forwarding (CQF) for port n.

29.3.10.20 MMCTL_P0_3_QCLOSED_NONEMPTY : Port Queue Status Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3BE0



Bit	Symbol	Function	R/W
7:0	P0_Q_STATUS[7:0]	Port 0 per-queue bit indication on whether the queue transitioned from open to closed state while frames were still queued.	R
15:8	P1_Q_STATUS[7:0]	Port 1 per-queue bit indication on whether the queue transitioned from open to closed state while frames were still queued.	R
23:16	P2_Q_STATUS[7:0]	Port 2 per-queue bit indication on whether the queue transitioned from open to closed state while frames were still queued.	R
31:24	P3_Q_STATUS[7:0]	Port 3 per-queue bit indication on whether the queue transitioned from open to closed state while frames were still queued.	R

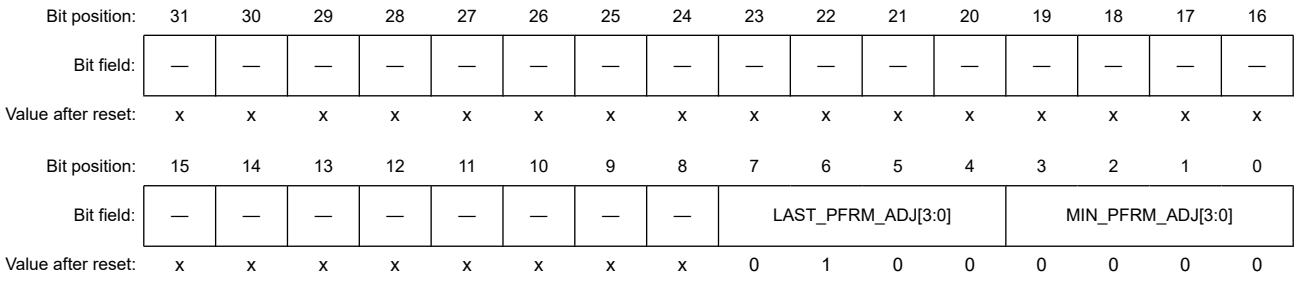
Per-port/queue status indications for ports 0 through 3. Latches when a queue is closed and there are frames still queued. Only relevant for Ethernet ports.

The value is reset to 0 after the bit is read.

29.3.10.21 MMCTL_PREEMPT_EXTRA : Frame Preemption Extra Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3BE8



Bit	Symbol	Function	R/W
3:0	MIN_PFRM_ADJ[3:0]	Adjust the minimum mPacket length, in increments of 4 bytes.	R/W
7:4	LAST_PFRM_ADJ[3:0]	Adjust the preemptable threshold when reaching the end of the frame, in increments of 4 bytes. Incrementing this value increments the length of the last mPacket.	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

Must not be changed.

29.3.11 DLR Module Registers

29.3.11.1 DLR_CONTROL : DLR Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	US_TIME[11:8]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	US_TIME[7:0]								—	—	—	IGNORE_INVTM	—	LOOP_FILTER_ENA	AUTOFLUSH	ENABLE
Value after reset:	0	1	1	0	0	1	0	0	x	x	x	0	x	0	0	0

Bit	Symbol	Function	R/W
0	ENABLE	Enable DLR extension module. When set, the DLR module becomes active. When DLR is enabled, the LOOP_FILTER_ENA must also be enabled for proper DLR operation. When cleared, no DLR frame detection occurs and all DLR module statistics registers are cleared.	R/W
1	AUTOFLUSH	Enable automatic flushing of unicast entries in address table if ring reconfiguration occurs (see also DLR interrupt IRQ_flush_macaddr_ena in DLR_IRQ_CONTROL).	R/W
2	LOOP_FILTER_ENA	Enable the loop filter function. When set to 1, the ingress loop filter is enabled. This can be enabled regardless of the DLR ENABLE state, allowing the loop filter function to operate when DLR is not used.	R/W
3	—	The read value is undefined. The write value should be 0.	R/W
4	IGNORE_INVTM	Enable ignore beacon frames with invalid timeout timer. When enabled (set to 1) frames with timeout timer value not within a range of 200 microseconds to 500 milliseconds are ignored and parameters are not locally stored or considered for state transitions. The invalid timeout timer value is always stored within the DLR_INV_TMOUT register irrespective of the value of this bit. Ignored frames are forwarded normally.	R/W
7:5	—	The read values are undefined. The write value should be 0.	R/W
19:8	US_TIME[11:0]	Number of clock cycles required for 1 microsecond for the switch operating clock. This LSI operates at 200 MHz, therefore this register must be set to 0xC8. The value after reset must be changed.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The DLR_CONTROL register is used to select the DLR operation.

29.3.11.2 DLR_STATUS : DLR Status Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TOPOLOGY[7:0]								—	—	—	—	—	—	LINK_STATUS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	x	x	x	x	x	x	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	NODE_STATE[7:0]								—	—	—	—	—	—	LastBcnRcvPort[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
1:0	LastBcnRcvPort[1:0]	Last Beacon Receive Port Bit 0: Set if beacon frame from active supervisor received on port 0 Bit 1: Set if beacon frame from active supervisor received on port 1	R
7:2	—	The read values are undefined.	R
15:8	NODE_STATE[7:0]	Local Node Current State 0x00: IDLE_STATE 0x01: NORMAL_STATE 0x02: FAULT_STATE Others: Reserved	R
17:16	LINK_STATUS[1:0]	Link Status This is a direct representation of the top level input pins (ETHSW_PHYLINK0, ETHSW_PHYLINK1). Bit 16: Set if port 0 link is up Bit 17: Set if port 1 link is up	R
23:18	—	The read values are undefined.	R
31:24	TOPOLOGY[7:0]	Current Network Topology 0x00: Linear topology when local node is in IDLE state 0x01: Ring topology when local node is not in IDLE state Others: Reserved	R

29.3.11.3 DLR_ETH_TYP : DLR Ethernet Type Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C08

Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DLR_ETH_TYP[15:0]														
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	1	0	0	0	0	0	0	0	1	1	1	0	0	0	0	1

Bit	Symbol	Function	R/W
15:0	DLR_ETH_TYP[15:0]	Ethernet type to compare for DLR frame detection (initial value is 0x80E1)	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.11.4 DLR_IRQ_CONTROL : DLR Interrupt Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	atomic_AND	atomic_OR	low_int_en	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	IRQ_frm_dscrd1	IRQ_frm_dscrd0	IRQ_bec_rcv1_ena	IRQ_bec_rcv0_ena	IRQ_invalid_tmr_ena	IRQ_ip_addr_chng_ena	IRQ_sup_ignord_ena	IRQ_link_chng1_ena	IRQ_link_chng0_ena	IRQ_supr_chng_ena	IRQ_bec_tmr1_exp_ena	IRQ_bec_tmr0_exp_ena	IRQ_stop_nbchk1_ena	IRQ_stop_nbchk0_ena	IRQ_flush_macaddr_ena	IRQ_state_chng_ena
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IRQ_state_chng_ena	Enable Interrupt for State Change When enabled, an interrupt is generated when state change occurs for the local beacon based DLR ring node. The interrupt service routine must re-read the beacon frame parameters and clear the bit afterwards.	R/W
1	IRQ_flush_macaddr_ena	Enable Flush Local MAC Address Table Interrupt. When enabled, an interrupt is generated when unicast MAC address learning table should be flushed.	R/W
2	IRQ_stop_nbchk0_ena	Enable Stop Request Neighbor Check Timeout Timer Interrupt for Port 0.	R/W
3	IRQ_stop_nbchk1_ena	Enable Stop Request Neighbor Check Timeout Timer Interrupt for Port 1.	R/W
4	IRQ_bec_tmr0_exp_ena	Enable Interrupt on Beacon Timeout Timer Expire for Port 0.	R/W
5	IRQ_bec_tmr1_exp_ena	Enable Interrupt on Beacon Timeout Timer Expire for Port 1.	R/W
6	IRQ_supr_chng_ena	Enable Interrupt on Ring Supervisor Change.	R/W
7	IRQ_link_chng0_ena	Enable Link Status Change Interrupt Event for Port 0.	R/W
8	IRQ_link_chng1_ena	Enable Link Status Change Interrupt Event for Port 1.	R/W
9	IRQ_sup_ignord_ena	Enable interrupt on beacon frame detection from a supervisor with lower precedence than the current ring supervisor or lower numeric value for MAC address when precedence is same.	R/W
10	IRQ_ip_addr_chng_ena	Enable interrupt on IP address change detection within beacon frame from ring supervisor.	R/W
11	IRQ_invalid_tmr_ena	Enable interrupt on invalid range for beacon timeout timer value detection.	R/W
12	IRQ_bec_rcv0_ena	Enable interrupt on beacon frame detection on port 0.	R/W
13	IRQ_bec_rcv1_ena	Enable interrupt on beacon frame detection on port 1.	R/W
14	IRQ_frm_dscrd0	Enable interrupt on frame discard due to source address match with the local address on port 0.	R/W
15	IRQ_frm_dscrd1	Enable Interrupt on Frame discard due to source address match with the local address on port 1.	R/W
28:16	—	The read values are undefined. The write value should be 0.	R/W
29	low_int_en	Enable active-low interrupt. Asserted to use active-low interrupt signal instead of active-high interrupt signal.	R/W
30	atomic_OR	When set during a register-write, the enable bits are ORed into the current setting of the register. By writing this bit at the same time, only the target bit can be set to 1.	W
31	atomic_AND	When set during a register-write, the enable bits are ANDed with the current setting of the register. By writing this bit at the same time, only the target bit can be set to 0.	W

If any of the interrupt enable bit is set and a corresponding event occurs, the DLR interrupt (DLR_INT bit) within the global INT_STAT_ACK interrupt status register asserts. In addition, ETHSW_DLR interrupt asserts. To clear any of the interrupts, the DLR_IRQ_STAT_ACK register must be written.

29.3.11.5 DLR_IRQ_STAT_ACK : DLR Interrupt Status/ACK Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	frm_dscrd1_IRQ_pending	frm_dscrd0_IRQ_pending	bec_rcv1_IRQ_pending	bec_rcv0_IRQ_pending	invalid_tmr_IRQ_pending	ip_chng_IRQ_pending	sup_ignord_IRQ_pending	Link1_IRQ_pending	Link0_IRQ_pending	suprchng_IRQ_pending	bec_tmr1_IRQ_pending	bec_tmr0_IRQ_pending	nbchk1_IRQ_pending	nbchk0_IRQ_pending	flush_IRQ_pending	state_chng_IRQ_pending
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	state_chng_IRQ_pending	Latched State Change Event Asserts whenever local beacon based DLR node state changes. To clear the latch, the bit must be written with 1.	R/W
1	flush_IRQ_pending	Latched Flush Event for MAC Address Learning Table When asserted, MAC address learning table should be flushed. To clear the latch, the bit must be written with 1.	R/W
2	nbchk0_IRQ_pending	Stop Request Event for Neighbor Check Timeout Timer for Port 0 When asserted, neighbor check timeout timer should be stopped. To clear the latch, the bit must be written with 1.	R/W
3	nbchk1_IRQ_pending	Stop Request Event for Neighbor Check Timeout Timer for Port 1 When asserted, neighbor check timeout timer should be stopped. To clear the latch, the bit must be written with 1.	R/W
4	bec_tmr0_IRQ_pending	Beacon Timeout Timer Expire Event for Port 0 Asserted when beacon timeout timer expired for port 0. To clear the latch, the bit must be written with 1.	R/W
5	bec_tmr1_IRQ_pending	Beacon Timeout Timer Expire Event for Port 1 Asserted when beacon timeout timer expired for port 1. To clear the latch, the bit must be written with 1.	R/W
6	supr_chng_IRQ_pending	Latched Supervisor Change Event Asserted when ring supervisor changes for DLR ring. To clear the latch, the bit must be written with 1.	R/W
7	Link0_IRQ_pending	Latched Link Status Change Event for Port 0 Asserts whenever link status change is detected on Port 0. To clear the latch, the bit must be written with 1.	R/W
8	Link1_IRQ_pending	Latched Link Status Change Event for Port 1 Asserts whenever link status change is detected on Port 1. To clear the latch, the bit must be written with 1.	R/W
9	sup_ignord_IRQ_pending	Latched Event for Beacon Frame Detection from Ignored Supervisor Asserted when beacon frame detected from a supervisor with lower precedence or lower numeric value for the MAC address when precedence is the same. To clear the latch, the bit must be written with 1.	R/W
10	ip_chng_IRQ_pending	Latched IP Address Change Event Asserted when IP address change detection within beacon frame from ring supervisor. To clear the latch, the bit must be written with 1.	R/W
11	invalid_tmr_IRQ_pending	Latched Event on Invalid Beacon Timeout Timer Value Detection Within Beacon Frame on Port 0 or Port 1 To clear the latch, the bit must be written with 1.	R/W
12	bec_rcv0_IRQ_pending	Latched Event on Beacon Frame Detection on Port 0 To clear the latch, the bit must be written with 1.	R/W

Bit	Symbol	Function	R/W
13	bec_rcv1_IRQ_pending	Latched Event on Beacon Frame Detection on Port 1 To clear the latch, the bit must be written with 1.	R/W
14	frm_dscrd0_IRQ_pending	Latched Event on Frame Discard Due to Source Address Match with the Local Address on Port 0 (Loop Filter) To clear the latch, the bit must be written with 1.	R/W
15	frm_dscrd1_IRQ_pending	Latched Event on Frame Discard Due to Source Address Match with the Local Address on Port 1 (Loop Filter) To clear the latch, the bit must be written with 1.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.11.6 DLR_LOC_MAClo : DLR Local MAC Address Low Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C14

Bit position:	31																												0
Bit field:	LOC_MAC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	LOC_MAC[31:0]	First 4 octets of the Local MAC address for loop filter Bits [7:0] is first byte, …, bits [31:24] is 4th byte of address.	R/W

29.3.11.7 DLR_LOC_MAChi : DLR Local MAC Address High Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C18

Bit position:	31																15												0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LOC_MAC[15:0]												
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	LOC_MAC[15:0]	Last 2 octets of local MAC address for loop filter Bits [7:0] is 5th byte of the local MAC address. Bits [15:8] is 6th (last) byte of the local MAC address.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.11.8 DLR_SUPR_MAClo : DLR Supervisor MAC Address Low Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C20

Bit position:	31																												0
Bit field:	SUPR_MAC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SUPR_MAC[31:0]	First 4 octets of the active ring supervisor of the MAC address extracted from the Source Address field of the beacon frame. Bits [7:0] is first byte, …, bits [31:24] is 4th byte of address.	R

Type1 parameter (see (6) Beacon Frame Parameter Extraction.)

29.3.11.9 DLR_SUPR_MAChi : DLR Supervisor MAC Address High Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C24

Bit position:	31								23							16	15													0
Bit field:	—	—	—	—	—	—	—	—	PRECE[7:0]								SUPR_MAC[15:0]														
Value after reset:	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SUPR_MAC[15:0]	Last 2 octets of the active ring supervisor of the MAC address extracted from the Source Address field of the beacon frame. Bits [7:0] is 5th byte, bits [15:8] is 6th byte.	R
23:16	PRECE[7:0]	Precedence value of the ring supervisor extracted from the Supervisor precedence field of the beacon frame.	R
31:24	—	The read values are undefined.	R

Type1 parameter (see (6) Beacon Frame Parameter Extraction.)

29.3.11.10 DLR_STATE_VLAN : DLR Ring Status/VLAN Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C28

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	VLANINFO[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	VLAN VALID	RINGSTAT[7:0]							
Value after reset:	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RINGSTAT[7:0]	DLR ring state extracted from the Ring State field of the beacon frame. 0x01: RING_NORMAL_STATE 0x02: RING_FAULT_STATE Others: Unused	R
8	VLANVALID	VLAN Valid When asserted, the current VLAN control field bits [31:16] contain valid VLAN ID.	R
15:9	—	The read values are undefined.	R
31:16	VLANINFO[15:0]	IEEE 802.1Q VLAN Tag control field extracted from the VLAN info field of the beacon frame.	R

Type1 parameter (see (6) Beacon Frame Parameter Extraction.)

29.3.11.11 DLR_BEC_TMOUT : DLR Beacon Timeout Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C2C

Bit position:	31																												0
Bit field:	BEC_TMOUT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	BEC_TMOUT[31:0]	Beacon timeout timer value extracted from the Beacon Timeout in microseconds field of the beacon frame. Invalid timeout timer values are not written to this register and are not considered for state transition when ignore enabled with bit 4 of the DLR_CONTROL register. Expected value is in the range between minimum 200 microseconds and maximum 500 milliseconds. Typical value is 1960 microseconds.	R

Type1 parameter (see (6) Beacon Frame Parameter Extraction.)

29.3.11.12 DLR_BEC_INTRVL : DLR Beacon Interval Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C30

Bit position:	31																												0
Bit field:	BEC_INTRVL[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	BEC_INTRVL[31:0]	Beacon interval extracted from the Beacon Interval field of the beacon frame Expected value is in a range between minimum 100 microseconds and maximum 100 milliseconds. Typical value is 400 microseconds.	R

Type1 parameter (see (6) Beacon Frame Parameter Extraction.)

29.3.11.13 DLR_SURR_IPADR : DLR Supervisor IP Address Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C34

Bit position:	31																												0
Bit field:	SUPR_IPADR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SUPR_IPADR[31:0]	IP address of the ring supervisor extracted from the Source IP address field of the beacon frame. A value of 0x0 can be received when supervisor has no IP address.	R

Type2 parameter (see (6) Beacon Frame Parameter Extraction.)

29.3.11.14 DLR_ETH_STYP_VER : DLR Sub Type/Protocol Version Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C38

Bit position:	31								23								16	15							8	7							0
Bit field:	—	—	—	—	—	—	—	—	SPORT[7:0]									PROTVER[7:0]								SUBTYPE[7:0]								
Value after reset:	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SUBTYPE[7:0]	DLR Ring Ether Sub Type extracted from the Ring Sub Type field of the beacon frame. Value should be 0x02.	R
15:8	PROTVER[7:0]	DLR Ring Protocol Version extracted from the Ring Protocol Version field of the beacon frame.	R
23:16	SPORT[7:0]	Source port extracted from the Source Port field of the beacon frame.	R
31:24	—	The read values are undefined.	R

Type1 parameter (see (6) Beacon Frame Parameter Extraction.)

29.3.11.15 DLR_INV_TMOUT : DLR Beacon Timeout Timer Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C3C

Bit position:	31																															0
Bit field:	INV_TMOUT[31:0]																															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	INV_TMOUT[31:0]	Last out of range Beacon timeout timer value extracted from beacon frame on any of the port. Valid range is between 200 microseconds and 500 milliseconds. This register is always written whenever a new invalid value is received. Contains a valid value when bit 11 of the DLR_IRQ_STAT_ACK register is asserted.	R

Type3 parameter (see (6) Beacon Frame Parameter Extraction.)

29.3.11.16 DLR_SEQ_ID : DLR Sequence ID Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C40

Bit position:	31																															0
Bit field:	SEQ_ID[31:0]																															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SEQ_ID[31:0]	Sequence ID of the last beacon frame extracted from the Sequence ID field of the beacon frame on port 0 or port 1. Sequence ID of the ignored frames is not stored.	R

Type2 parameter (see (6) Beacon Frame Parameter Extraction.)

29.3.11.17 DLR_DSTlo : DLR Beacon Destination Address Low Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C58

Bit position:	31																												0
Bit field:	DLR_DST[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	1	1	0	1	1	0	0	0	0	1	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
31:0	DLR_DST[31:0]	First 4 octets of the beacon frame destination multicast address (01-21-6C-00-00-01). Bits [7:0] is first byte, …, bits [31:24] is 4th byte of address.	R/W

29.3.11.18 DLR_DSThi : DLR Beacon Destination Address High Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3C5C

Bit position:	31															15													0

Bit	Symbol	Function	R/W
7:0	RX_LF_STAT1[7:0]	Number of discarded frames in port 1 due to loop filtering when LOOP_FILTER_ENA is set to 1. Saturates at 255. Clear when written. Also cleared when LOOP_FILTER_ENA is set to 0.	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.12 PRP Module Registers

29.3.12.1 PRP_CONFIG : PRP Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PRP_AGE_ENA
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	RCT_LEN_CHK_DIS	TX_RCT_1588	TX_RCT_UNKNOWN	TX_RCT_MULTICAST	TX_RCT_BROADCAST	TX_RCT_MODE[1:0]		RX_REMOVE_RCT	RX_DUP_ACCEPT	PRP_ENA
Value after reset:	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PRP_ENA	Enable PRP Operation All other configuration registers must have been configured correctly before setting this bit. When cleared, the statistics counters are cleared also. Before re-enabling, the history memory should be cleared by executing the RM_ADDR_CTRL.CLEAR_MEMORY command.	R/W
1	RX_DUP_ACCEPT	Enable Duplicate Accept Mode of Operation at Receive When this bit is 1, the receivers do not perform duplicate detection and forward all received frames unmodified. When this bit is 0, the receivers try to detect and discard duplicates. Set this bit to 0 for normal operation. Even when this bit is 0, BPDU and IEEE 1588 frames are always accepted without a duplicate check. Using receive duplicate accept can be used to perform duplicate detection at the application and not having the hardware to perform it. Aside from this use, duplicate accept mode is a test setting (IEC: 4.2.6) not intended to be used during normal operation.	R/W

Bit	Symbol	Function	R/W
2	RX_REMOVE_RCT	Allow PRP Port RX to Remove the RCT When this bit is 1, the RCT is removed from frames received at the PRP ports before forwarding. This has no effect on other ports. When this bit is 0, the RCT is not removed. Duplicate detection occurs normally, independent from this setting. BPDU and IEEE 1588 Layer 2 frames are not affected by this setting and are received unmodified always. The RCT is removed only if the source node is known to be a Double attached nodes (DAN) as indicated by having a port mask containing both ports within the address table and the LAN ID matches the port where it is received.	R/W
4:3	TX_RCT_MODE[1:0]	Control Appending the RCT to Transmitted Frames on the Redundant Ports Normally the setting should be 00b or 01b. This allows Single attached nodes (SAN) and Double attached nodes (DAN) within the PRP LAN segments ensuring the RCT is only appended to frames sent to DANs. BPDU frames do not get an RCT appended (IEC: 4.2.7.5.1), independent from this setting. Frames forwarded to a port that is not within the PRP_GROUP do not get an RCT appended (even if at the same time the frame is duplicated to the PRP_GROUP where it can get the RCT appended). The following modes are available. 0 0: Append RCT if group only: Append RCT, if frame is duplicated to exactly the ports listed in the PRP_GROUP register. If the frame is sent to only one of the ports or is for example, flooded also to other ports, no RCT is appended. 0 1: Append RCT to group always: Append the RCT always if the frame is duplicated to at least the two ports listed in the PRP_GROUP. This includes flooded frames even if they are additionally sent on other ports outside the PRP_GROUP. If the frame is sent to only one of the PRP_GROUP ports, no RCT is appended. 1 0: Disable RCT append: The transmitters do not append the RCT even if frames are duplicated to the PRP_GROUP ports. This represents the IEC: 4.2.6 duplicate accept mode of operation. 1 1: Append RCT always forced: The transmitters append the RCT to all frames transmitted on any of the PRP_GROUP ports, no matter if they are duplicated or not or if they are flooded.	R/W
5	TX_RCT_BROADCAST	Should be 1 normally. 0: Do not append RCT to broadcast frames. This further restricts modes 00b, 01b, 11b. 1: Allow appending RCT to broadcast frames.	R/W
6	TX_RCT_MULTICAST	Should be 1 normally. 0: Do not append RCT to multicast frames. This further restricts modes 00b, 01b, 11b. 1: Allow appending RCT to multicast frames.	R/W
7	TX_RCT_UNKNOWN	Should be 1 normally. 0: Do not append RCT to frames flooded because the destination is unknown. This further restricts modes 00b, 01b, 11b. 1: Allow appending RCT to frames that have unknown destination and are hence flooded.	R/W
8	TX_RCT_1588	Setting this bit affects IEEE 1588 frames that are forwarded through the switch (for example, when used as RedBox) to both PRP_GROUP ports. Locally generated IEEE 1588 frames (peer-delay request/response) are not affected by this setting. Normally, this bit should be set to 0 as IEEE 1588 frames should not be considered for duplicate detection (IEC 62439-3: A.4.4). 0: Do not append RCT to IEEE 1588 frames (frame type 0x88F7) frames even if they are duplicated. 1: Allow appending RCT to IEEE 1588 frames. Defines to treat those frames as any other frame according to the configured TX_RCT_xxx settings above.	R/W
9	RCT_LEN_CHK_DIS	When set to 1, disables the RCT length field checking against the actual frame length.	R/W
15:10	—	The read values are undefined. The write value should be 0.	R/W
16	PRP_AGE_ENA	Enable History Memory Aging Timer The timer value is configured with the PRP_AGETIME register.	R/W
31:17	—	The read values are undefined. The write value should be 0.	R/W

29.3.12.2 PRP_GROUP : PRP Port Group Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	LANB_MASK[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	PRP_GROUP[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	PRP_GROUP[2:0]	Defines which two ports should be treated as redundant ports for PRP. Exactly 2 bits must be set in the mask. Only line ports are supported. Bit 0 = Port 0, Bit 1 = Port 1, Bit 2 = Port 2 Setting that is not exactly 2 bits leads to unpredictable behavior.	R/W
15:3	—	The read values are undefined. The write value should be 0.	R/W
18:16	LANB_MASK[2:0]	Defines which of the ports is considered the LAN B port. This port has the RCT containing the LAN B identifier. The other port uses LAN A identifier for the RCT. Exactly 1 bit must be set to match one of the 2 bits in the PRP_GROUP mask. Bit 16 = Port 0, Bit 17 = Port 1, Bit 18 = Port 2 The setting can be changed at any time during operation. For example, if management detects the ports were connected to the wrong networks, it is sufficient to swap the declaration of LAN A/B in this register and there is no need to physically change connections.	R/W
31:19	—	The read values are undefined. The write value should be 0.	R/W

The PRP_GROUP register defines two ports that must be used for PRP and their LAN ID association.

29.3.12.3 PRP_SUFFIX : PRP RCT Suffix

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D08

Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PRP_SUFFIX[15:0]														
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	1	0	0	0	1	0	0	0	1	1	1	1	1	0	1	1

Bit	Symbol	Function	R/W
15:0	PRP_SUFFIX[15:0]	The Redundancy Control Trailer (RCT) suffix (initial value is 0x88FB)	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.12.4 PRP_LANID : PRP LAN Identifier

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D0C

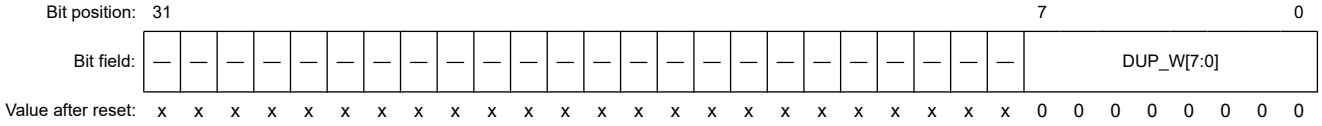
Bit position:	31																							7		4	3		0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LANBID[3:0]			LANAID[3:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	1	0	1	1	1	0	1	0

Bit	Symbol	Function	R/W
3:0	LANAID[3:0]	LAN A Identifier	R/W
7:4	LANBID[3:0]	LAN B Identifier	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.12.5 DUP_W : PRP Max Duplicate Detection Window Size

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D10

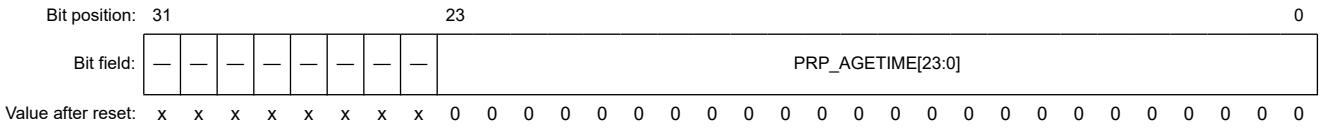


Bit	Symbol	Function	R/W
7:0	DUP_W[7:0]	Maximum Duplicate Detect Window Size If the current sequence number of the frame is in the range of expected, it is treated as duplicate (it is an old sequence number). If a sequence number with a value beyond this window is found, the frame is accepted and an increment of CntOutOfSeqLow occurs. The valid value is 2 to 255. Recommended value is > 50. Setting value of 0 or 1 causes all frames with a sequence number less than the minimum received to be accepted with an out-of-sequence error indication.	R/W
31:8	—	The read values are undefined. The write value should be 0.	R/W

29.3.12.6 PRP_AGETIME : PRP Aging Time Define Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D14



Bit	Symbol	Function	R/W
23:0	PRP_AGETIME[23:0]	Timeout in steps of 32 switch operating clock cycles to control aging of duplicate history data. Every age-time one entry of the history table is inspected for invalidating. Because only a single age bit is used, this requires at maximum two table rounds until an entry is removed. The timeout must be chosen to guarantee the full table is covered in EntryForgetTime / 2 (200 ms). A 24-bit value is available. A value of 0 disables the aging process. For an example setting of 200 ms with a 4096-entries table and the switch clock running at 200 MHz (5 ns): Age-time = 200 ms / (4096 × 5 ns) / 32 = 305.	R/W
31:24	—	The read values are undefined. The write value should be 0.	R/W

29.3.12.7 PRP_IRQ_CONTROL : PRP Interrupt Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D18

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	SEQMISSING	OUTOFSEQ	WRONGLAN	MEMTOOLATE
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
0	MEMTOOLATE	Enable Interrupt for Memory Error Indications. When enabled, an interrupt is generated when the memory transactions for a frame cannot be completed in time. For transmit, it means a frame was sent without appending an RCT. For receive, it means an RCT cannot be checked and the frame was accepted.	R/W
1	WRONGLAN	Enable interrupt for frames received at a redundant port with an invalid LAN identifier in its redundancy trailer. This event also caused the incrementing of the CntErrWrongLan statistics.	R/W
2	OUTOFSEQ	Enable interrupt for frames received and accepted but have an unexpected sequence number. This event also caused the incrementing of the CntOutOfSeq statistics.	R/W
3	SEQMISSING	Enable interrupt for frames received and accepted that caused the history to skip a sequence number that was never received (for example, a missing sequence number is being ignored and is now treated as a candidate for dropping). This event also caused the incrementing of the CntMissing statistics.	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

If any of the interrupt enable bits is set and a corresponding event occurs, the PRP interrupt (PRP_INT bit) within the global INT_STAT_ACK interrupt status register and the ETHSW_PRP interrupt assert. To clear any of the interrupts, write to the PRP_IRQ_STAT_ACK register.

29.3.12.8 PRP_IRQ_STAT_ACK : PRP Interrupt Status/ACK Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D1C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	SEQMISSING	OUTOFSEQ	WRONGLAN	MEMTOOLATE
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
0	MEMTOOLATE	Interrupt Pending Indication Bits corresponding to the bits defined in PRP_IRQ_CONTROL. If an event occurs, the corresponding bit is latched high. To clear the bit, write 1 to it. The latches operate independently of the PRP_IRQ_CONTROL register. That is, even when the interrupt is disabled, the event occurrences can still be inspected.	R/W

Bit	Symbol	Function	R/W
1	WRONGLAN	This bit functions the same as MEMTOOLATE bit.	R/W
2	OUTOFSEQ	This bit functions the same as MEMTOOLATE bit.	R/W
3	SEQMISSING	This bit functions the same as MEMTOOLATE bit.	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

The PRP_IRQ_STAT_ACK register is used to clear any of the interrupts.

29.3.12.9 RM_ADDR_CTRL : PRP History Memory Transactions Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BUSY	—	CLEAR	—	—	READ	WRITE	—	CLEAR_MEMORY	CLEAR_DYNAMIC	—	—	—	—	—	—
Value after reset:	0	x	0	x	x	0	0	x	0	0	x	x	x	x	x	x

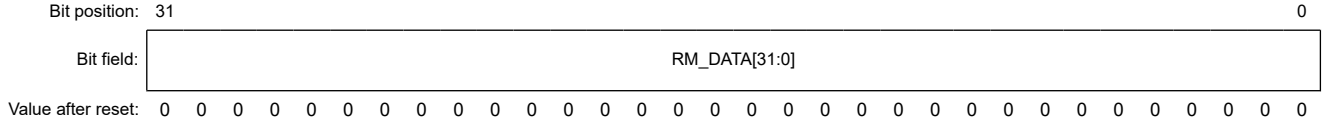
Bit position:	15	14	13	12	11											0
Bit field:	—	—	—	—	address[11:0]											
Value after reset:	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	address[11:0]	Memory Address for Read and Write Transactions This is the address of an entry. The address is the same as the address of an entry in the MAC address lookup table. Therefore, to find data for a specific MAC address, the MAC address table must first be searched (lookup) to retrieve the address of an entry.	R/W
21:12	—	The read values are undefined. The write value should be 0.	R/W
22	CLEAR_DYNAMIC	When set to 1, scan the complete table for valid dynamic history entries and deletes them (writes entry with all 0s). The stored sequence numbers (for transmit RCT generation) of source addresses associated with non-redundant local ports are not modified. This bit is cleared when the function has completed.	R/W
23	CLEAR_MEMORY	When set to 1, write all memory locations with 0. This bit is cleared when the function has completed. The bit is set on reset to clear the memory and deasserts when completed.	R/W
24	—	The read value is undefined. The write value should be 0.	R/W
25	WRITE	When set to 1, perform a Single Write Transaction. The RM_DATA/RM_DATA_HI registers must be set prior to starting the transaction. This bit is cleared when the function has completed.	R/W
26	READ	When set to 1, perform Single Read Transaction. Data is returned in RM_DATA/RM_DATA_HI registers. This bit is cleared when the function has completed.	R/W
28:27	—	The read values are undefined. The write value should be 0.	R/W
29	CLEAR	When set to 1, write all 0s to the entry selected by the given address. Avoids the need to set the data registers to a 0 value. This bit is cleared when the function has completed.	R/W
30	—	The read value is undefined. The write value should be 0.	R/W
31	BUSY	Transaction Busy Indication Controller is busy when this bit is 1. As long as the controller is busy, the corresponding command bit is set. When it becomes non-busy again, all command bits are cleared. No other commands are allowed when BUSY = 1. A write to this register must be avoided as long as it is busy.	R

29.3.12.10 RM_DATA : PRP Memory Data Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D24

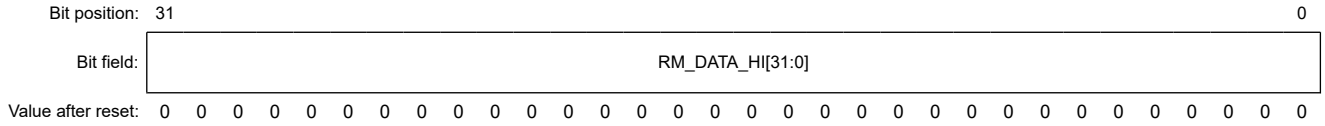


Bit	Symbol	Function	R/W
31:0	RM_DATA[31:0]	Memory data register for read/write transactions controlled by RM_ADDR_CTRL. It contains bits [31:0] of a memory entry.	R/W

29.3.12.11 RM_DATA_HI : PRP Memory Data Higher Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D28

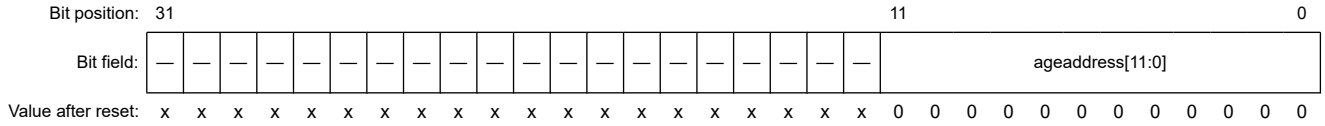


Bit	Symbol	Function	R/W
31:0	RM_DATA_HI[31:0]	A Second Data Register It contains bits [63:32] of a memory entry.	R/W

29.3.12.12 RM_STATUS : PRP Memory Controller Status Indication

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D2C

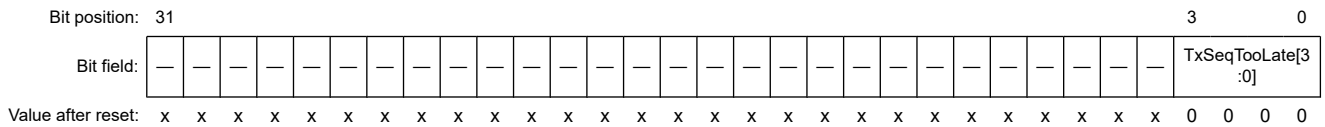


Bit	Symbol	Function	R/W
11:0	ageaddress[11:0]	Address of an entry which the aging process inspects when the aging timer expires next time.	R
31:12	—	The read values are undefined.	R

29.3.12.13 TxSeqTooLate : PRP Frame Transmission Retrieval of Failed Sequence

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D30

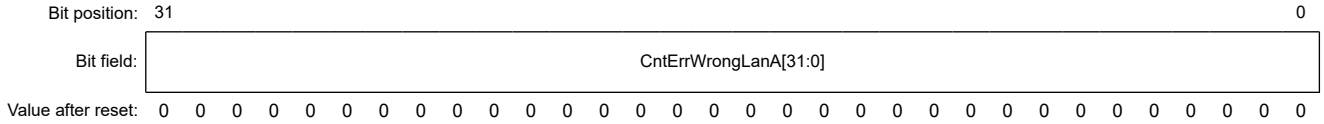


Bit	Symbol	Function	R/W
3:0	TxSeqTooLate[3:0]	Retrieval of a Sequence Number Failed A frame was transmitted and duplicated without appending the RCT. One bit per port, latched high when such an event occurred. Writing 1 to the register in the corresponding bit position clears the latch. This can happen on ports that transmit to the redundant ports therefore, the RedBox function requires to retrieve the sequence number for the frame (based on its source address). If that source address lookup took too long and the frame got forwarded before the lookup can complete, the frame is transmitted without appending an RCT (it is still duplicated). Latches are also cleared when PRP_CONFIG.PRP_ENA = 0.	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

29.3.12.14 CntErrWrongLanA : PRP Wrong ID LAN-A Count Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D34

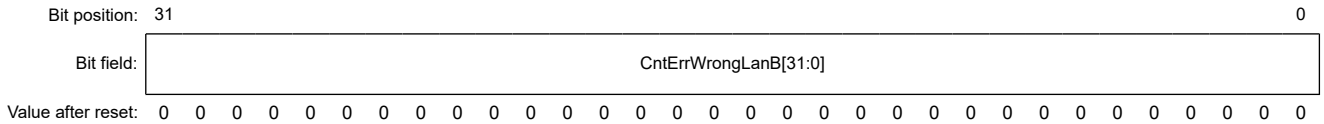


Bit	Symbol	Function	R/W
31:0	CntErrWrongLanA[31:0]	Valid frames received on LAN A which have an RCT (valid length + suffix) but LAN ID is not matching LAN A.	R

29.3.12.15 CntErrWrongLanB : PRP Wrong ID LAN-B Count Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D38

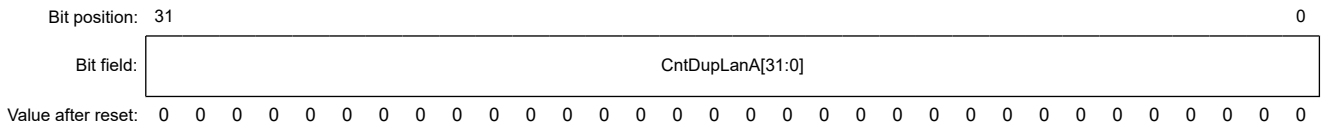


Bit	Symbol	Function	R/W
31:0	CntErrWrongLanB[31:0]	Valid frames received on LAN B which have an RCT (valid length + suffix) but LAN ID is not matching LAN B.	R

29.3.12.16 CntDupLanA : PRP Duplicate LAN-A Count Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D3C

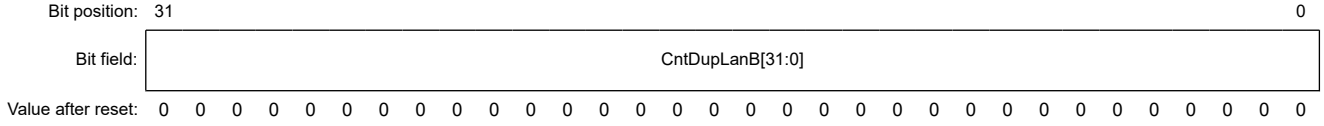


Bit	Symbol	Function	R/W
31:0	CntDupLanA[31:0]	Valid frames received on LAN A that were dropped by duplicate detection.	R

29.3.12.17 CntDupLanB : PRP Duplicate LAN-B Count Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D40

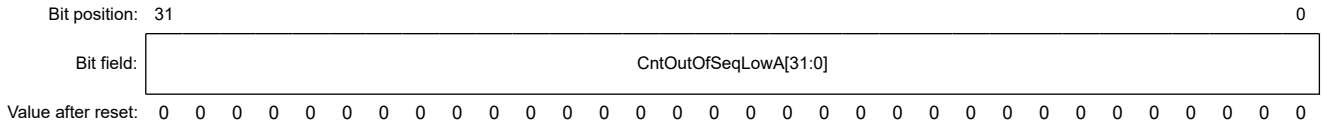


Bit	Symbol	Function	R/W
31:0	CntDupLanB[31:0]	Valid frames received on LAN B that were dropped by duplicate detection.	R

29.3.12.18 CntOutOfSeqLowA : PRP Sequence Error Low LAN-A Count Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D44

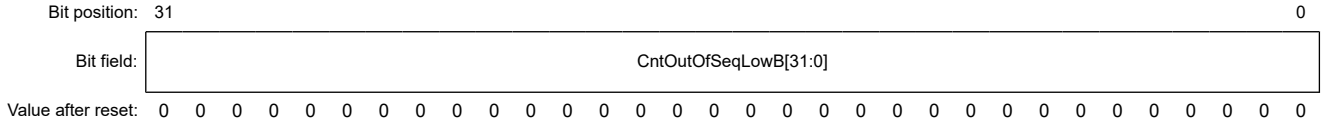


Bit	Symbol	Function	R/W
31:0	CntOutOfSeqLowA[31:0]	Valid and accepted frames received on LAN A with a sequence number less than last window (DUP_W).	R

29.3.12.19 CntOutOfSeqLowB : PRP Sequence Error Low LAN-B Count Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D48

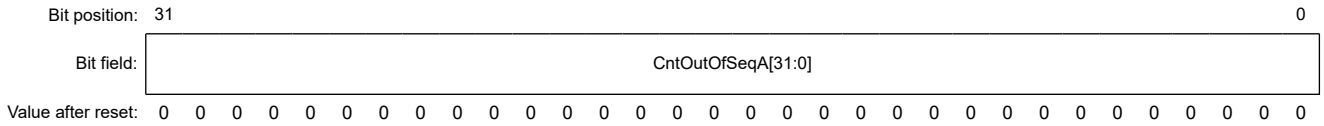


Bit	Symbol	Function	R/W
31:0	CntOutOfSeqLowB[31:0]	Valid and accepted frames received on LAN B with a sequence number less than last window (DUP_W).	R

29.3.12.20 CntOutOfSeqA : PRP Sequence Error LAN-A Count Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D4C

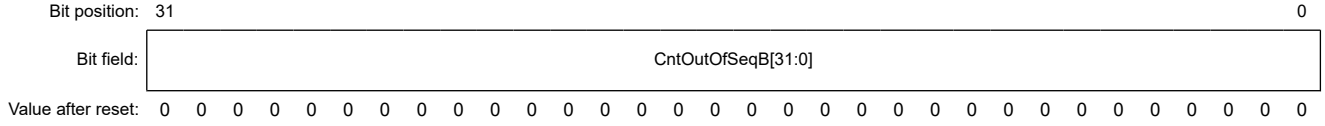


Bit	Symbol	Function	R/W
31:0	CntOutOfSeqA[31:0]	Valid and accepted frames received on LAN A with an unexpected sequence number. Increments also with CntOutOfSeqLowA.	R

29.3.12.21 CntOutOfSeqB : PRP Sequence Error LAN-B Count Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D50

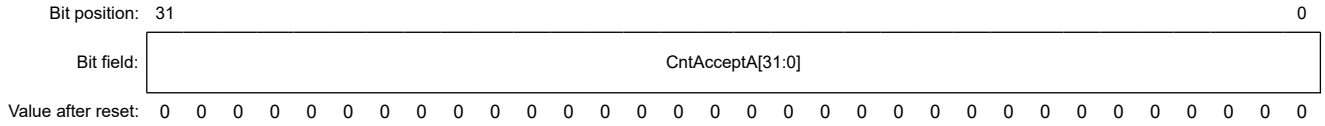


Bit	Symbol	Function	R/W
31:0	CntOutOfSeqB[31:0]	Valid and accepted frames received on LAN B with an unexpected sequence number. Increments also with CntOutOfSeqLowB.	R

29.3.12.22 CntAcceptA : PRP Valid Frame LAN-A Count Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D54

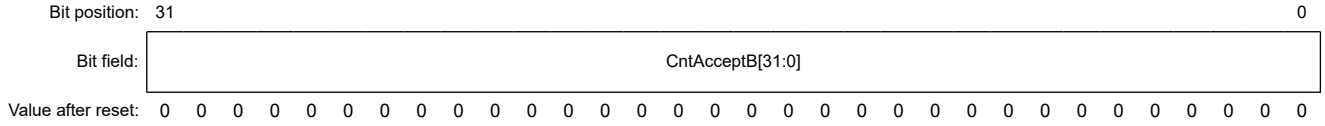


Bit	Symbol	Function	R/W
31:0	CntAcceptA[31:0]	Valid frames received on LAN A which had a valid sequence number in the expected range.	R

29.3.12.23 CntAcceptB : PRP Valid Frame LAN-B Count Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D58

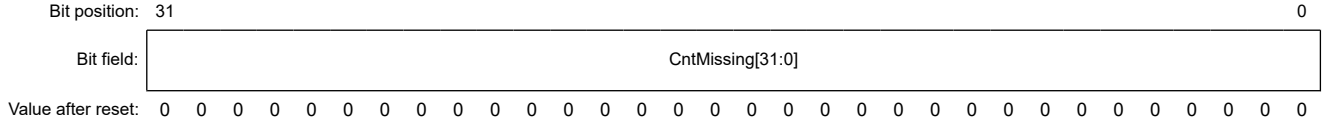


Bit	Symbol	Function	R/W
31:0	CntAcceptB[31:0]	Valid frames received on LAN B which had a valid sequence number in the expected range.	R

29.3.12.24 CntMissing : PRP Drop History Adjustment Count

Base address: ETHSW = 0x8012_0000

Offset address: 0x3D5C



Bit	Symbol	Function	R/W
31:0	CntMissing[31:0]	Indicates adjustment of the drop history as a frame was received with a sequence number of expected + history + 1. This occurs if the same frame was dropped in both LAN segments (one sequence number is missing) and the history is now extended beyond that sequence number (causing it to be treated as drop allowed).	R

29.3.13 Integrated Hub Module Registers

29.3.13.1 HUB_CONFIG : HUB Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	JAM_WAIT_IDLE	PRMB_GEN_DIS	CRS_GEN	IPG_WAIT[2:0]			—	TIMER_SEL	HUB_ISOLATE	TRIGGER_MODE	RETRANSMIT_ENA	HUB_ENA
Value after reset:	x	x	x	x	0	0	0	1	1	0	x	0	0	0	0	0

Bit	Symbol	Function	R/W
0	HUB_ENA	Enable Integrated HUB Operation All other configuration registers must be configured correctly before setting this bit. When cleared, the HUB statistics counters are also cleared, if any.	R/W
1	RETRANSMIT_ENA	Enable Hub Retransmit Capability When this bit is 1 and a collision occurs while a MAC of the Hub Group is transmitting, the MAC is allowed to retransmit if possible (following IEEE 802.3 half-duplex backoff rules). When this bit is 0 and a collision occurs, the MAC does not retransmit the frame and the frame is discarded. This bit must be set to 0 when TRIGGER_MODE = 1.	R/W
2	TRIGGER_MODE	Enable Single Frame Trigger Mode When this bit is 1, the HUB sends a single frame (single MAC transmit) only when allowed by a trigger event. Trigger events are generated by the settings in HUB_TRIGGER_IMMEDIATE and HUB_TRIGGER_AT registers, individually per port. The RETRANSMIT_ENA bit must be set to 0 when trigger mode is active.	R/W
3	HUB_ISOLATE	Isolate all hub ports from the other ports of the switch and allow communication with management port only. It is then up to the application of the management port to implement some bridging functionality to other ports as required. When this bit is 1, frames received at any of the hub ports are always forwarded to the management port. No lookup or flooding occurs. In addition, all frames from ports outside the Hub Group that need forwarding to the Hub Group are always forwarded to the management port. The setting has no effect on forwarding in-between non-hub ports and forwarding to/from the management port. When this bit is 0, normal forwarding is performed and the HUB_DEFPORT mask is used when forwarding traffic to the hub-group from any other port. This setting only controls forwarding within the switch. The Hub PHY copy function is not affected by this setting.	R/W
4	TIMER_SEL	Select the timer to use for timed triggers 0: Timer 0 1: Timer 1	R/W
5	—	The read value is undefined. The write value should be 0.	R/W
8:6	IPG_WAIT[2:0]	Configures the number of bytes to wait before allowing a new frame through the HUB. Do not change.	R/W

Bit	Symbol	Function	R/W
9	CRS_GEN	When set to 1, the integrate HUB generates a local CRS signal whenever a frame is being copied. This prevents the local ports from transmitting frames until the frame is completed. Default is disabled (relies on the CRS from the PHY). Do not change.	R/W
10	PRMB_GEN_DIS	When set to 1, the preamble regeneration when transmitting frames is disabled. When 0, the HUB ensures that the frame contains 7 bytes of preamble plus the SFD. Do not change.	R/W
11	JAM_WAIT_IDLE	When set to 1, the HUB will wait until all ports are IDLE after a collision event to resume forwarding traffic between the ports. When 0, the HUB will resume forwarding traffic when at most 1 port is non-IDLE. Do not change.	R/W
31:12	—	The read values are undefined. The write value should be 0.	R/W

The HUB_CONFIG register enables the integrated hub operation and set mode.

29.3.13.2 HUB_GROUP : HUB Port Group Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	HUB_GROUP[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	HUB_GROUP[2:0]	Define all ports that should be combined to a Hub Group. One bit per port (bit 0 = port 0, bit 1 = port 1, and bit 2 = port 2). A portmask with at least 1 bit set (typically at least 2 are set). The MACs of the Hub group must be configured to identical speed and half-duplex operation. The group should not collide with any other group settings of the switch that may be active such as DLR as this can lead to unpredictable behavior. Only setting a single port allows the port to use the trigger capabilities.	R/W
31:3	—	The read values are undefined. The write value should be 0.	R/W

29.3.13.3 HUB_DEFPORT : HUB Default Port Selection Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	HUB_DEFPORT[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	HUB_DEFPORT[2:0]	The default port within the Hub Group where all traffic from a port outside the group is forwarded to port (bit 0 = port 0, bit 1 = port 1, and bit 2 = port 2). If a frame should be forwarded to any of the hub ports, the frame is sent to this port only. The copy function of the hub copies it to all PHY interfaces of the group eventually. Portmask with exactly 1 bit from the hub group set. Forced forwarding of the management port can be used to direct frames to other ports within the group.	R/W
31:3	—	The read values are undefined. The write value should be 0.	R/W

29.3.13.4 HUB_TRIGGER_IMMEDIATE : HUB Transmission Trigger Immediate Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	HUB_TRIGGER_IMMEDIATE[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	HUB_TRIGGER_IMMEDIATE[2:0]	Trigger immediate transmission of a single frame from given port within the hub group (bit 0 = port 0, bit 1 = port 1, and bit 2 = port 2). Portmask with at maximum having a single bit set. Setting a port bit that is not within the hub group has no effect (register write is ignored). When set, the specified port is allowed to send a single frame immediately. The register is cleared when transmission started and an interrupt can be generated. If no frame is waiting at the port at the time of writing this register, the trigger is kept active until a frame arrives. It is then transmitted and the register is cleared.	R/W
31:3	—	The read values are undefined. The write value should be 0.	R/W

29.3.13.5 HUB_TRIGGER_AT : HUB Transmission Trigger At Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	HUB_TRIGGER_AT[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	HUB_TRIGGER_AT[2:0]	Trigger Transmission of a Single Frame at a Specific Time (bit 0 = port 0, bit 1 = port 1, and bit 2 = port 2). Portmask with at maximum having a single bit set. Setting a port bit that is not within the hub group has no effect (register write is ignored). The HUB_TTIME register should be written first to avoid unexpected triggering on an older/invalid timer value. The register is cleared when transmission has started and an interrupt can be generated. The register is also cleared if the port has no frame to transmit at the time of the trigger. The trigger interrupt occurs and the register clears but no frame is transmitted. A frame arriving after the trigger time is not transmitted (this is in contrast to the trigger immediate function).	R/W
31:3	—	The read values are undefined. The write value should be 0.	R/W

29.3.13.6 HUB_TTIME : HUB Transmission Time Define Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E14

Bit position:	31																												0
Bit field:	HUB_TTIME[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	HUB_TTIME[31:0]	Define the Time Value when a Trigger Should Occur A 32-bit value compared with the timer. The value is compared with the 32-bit timer selected by HUB_CONFIG.TIMER_SEL and if the timer reaches (or crosses) the value, the port given in HUB_TRIGGER_AT is allowed to transmit one frame.	R/W

29.3.13.7 HUB_IRQ_CONTROL : HUB Interrupt Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E18

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TRIGGER_TIMER	TRIGGER_IMMEDIATE	CHANGE_DET	RX_TRIGGER[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	RX_TRIGGER[2:0]	Enable Interrupt on Receive Pattern Match Trigger Function One bit per port. Bit 0 = Port 0, Bit 1 = Port 1, Bit 2 = Port 2. When enabled, an interrupt is generated when any receive pattern matcher caused the indicated hub port to transmit one frame (trigger mode) and transmission has begun. This interrupt is in addition to the match interrupt capability associated with the pattern that can be enabled in the PATTERN_CTRL register. This trigger interrupt typically occurs shortly after the pattern match interrupt occurred (about 1 µs later in a 100 Mbps port which is the time between frame receive and transmit start following the IPG delay). Therefore, it can cause two separate interrupts for the same event to the system if both are enabled, which may cause unwanted processing overhead.	R/W
3	CHANGE_DET	Enable interrupt for hub TX state machine port state change request detection Assert when the HUB_STATUS register bit TX_Change_Pending asserts.	R/W

Bit	Symbol	Function	R/W
4	TRIGGER_IMMEDIATE	Enable interrupt when hub transmit started after writing the HUB_TRIGGER_IMMEDIATE register The event is caused when the transmission has started and the HUB_TRIGGER_IMMEDIATE register is cleared and can accept a new command.	R/W
5	TRIGGER_TIMER	Enable interrupt when hub transmit started after writing the HUB_TRIGGER_TIME register and the timeout value is reached (register HUB_TTIME). The event is caused when the transmission has started and the HUB_TRIGGER_TIME register is cleared.	R/W
31:6	—	The read values are undefined. The write value should be 0.	R/W

If any of the interrupt enable bits is set and a corresponding event occurs, the Hub interrupt (HUB_INT) within the global INT_STAT_ACK Interrupt Status register asserts. To clear any of the interrupts, write to the HUB_IRQ_STAT_ACK register.

29.3.13.8 HUB_IRQ_STAT_ACK : HUB Interrupt Status/ACK Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E1C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TRIGGER_TIMER	TRIGGER_IMMEDIATE	CHANGE_DET	RX_TRIGGER[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	RX_TRIGGER[2:0]	Interrupt Pending Indication Bits corresponding to the bits defined in HUB_IRQ_CONTROL. If an event occurs, the corresponding bit is latched high. To clear the bit, write 1 to it. The latches operate independently of the HUB_IRQ_CONTROL register. That is, even when the interrupt is disabled, the event occurrences can still be inspected.	R/W
3	CHANGE_DET	This bit functions the same as RX_TRIGGER bit.	R/W
4	TRIGGER_IMMEDIATE	This bit functions the same as RX_TRIGGER bit.	R/W
5	TRIGGER_TIMER	This bit functions the same as RX_TRIGGER bit.	R/W
31:6	—	The read values are undefined. The write value should be 0.	R/W

To clear any of the interrupts, write to the HUB_IRQ_STAT_ACK register.

29.3.13.9 HUB_STATUS : HUB Status Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TX_Change_Pending	Speed_OK	TX_BUSY	TX_ACTIVE	—	—	—	—	—	—	PORTS_ACTIVE[2:0]		
Value after reset:	x	x	x	0	0	0	0	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	PORTS_ACTIVE[2:0]	When this bit is 1, it shows the currently active ports of the Hub group which are allowed for transmit. It can differ from the HUB_GROUP setting if a port is disabled or has no link for example. One bit per port. Bit 0 = Port 0, Bit 1 = Port 1, Bit 2 = Port 2.	R
8:3	—	The read values are undefined.	R
9	TX_ACTIVE	When this bit is 1, the hub global transmit state machine has successfully entered Hub mode and is now controlling the hub group. The bit reacts with some delay following a write into the HUB_CONFIG/HUB_GROUP registers until it successfully enters or leaves the hub operational mode. The state machine may not enter hub mode even when enabled through the HUB_CONFIG register, as long as the ports are still transferring data or a misconfiguration exists (speed differences, no group defined).	R
10	TX_BUSY	When this bit is 1, the local device currently transmits data to all ports within the hub group. The bit is informal and toggles during normal operation.	R
11	Speed_OK	When this bit is 1, it indicates that the port speed of all group ports match. This bit must be set to 1 to allow the TX state machine to enter active state and may indicate a misconfiguration or link failure that changed the speed of the attached PHY of a port. It is important that all PHYs at all time when they are part of the Hub group operate with the same MAC interface speed even if the link is disconnected (the PHY must not change its MAC interface speed from 100 Mbps to 10 Mbps after the link dropped). The hub is inoperable (not transmitting) and cannot enter the active state as long as this bit is 0. The bit is valid as soon as the hub group is defined (HUB_GROUP) and enabled (HUB_CONFIG). It may give an indication why the TX_ACTIVE is not getting set.	R
12	TX_Change_Pending	Indicate a pending change request in the hub transmitter that is unsolved and cause the hub to stop operation (no longer performing any transmissions). A state change is requested when a port of the hub group changed its operational mode unexpectedly (link fail, MAC speed change). It also asserts if, for example, the hub is disabled in the middle of a transmission until the transmission has ended normally, which will then allow the hub to become disabled (and eventually deassert TX_ACTIVE). The bit deasserts if the misconfiguration has been resolved and the hub is allowed to perform transmissions. The hub is inoperable if this bit is set and the misconfiguration may need the intervention of the application to be resolved (speed mismatch persists).	R
31:13	—	The read values are undefined.	R

The HUB_STATUS register shows informal real-time status information of the hub.

29.3.13.10 HUB_OPORT_STATUS : HUB Output Port Status Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E24

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	HUB_OPORT_STATUS[2:0]		
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	HUB_OPORT_STATUS[2:0]	Per Output Port Data Available Status One bit per port. Bit 0 = Port 0, …, Bit 2 = Port 2. When this bit is set to 1, it indicates the output port has data available for transmission (any queue of the port has data). This is a real-time indication of all line ports of the switch, not only the ones of the hub group.	R
31:3	—	The read values are undefined.	R

29.3.14 TDMA Scheduler Registers

29.3.14.1 TDMA_CONFIG : TDMA Configuration Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E80

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	OUT_CT_ENA[3:0]				—	—	—	—	IN_CT_ENA[3:0]			
Value after reset:	x	x	x	x	1	1	1	1	x	x	x	x	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TIMER_SEL_ACTIVE	—	—	HOLD_REQ_CLR	OUT_CT_WREN	IN_CT_WREN	RED_OVRD	RED_OVRD_ENA	RED_PERIOD	—	TIMER_SEL	WAIT_START	TDMA_ENA
Value after reset:	x	x	x	0	x	x	0	0	0	0	0	0	x	0	0	0

Bit	Symbol	Function	R/W
0	TDMA_ENA	Enable TDMA Scheduler The bit should be set only after all other TDMA scheduler configuration registers have been correctly configured. When set, the scheduler begins with its first cycle at the time given in TDMA_START. Before that time is reached, the queue state is not changed, but can be preset with the control register MMCTL_QGATE. Clearing the bit is allowed any time to disable the TDMA scheduler allowing all ports to transmit normally again. The scheduler must be enabled before the timer has reached the value in TDMA_START. Enabling it too late causes the scheduler to start after the timer has wrapped around and then reached the start value.	R/W
1	WAIT_START	Status bit which is set as long as the scheduler is enabled but has not yet reached the time given in register TDMA_START. The bit clears when the start time has reached and the scheduler has begun with the very first cycle.	R

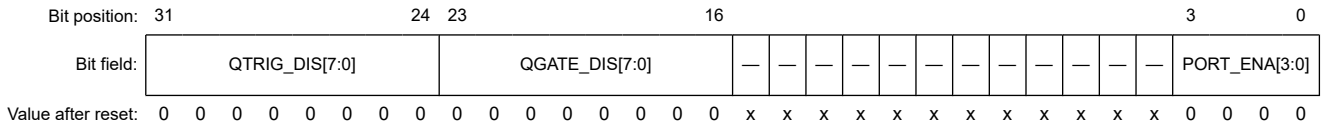
Bit	Symbol	Function	R/W
2	TIMER_SEL	Select which timer to use as the time source for the scheduler The selected timer can only be changed when TDMA_ENA is 0. Read TIMER_SEL_ACTIVE to verify that the written value is being used. 0: Timer 0 1: Timer 1	R/W
3	—	The read value is undefined. The write value should be 0.	R/W
4	RED_PERIOD	Read only bit indicating the current period for Profinet This bit is set to 1 if the period is RED, set by the TCV. It may differ from the current period if RED_OVRD_ENA is set to 1.	R
5	RED_OVRD_ENA	Enables overriding the RED period status, regardless of the indication by the TCV. The value is set in RED_OVRD.	R/W
6	RED_OVRD	Override Value for the RED Period When set to 1, the period is overridden to be RED, otherwise set to GREEN. Valid only when RED_OVRD_ENA is set to 1.	R/W
7	IN_CT_WREN	Enable writing the IN_CT_ENA control to the ingress ports.	W
8	OUT_CT_WREN	Enable writing the OUT_CT_ENA control to the egress ports.	W
9	HOLD_REQ_CLR	Writing 1 to this register clears the state of TDMA hold request.	W
11:10	—	The read values are undefined. The write value should be 0.	R/W
12	TIMER_SEL_ACTIVE	Return the current timer being used for the TDMA Scheduler 0: Timer 0 1: Timer 1	R
15:13	—	The read values are undefined. The write value should be 0.	R/W
19:16	IN_CT_ENA[3:0]	On read, return the current status of the ingress Cut-Through enable indicated by the TDMA scheduler. On write, override the ingress Cut-Through enable if IN_CT_WREN is also 1.	R/W
23:20	—	The read values are undefined. The write value should be 0.	R/W
27:24	OUT_CT_ENA[3:0]	On read, return the current status of the egress Cut-Through enable indicated by the TDMA scheduler. On write, override the egress Cut-Through enable if OUT_CT_WREN is also 1.	R/W
31:28	—	The read values are undefined. The write value should be 0.	R/W

The TDMA_CONFIG register configures and enables the TDMA scheduler. All other TDMA-related registers must be configured before enabling the scheduler.

29.3.14.2 TDMA_ENA_CTRL : TDMA Scheduling Enable Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E84



Bit	Symbol	Function	R/W
3:0	PORT_ENA[3:0]	Set to 1 to indicate that a port is operating in TDMA mode. When set to 1 for a port, the port does not prefetch another frame until the current frame in progress is done and if TDMA_PREBUF_DIS in COMMAND_CONFIG is set to 1. This helps adding precision to the queue gating operations indicated by the TDMA at the expense of loss of line rate.	R/W
15:4	—	These bits are read as 0. The write value should be 0.	R/W
23:16	QGATE_DIS[7:0]	One bit per output queue. When a bit is set to 1, the TDMA scheduler gating commands do not affect the queue even if the queue mask in the TCV control data is set to 1.	R/W
31:24	QTRIG_DIS[7:0]	One bit per output queue. When a bit is set to 1, the TDMA scheduler triggering commands do not affect the queue even if the queue mask in the TCV control data is set to 1.	R/W

The TDMA_ENA_CTRL register controls whether the TDMA scheduler acts over specific ports and queues.

29.3.14.3 TDMA_START : TDMA Start Time Set Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E88

Bit position:	31																												0
Bit field:	TDMA_START[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TDMA_START[31:0]	Set the start time for the very first cycle after system initialization has completed. The value is compared with the system time (selected in TDMA_CONFIG.TIMER_SEL) and when it is reached (crossed), the scheduler begins with its first cycle. The 2nd cycle is then at TDMA_START + TDMA_CYCLE.	R/W

29.3.14.4 TDMA_MODULO : TDMA System Timer Modulo

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E8C

Bit position:	31																												0
Bit field:	TDMA_MODULO[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TDMA_MODULO[31:0]	The System Timer Modulo This setting gives the maximum time value + 1 the 32-bit timer (selected TDMA_CONFIG.TIMER_SEL) will reach before it wraps around. For example, if the timer represents nanoseconds and wraps once per second, then the modulo given in this register must be 1,000,000,000. This means the timer presents values from 0 to 999,999,999 at the 32-bit timer input. It is not expected that the values at the 32-bit timer increment continuously. Relevant for this setting is only the possible range of values. Setting a value of 0 indicates a wrap-around at 2^{32}.	R/W

29.3.14.5 TDMA_CYCLE : TDMA Periodic Cycle Set Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E90

Bit position:	31																												0
Bit field:	TDMA_CYCLE[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TDMA_CYCLE[31:0]	The periodic cycle time for the scheduler given in system timer time. For example, if the 32-bit timer (selected TDMA_CONFIG.TIMER_SEL) represents nanoseconds and the cycle time is 800 µs, a value of 800,000 must be set. The cycle time can be manipulated any time during TDMA operation to possibly compensate for a drifting system timer (usually the system timer should be adjusted and locked to a master clock).	R/W

29.3.14.6 TCV_SEQ_ADDR : TCV Sequence Address Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E94

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ADDR_AINC	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	TCV_S_ADDR[11:0]											
Value after reset:	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	TCV_S_ADDR[11:0]	Address to write to or read from in the TCV sequence table.	R/W
30:12	—	The read values are undefined. The write value should be 0.	R/W
31	ADDR_AINC	When set to 1, read and write operations performed using TCV_SEQ_CTRL causes the address in TCV_S_ADDR to auto-increment after the operation.	R/W

The TCV_SEQ_ADDR register programs the address (entry) to read or write in the TCV sequence table. This register also enables address auto-increment.

29.3.14.7 TCV_SEQ_CTRL : TCV Sequence Table Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E98

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	READ_MODE	—	GPIO[7:0]								—	—	—	—	—	—
Value after reset:	0	x	0	0	0	0	0	0	0	0	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	TCV_D_IDX[8:0]									INT	START
Value after reset:	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	START	Indicate this TCV must be executed after the next cycle start When set, identifies this TCV to be a cycle start vector. The OFFSET in the TCV is taken as the offset after the next cycle starts. The offset value can be 0. This bit should be always set to 1 for entry 0.	R/W
1	INT	Indicates this TCV generates an interrupt to the CPU when activated When set to 1, an interrupt is generated to the CPU when this TCV is executed (for example, after the indicated OFFSET relative to the cycle start).	R/W
10:2	TCV_D_IDX[8:0]	Index to the TCV Data Entry Index in the TCV Data Table. Select which entry in the TCV data to use for the time offset and control information.	R/W
21:11	—	The read values are undefined. The write value should be 0.	R/W
29:22	GPIO[7:0]	Generic bits that control the output pins ETHSW_TDMAOUTn (n = 0 to 7) The value of these bits is propagated to ETHSW_TDMAOUTn when the vector is executed. The output pin can be configured for level, toggle, or strobe operation using the TDMA_GPIO register.	R/W
30	—	The read value is undefined. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
31	READ_MODE	When set to 1, a read operation is performed instead of writing to the TCV sequence table. The read data (START, INT, TCV_D_IDX[8:0], and GPIO) can be obtained by reading this register afterwards. On read, this field always returns 0.	R/W

Control data to be written or read from the TCV sequence table. When written, the value of the field READ_MODE indicates whether the TCV sequence table is read or written from or to the address programmed in TCV_SEQ_ADDR.

29.3.14.8 TCV_SEQ_LAST : TCV Sequence Last Entry

Base address: ETHSW = 0x8012_0000

Offset address: 0x3E9C

Bit position:	31				27												16				11											0
Bit field:	—	—	—	—	ACTIVE[11:0]												—	—	—	—	LAST[11:0]											
Value after reset:	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	LAST[11:0]	Defines the last entry to read from the TCV sequence table when the TDMA scheduler is operating. After reading from this LAST entry, the next entry read is entry 0.	R/W
15:12	—	The read values are undefined. The write value should be 0.	R/W
27:16	ACTIVE[11:0]	Return the active TCV sequence entry.	R
31:28	—	The read values are undefined. The write value should be 0.	R/W

The TCV_SEQ_LAST register defines which is the last entry in the TCV_SEQ to be read, afterwards, it rolls back to entry TDMA_TCV_START. TCV entries are read sequentially starting from TDMA_TCV_START up to (TDMA_TCV_START + TCV_SEQ_LAST).

29.3.14.9 TCV_D_ADDR : TCV Data Address Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3EA0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	AINC_WR_ENA	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ADDR[8:0]								
Value after reset:	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	ADDR[8:0]	Address to read from/write to in the TCV data table Must be set before accessing TCV_D_CTRL and TCV_D_OFFSET.	R/W
30:9	—	The read values are undefined. The write value should be 0.	R/W
31	AINC_WR_ENA	Auto-Increment Enable When set to 1, auto-increments after writes to TCV_D_CTRL.	R/W

The TCV_D_ADDR register is the address register for read and write operations to the TCV data table.

29.3.14.10 TCV_D_OFFSET : TCV Data Offset Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3EA4

Bit position:	31																												0
Bit field:	TCV_D_OFFSET[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TCV_D_OFFSET[31:0]	32-bit time offset for the TCV data entry indicated by TCV_D_ADDR. When accessing the table, TCV_D_OFFSET must be read or written before TCV_D_CTRL.	R/W

29.3.14.11 TCV_D_CTRL : TCV Data Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3EA8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	PMASK[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	QGATE[7:0]								HOLD_REQ	GATE_MODE	TRIGGER_MODE	IN_CT_ENA	OUT_CT_ENA	RED_PERIOD	INC_CTR1	INC_CTR0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	INC_CTR0	Increment Control for Counter 0 When set to 1, the counter is enabled. This counter can be used to keep track of the number of cycles since the start of the TDMA operation. For Profinet, it tracks the SendClock number so it is possible for software to recover the current state after a lockup or software reboot. This may not be required as the current cycle number can be determined by reading the current absolute time.	R/W
1	INC_CTR1	Increment Control for Counter 1 When set to 1, the counter is enabled. This is a smaller counter that can trigger periodic interrupts. For Profinet, it can be used to keep track of the phase when the reduction ratio is greater than 1.	R/W
2	RED_PERIOD	Period Color Control (for Profinet IRT) When set to 1, indicates to the ingress RED_GUARD and MAC bridge functions that the RED period is active. This control is passed to the pattern matchers. Set this bit to 0 if period color identification is not required.	R/W
3	OUT_CT_ENA	Output Cut-Through Enable Enable Cut-Through (CT) operation in the output memory read controller. This is used to disable CT in the YELLOW period and initiate the YELLOW port byte counter. When GATE_MODE and TRIGGER_MODE are both 0 and OUT_CT_ENA is set to 1, the cut-through state for each port is set to the value in PMASK where 1 enables cut-through, and 0 disables it. If GATE_MODE is set to 1 then the cut-through state is changed for the ports selected in PMASK(P) to the value in OUT_CT_ENA. If GATE_MODE is set to 0 and TRIGGER_MODE is set to 1, the cut-through state is not changed. Set this bit to 1 if control on the Cut-Through mode of the switch is not required.	R/W

Bit	Symbol	Function	R/W
4	IN_CT_ENA	Input Cut-Through Enable When set to 1, allows changing the ingress cut-through state in the input frame receiver. The IN_CT_ENA is effective when GATE_MODE and TRIGGER_MODE are both 0. When GATE_MODE and TRIGGER_MODE are both 0, and IN_CT_ENA is set to 1, the ingress cut-through state is changed for all ports to the values in PMASK(P), where 1 enables cut-through, and 0 disables it. Set this bit to 1 if control on the Cut-Through mode of the switch is not required.	R/W
5	TRIGGER_MODE	Trigger mode enable when set to 1. GATE_MODE must be 0, otherwise, GATE_MODE has precedence. When set to 1, QGATE causes a single-frame transmission between the closed queues selected QGATE on the ports selected by PMASK. GATE_MODE must be set to 0 for trigger operation.	R/W
6	GATE_MODE	Gate mode enable when set to 1. When set to 1, changes the state of the queues indicated in QGATE for the ports selected by PMASK.	R/W
7	HOLD_REQ	Preemption hold request. Generates a hold request to ports enabled in PMASK. When set to 1, a hold request operation (see section 29.4.18.7. MM_CTL.request (hold_req)) can be generated for the ports selected in PMASK. TRIGGER_MODE must be set to 0 for HOLD_REQ to be executed.	R/W
15:8	QGATE[7:0]	Bits mask, one per output queue Bit mask that controls which queues are gated or triggered in the current time slot. A value of 0 closes (disables) the queue when GATE_MODE is 1. A value of 1 opens (enables) the queue if GATE_MODE is set to 1, or triggers a frame if TRIGGER_MODE is 1 and GATE_MODE is 0. PMASK selects which ports are affected.	R/W
19:16	PMASK[3:0]	Bits mask, one per output port Bit mask (one per output port) that controls which queues of the ports are gated, triggered, hold request generation, and which ports change their Cut-Through mode setting. A value of 1 enables the port.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

The TCV_D_CTRL register control bits for the TCV entry indicated by TCV_D_ADDR. When accessing the table, TCV_D_OFFSET must be read or written before TCV_D_CTRL.

29.3.14.12 TDMA_CTR0 : TDMA Counter 0

Base address: ETHSW = 0x8012_0000

Offset address: 0x3EAC

Bit position:	31																													0
Bit field:	TDMA_CTR0[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TDMA_CTR0[31:0]	32-bit counter that is incremented when the TCV field INC_CTR0 is set to 1. The counter can be initialized with software by writing a value. The counter rolls over from 0xFFFFFFFF to 0x00000000.	R/W

29.3.14.13 TDMA_CTR1 : TDMA Counter 1

Base address: ETHSW = 0x8012_0000

Offset address: 0x3EB0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	INT_VALUE[7:0]								MAX[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	WRITE_ENA	VALUE[7:0]							
Value after reset:	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	VALUE[7:0]	Current Counter Value Can be written if bit WRITE_ENA is set to 1. On read, returns the current counter value.	R/W
8	WRITE_ENA	Write Enable for VALUE Must be set to 1 to override the counter value. This bit is a self-clearing bit.	W
15:9	—	The read values are undefined. The write value should be 0.	R/W
23:16	MAX[7:0]	Counter Maximum Value The counter increments up to MAX and then rolls over back to 0.	R/W
31:24	INT_VALUE[7:0]	Interrupt Value Set the value at which an interrupt to the CPU is generated.	R/W

TDMA_CTR1 is an 8-bit counter that is incremented when the TCV field INC_CTR1 is set to 1. The counter can be initialized with software by writing a value.

29.3.14.14 TDMA_TCV_START : TDMA TCV Sequence Entry Start

Base address: ETHSW = 0x8012_0000

Offset address: 0x3EB4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TDMA_TCV_START[11:0]											
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	TDMA_TCV_START[11:0]	Define the TCV_SEQ entry to start from. When the TDMA is first enabled or the last TCV sequence is executed, the cycle is restarted from this TCV sequence entry.	R/W
31:12	—	The read values are undefined. The write value should be 0.	R/W

29.3.14.15 TIME_LOAD_NEXT : TDMA Calculated Next Loading Time

Base address: ETHSW = 0x8012_0000

Offset address: 0x3EB8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TIME_LOAD_NEXT[31:0]																															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TIME_LOAD_NEXT[31:0]	Status giving the calculated time the scheduler loads into its internal compare register after the current running slot end is reached (not the end of the current slot).	R

29.3.14.16 TDMA_IRQ_CONTROL : TDMA IRQ Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3EBC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CTR1_INT_EN	—	—	—	—	—	—	—	—	—	—	—	—	TCV_INT_EN
Value after reset:	x	x	0	x	x	x	x	x	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	TCV_INT_EN	Enable Interrupts Generated by the TCV	R/W
12:1	—	The read values are undefined. The write value should be 0.	R/W
13	CTR1_INT_EN	Enable Interrupts Generated from Counter 1	R/W
31:14	—	The read values are undefined. The write value should be 0.	R/W

The TDMA_IRQ_CONTROL register is the interrupt enable for TDMA scheduler interrupts.

If any of the interrupt enable bit is set and a corresponding event occurs, the TDMA interrupt (TDMA_INT) within the global INT_STAT_ACK interrupt status register asserts. To clear any of the interrupts, write to the TDMA_IRQ_STAT_ACK register.

29.3.14.17 TDMA_IRQ_STAT_ACK : TDMA IRQ Status/ACK Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3EC0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CTR1_ACK	—	—	—	—	—	—	—	—	—	—	—	—	TCV_ACK
Value after reset:	x	x	0	x	x	x	x	x	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	TCV_ACK	TCV Execution Event If an event occurs, the bit is latched high. To clear the bit, write 1 to it. The latches operate independently of the TDMA_IRQ_CONTROL register. That is, even when the interrupt is disabled, the event occurrences can still be inspected. To determine the index of the interrupt, the ISR should read the active TCV index from TCV_SEQ_LAST.ACTIVE. However, this is the current value and if the ISR takes too long to service, then ACTIVE may be already in a subsequent index.	R/W
12:1	—	The read values are undefined. The write value should be 0.	R/W

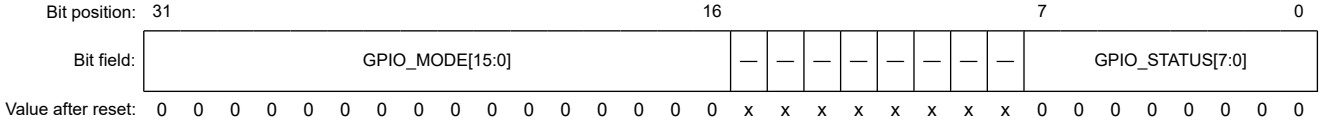
Bit	Symbol	Function	R/W
13	CTR1_ACK	Counter 1 Event If an event occurs, the bit is latched high. To clear the bit, write 1 to it. The latches operate independently of the TDMA_IRQ_CONTROL register. That is, even when the interrupt is disabled, the event occurrences can still be inspected.	R/W
31:14	—	The read values are undefined. The write value should be 0.	R/W

To clear any of the TDMA scheduler interrupts, write to the TDMA_IRQ_STAT_ACK register.

29.3.14.18 TDMA_GPIO : TDMA GPIO Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3EC4



Bit	Symbol	Function	R/W
7:0	GPIO_STATUS[7:0]	Status of the GPIO Output Pins The GPIO pins are driven directly from the TCV sequence table. This is the real-time status of the pins. Setting a pin in strobe mode may cause the state to be missed.	R
15:8	—	The read values are undefined. The write value should be 0.	R/W
31:16	GPIO_MODE[15:0]	2 bits per GPIO pin to configure its operating mode Bit 0/1 = GPIO0, …, Bit 6/7 = GPIO3, and so on. 0: Level mode 1: Strobe mode. The strobe duration is 16 cycles of the switch operating clock. 2: Toggle mode. A setting of 1 in the TCV sequence table for the corresponding pin causes a toggle in the GPIO. 3: Reserved	R/W

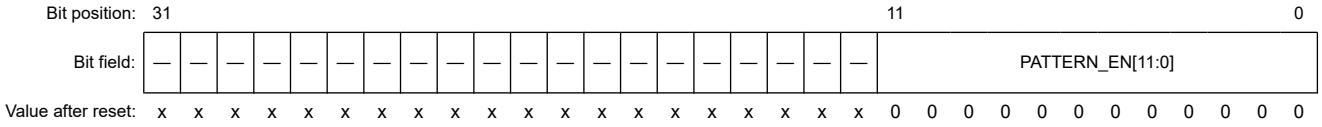
The TDMA_GPIO register indicates the GPIO configuration and status.

29.3.15 RX Pattern Matcher Registers

29.3.15.1 RXMATCH_CONFIGn : RX Pattern Matcher Configuration for Port n (n = 0 to 3)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3F00 + 0x4 × n



Bit	Symbol	Function	R/W
11:0	PATTERN_EN[11:0]	Enable Patterns on the Port (RX) One bit per pattern. When a bit is set, the corresponding pattern is searched within frames received at the port. The match function of the pattern executed is defined in its PATTERN_CTRLn (n: pattern). Multiple patterns can be enabled at the same time (allowing any match). If multiple patterns are enabled, they should be exclusive to each other. If multiple patterns match simultaneously, the executing function is unpredictable if the controls differ.	R/W
31:12	—	The read values are undefined. The write value should be 0.	R/W

The RXMATCH_CONFIGn register configures/enables pattern matchers for port n. The register defines the active patterns that are searched individually for every port. One register per port exists.

29.3.15.2 PATTERN_CTRLn : RX Pattern Matcher Function Control for Pattern n (n = 0 to 11)

Base address: ETHSW = 0x8012_0000

Offset address: 0x3F40 + 0x4 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	QUEUESEL[3:0]				—	TIMER_SEL	MATCH_LT	SWAP_BYTES	IMC_TRIGGER_DLY	IMC_TRIGGER	—	—	PORTMASK[3:0]			
Value after reset:	0	0	0	0	x	0	0	0	0	0	x	x	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	LEARNING_DIS	PRIORITY[2:0]			VLAN_SKIP	MATCH_NOT_RED	MATCH_RED	HUBTRIGGER	FORCE_FORWARD	TIMER_SEL_OVR	MODE[1:0]		SET_PRIO	DISCARD	MGMTFWD	MATCH_NOT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MATCH_NOT	When set, a match is reported and the functions of this control are executed if the pattern does not match. When cleared (default), the following control executes when the pattern matches an incoming frame. This bit is available only in PATTERN_CTRL0. It is ignored and must be 0 in all other PATTERN_CTRLn registers. When set, the PATTERN_CTRL0 is used if no patterns (including PATTERN_CTRL0) report a match and the PATTERN_CTRL0 has been enabled for a port.	R/W
1	MGMTFWD	When set, the frame is forwarded to the management port only (suppressing destination address lookup). If the pattern is applied to the management port, this setting has no effect.	R/W
2	DISCARD	When set, the frame is discarded.	R/W
3	SET_PRIO	Set frame priority, overriding normal classification. When a match occurs, the priority of the frame is set as given in the PRIORITY bits. This priority takes precedence over (ignores) settings in the PRIORITY_CFGn register of the port where the frame is received.	R/W
5:4	MODE[1:0]	Selects the operating mode 0 0: Mode 1: Fixed 12-byte match 0 1: Mode 2: 2-byte table lookup 1 0: Mode 3: 2-byte range match at set offset 1 1: Mode 4: 2-byte range not-match at set offset	R/W
6	TIMER_SEL_OVR	Overrides the default timer to use by timestamp operations when set to 1, using instead the value in TIMER_SEL.	R/W
7	FORCE_FORWARD	When set, the frame is forwarded to the ports indicated in PORTMASK, ignoring the result from L2 lookups.	R/W
8	HUBTRIGGER	When set, the port defined in the PORTMASK setting is allowed for transmitting one frame. Usable for Hub mode only and if the hub is configured to operate in Trigger mode. The port mask should contain only a single port from within the hub group. A hub trigger is a global event and can occur only once until the enabled port transmits the frame. Therefore, if multiple patterns match simultaneously, only one trigger (of which, one is unknown) is executed. All other triggers that may follow are ignored as long as a pending trigger has not been processed (that is, frame transmit has not started yet).	R/W
9	MATCH_RED	Enable the pattern matcher only when the TDMA indicates that this is the RED period.	R/W
10	MATCH_NOT_RED	Enable the pattern matcher only when the TDMA indicates that this is not the RED period.	R/W

Bit	Symbol	Function	R/W
11	VLAN_SKIP	When set to 1, for operating modes 1, 2, and 3. The first Length/Type after the MAC source address is compared against 0x8100. If it matches, a VLAN tag is assumed and 4 bytes are skipped.	R/W
14:12	PRIORITY[2:0]	Priority of the frame used when SET_PRIO is set. The priority is used to forward the frame into the corresponding output queue of a port. A higher value defines a higher priority.	R/W
15	LEARNING_DIS	When set to 1, the hardware learning function is not executed.	R/W
19:16	PORTMASK[3:0]	A port mask used depending on the control bits (for example, HUBTRIGGER). One bit per port: Bit 16 = Port 0, Bit 17 = Port 1, Bit 18 = Port 2.	R/W
21:20	—	The read values are undefined. The write value should be 0.	R/W
22	IMC_TRIGGER	When set, the ports defined in the PORTMASK setting are allowed for transmitting one frame from the queues indicated by QUEUESEL. The trigger request is sent to the integrated memory controller.	R/W
23	IMC_TRIGGER_DLY	When set, the ports defined in the PORTMASK setting are allowed for transmitting one frame from the queues indicated by QUEUESEL. The trigger request is sent to the integrated memory controller and the event is delayed by the value programmed in MMCTL_DLY_QTRIGGER_CTRL.	R/W
24	SWAP_BYTES	Applicable only for operating modes 1, 2, and 3. When set to 1, the byte order is swapped from the order received by the frame. When set to 0, the first byte received by the frame is set into position 0 for comparison. When set to 1, the first byte received is set into position 3 (for mode 1) or position 2 (for mode 2 and 3) for comparison.	R/W
25	MATCH_LT	For operating modes 1, 2, and 3. When set to 1, the Length/Type field in the frame after the MAC source address is compared against the value in length_type in the compare register. If VLAN_SKIP is set and the frame has a VLAN tag with Length/Type of 0x8100 then the comparison is performed in the Length/Type following the VLAN tag.	R/W
26	TIMER_SEL	Override value to use when TIMER_SEL_OVR is set to 1 for selecting the timer for this frame. 0: Timer 0 1: Timer 1	R/W
27	—	The read value is undefined. The write value should be 0.	R/W
31:28	QUEUESEL[3:0]	A queue selector for the HUBTRIGGER function. Selects the queue to trigger a frame, or sets from 0x8 to 0xF to select one among all queues.	R/W

The PATTERN_CTRLn register controls the function that is executed on pattern matcher n.

For every pattern data set, one PATTERN_CTRLn register defines the function that is executed when the pattern matches onto a received frame. If a pattern is applied to received traffic of a port controlled by the register of the port RXMATCH_CONFIGn (n = 0 to 3).

A control bit acts independently of each other. Therefore, if multiple bits are set, those functions will all execute and/or affect the frame simultaneously.

29.3.15.3 PATTERN_IRQ_CONTROL : RX Pattern Matcher Interrupt Control Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3F80

Bit position:	31												19		16					11											0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	ERROR_INT[3:0]				—	—	—	—	MATCHINT[11:0]											
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	MATCHINT[11:0]	Enable Interrupt on Receive Pattern Match One bit per pattern. Bit 0 = pattern 0, …, Bit 7 = pattern 7, … If set and the corresponding pattern match occurs when processing received frames (on any port), an interrupt occurs. The corresponding ETHSW_PTRNn (n = 0 to 11) interrupt also asserts as long as the interrupt is not cleared. The interrupt occurs following the CRC check of the frame by the MAC RX. Even if the frame is eventually dropped by the switch due to other rules, the match interrupt can still occur (it does not occur if the frame is dropped by the MAC).	R/W
15:12	—	The read values are undefined. The write value should be 0.	R/W
19:16	ERROR_INT[3:0]	Enable Interrupt on Internal Pattern Matcher Error One bit per port. Bit 16 = port 0, …, Bit 19 = port 4 When set to 1, an interrupt occurs. The error occurs because the pattern matcher response was not received before a new frame was started at the port.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

Interrupt enable control.

If any of the patterns match (globally) and the interrupt enable bit of the pattern is set, the PATTERN interrupt (PATTERN_INT) within the global INT_STAT_ACK interrupt status register asserts. To clear any of the interrupts, write to the PATTERN_IRQ_STAT_ACK register.

29.3.15.4 PATTERN_IRQ_STAT_ACK : RX Pattern Matcher Interrupt Status/ACK Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3F84

Bit position:	31												19				16				11											0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	ERROR_INT[3:0]				—	—	—	—	MATCHINT[11:0]											
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	MATCHINT[11:0]	Interrupt pending indication for the corresponding pattern match events (see section 29.3.15.3. PATTERN_IRQ_CONTROL : RX Pattern Matcher Interrupt Control Register). If an event occurs, the corresponding bit is latched high. To clear the bit, write 1 to it. The latches operate independently of the PATTERN_IRQ_CONTROL register. That is, even when the interrupt is disabled, the event occurrences can still be inspected.	R/W
15:12	—	The read values are undefined. The write value should be 0.	R/W
19:16	ERROR_INT[3:0]	Interrupt pending indication for a pattern matcher error, per port. If an event occurs, the corresponding bit is latched high. To clear the bit, write 1 to it.	R/W
31:20	—	The read values are undefined. The write value should be 0.	R/W

Interrupt status and acknowledge register.

To clear any of the pattern matcher interrupts, write to the PATTERN_IRQ_STAT_ACK register.

29.3.15.5 PTRN_VLANID : Custom VLAN ID Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3F88

Bit position:	31																15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PTRN_VLANID[15:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PTRN_VLANID[15:0]	Custom VLAN ID to use. The default VLAN ID 0x8100 is always considered by the hardware. This value can be changed to detect other VLANs like 0x8808.	R/W
31:16	—	The read values are undefined. The write value should be 0.	R/W

29.3.15.6 PATTERN_SEL : RX Pattern Number Selection Register

Base address: ETHSW = 0x8012_0000

Offset address: 0x3F8C

Bit position:	31																											3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PATTERN_SEL[3:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	PATTERN_SEL[3:0]	Define the pattern number which is selected for read/write through the PTRN_CMP_* and PTRN_MSK_* registers. A read or write operation into any of the PTRN_CMP and PTRN_MSK registers affects the pattern that is selected by this register. To configure a specific pattern dataset, this selection register must first be set to the pattern number of interest.	R/W
31:4	—	The read values are undefined. The write value should be 0.	R/W

29.3.15.7 PTRN_CMP_30 : Pattern Compare Value Bytes 3 .. 0

Base address: ETHSW = 0x8012_0000

Offset address: 0x3FC0

Bit position:	31																												0
Bit field:	PTRN_CMP_30[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PTRN_CMP_30[31:0]	Pattern Compare Value Bytes 3 .. 0 First byte (byte 0) is bits [7:0]. 4th byte (byte 3) is bits [31:24].	R/W

29.3.15.8 PTRN_CMP_74 : Pattern Compare Value Bytes 7 .. 4

Base address: ETHSW = 0x8012_0000

Offset address: 0x3FC4

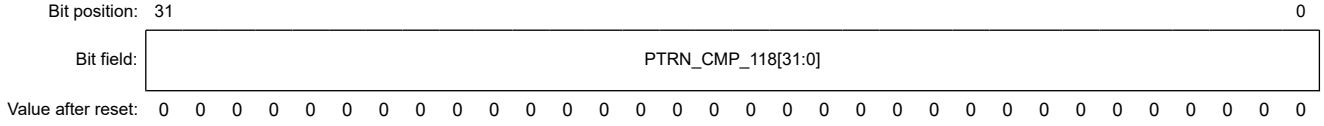
Bit position:	31																												0
Bit field:	PTRN_CMP_74[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PTRN_CMP_74[31:0]	Pattern Compare Value Bytes 7 .. 4 First byte (byte 4) is bits [7:0]. 4th byte (byte 7) is bits [31:24].	R/W

29.3.15.9 PTRN_CMP_118 : Pattern Compare Value Bytes 11 .. 8

Base address: ETHSW = 0x8012_0000

Offset address: 0x3FC8

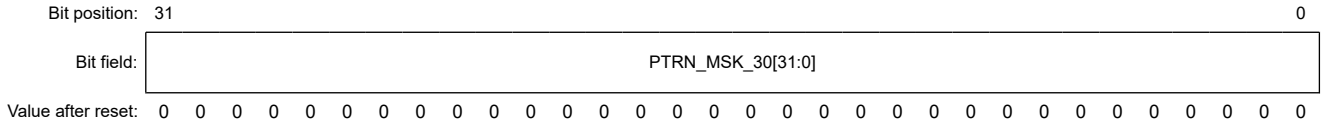


Bit	Symbol	Function	R/W
31:0	PTRN_CMP_118[31:0]	Pattern Compare Value Bytes 11 .. 8 First byte (byte 8) is bits [7:0]. 4th byte (byte 11) is bits [31:24].	R/W

29.3.15.10 PTRN_MSK_30 : Pattern Mask for Bytes 3 .. 0

Base address: ETHSW = 0x8012_0000

Offset address: 0x3FD0

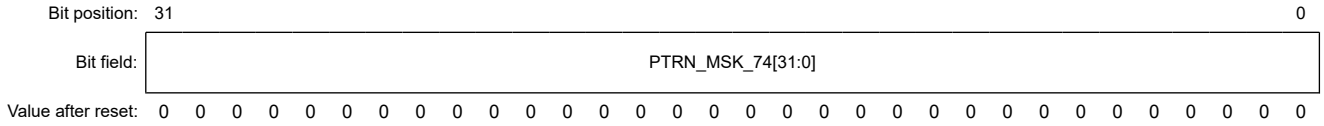


Bit	Symbol	Function	R/W
31:0	PTRN_MSK_30[31:0]	Pattern Mask for Bytes 3 .. 0	R/W

29.3.15.11 PTRN_MSK_74 : Pattern Mask for Bytes 7 .. 4

Base address: ETHSW = 0x8012_0000

Offset address: 0x3FD4

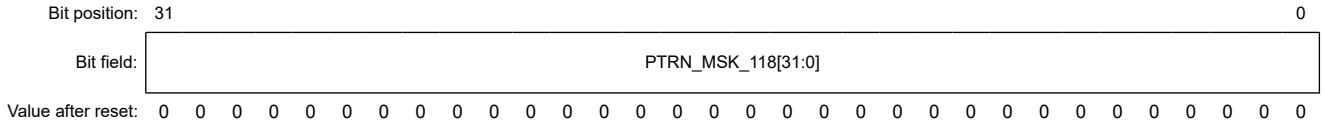


Bit	Symbol	Function	R/W
31:0	PTRN_MSK_74[31:0]	Pattern Mask for Bytes 7 .. 4	R/W

29.3.15.12 PTRN_MSK_118 : Pattern Mask for Bytes 11 .. 8

Base address: ETHSW = 0x8012_0000

Offset address: 0x3FD8



Bit	Symbol	Function	R/W
31:0	PTRN_MSK_118[31:0]	Pattern Mask for Bytes 11 .. 8	R/W

29.3.16 PTP Timer Pulse Control Registers

The registers control the PTP pulse generator. The PTP pulse generator operates based on the current time of the PTP timer and the register values and generates a pulse signal of any cycle from any start time. The pulse width can be set arbitrarily.

The register controls the pulse signal of ETHSW_PTPOUTn (n = 0 to 3) for interrupt signals or external output pins.

29.3.16.1 SWTMENn : PTP Timer Pulse Output Enable n Register (n = 0 to 3)

Base address: ETHSW_PTP = 0x8011_0400

Offset address: 0x400 + 0x100 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OUTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OUTEN	Enable ETHSW_PTPOUTn Signal Output 0: Disabled 1: Enabled	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be set after setting completion of SWTMSTSEC, SWTMSTNS, SWTMPSEC, SWTMPNS, SWTMWTH, and SWTMMAXP registers. When this register is set to 1, changing SWTMSTSEC, SWTMSTNS, SWTMPSEC, SWTMPNS, SWTMWTH, and SWTMMAXP has no effect.

29.3.16.2 SWTMSTSECn : PTP Timer Pulse Start Second n Register (n = 0 to 3)

Base address: ETHSW_PTP = 0x8011_0400

Offset address: 0x404 + 0x100 × n

Bit position:	31	0
Bit field:	STSEC[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	STSEC[31:0]	Start Time by Second	R/W

29.3.16.3 SWTMSTNSn : PTP Timer Pulse Start Nanosecond n Register (n = 0 to 3)

Base address: ETHSW_PTP = 0x8011_0400

Offset address: 0x408 + 0x100 × n

Bit position:	31	0
Bit field:	STNS[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

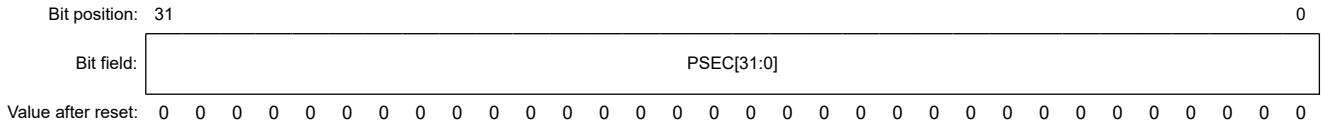
Bit	Symbol	Function	R/W
31:0	STNS[31:0]	Start Time by Nanosecond	R/W

Note: When SWTMMAXP is not 0, the value set in this register must be less than the value set in SWTMMAXP (SWTMSTNS < SWTMMAXP). When SWTMMAXP is 0, this register can be set to any value.

29.3.16.4 SWTMPSECn : PTP Timer Pulse Period Second n Register (n = 0 to 3)

Base address: ETHSW_PTP = 0x8011_0400

Offset address: 0x40C + 0x100 × n

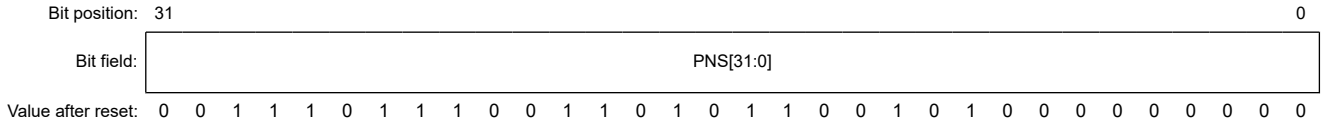


Bit	Symbol	Function	R/W
31:0	PSEC[31:0]	Period by Second	R/W

29.3.16.5 SWTMPNSn : PTP Timer Pulse Period Nanosecond n Register (n = 0 to 3)

Base address: ETHSW_PTP = 0x8011_0400

Offset address: 0x410 + 0x100 × n



Bit	Symbol	Function	R/W
31:0	PNS[31:0]	Period by Nanosecond	R/W

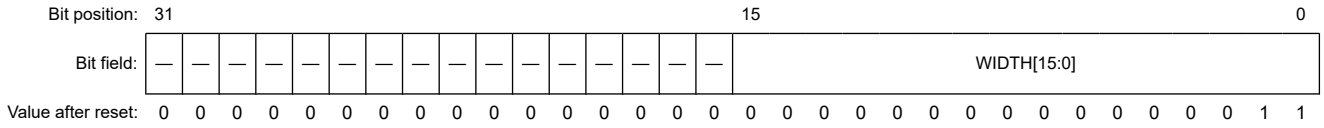
Note: The value set in this register must be larger than 16 × ATIME_INC[6:0] value (128 ns).

Note: When SWTMMAXP is not 0, the value set in this register must be less than or equal to the value set in SWTMMAXP (SWTMPNS ≤ SWTMMAXP). When SWTMMAXP is 0, this register can be set to any value.

29.3.16.6 SWTMWTHn : PTP Timer Pulse Width n Register (n = 0 to 3)

Base address: ETHSW_PTP = 0x8011_0400

Offset address: 0x414 + 0x100 × n



Bit	Symbol	Function	R/W
15:0	WIDTH[15:0]	Set the Pulse Width of ETHSW_PTPOUTn in the cycle number of ts_clk (8 ns). Output pulse width is the set value × 8 (ns). The ETHSW_PTPOUTn is set to 0 when this register is 0x0000.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: If ETHSW_PTPOUT is used as pulse event, do not change the value of this register (use the initial value). When it is used as external signal, appropriate width must be specified.

29.3.16.7 SWTMMAXPn : PTP Timer Pulse Max Nanosecond n Register (n = 0 to 3)

Base address: ETHSW_PTP = 0x8011_0400

Offset address: 0x418 + 0x100 × n

Bit position:	31																												0
Bit field:	MAXP[31:0]																												
Value after reset:	0	0	1	1	1	0	1	1	1	0	0	1	1	0	1	0	1	1	0	0	1	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	MAXP[31:0]	Sets the boundary value in nanoseconds to carry from the nanosecond field to the second field. The same value as ATIME_EVT_PERIOD register must be set. Allowable value is 10^9 or 0 only.	R/W

Note: This register is set to the same value as of ATIME_EVT_PERIOD register.

Note: This register sets the boundary value in nanoseconds to carry from the nanosecond field to the second field. When the nanosecond field reaches the set value of this register, the second field is carried up. This register is normally used with the initial value of 0x3B9ACA00 (= 10^9). In this case, the nanosecond field counts from 0x0 to 0x3B9AC9FF (= 10^9 - 1) and then carries to the second field. If 0 is set in this register, the boundary value for carrying to the second field is interpreted as 0x100000000 (= 2^{32}). In this case, the nanosecond field is fully counted from 0x0 to 0xFFFFFFFF (= 2^{32} - 1) and then carries to the second field.

29.3.16.8 SWTMLATSECn : PTP Timer Pulse Latch Second n Register (n = 0 to 3)

Base address: ETHSW_PTP = 0x8011_0400

Offset address: 0x41C + 0x100 × n

Bit position:	31																												0
Bit field:	LATSEC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	LATSEC[31:0]	Latch the time of second count at the ETHSW_PTPOUTn rising edge.	R/W

Note: This register is updated when the PTPOUT signal rises, and the updated value is expressed in the formula t_{START} + t_{PERIOD} × n (n = 0, 1, 2, …) in seconds of the rise target time. t_{START} = {SWTMSTSEC, SWTMSTNS}, t_{PERIOD} = {SWTMPSEC, SWTMPNS}

Note: Since SWTMLATSEC is a 32-bit register, it will be 0x00000000 when incremented in the state of 0xFFFFFFFF.

29.3.16.9 SWTMLATNSn : PTP Timer Pulse Latch Nanosecond n Register (n = 0 to 3)

Base address: ETHSW_PTP = 0x8011_0400

Offset address: 0x420 + 0x100 × n

Bit position:	31																												0
Bit field:	LATNS[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	LATNS[31:0]	Latch the time of nanosecond count at the ETHSW_PTPOUTn rising edge.	R/W

Note: This register is updated when the PTPOUT signal rises, and the updated value is expressed in the formula t_{START} + t_{PERIOD} × n (n = 0, 1, 2, …) in nanoseconds of the rise target time. t_{START} = {SWTMSTSEC, SWTMSTNS}, t_{PERIOD} = {SWTMPSEC, SWTMPNS}

29.3.16.10 SWPTPOUTSEL : ETHSW_PTPOUT Select Register

Base address: ETHSW_PTP = 0x8011_0400

Offset address: 0x004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	EVTSEL3	EVTSEL2	EVTSEL1	EVTSEL0	IOSEL3	IOSEL2	IOSEL1	IOSEL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IOSEL0	Select the source of the ETHSW_PTPOUT0 output signal 0: Pulse generator 0 output 1: TDMA_GPIO[4] output	R/W
1	IOSEL1	Select the source of the ETHSW_PTPOUT1 output signal 0: Pulse generator 1 output 1: TDMA_GPIO[5] output	R/W
2	IOSEL2	Select the source of the ETHSW_PTPOUT2 output signal 0: Pulse generator 2 output 1: TDMA_GPIO[6] output	R/W
3	IOSEL3	Select the source of the ETHSW_PTPOUT3 output signal 0: Pulse generator 3 output 1: TDMA_GPIO[7] output	R/W
4	EVTSEL0	Select the source of the ETHSW_PTPOUT0 event for GIC, DMAC, and ELC 0: Pulse generator 0 output 1: TDMA_GPIO[4] output	R/W
5	EVTSEL1	Select the source of the ETHSW_PTPOUT1 event for GIC, DMAC, and ELC 0: Pulse generator 1 output 1: TDMA_GPIO[5] output	R/W
6	EVTSEL2	Select the source of the ETHSW_PTPOUT2 event for GIC, DMAC, and ELC 0: Pulse generator 2 output 1: TDMA_GPIO[6] output	R/W
7	EVTSEL3	Select the source of the ETHSW_PTPOUT3 event for GIC, DMAC, and ELC 0: Pulse generator 3 output 1: TDMA_GPIO[7] output	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

The SWPTPOUTSEL register is used to specify the source of ETHSW_PTPOUTn event and output signal (n = 0 to 3).

This register can only be written when protection is unlocked by the specific sequence using the section 27.3.1. PRCMD : Ethernet Protect Register. For the protection unlock procedure, see section 27.3.1. PRCMD : Ethernet Protect Register. The special sequence is not necessary when reading the value of this register.

29.4 Operation

29.4.1 Ethernet Frame Format Overview

29.4.1.1 Overview

The IEEE 802.3 Standard defines the Ethernet Frame format as follows:

- An Ethernet frame has a minimum length of 64 bytes and a maximum length of 1518 bytes, excluding the preamble and the SFD bytes.
- An Ethernet frame consists of the following fields:
  - Seven bytes preamble
  - Start frame delimiter (SFD)
  - Two address fields
  - Length or type field
  - Data field
  - Frame check sequence (CRC value)
  - An EXTENSION field is defined only for half-duplex implementations and is not supported.

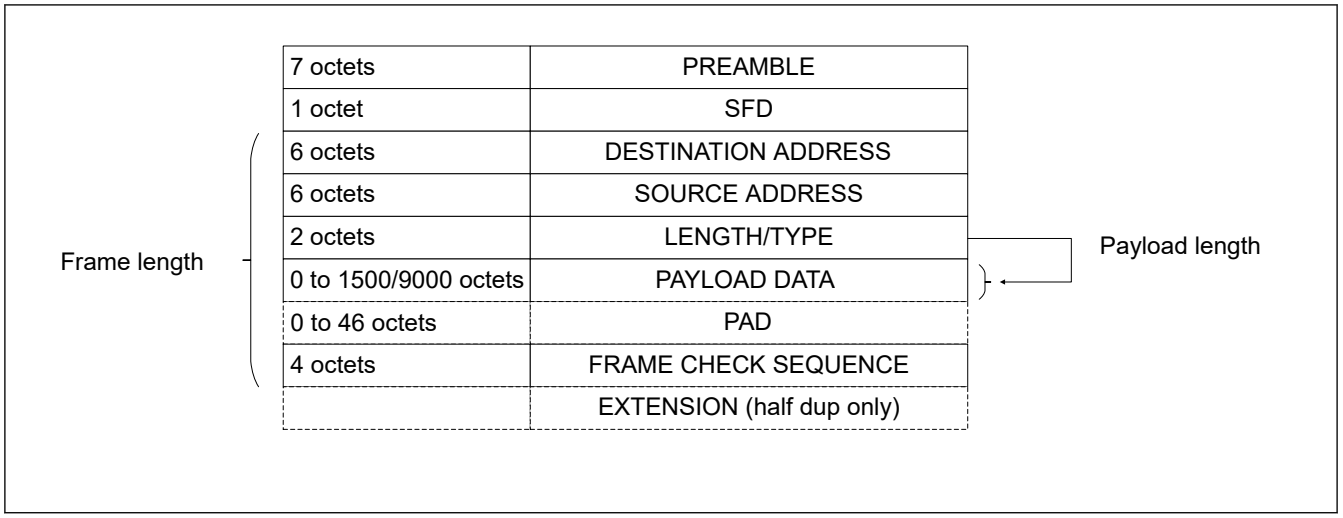


Figure 29.3 MAC frame format overview

Optionally MAC frames can be VLAN tagged with an additional 4-byte field (TPID and VLAN Info) inserted between the MAC Source Address and the Type/Length Field. VLAN tagging is defined by the IEEE P802.1Q specification. VLAN tagged frames have a maximum length of 1522 bytes (tagged standard frames) or 9022 bytes (tagged jumbo frames), excluding the preamble and the SFD bytes.

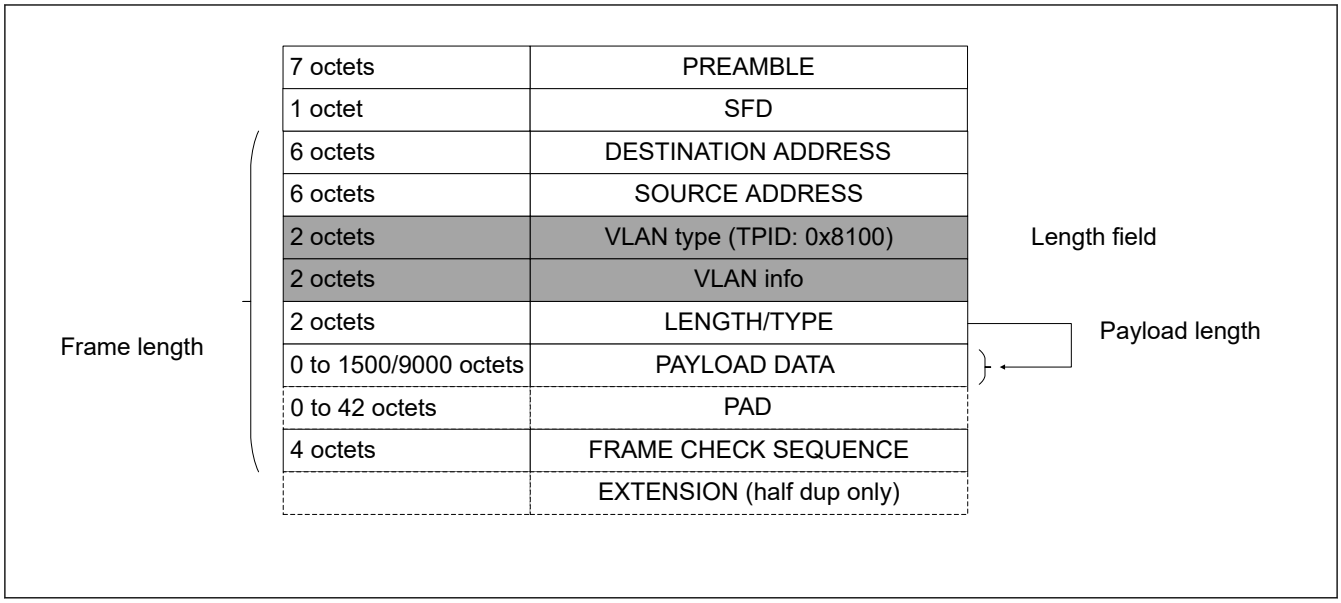

Figure 29.4 VLAN tagged MAC frame format overview

Table 29.5 MAC frame definition

Term	Description
Frame length	The length, in octets, defines the length of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length (typical 1518).
Payload Length	The Length/Type field indicates the length of the payload section of the frame or identifies the type of the frame. The most significant byte is sent/received first. ● If the Length/Type field is set to a value less than 1536 (0x600), it is interpreted as a Length field indicating the number of following payload octets. A Length/Type field less than 46 indicates the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN tagged frames, a value less than 42 indicates a padded frame. ● If the Length/Type field is set to a value larger or equal to 1536 (0x600), it is interpreted as a Type field.
Destination and Source Address	48-Bit MAC addresses The least significant byte is sent/received first and the first two bits (two least significant bits) of the MAC address are used to distinguish MAC frames.

In typical Ethernet switching application, the MAC, on receive, should be programmed to accept every frame (Promiscuous mode), to check but not to change the frame FCS and forward the frame with the FCS field to the Switch. On transmit, the MAC should be programmed not to overwrite the source MAC address received from the switch and to transmit the frame with the FCS received from the switch.

However, since frame manipulation functions within the switch are used, CRC is stripped by the MAC receivers and is appended by the MAC transmitters.

29.4.1.2 MAC Address Overview

The destination address bit 0 is used to differentiate multicast and unicast addresses:

- If bit 0 is set 0, the MAC address is an individual (unicast) address.
- If bit 0 is set 1, the MAC address defines a group address (multicast address).
- If all 48 bits of the MAC address are set to 1, it indicates a broadcast address.

In addition, the first 24 bits of the MAC address define a vendor ID.

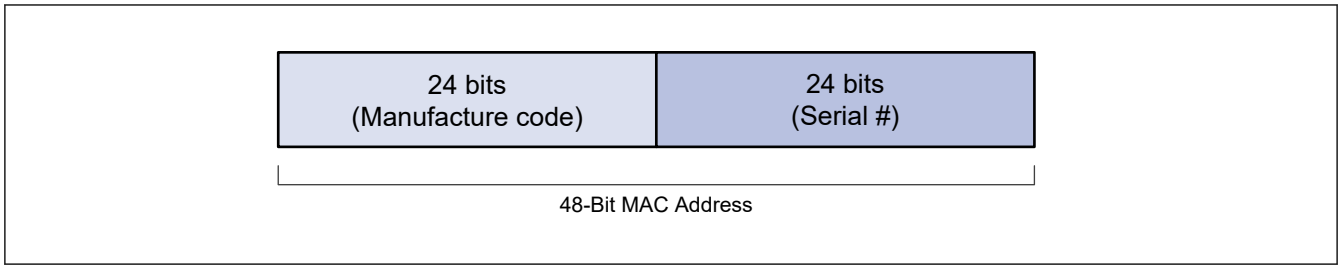

Figure 29.5 MAC address overview

29.4.1.3 VLAN Tag Overview

A VLAN tagged frame provides a 16-bit VLAN information field. For VLAN priority resolution (see (2) VLAN Priority Look Up), the switch uses the upper 4 bits of the first word (octet) of the VLAN Info field, that is the 3 bits priority field and the 1 bit CFI field can be used for priority classification.

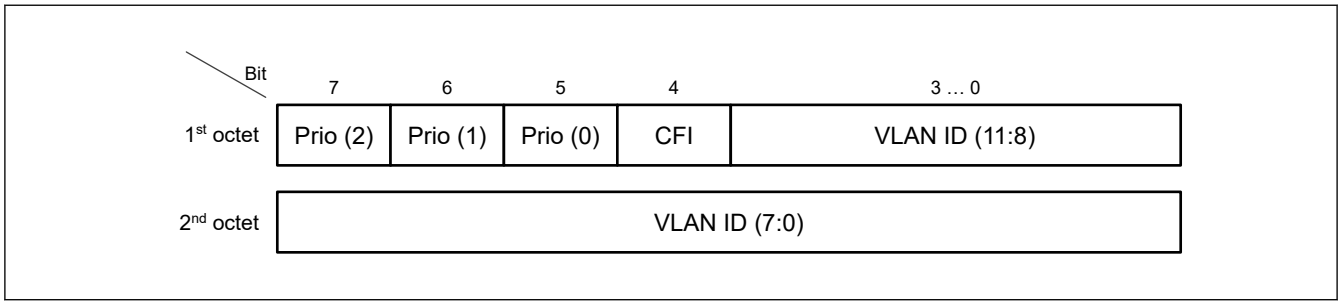

Figure 29.6 VLAN info fields

29.4.1.4 Pause Frames

The receiving device to indicate congestion to the emitting device, which should then stop sending data, generates a pause frame.

The Length/Type set to 0x8808 indicates a pause frame. The first two bytes of a pause frame following the type defines a 16-bit Opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload byte 2 (byte P1) and byte 3 (byte P2) as defined in Table 29.6. The pause quanta byte P1 is the most significant.

Table 29.6 Pause frame format (values in hex)

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01
Preamble							SFD	Multicast Destination Address					

15	16	17	18	19	20	21	22	23	24	25	26	27-68
00	00	00	00	00	00	88	08	00	01	hi	lo	00
Source Address						Type		Opcode		P1	P2	Pad (42)

69	70	71	72
xx	xx	xx	xx
CRC-32			

There is no Payload Length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00). If a pause frame with a pause value greater than 0 (XOFF Condition) is received, the MAC stops transmitting data as soon as the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512-bit times.

Pause frames are terminated in the MAC layer and are not forwarded by the switch.

29.4.1.5 Interspersed Traffic Frame Formats

When traffic preemption is enabled, frames are interspersed as express frames are transmitted. The IEEE 802.3br standard defines an mPacket as a segment of a preempted MAC frame, which retains the format of an Ethernet frame and has control information to allow reconstructing the original MAC frame.

The IEEE 802.3br specification describes the two frame formats for traffic interspersing as shown in Figure 29.7. The first format is used for express traffic, and the initial mPacket of a preemptable frame (which can be the whole frame if it does not get preempted). The difference with a regular Ethernet frame is that the SFD is replaced by the SMD (Start mPacket Delimiter). The second format is for mPackets that are a continuation of a preemptable frame (a preemptable frame that was preempted). The SFD and one byte of preamble are replaced by the SMD and a fragment count.

The SMD encodings are defined in the IEEE 802.3br standard as shown in Table 29.7. Express packets use SMD-E, which is identical as the SFD for standard Ethernet frames. Preemptable frames use the SMD-Sx encoding, of which there are four different values. The SMD-Sx is changed for every packet so the receiver can detect a new mPacket start in the case of the loss of the last mPacket of the previous frame. Continuation mPackets use the encodings of SMD-Cx of which there are also four different values to detect the loss of up to three mPackets along with FRAG_COUNT to detect the loss of fragments (see Table 29.8). Finally, SMD-R and SMD-V are used for response and verification frames (see section 29.4.1.6. Preemption Verify and Response Frames).

The CRC of an mPacket is referred as the mCRC and is calculated from the first octet of the full preemptable frame, up to the last octet of the current mPacket. See clause 99.3.6 of the IEE802.3br specification for more details.

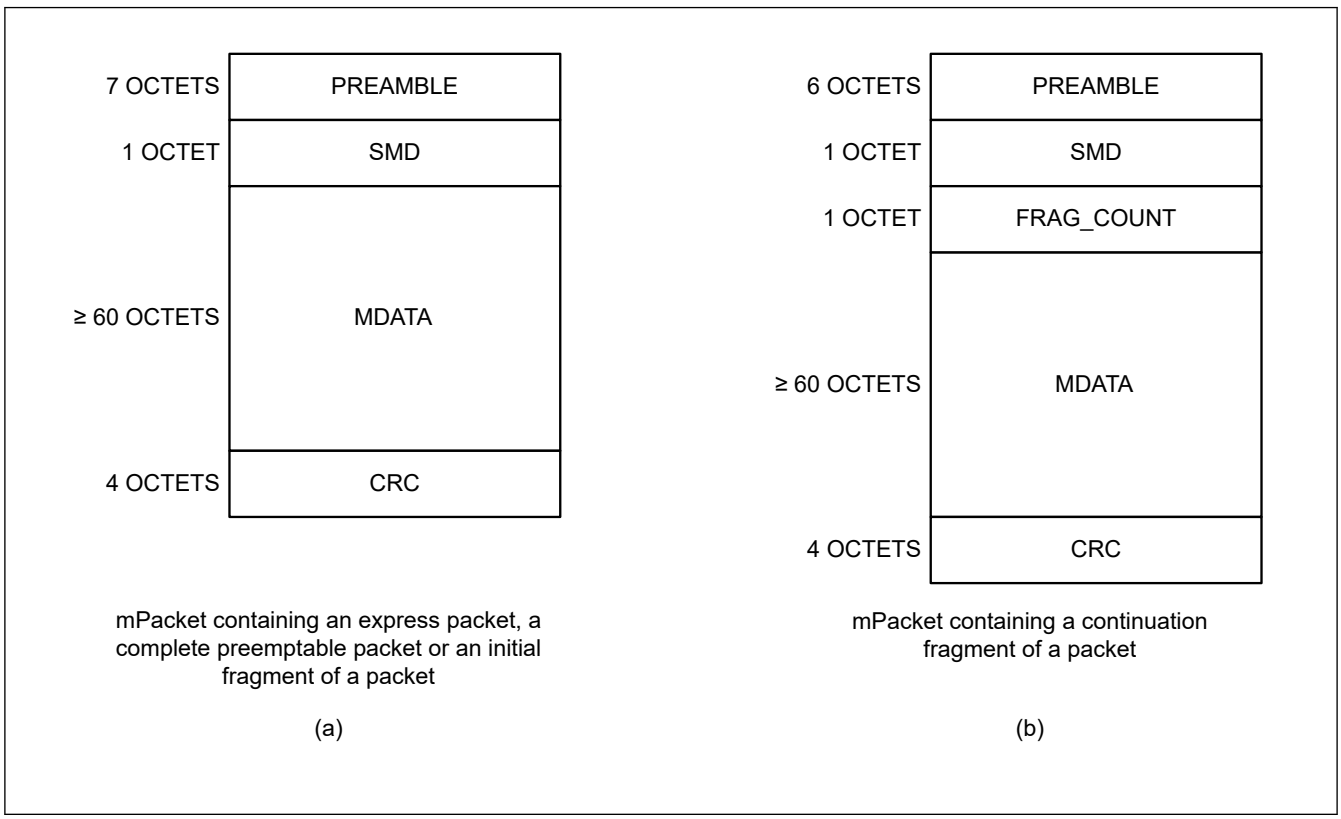

Figure 29.7 Interspersed traffic frame formats

Table 29.7 SMD encoding (1 of 2)

mPacket type	Notation	Frame count	Value
Verify packet	SMD-V	—	0x07
Respond packet	SMD-R	—	0x19
Express packet	SMD-E	—	0xD5

Table 29.7 SMD encoding (2 of 2)

mPacket type	Notation	Frame count	Value
Preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
Continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

Table 29.8 FRAG_COUNT values

Frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

29.4.1.6 Preemption Verify and Response Frames

When traffic preemption is enabled, the IEEE 802.3br specification defines to additional frames that are used to verify that both link partners support traffic preemption.

The verify frame is generated when one preemption is enabled by software. This frame is a minimum length Ethernet frame with the SFD replaced by SMD-V and the Data field (mData) consists of 60 bytes of 0x00. The FCS is an mCRC (same FCS but with a different inversion mask).

A response frame is generated in response to a verify frame and its format is the same as a verify frame but using SMD-R instead.

Table 29.9 Verify and response frames

Frame	Preamble (7)	SMD (1)	mData (60)	FCS (4)
Verify	7 × 0x55	SMD-V (0x07)	60 × 0x00	mCRC
Response	7 × 0x55	SMD-R (0x19)	60 × 0x00	mCRC

29.4.1.7 Industrial Automation — TSN Frames

The IEC/IEEE 60802 specification is a joint effort defining the use of TSN for industrial applications. Of interest is the definition of the IA-TSN profile that lists requirements for devices to be able to forward time-sensitive traffic over TSN. The time-sensitive frames are identified using the destination MAC address and VLAN ID. The OUI is a multicast reserved value and the Extension Identifier is used as an index that, together with a VLAN ID, defines a single stream.

Table 29.10 shows the definition of the IA-TSN profile MAC destination address. The OUI value shown is the selected value at the time of writing but can be changed with the control register IALK_OUI. The ID field identifies the stream and it is selected for each stream as the streams are created in the network.

See section 29.4.3.9. Industrial Automation Profile for TSN (TSN-IA-Profile) Forwarding Table for details on the IA-TSN-profile support.

Table 29.10 IA-TSN profile MAC destination address

	OUI			Extension Identifier		
Octet	1	2	3	4	5	6
Value	0x01	0x0E	0xCF	ID[23:16]	ID[15:8]	ID[7:0]

29.4.2 IP Frame Format

29.4.2.1 Definitions

The following sections use the term datagram to describe the protocol specific data unit, which is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

29.4.2.2 Ethernet Types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet Type/Length field is used to differentiate several datagram types. Table 29.11 lists the Ethernet types.

Table 29.11 Ethernet type value examples

Type	Description
0x8100	VLAN tagged frame. The actual type is found 4 octets later in the frame
0x0800	IPv4
0x86DD	IPv6
0x8808	MAC control frames (slow protocols, flow control)

29.4.2.3 IPv4 Datagram Format

Figure 29.8 shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The most significant bit is bit 31 in the Figure 29.8. The first sent/received byte is the leftmost byte of the first word (for example, Version/IHL field).

The IP Header can contain additional options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is followed by the payload immediately, which can contain further protocol headers such as TCP or UDP as indicated by the protocol field value. The complete IP datagram is transported in the payload section of an Ethernet frame.

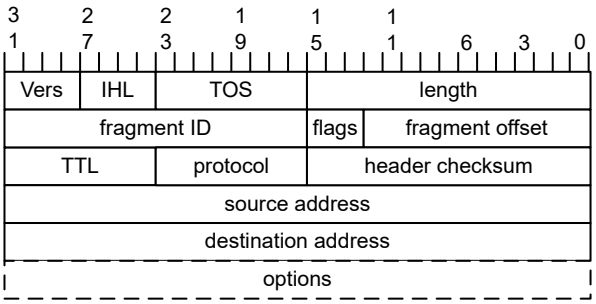

Figure 29.8 IPv4 header format

Table 29.12 IPv4 header fields (1 of 2)

Field Name	Description
Vers	4-bit IP version information. It is 4 for IPv4 frames.
IHL	4-bit IP header length information. Determines number of 32-bit words found within the IP header. The default value, if no options are present is 5.
TOS	Type of Service/DiffServ field
Length	Total length of the datagram in bytes. It includes all octets of header and payload.

Table 29.12 IPv4 header fields (2 of 2)

Field Name	Description
Fragment ID, flags, fragment offset	Fields used for IP fragmentation
TTL	Time-to-live. If 0, datagram must be discarded.
Protocol	Protocol Identifier of protocol that follows in the datagram
Header checksum	Checksum over all IP header fields
Source address	Source IP address
Destination address	Destination IP address

29.4.2.4 IPv6 Datagram Format

Figure 29.9 shows the IP Version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of 10 words (40 bytes).

The next header field identifies the type of the header to follow the IPv6 header. It is defined identical to the protocol identifier within IPv4 with new definitions for identifying so-called extension headers, which can be inserted between the IPv6 header and the protocol header, shifting the protocol header accordingly.

The most significant bit is bit 31 in Figure 29.9. The first sent/received byte is the leftmost byte of the first word (for example, Version/Traffic class fields).

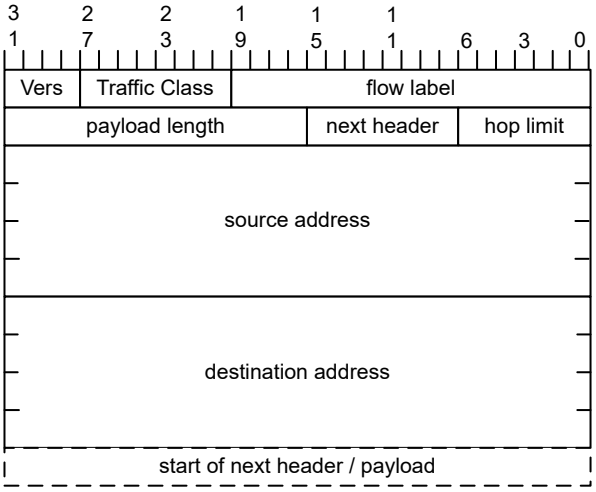

Figure 29.9 IPv6 header format

Table 29.13 IPv6 header fields (1 of 2)

Field Name	Description
Vers	4-bit IP version information. It is 6 for all IPv6 frames.
Traffic Class	8-bit field defining the traffic class.
Flow Label	20-bit flow label identifying frames of the same flow.
Payload Length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next Header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.
Hop limit	Hop counter, decremented by 1 by each station that forwards the frame. If hop limit is 0, the frame must be discarded.
Source Address	128-bit IPv6 source address

Table 29.13 IPv6 header fields (2 of 2)

Field Name	Description
Destination Address	128-bit IPv6 destination address

29.4.3 Switch Functional Description

29.4.3.1 Overview

The switch implements the following main functions:

- Input/output VLAN processing
- Input frame parsing and priority extraction
- Input port selection
- Output port resolution
- Frame queuing
- Output queue scheduling

29.4.3.2 VLAN Input Processing Function

(1) Overview

The VLAN input processing function is used on each switch input port to inspect and manipulate the VLAN tag of frames entering the switch. It performs the following functions:

- Input frame parsing
- VLAN tag insertion or manipulation

Based on the information of the input processing function, the frame can be switched to the corresponding output port or is discarded.

VLAN input processing is not performed for BPDU frames.

(2) Terms and Definitions

- VLAN information: The 16-bit field following the VLAN type field within a frame.
- VLAN ID: The lower 12 bits of the VLAN information field.
- VLAN priority: The upper 3 bits of the VLAN information field. Used to prioritize incoming frames. A value of 0 represents lowest priority, a value of 7 represents highest priority.

(3) Configuration Information

The switch management provides the following information to configure and control the operation of the function:

- SYSTEM_TAGINFOn: 16-bit value. The VLAN information field (VLAN ID and priority) used for tag insertion operations.
- Mode of operation: There are different modes of operation, which define how incoming frames must be processed for a port. The function can be enabled and configured individually per port: See registers VLAN_IN_MODE*1 and VLAN_IN_MODE_ENA*2.

Note 1. See section 29.3.1.11. VLAN_IN_MODE : VLAN Input Manipulation Mode Register.
Note 2. See section 29.3.1.13. VLAN_IN_MODE_ENA : VLAN Input Mode Enable Register.

Note: If the VLAN input processing function is not enabled (the port bit of VLAN_IN_MODE_ENA register = 0), the mode setting has no effect.

(4) Modes of Operation

The VLAN input processing function modifies the frames before they enter the switching engine. This means, if a VLAN tag is inserted, the switch only acts on the inserted VLAN tag (priority) and any original tag that was found in the frame before the modification, if any, has no effect within the switch.

In addition, if VLAN verification is enabled for a port (see section 29.3.1.5. VLAN_VERIFY : Verify VLAN Domain Register), the VLAN ID used for insertion (SYSTEM_TAGINFOn) must also be configured in the global VLAN resolution table (see section 29.3.1.67. VLAN_RES_TABLEn : 32 VLAN Domain Entries (n = 0 to 31)), to ensure the switch accepts frames, which contain the inserted tag.

When, in any of the modes, a tag is inserted, it is always inserted as first tag (outer) and its information field is set as programmed in the SYSTEM_TAGINFOn register for the port n where the frame is received.

Input manipulation can be enabled per port with register VLAN_IN_MODE_ENA and its port individual mode is configured in register VLAN_IN_MODE.

Table 29.14 Input manipulation modes

Mode	VLAN_IN_MODE bits [1:0]	Description
1	00b	Single Tagging with Passthrough/VLAN ID (VID) Overwrite. Insert Tag if untagged frame. Leave frame unmodified if tagged and VID > 0. If tagged with VID = 0 (priority tagged), then the VID is overwritten with the VID from SYSTEM_TAGINFO and priority is kept.
2	01b	Single Tagging with Replace If untagged, add the tag, if single tagged, overwrite the tag.
3	10b	Tag Always Insert a tag always. This results in a single tagged frame when an untagged is received, and a double tagged frame, when a single tagged frame is received (or triple tagged if double-tagged received).
4	11b	Reserved Mode is not implemented and should not be configured.

(5) VLAN PCP remap

The VLAN.PCP field can be remapped by the switch on ingress, regardless of whether VLAN input manipulation being enabled or the VLAN mode. This function is only available for the line ports (i.e. not for the management ports). The remapping also applies to the VLAN using the EtherType 0x8100 (0x8808 is not supported), and only for the outmost VLAN matching this EtherType.

The PCP is remapped before priority resolution is performed which means that the VLAN Priority Lookup function, section 29.4.3.5. Frame Classification and Priority Resolution (2) VLAN Priority Look Up, uses the remapped PCP value.

The PCP remapping is configurable per port via the control register PRIORITY_CFGn.PCP_REMAP. The configuration is a simple remap where each PCP value from 0 to 7 can be mapped to a new value between 0 to 7. The default configuration is to not do any remapping.

29.4.3.3 VLAN Output Processing Function

(1) Overview

The VLAN output processing function is used on a switch output port to manipulate the VLAN tag of the outgoing frames that leave the switch. Frames are processed based on the output processing mode, and the number of tags the frame contains.

VLAN output processing is not performed on BPDU frames.

(2) Configuration Information

The switch management provides the information on operating mode to configure and control the operation of the function. There are three different modes of operation, which define how the outgoing frames should be processed.

(3) Modes of Operation

The VLAN output processing function is configured to operate in one of the following modes, which define the way outgoing frames should be treated.

(a) Mode 0: Disabled

No frame manipulation occurs.

(b) Mode 1: Strip Mode

In Strip mode, all the tags (single or double) are removed from frame.

(c) Mode 2: Tag Through Mode

Always removes first tag from frame only. In Tag Through mode, the inner tag is passed through while the outer tag is removed for a double tagged frame. The following rules apply:

- When a single tagged frame is received, strip the tag from the frame
- When a double tagged frame is received, strip the outer tag from the frame

(d) Mode 3: VLAN Domain Mode / Transparent Mode

The following function is implemented: VLAN Domain Mode: The first tag of a frame is removed (same as Mode 2) when the VLAN is defined as untagged for the port. The following rules apply:

- If VLAN ID of the frame is found in the VLAN table (see (b) VLAN Domain Resolution / VLAN Table) and the port is defined as tagged for the VLAN, the frame is not modified.
- If VLAN ID of the frame is found in the VLAN table and the port is defined as untagged for the VLAN, the first VLAN tag is removed from the frame.
- If VLAN ID of the frame is not found in the VLAN table, the frame is not modified.

Note: The VLAN table is extended by a 2nd port mask to store the tagged bit for each entry of every port (in addition to the member port mask). This tagged bit mask is accessed using the control bits [30:28] when writing the VLAN_RES_TABLEn registers.

29.4.3.4 Frame Snooping

(1) Overview

To allow inspecting specific frames of different protocols for management purposes, a programmable generic frame parsing module is implemented that allows marking a frame for snooping. Snooping allows several functions such as a copy is sent to the management port for inspection while the frame is forwarded normally.

The generic approach allows searching for multiple arbitrary length patterns within a frame to identify (match) a frame for snooping. The following is a non-exhaustive list of examples how the generic parsing can be used:

- Mark frames with specific Ethernet type
- Mark frames with specific payload contents
- Mark IP frames with any IP protocol and sub protocol (extension headers) values
- Mark TCP/IP or UDP/IP frames with specific port numbers

When a frame is marked for snooping, it can be forwarded to the management port exclusively or as a copy, or become discarded.

If none of the given rules match, the frame is processed normally. If a frame is coming from the management port itself, the snooping rules are ignored (to avoid the frame be routed back to the management port again). However, the management port can use forced forwarding mechanisms to direct any frame to specific output ports if needed.

The function is configured using registers GPARSERn and GARITHn, and the management port is defined by register MGMT_CONFIG.

(2) Snooping Dataflow Description

Figure 29.10 shows the functions involved to mark a frame for snooping. Every frame is inspected, in parallel, with up to 8 individually programmable parsers. These parsers allow comparing a specific pattern from 1 to 16 bits at a certain position within the frame and report a match if the pattern is found.

The match result of each individual parser is then provided to an arithmetic block, which can perform Boolean operations on the result from up to 4 parsers to form a final match decision. Two of such arithmetic modules are available and independently programmable.

When any of the arithmetic blocks reports a match, the final snooping decision for the frame is provided to the switch forwarding.

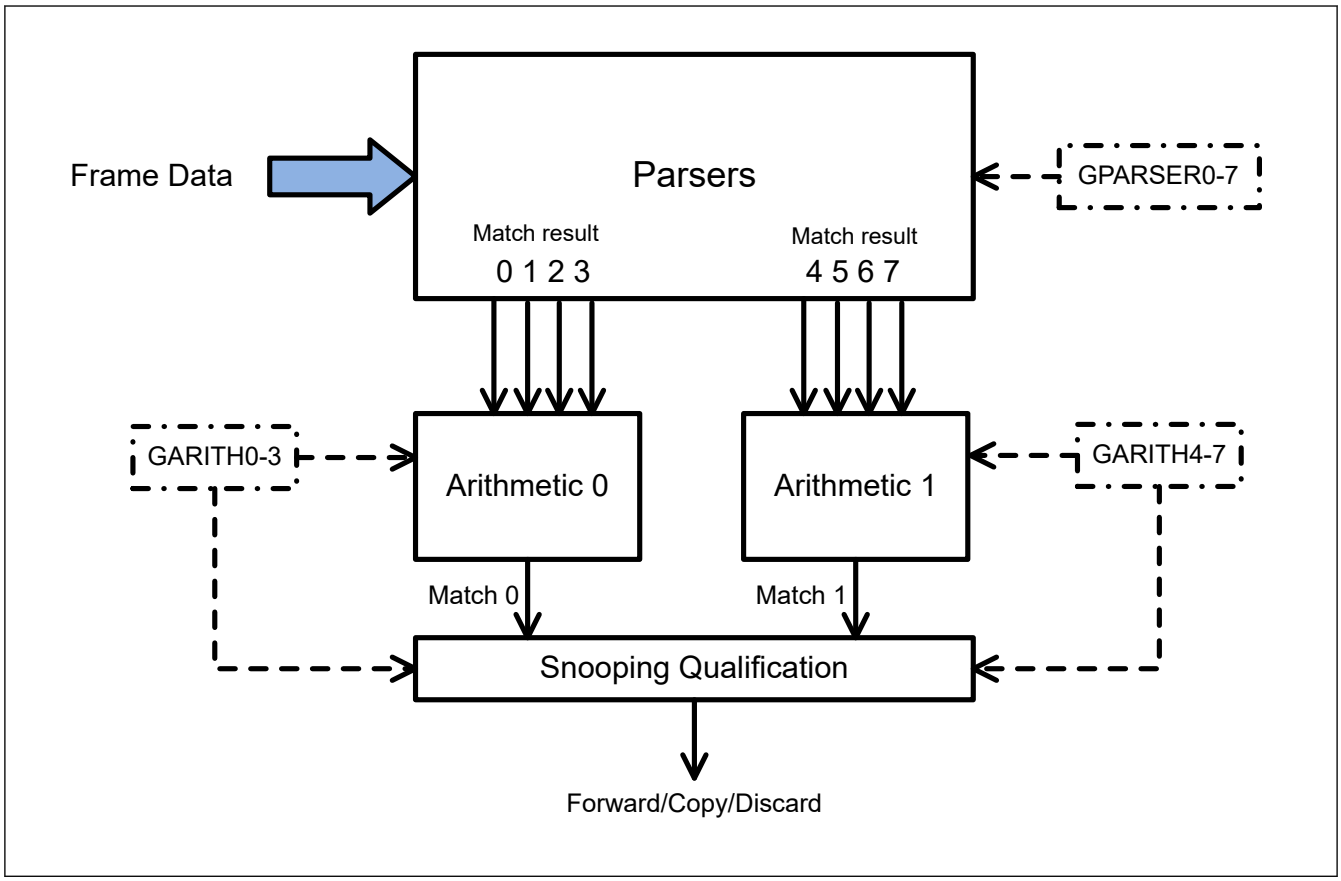

Figure 29.10 Snooping function overview

(3) Generic Parser

Each individual parser can inspect a frame as programmed by register GPARSERn (n = 0 to 7). Figure 29.11 shows the interpretation of the individual settings.

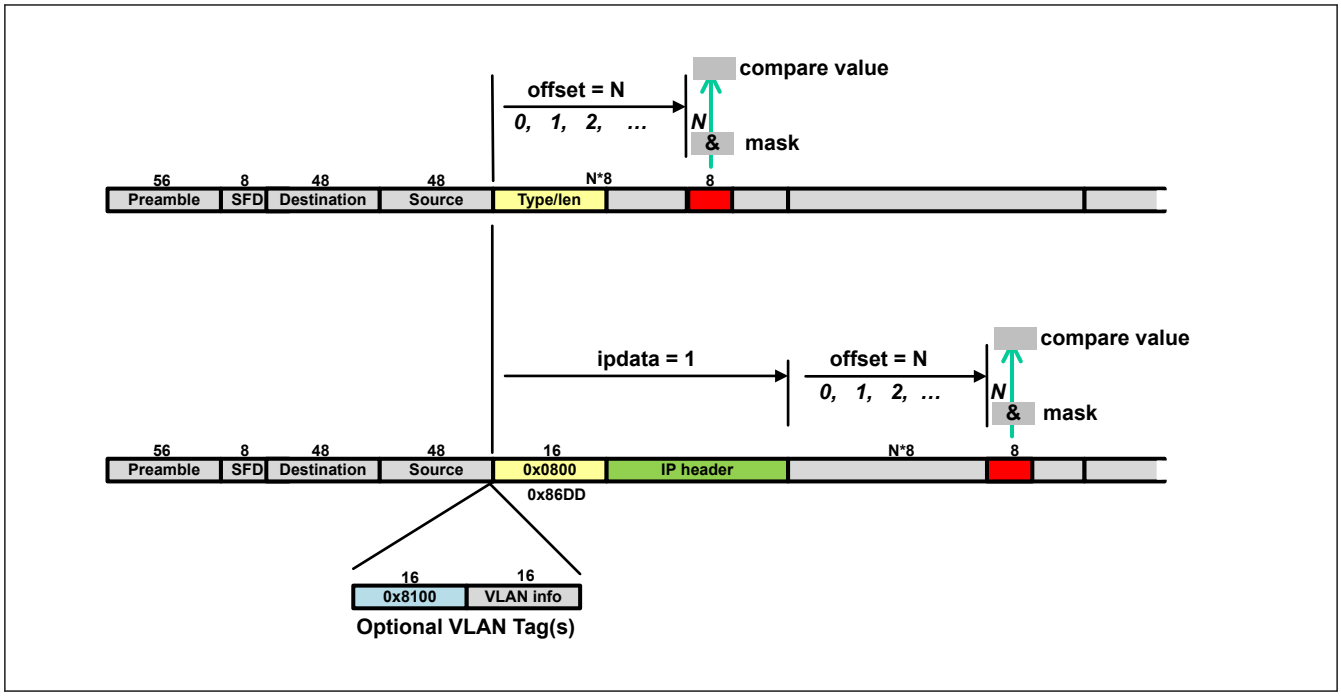

Figure 29.11 Generic parser configuration parameters

The parser acts as follows:

1. It extracts the bytes at the given offset of the frame. The offset can either be specified starting after the MAC source address, starting after any optional VLAN tags, or starting after an IP header.
2. It then applies a bitmask (AND) to the byte to mask out bits that should be ignored.
3. It then compares the result with the given pattern (compare value). If the pattern matches, a match indication is produced.

Instead of the mask & compare function, additional compare options allow to compare against a 16-bit value (for type comparisons) or alternatively (OR) two different byte values instead.

(4) Parser Limitations

The parser when inspecting frames has limitations. If a limit is reached, the parser is ignored and the frame is forwarded normally as if no parser was active (treated as a no match).

The limitations are as follows:

- The bytes that can be inspected can be at maximum at position 67 after the first byte of the destination address of the frame. If the offset together with, for example, VLAN tags falls beyond this limit, the snooping may not have an effect on the frame.
- The bytes within the last 8 bytes of a frame cannot be inspected. That is, if the last byte of the CRC field is 8 bytes or less after the byte to compare.

(5) Arithmetic Function

The match result of four parsers is connected to an arithmetic module combining the results of the parsers to a final match decision.

The arithmetic function implements 4 stages (arith 0, 1, 2, 3 as shown in Figure 29.12) and Boolean operations at every stage allow to implement complex combinations of the parser results. At each stage, the following can be configured:

- Select parser match result (match) or its inverted (no match)
- Select a result of a previous stage (only for the last 3 stages, arith 1, 2, 3)
- Define if the selected inputs should be ORed or ANDed and if the result should be inverted

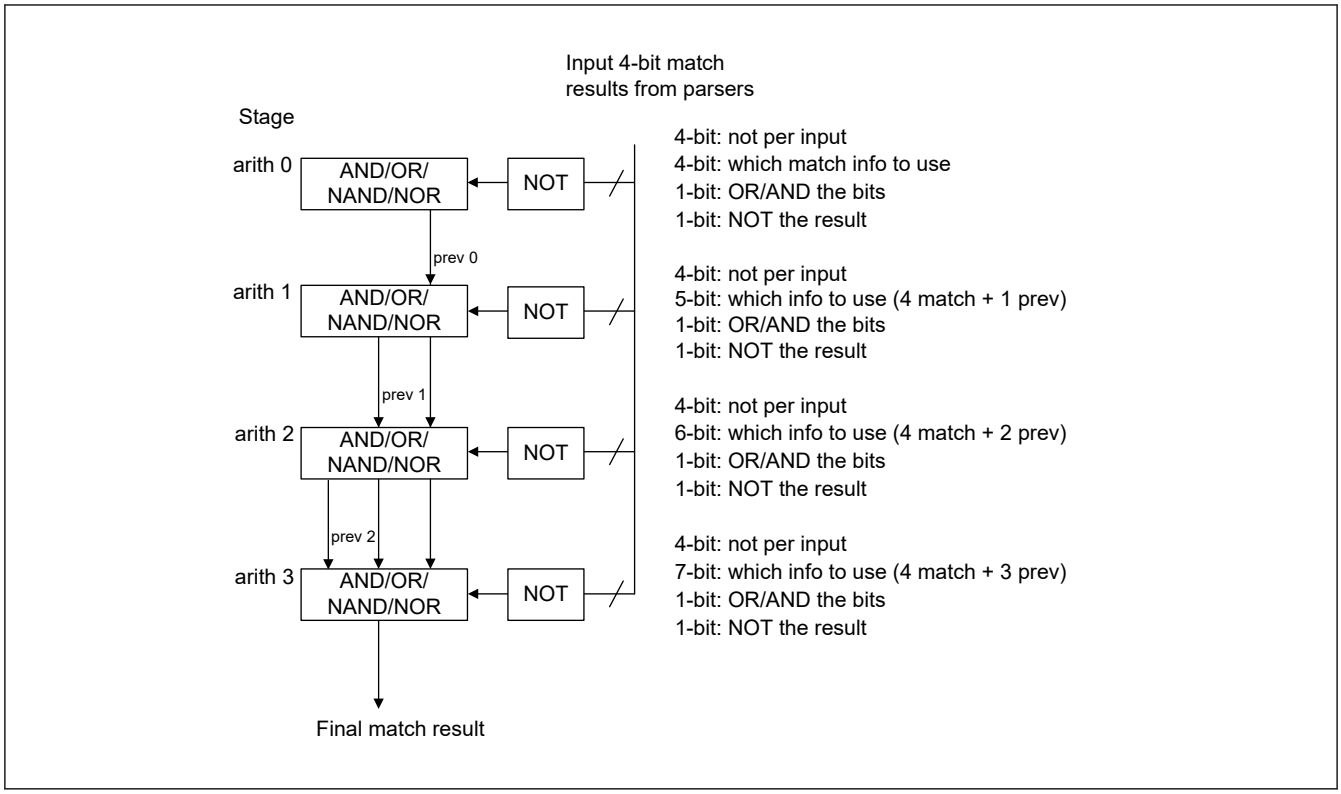

Figure 29.12 Snooping arithmetic function

The arithmetic function for the first 4 parsers (0 to 3) is configured in registers GARITH0-3. The arithmetic function of the next 4 parsers (4 to 7) is configured in registers GARITH4-7.

The configuration of the last stage (arith 3, register GARITH3 or GARITH7) also includes the configuration bits for the snooping function to define if the frame should be forwarded to management or copied or discarded eventually.

(6) Snooping Qualification

The last stage following the arithmetic modules qualifies the results from both arithmetic functions to provide the final decision to the switch how it should process the frame:

1. Forward it to the management port only.
2. Forward it normally and also copy it to the management port.
3. Discard it.

If both arithmetic functions match for the same frame but have different snooping actions configured, the action with the lower number is executed (forward to management port only before copy or before discard).

29.4.3.5 Frame Classification and Priority Resolution

(1) Overview

When a frame is received on an input port, several information are extracted from the frame as the Ethernet MAC Address, VLAN tag, and IP headers to determine the frame type and perform the relevant classification actions.

In addition, the MAC address table can provide a priority indication for the destination MAC address if the switch management software has programmed the address table accordingly (static entries).

The frame is classified as a high priority or as a low priority frame and is eventually queued in a corresponding priority queue at the output ports. A higher queue number is given a higher priority.

(2) VLAN Priority Look Up

On each port, an 8-entry programmable priority table is implemented. The registers VLAN_PRIORITYn contain the priority mapping for a port n. The switch uses 3 bits from the VLAN tag information (3 bit VLAN priority, see section

29.4.1.3. VLAN Tag Overview) to extract the corresponding bits from the table, that indicates which priority the frame should be finally classified.

The index in the mapping table is the 3 bits of the first octet of the VLAN info with bit 5 (Prio (0)) being the LSB and bit 7 (Prio (2)) being the MSB (see section 29.4.1.3. VLAN Tag Overview for VLAN tag details).

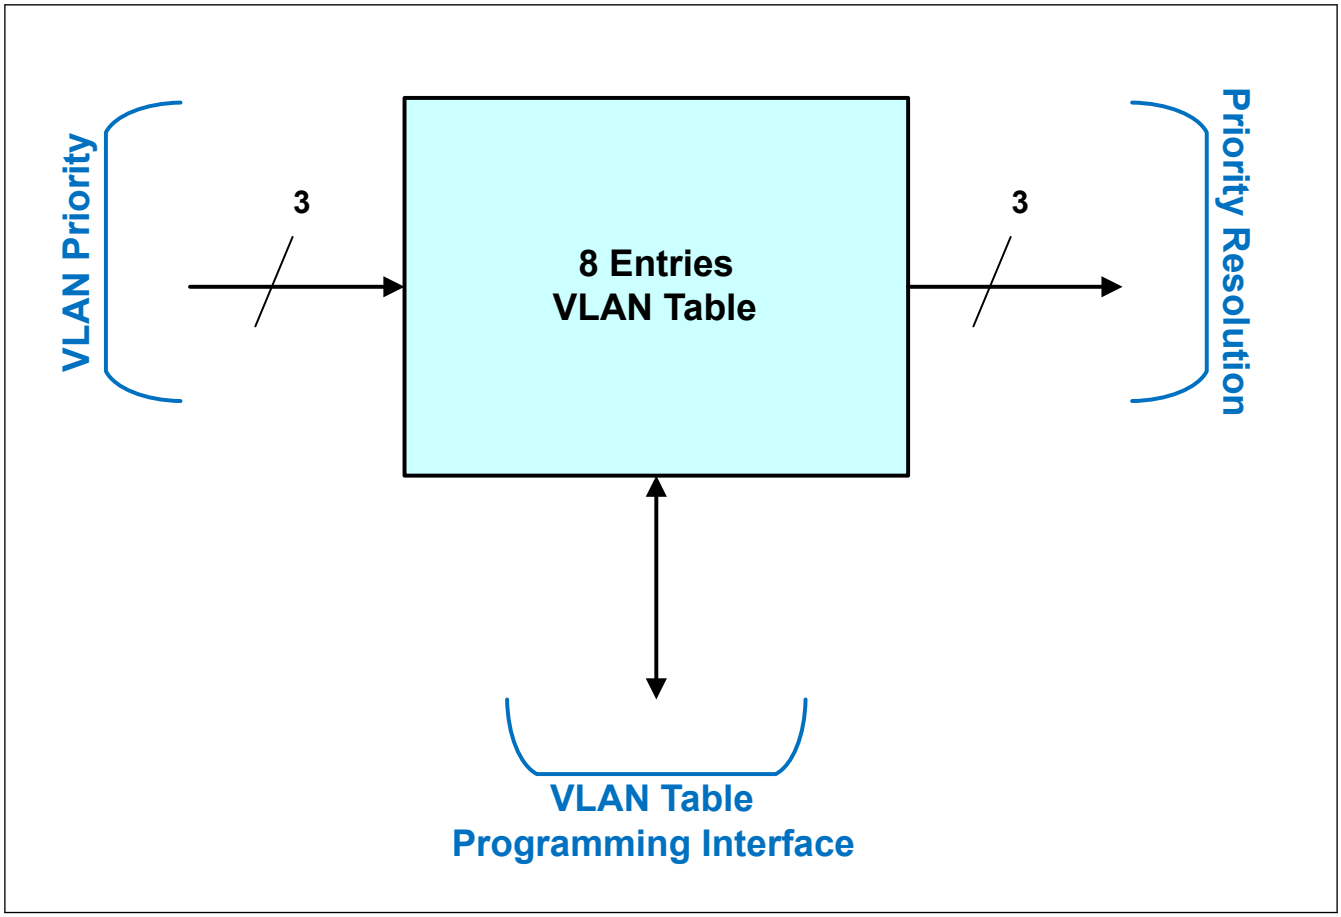

Figure 29.13 VLAN table overview

(3) IPv4 and IPv6 Priority Look Up

The switch can classify both IPv4 and IPv6 frames: A 64-entry table is implemented per port to classify the IPv4 Frames and a 256-entry table is implemented per port to classify IPv6 Frames (the IP classify tables) (see section 29.3.1.48. IP_PRIORITYn : IP Priority Register n (n = 0 to 3)).

On the IPv4 classify table entry, the 6-bit DiffServ field of the frame is provided and the table returns the 3-bit priority information.

On the IPv6 classify table entry, the 8-bit Traffic Class field is provided and the table returns the 3-bit priority information.

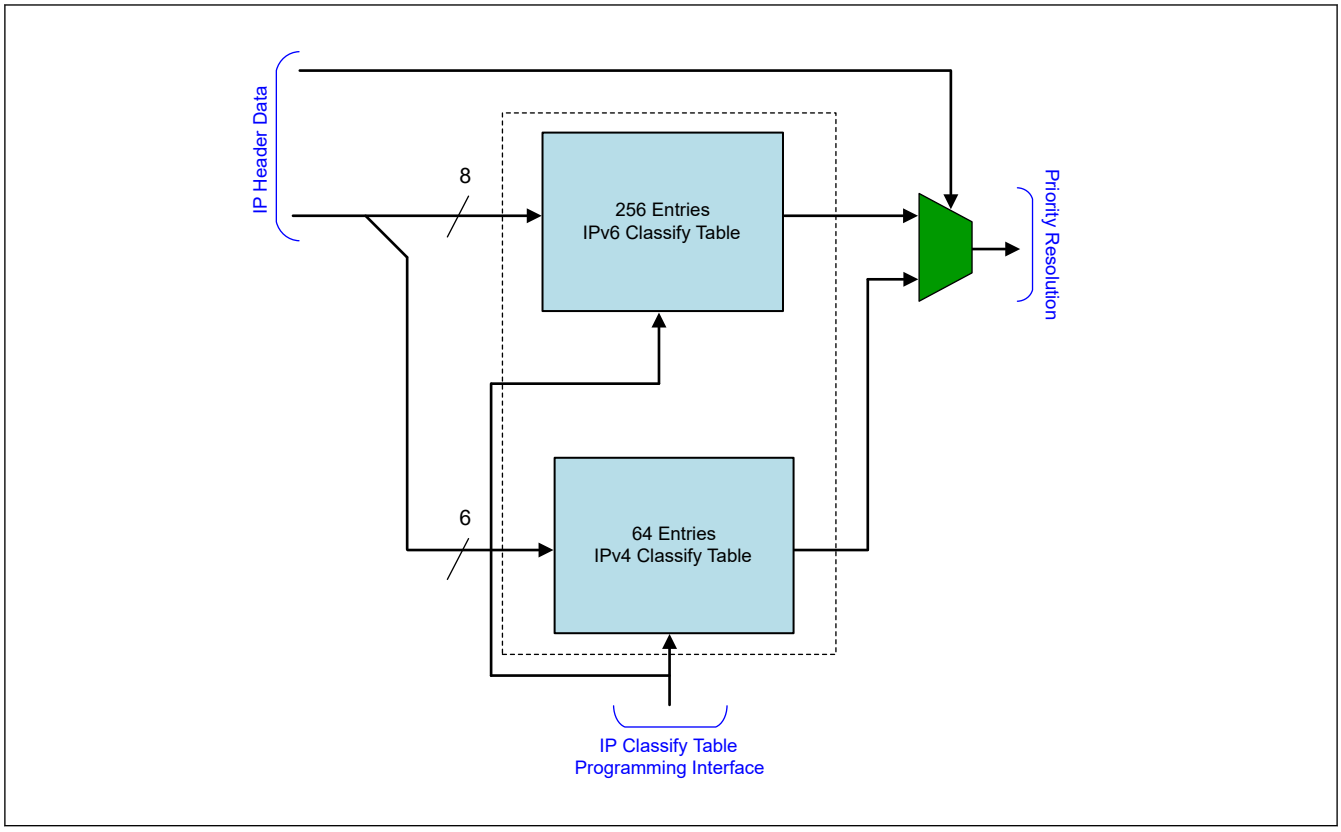

Figure 29.14 IP classify tables overview

(4) Priority Resolution

The priority resolution function, for a Port n, is, on each port independently, programmable with the registers PRIORITY_CFGn to enable or disable VLAN, IP, MAC address, or type based classification.

In addition, the optional Receive Pattern Matcher (see section 29.4.14. Receive Pattern Matcher) can be used to override the classification.

The priority resolution implements the following ruleset (and precedence) depending on which classifications are enabled (PRIORITY_CFGn) and which fields are found within the frame:

- If the Pattern Match classification is enabled (PATTERN_CTRL.SET_PRIO) and a match occurs, the defined priority from the PATTERN_CTRL register is used, ignoring the settings in PRIORITY_CFGn
- Otherwise, if IP classification is enabled and IP header found → map priority according to IP_PRIORITY table
- Otherwise, if VLAN classification is enabled and VLAN tag found → map priority according to VLAN_PRIORITY table
- Otherwise, if MAC classification is enabled and MAC address found → take priority from address table
- Otherwise, if TYPE classification is enabled and the frame type (following any VLAN tags) matches an entry of the PRIORITY_TYPE defined values, use the priority from that matching PRIORITY_TYPE
- Otherwise, if it is a BPDU frame transmitted by the management port, and the priority setting in the register MGMT_CONFIG is non-zero, this priority is used
- Otherwise, use default priority as specified in PRIORITY_CFG

(5) Bridge Control Protocol Identification

To allow for implementation of bridge control protocols like the Spanning tree protocol, an input module is implemented that marks all management frames (Bridge Protocol Data Units, BPDU) when they enter the switch. The mark then can be used by the input port blocking function (see (b) Input Port Blocking) to drop the frame after the address learning.

In addition, the function can be configured to pass all frames or to pass only management frames (covering spanning tree port states such as blocking, listening, learning) and discard all other frames.

29.4.3.6 Input Port Selection

The port selection constantly checks (polling) all input ports for available data and if any data is available, a port is selected and frame data is read from the input. All inputs are served simultaneously using a multiplexed access for storing the frame data into the shared memory. No receive FIFO exists allowing for very low forwarding delays as no copying from a receive FIFO into an output queue is needed.

29.4.3.7 Layer 2 Look Up Engine

(1) Overview

The switch is using the lookup memory to perform address lookups and determine to which port a frame should be forwarded to. By using a port mask, it is possible to forward a frame to one or many destination ports (for example, multicast). For instance, software can add (static) multicast addresses and define that traffic is forwarded only to the ports that have subscribed to the multicast domain.

In addition to the destination lookup, the source address of each incoming frame is searched, and if found, the corresponding aging bit of an entry (dynamic record) becomes set. The aging bit is used by the aging process to determine if an entry should be removed from the memory. The aging process periodically clears the aging bit of each entry and verifies if the bit is set again after some time. If the bit is not set, the entry is considered to be outdated and can be removed from the lookup memory.

(2) Hash Based Lookup

A hash code is calculated using the frame destination MAC address. It is used as an entry (address) to a table, which contains, for each hash value MAC addresses with destination port mask and validity information.

As one hash code value can represent more than one MAC address, the memory implements for each hash value, up to eight MAC address entries, which are searched linearly.

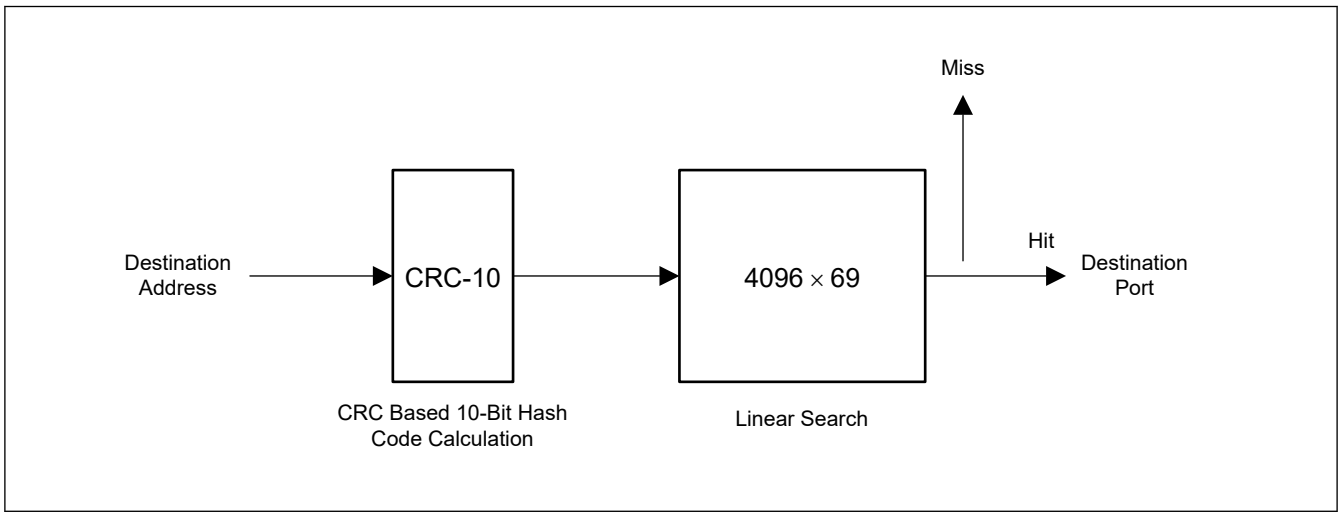

Figure 29.15 Port look-up overview

(3) Hash Code

For MAC address table 4096 entries, a 10-bit hash value is calculated from the 48-bit MAC address. The hash code is using a CRC-10:

$x^{10} + x^9 + x^5 + x^4 + x + 1$ (0x233)

(4) Address Memory

The address memory is divided into blocks. Each block contains eight records, which contain up to 69-bit of information each. Each record contains the 48-bit MAC address (first byte in bits [7:0]), VLAN number if IVL is supported, and provides the necessary forwarding information as well as priority or aging information. Figure 29.16 and Figure 29.17 show the physical format of each record. See section 29.3.1.83. LK_CTRL : Learning/Lookup Function Global Configuration Register for details on how to manually program individual records.

Two types of records are defined:

- Dynamic Record:
  The dynamic entry provides the MAC address together with destination port number and aging information. These entries are created by the learning function based on received frames. Dynamic entries are deleted by the aging function if not updated.
- Static Multiport/Priority Record:
  Switch Management can also write static entries in the table, which can include priority information as well as multiple destination ports for forwarding. The MAC address can be unicast or multicast. These records can be used to specify the ports to participate in a specific multicast domain or to assign a MAC address based priority to a frame. The aging and learning functions ignore static records.

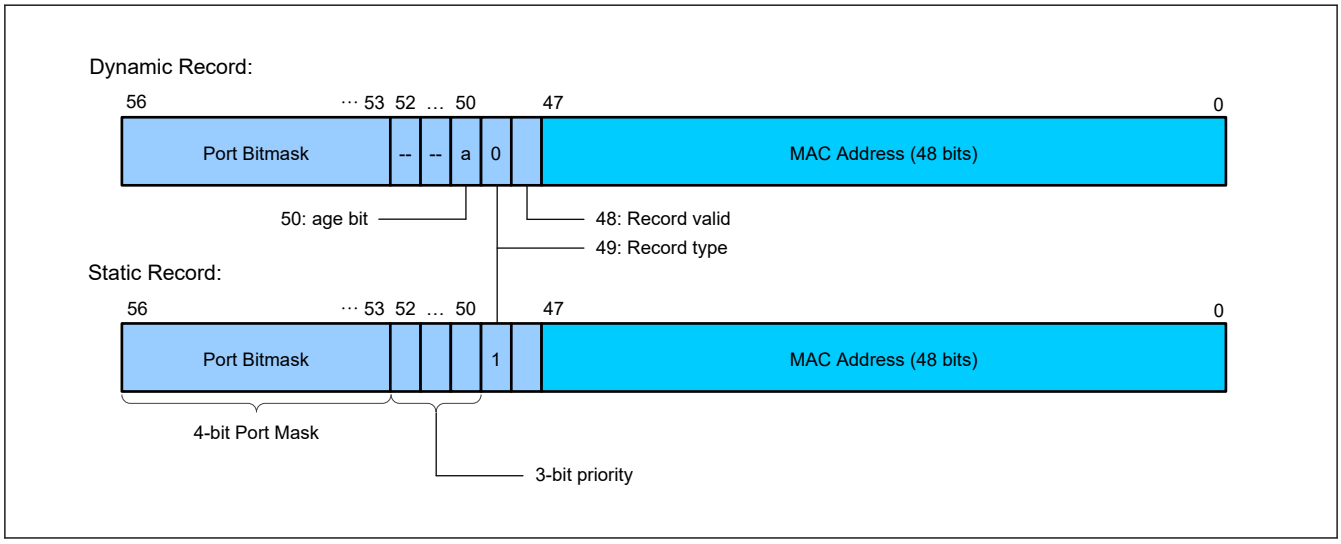

Figure 29.16 Address memory record types (IVL support disabled)

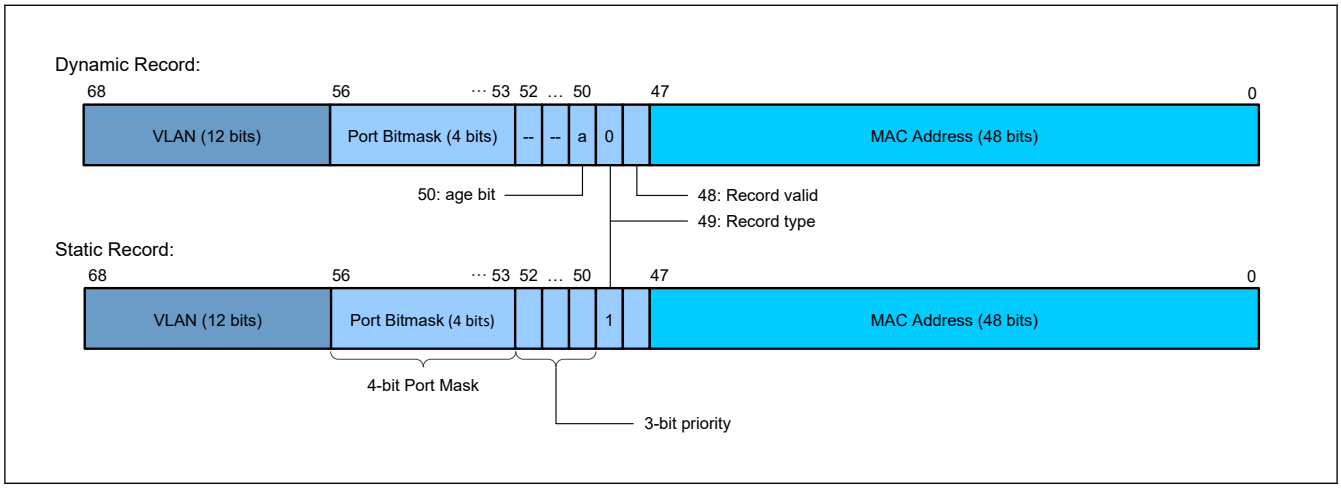

Figure 29.17 Address memory record types (IVL support enabled)

Bit 49 of the record determines which type of record is found in the table:

- If the bit is 0, a dynamic entry is available and bit 50 holds the aging bit. Bits [56:53] indicate at which port the address has been received.
- If the bit is 1, a static entry is available with a 3-bit priority field followed by the port bit mask.

Bit 53 of the record represents port 0, bit 54 port 1, and so on. The frame is forwarded to all ports that have a value of 1 in the port bitmask. The source port is removed dynamically from the bitmask during forwarding (a frame is not forwarded to the port where it came from).

29.4.3.8 Layer 2 Look Up Engine Operational Description

(1) General

The host CPU can be used to configure the lookup options. The switch performs self initialization of the address table after reset for normal operation. Lookup and Learning are performed fully autonomously by the hardware without processor intervention.

It should be noted, that all address table memory transactions from the processor consume time that is lost for the hardware to perform lookups required for frame forwarding. It influences the overall switch performance and therefore should be reduced to a minimum during operation.

(2) Memory Write

Writing to memory is performed in two steps.

1. The LK_DATA_LO/HI/HI2 registers are set with the data to write.
2. The LK_ADDR_CTRL register is written to start the transaction.

When the transaction is started (by writing into LK_ADDR_CTRL), the interface controller requires some time until the transaction is completed. Software can either poll the BUSY bit within the LK_ADDR_CTRL register or set the WAIT_COMP bit when writing to the register. Using the WAIT_COMP bit ensures that the CPU cannot access the registers until the transaction is completed (the processor bus is held in wait, freezing processor activity).

(3) Memory Read

Reading from the memory is performed in two steps similar to writing. However, first, the transaction is executed and the data is delivered to the LK_DATA_LO/HI/HI2 registers after completion.

1. The register LK_ADDR_CTRL is written to start a READ transaction.
2. On completion of the transaction, data is available in LK_DATA_LO/HI/HI2.

(4) Power on Initialization

After power on reset, the switch performs self initialization of the lookup table functions and enables automatic learning. The host CPU may perform additional configuration or add static table entries as needed. The learning functionality and other options are configured with the Learning/Lookup Function Global Configuration Register (LK_CTRL).

(5) Destination MAC Address Lookup

The 48-bit destination MAC address of each frame is extracted. If the frame is a unicast or multicast frame (see section 29.4.1.2. MAC Address Overview for definition) the look up function can provide three results with three different associated actions performed:

1. The address is found in the table:
   The switch forwards the frame to the ports provided by the port mask of the entry.
2. The address is in the table but is associated with the port on which it was received:
   The switch discards the frame and does not forward it to any port.
3. The address is not found in the table:
   The switch engine sends the received frame depending on the type of destination address to all ports (flooding) listed in:
   - UCAST_DEFAULT_MASK0/UCAST_DEFAULT_MASK1 for unicast frames
   - MCAST_DEFAULT_MASK0/MCAST_DEFAULT_MASK1 for multicast frames

Broadcast frames are always sent to all ports listed in the BCAST_DEFAULT_MASK0/BCAST_DEFAULT_MASK1. There are two sets of unicast, multicast, and broadcast default masks. Each mask can be used by a different set of ports by configuring the PORT_XCAST_MASK_SEL register.

Setting any of the default masks to all 0 would lead to discard of the frame.

In all cases, the port, where the frame was received from is automatically removed from the final forwarding port mask.

Note: Flooding and additional frame filtering can be further controlled with the mechanism described in (3) Broadcast / Multicast / VLAN Domain Resolution.

(6) Automatic Learning / Migration

The hardware allows performing automatic learning of source addresses of incoming frames. When a frame is received from any port, its source address is searched in the lookup memory in addition to the destination address lookup described before.

If learning is enabled (see section 29.3.1.83. LK_CTRL : Learning/Lookup Function Global Configuration Register), the following tasks are performed:

- Checks the INPUT_LEARN_BLOCK register. If learning is disabled for a port, the source address of incoming frames is ignored.
- If the frame is marked as a management frame (BPDU, see (7) Bridge Protocol Frame Resolution), the source address is never learned (independent of INPUT_LEARN_BLOCK).
- If the source lookup was successful, the port mask is verified to match the incoming port number where the frame was received. If a mismatch occurs, the forwarding port mask is updated accordingly (migration), but only if the entry is a dynamic entry. Static entries are not changed.
- If the source lookup failed, the new address is added to the lookup memory (if allowed by configuration in LK_CTRL). If there is no more space in the table, the new entry replaces an arbitrary entry with an identical matching hash value (i.e. one of the 8 entries for the hash is deleted).
- The aging bit of the entry is set. The aging function continuously scans the table and clears the bit to detect outdated entries.
- An interrupt is generated whenever a source address is not found in the table (this is independent from learning having entered an address or not). See section 29.3.1.84. LK_STATUS : Status Bits and Table Overflow Counter Register.

If automatic learning is disabled, no inspection of the frame source address is performed. It is then the responsibility of the software to place the addresses in the lookup memory (static configuration). The learning interrupt still indicates when new addresses arrive.

The management frames (BPDU, see (7) Bridge Protocol Frame Resolution) are never learned, and it is the responsibility of the software to add a source address of such frames if necessary.

(7) Aging

Aging refers to deleting old entries within the table. It processes as follows:

1. For each entry, an aging bit is implemented. The bit is set whenever the source address is found within a received frame.
2. When the aging process (timer) inspects an entry, it resets the aging bit to 0. If it finds an entry with the aging bit already being 0, the entry is deleted.
3. Static entries are not affected by the aging process and kept always.

This process runs continuously in the background processing one entry at a time. The aging period is programmable (see section 29.3.1.90. LK_AGETIME : Period of the Aging Timer), giving a range from seconds to several minutes. Aging can also be disabled completely under software control.

(8) Independent VLAN Learning (IVL) Mode

The default switch operation is to perform lookup and learning procedures on MAC addresses only. That is, MAC addresses are shared over all VLANs, if any (Shared VLAN Learning, SVL Bridge).

If independent VLAN learning is enabled (LK_CTRL), it manages MAC addresses together with VLAN identifiers, allowing identical MAC addresses in multiple VLANs.

A VLAN identifier of all 0 means that there is no VLAN associated with the entry (the null VLAN identifier is defined in IEEE 802.1Q Clause 9.6 as a wildcard) and the MAC address is therefore allowed in any VLAN.

(a) Lookup Processing

The lookup process searches the address table for matching MAC addresses.

The configured SYSTEM_TAGINFOn of the port is used as the VLAN ID when an untagged frame, or a priority tagged (VID = 0) is received. The use of the SYSTEM_TAGINFOn setting always applies and is independent from any VLAN input manipulation settings (see section 29.4.3.2. VLAN Input Processing Function).

If the MAC address is found, the VLAN ID of the entry is further inspected and considered as follows:

Table 29.15 Lookup VLAN match decisions

VLAN ID in frame or SYSTEM_TAGINFOn	VLAN ID in table	Match decision
0/untagged	Any	Matches (shared MAC address)
Any	0	Matches (shared MAC address)
!0	!0	Matches only if VLAN id matches (independent VLAN)

Note: If the SYSTEM_TAGINFOn has the null VLAN ID (default) and if multiple table entries for the same MAC address with different VLAN IDs are available, any of these will be matching (which of them is arbitrary and is not predictable).

(b) Learning

When the lookup of the frame source address does not match any entry as previously described, the MAC address is inserted into the table with:

- Untagged frame: The VLAN ID of the entry is set to the value programmed in SYSTEM_TAGINFOn of the port.
- Priority tagged frame (VLAN ID = 0): The VLAN ID of the entry is set to the value programmed in SYSTEM_TAGINFOn of the port.
- Tagged frame: The VLAN ID of the frame is stored.

Note: This use of the SYSTEM_TAGINFOn setting always applies and is independent from any VLAN input manipulation settings (see section 29.4.3.2. VLAN Input Processing Function).

29.4.3.9 Industrial Automation Profile for TSN (TSN-IA-Profile) Forwarding Table

This is a TSN profile designed for applications in industrial environments where time-sensitive streams must have a controlled latency through the network. It is defined by the IEC/IEEE 60802 joint taskforce. Supports the number of required streams (8 K at the time of writing) without increasing the size of the hash-based forwarding database.

(1) General

The IA-TSN-profile requires the switch to be capable of forwarding 8 K or more distinct streams in addition to at least supporting 2 K or more distinct MAC addresses for non-IA traffic. The IA-TSN-profile identifies the different streams by the MAC destination address (see section 29.4.1.7. Industrial Automation — TSN Frames) and up to 4 distinct VLAN IDs.

Supporting these many streams by solely using a hash-based forwarding database poses a challenge because the inherent collisions which limits the maximum number of usable entries in the table. The IA forwarding database (IA-FDB) uses a direct-index address based on the frame's ID and the VLAN ID to allow a packed storage of all the streams, relieving the hash-based FDB from this task.

The IA-FDB is disabled by default and does not have an automatic learning function like the L2 FDB. Therefore, it must be enabled by firmware on a per-port basis and be manually configured as streams are created in the network.

When the IA-FDB is enabled, the port initiates an L2 lookup in both the hash-based FDB and the IA-FDB, and uses the result from the IA-FDB if the lookup results in a found entry in the table such as a hit.

(2) Forwarding Flow Using IA-FDB

As mentioned before, the IA-FDB is used for storing the forwarding information for IA-TSN frames. The IA-FDB is enabled per port using the IALK_CONTROL.IA_LKUP_ENA control field. Figure 29.18 shows the decision process when using the IA-FDB as part of the lookup process. The IA-FDB lookup is executed in parallel to the L2 hash-based FDB. The L2 hash table returns a found (hit) flag if the entry is found in the L2 FDB, along with a port mask. The IA-FDB also returns a found flag with a corresponding port mask and a learn_ok flag that is used to inhibit learning for this frame.

The found flags are used to determine the result, with the IA-FDB having priority over the L2 FDB. When none of the tables return a hit indication the frame is flooded based on it being unicast or multicast.

Note: The port also issues a look up requests to the IA-FDB under the same conditions that it would for a destination lookup to the L2 FDB. This means that BPDU, broadcast, and frames from the management port with a force forward request do not generate a request. Also, the result is also subject to further filtering for exmample, same-port filtering (the source port is excluded from the destination port mask), VLAN domain verification, port mirroring, snooping, and pattern matcher modifications.

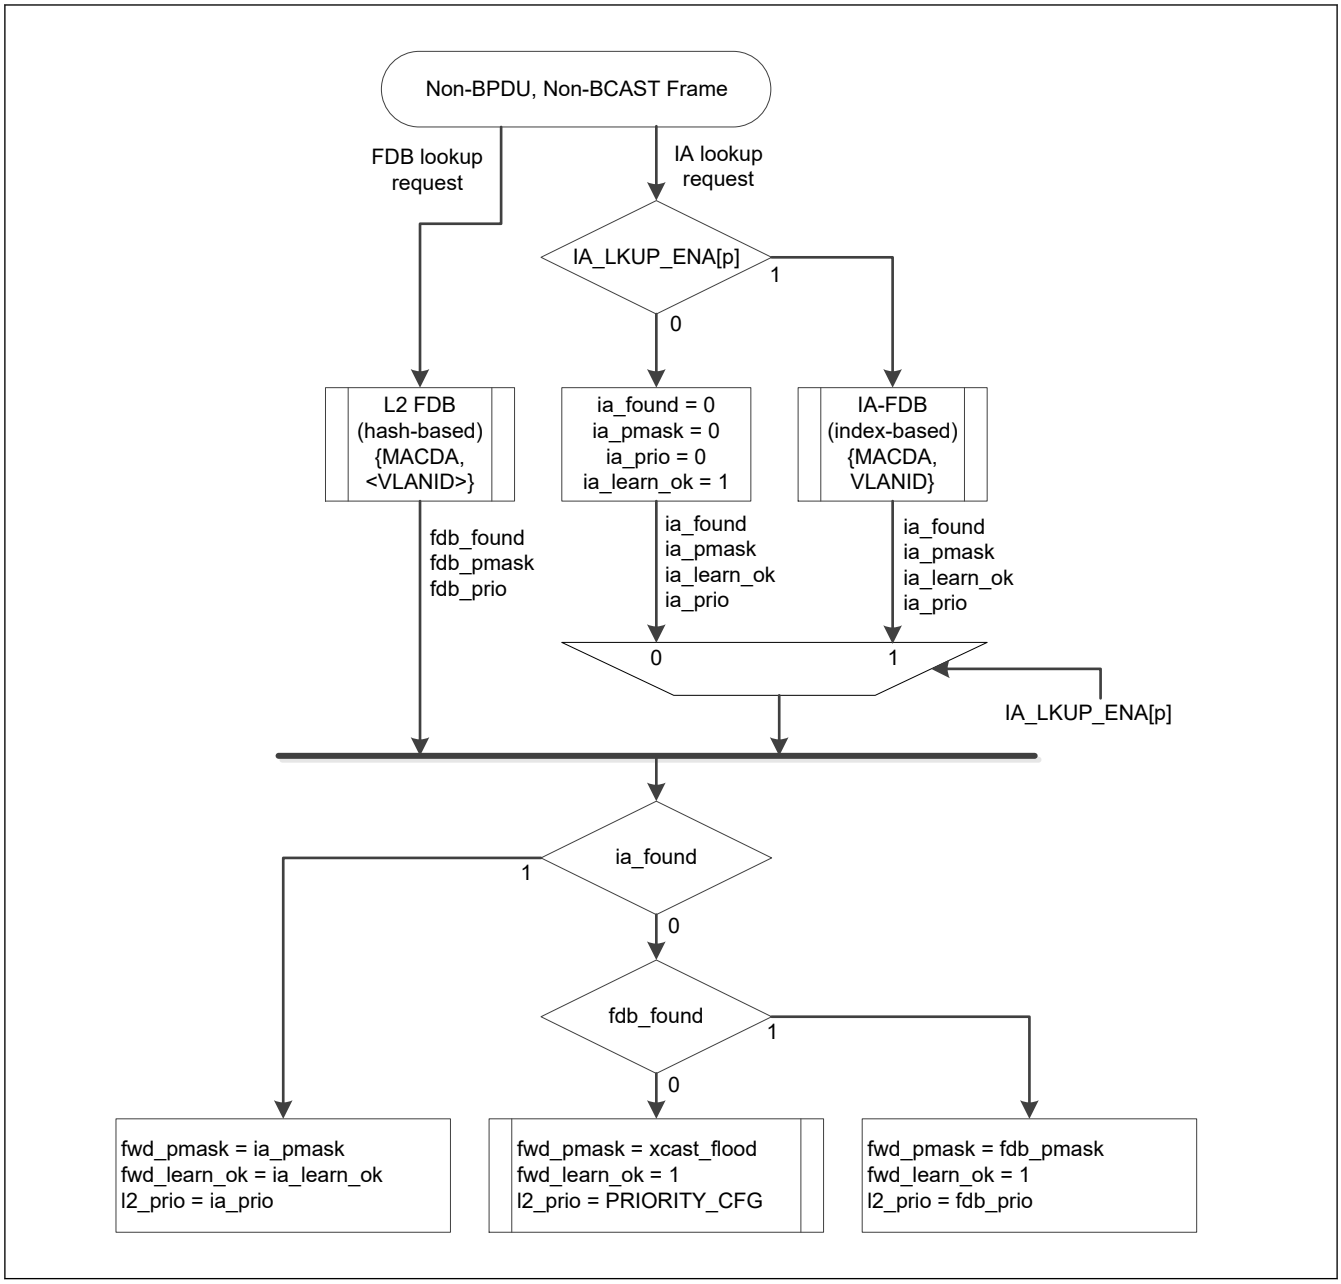

Figure 29.18 Forwarding flow using IA-FDB

(3) IA-FDB Lookup Flow

Figure 29.19 shows the look up process executed by the IA-FDB table for every port request. The flow is controlled MAC destination address of the frame (see section 29.4.1.7. Industrial Automation — TSN Frames for details on the MAC destination address format) and the VLAN ID of the frame (which can be the VLAN ID of the port if the frame has no VLAN tag).

The process can be summarized as follows:

1. Compare the OUI of the MAC destination address of the frame to the value configured in the IALK_OUI register. If it is not a match, return a not-found response.
2. Compare the ID of the MAC destination address of the frame to be within the range defined by IALK_ID_MIN and IALK_ID_MAX. The behavior when the ID is not within the range is configured in the IALK_ID_CONFIG register.
   (a) If the frame is not within the range and INVLD_ID_FLOOD is 0, return a not-found response.
   (b) If the frame is not within the range and INVLD_ID_FLOOD is 1, return a found response using the mask in INVLD_ID_FLOOD_MASK, the learn_ok value in INVLD_ID_LRN_ENA, and the priority from INVLD_ID_PRIO. To force a frame to be discarded the mask INVLD_ID_FLOOD_MASK must be set to 0.

Also, it is recommended to set INVLD_ID_LRN_ENA to 0 to prevent learning the MAC source address of the frame.

3. Calculate a new ID value by subtracting IALK_ID_SUB from the frame ID.
4. Check the number of enabled VLANS in IALK_VLAN_CONFIG.VLANS_ENABLED.
   (a) If VLANS_ENABLED is 0 (no VLANs), use the calculated ID as the entry address for the IA-FDB, and set n to 0 (used later to return learn_ok on a hit).
   (b) If VLANS_ENABLED is 1 or more, check whether the VLAN ID of the frame matches any of the registers IALK_VLANIDn (n = 0 to (VLANS_ENABLED - 1)). A match requires that IALK_VLANIDn.VLANID_ENA is set to 1 and IALK_VLANIDn.VLANID matches the VLAN ID of the frame, or that IALK_VLANIDn.VLANID is 0.
      (i) If there is match, calculate the entry address addr using the LSBits to select the VLAN and the MSBits from the calculated ID. The number of bits used to select the VLAN is $\log_2$(VLANS_EANBLED).
      (ii) If there is no match, the response is determined by the configuration in IALK_VLAN_CONFIG.
      If UNKWN_VLAN_FLOOD is 0, the response is not-found.
      Otherwise, the returned port mask is UNKWN_VLAN_FLOOD_MASK, learn_ok is given by UNKWN_VLAN_LRN_ENA and the priority is taken from UNKWN_VLAN_PRIO. To discard the frames with unknown VLAN set UNKWN_VLAN_FLOOD_MASK to 0.
5. Read from the FDB and return a valid and pmask (port-mask). A valid indicates whether the entry contains a valid port-mask.
6. If the entry is valid (valid is set to 1), return the port mask value in pmask and set learn_ok from IALK_VLANIDn.VLANID_LRN_ENA and the priority from IALK_VLANIDn.VLANID_PRIO. When no VLANS are enabled, n is set to 0.
7. If the entry is invalid, the response depends on whether VLANS are enabled.
   (a) If VLANs are disabled (VLANS_ENABLED = 0), the response is "not-found".
   (b) If VLANs are enabled (VLANS_ENABLED > 0), the response is found even though the entry in the table was invalid. The return port mask is taken from the flooding mask IALK_VLANIDn.VLANID_FLOOD_MASK, learn_ok is taken from IALK_VLANIDn.VLANID_LRN_ENA and the priority from IALK_VLANIDn.VLANID_PRIO. To discard frames whose valid entry is set to 0, set VLANID_FLOOD_MASK to 0.

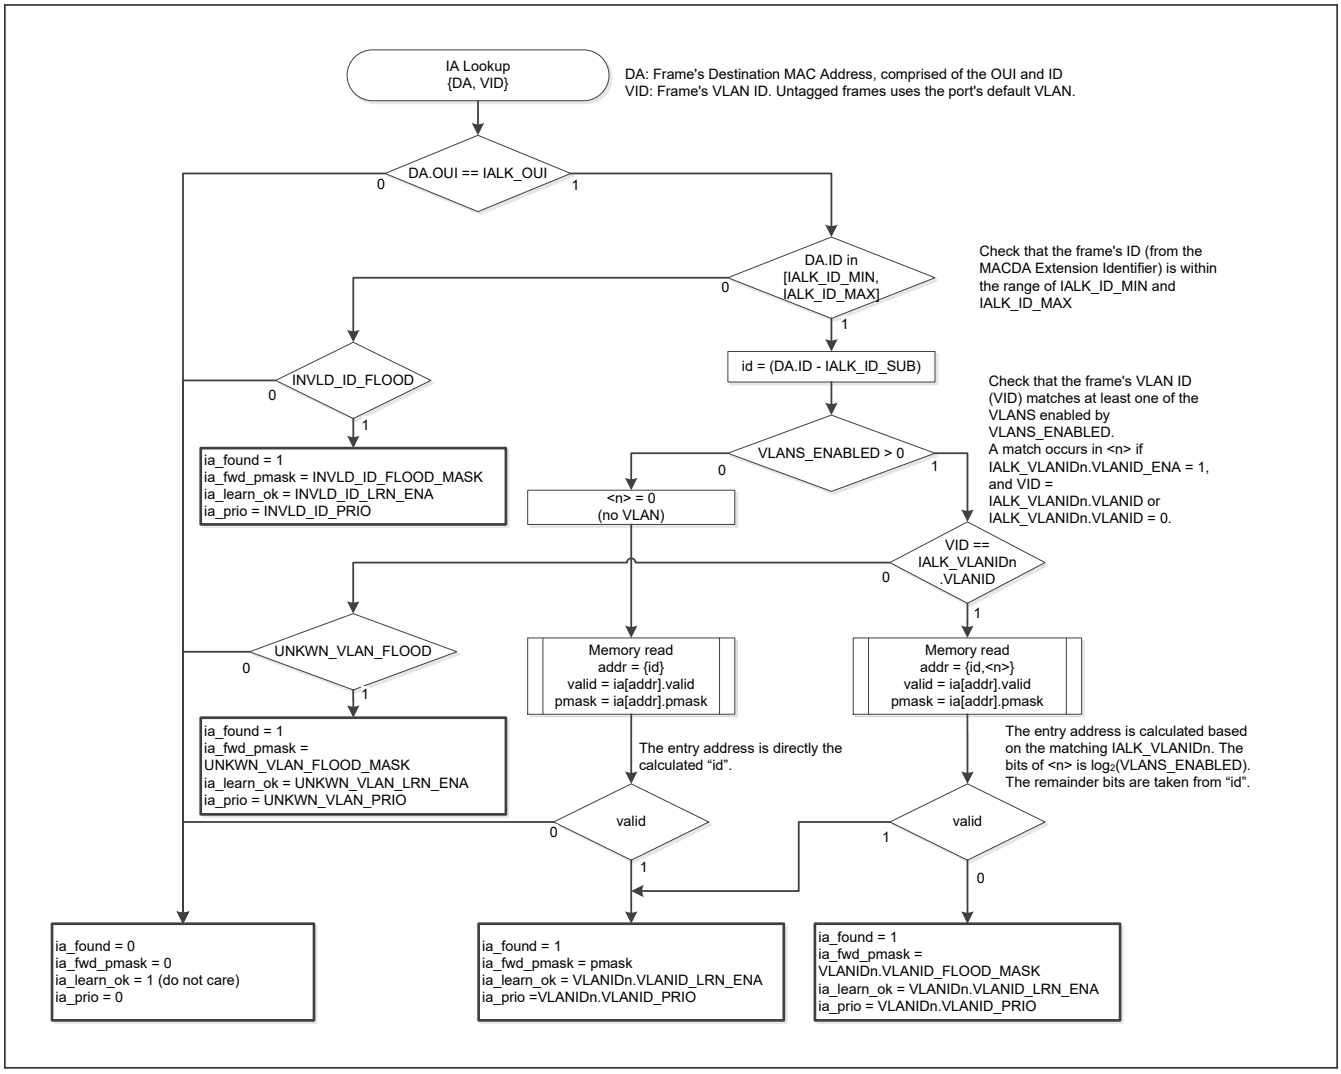

Figure 29.19 IA-FDB look-up flow

(4) IA-FDB Physical and Logical Layout

As previously shown, the IA-FDB is indexed by an entry address, in a direct and linear fashion. The entry address is composed by the index of the IALK_VLANIDn register matching the VLAN ID of the frame, and the adjusted ID from the MAC destination address of the frame.

The table must be configured during initialization for the number of intended VLANs to support using the configuration register IALK_VLAN_CONFIG.VLANS_ENABLED, and this must be done prior to enable the IA lookups in IALK_CONTROL.

When no VLANs are used, the ID is used directly as the address of the entry, taking as many bits as entries supported by the table. On the other hand, when at least 2 VLANs are enabled, the bits given by $\log_2$(VLANS_ENABLED) are used as the LSBits for the entry address, and the remainder bits are taken from the LSBits of the ID.

Figure 29.20 shows an example where 4 VLANs are enabled in VLANS_ENABLED and the total number of entries for the IA-FDB is 8192 where n corresponds to each of the 4 IALK_VLANIDn registers used for comparing the VLAN ID.

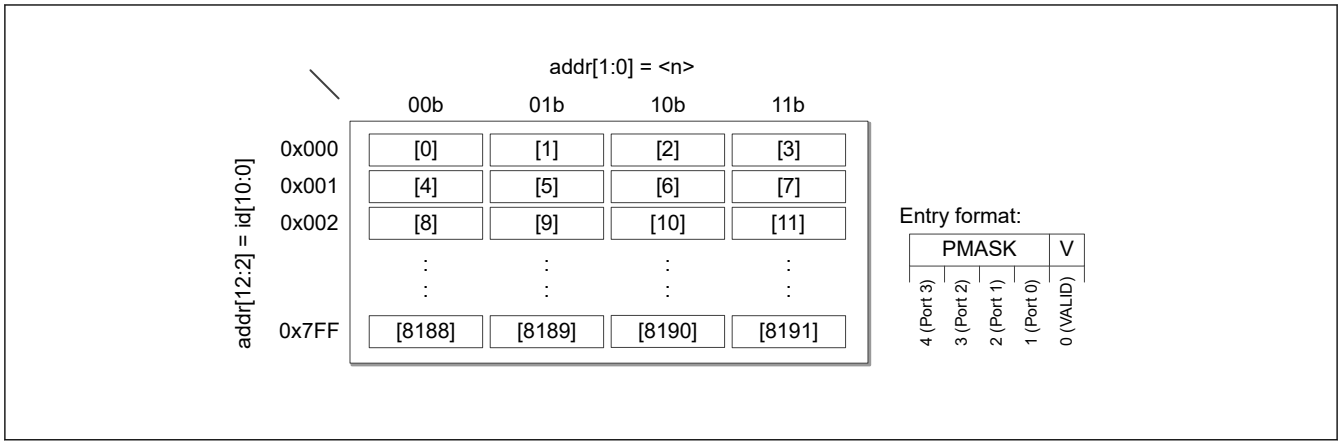

Figure 29.20 IA-FDB 4-VLANs logical geometry example

The IA FDB size is 8192 and supports up to 4 IA_VLANs.

(5) Programming

The IA-FDB initializes with all bits set to 0, which means that all entries are invalid, and all port masks are 0.

The programming of the IA-FDB is done using the control registers IALK_TBL_ADDR and IALK_TBL_DATA. To program an entry, the address must be calculated as previously explained, considering the number of enabled VLANs. This address is programmed in IALK_TBL_ADDR first, and then the entry can be written by writing the entry in IALK_TBL_DATA as indicated in the register description. The entry can also be read from IALK_TBL_DATA.

To facilitate initialization the address in IALK_TBL_ADDR can be configured to auto-increment for every read and write operation to IALK_TBL_DATA. The auto-increment value is a 4-bit field to allow incrementing within the same VLAN (see Figure 29.20). The address value rolls over automatically.

If the number of entries in the IA-FDB is not a power of 2, writing an invalid address in IALK_TBL_ADDR is not defined and should be prevented with software.

(6) Usage Notes

The programming of the registers IALK_ID_MIN, IALK_ID_MAX, and IALK_ID_SUB must be programmed so that the resulting ID, after being combined with the VLAN index n to form the entry address results in a value that is within the range of implemented entries. The hardware does not perform any range checks on the entry address and simply does the calculation as indicated in the previous sub-sections.

To re-iterate, the resulting forwarding port mask from the IA-FDB is still subject to other forwarding checks detailed on section 29.4.3.10. Frame Forwarding Tasks. It is recommended that the VLAN IDs used for IA-TSN traffic are not programmed in the VLAN table to prevent further filtering.

The register IALK_CONTROL allows disabling cut-through forwarding for frames returning a found response from the IA-FDB. The use of this feature is not specified in the IEC 60802. The default value is to disable cut-through, so it is recommended to set the cut-through enable when enabling the IA-FDB for a port.

The IEC/IEEE 60802 IA-TSN profile requires that IA-TSN frames are prevented from automatic hardware learning. To achieve this, various *_LRN_ENA bits must be set to 0. When LRN_ENA is set to 1, learning can occur only if also hardware learning is enabled in the LK_CTRL register.

The priority when a found response is returned can be set in the various *_PRIO fields. This priority is the same priority as the MAC address table priority as indicated in (4) Priority Resolution. The final priority/output queue follows the process described in that section. The entries in the IA-FDB are considered static entries.

29.4.3.10 Frame Forwarding Tasks

(1) Overview

When an input port has been selected, the frame is forwarded to its corresponding output ports as necessary. Output port resolution and switching are based on the information from the 2-stage destination MAC address lookup followed by additional resolution functions to allow frame duplication and flooding control, which are described in the following sections.

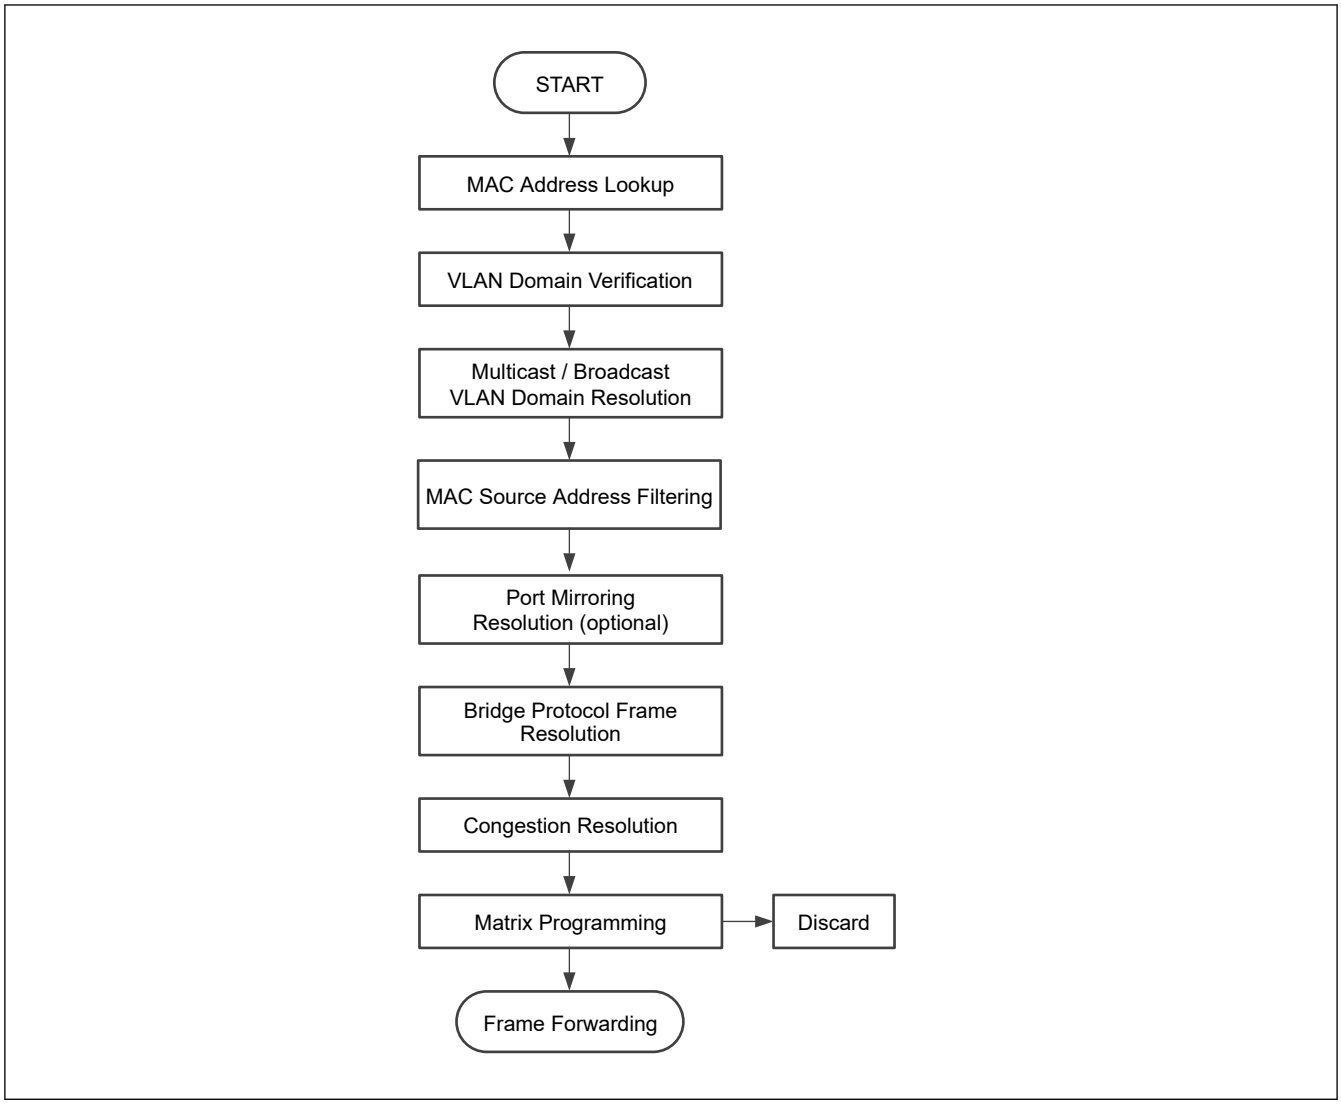

Figure 29.21 Frame forwarding tasks overview

(2) VLAN Domain Verification

When a frame is received at a port, it can be verified to be within the correct VLAN domain. The register VLAN_VERIFY is used to define if input verification should occur. Output verification is always implicitly done with the VLAN resolution function, which forwards a frame only to ports that are a member of the VLAN as defined by the VLAN table (see (b) VLAN Domain Resolution / VLAN Table). The following rules apply if the verify bit within VLAN_VERIFY for the port is enabled:

- If the VLAN ID of the frame is found within the table and the input port is member of the VLAN domain, the frame is forwarded normally.
- If the VLAN ID of the frame is found within the table but the input port is not a member of the VLAN domain, the frame is marked invalid and is discarded eventually.
- If the VLAN ID of the frame is not found in the VLAN table, or the frame has no VLAN tag, the frame is forwarded normally, or, if the discard bit for the port is set to 1 (VLAN_VERIFY.VLANDISC), it is discarded.

Note: When the VLAN_VERIFY does not enforce input verification, the output verification (VLAN domain resolution) is always active. To avoid unexpected behavior if VLAN domains are not used, the complete VLAN_RES_TABLEn should be programmed to have an all 1 port mask in all entries.

(3) Broadcast / Multicast / VLAN Domain Resolution

(a) Overview

To ensure that traffic within VLAN channels are always routed to the correct ports, for example, to avoid the duplication of critical information through a network, the switch implements a resolution mechanism that, for any frame that is switched to multiple ports, checks the VLAN ID provided with the current frame.

The VLAN resolution mechanism searches the VLAN resolution table (see section 29.3.1.67. VLAN_RES_TABLEn : 32 VLAN Domain Entries (n = 0 to 31)), which stores up to 32 unique VLAN IDs, each associated to a port bit mask. It is used to limit forwarding of frames only to ports that are member of a VLAN domain.

(b) VLAN Domain Resolution / VLAN Table

The VLAN resolution table (registers VLAN_RES_TABLEn) provides a unique VLAN ID / port bit mask association for up to 32 VLAN IDs. A default entry (register BCAST_DEFAULT_MASK0/BCAST_DEFAULT_MASK1) provides an additional port bit mask. The port bit mask implements one bit for each port.

Each port bit Mask indicates, if set to 1, that it is member of the VLAN and frames with the corresponding VLAN ID can be switched to the port. If the port bit Mask is set to 0, a frame with the corresponding VLAN ID is not switched to that port. If no VLAN ID matches, the default mask is applied.

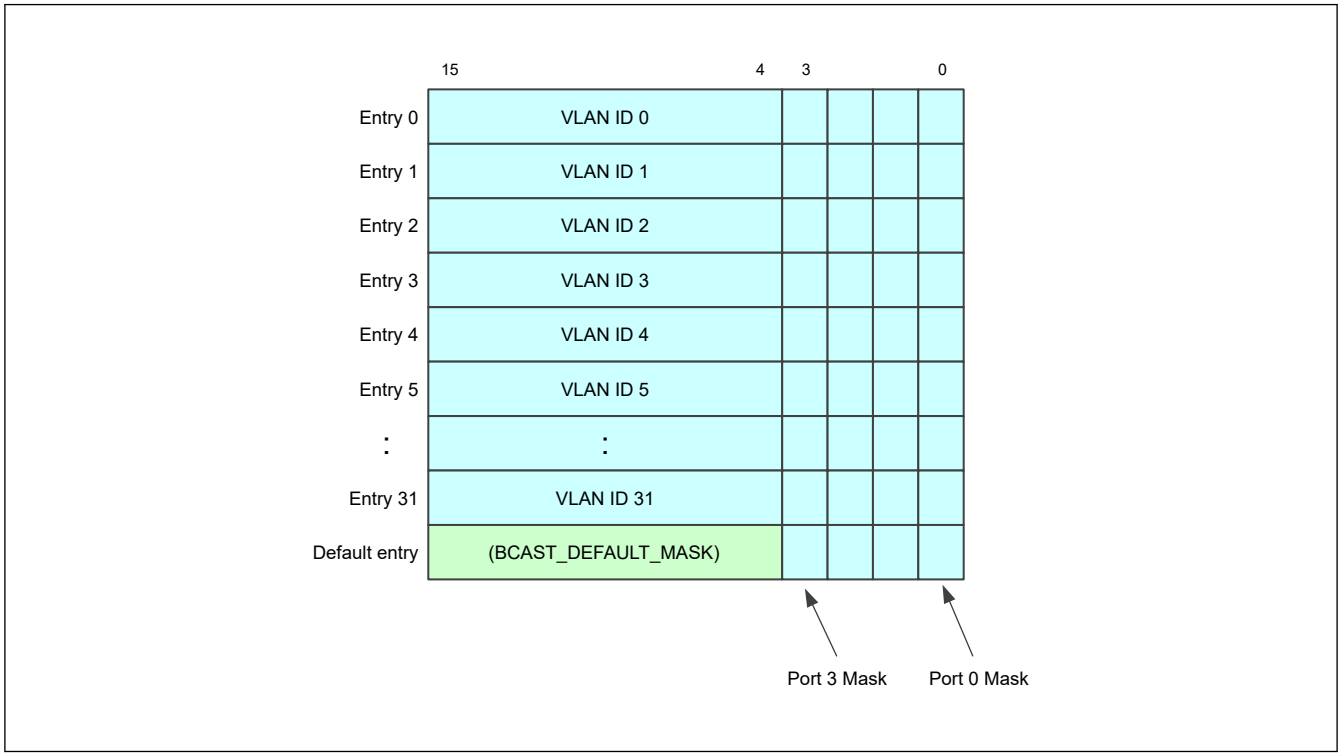

Figure 29.22 VLAN resolution table overview

Note: The port mask is found in bits [3:0] and the VLAN info is found at bits [15:4].

The VLAN table cannot be deactivated. To avoid unexpected behavior if VLAN domains are not used, all entries of the table (all VLAN_RES_TABLEn registers) should be programmed to have an all 1 port mask in all entries (reset default).

(c) VLAN Switching / Resolution Mechanism

The VLAN table is used for both, VLAN domain verification (see (2) VLAN Domain Verification) as well as VLAN resolution. Once the frame has passed any VLAN domain verification (not to be discarded by the verification function already), the forwarding resolution applies.

- If the destination MAC address (unicast or multicast) is found in the MAC address table:
  - If the frame carries a VLAN ID that is found in the VLAN resolution table, the frame can be forwarded only to the ports within the VLAN domain and is discarded if the destination port is not member of the VLAN domain.

  - If the frame carries a VLAN ID that is not found in the VLAN resolution table or does not contain a VLAN tag, it is forwarded as indicated by the lookup table (VLAN domain verification can be configured to discard the frame in this case if enabled).

- If the destination MAC address (unicast or multicast) is not found in the MAC address table, or if the destination address is the broadcast address, the frame is forwarded according to the following rules:
  - The destination port mask is loaded from the respective register U/M/BCAST_DEFAULT_MASK0 or U/M/BCAST_DEFAULT_MASK1 depending on unicast, multicast, or broadcast. Then the following filtering on this mask applies.
    - If the frame carries a VLAN tag, the VLAN resolution table is searched for a matching VLAN ID and the frame is sent only to ports that are associated with the VLAN ID.
    - If the frame carries a VLAN tag and the VLAN ID does not match any entry in the VLAN Resolution Table, or the frame does not carry a VLAN tag, the frame is forwarded to all ports that are enabled by the default mask.
    - If it cannot be associated with any VLAN group and if the default group is set to all 0s, the frame is discarded.

To disable the VLAN resolution, set all VLAN IDs to 0x000 and all Port bit mask to 1 in the VLAN resolution table. If the VLAN resolution is disabled, normal port flooding is implemented as described in (5) Destination MAC Address Lookup. The default entry can still be used to restrict flooding to only dedicated ports, if not programmed to all 1.

(4) MAC Source Address Filtering

The switch can be enabled to perform a source address check on the received frames of the line ports. This check allows limiting a single source MAC address to send frames to one or more destination ports, while blocking all other nodes from sending frames to them. A use case for this filter is to accelerate forwarding of EtherCAT frames when the switch operates as a stream adapter to create a virtual channel between the EtherCAT Master controller and one or more EtherCAT slaves connected to the switch. The filter is configured to operate on the port connected to the EtherCAT master to allow only frames with the source address of the master to be forwarded to the ports where the EtherCAT slaves are connected. Frames from the EtherCAT slaves towards the master must be forwarded first to the management port to do a MAC address replacement before forwarding these frames to the master.

The filter is enabled with the control register SRCFLT_ENA where two fields determine how the filter is applied.

- SRCENA: Defines on which receive ports the check is executed. Ports which are not enabled simply bypass the check. For EtherCAT, a single port would be enabled.
- DSTENA: Defines on which transmit ports the check is applied to. The destination ports that are not enabled are not affected by the filtering function. For EtherCAT, the ports connected to the slaves are enabled.

The MAC source address to accept is programmed in the register SRCFLT_MACADDR_HI/SRCFLT_MACADDR_LO. A 16-bit mask is provisioned to allow masking the last 16 bits of the address.

The filtering check is performed after the L2 lookup is done or flooding is calculated, and after the VLAN domain is verified. This means that the check is applied regardless on whether the destination address is known or if the destination ports DSTENA are present in the flooding masks. Optionally a filtered frame can be forwarded to the management port via the control bit SRCFLT_CONTROL.MGMT_FWD to allow the firmware to inspect the frame.

When a frame is discarded due to this function, the frame is only counted in the counter IDISC_SRCFLT as discarded if the final forwarding mask is zero. If MGMT_FWD is set to 1 then the frame is not counted as a discard, or if the resultant mask after removing the ports in DSTENA is non-zero (the frame is received by other port).

To further support EtherCAT, the filtering function implements a watchdog timer that resets when a frame with a source address matching the filtering address. The watchdog is enabled in the SRCFLT_CONTROL by the control bit WATCHDOG_ENA, and the watchdog expiration time is programmed in WATCHDOG_TIME in the same register. When the watchdog expires the interrupt SRCFLT_WD_INT in the global interrupts asserts. The interrupt is enabled in the INT_CONFIG register and its state can be read in the INT_STAT_ACK register. When the watchdog expires, it stops operating until it is disabled and enabled again using WATCHDOG_ENA.

(5) Port Mirroring

The optional function allows duplicating traffic to a dedicated mirror port. Any one of the ports can be assigned to act as a mirror port (register MIRROR_CONTROL).

The mirror port then is always added to the list of output ports and therefore receives a copy of the frame, if any of the following rules matches with the currently processed frame:

- Ingress Port Number Match
  When a frame is received on port n and the corresponding bit in the register MIRROR_ING_MAP is set to 1, the frame is mirrored.
- Egress Port Number Match
  When a frame is forwarded to port n and the corresponding bit in the register MIRROR_EG_MAP is set to 1, the frame is mirrored.
- MAC Ingress SA Match
  When the Ingress Port Number match succeeded (see above) and the MAC source address matches the MIRROR_ISRC_0 and MIRROR_ISRC_1, the frame is mirrored.
- MAC Ingress DA Match
  When the Ingress Port Number match succeeded (see above) and the MAC destination address matches the MIRROR_IDST_0 and MIRROR_IDST_1, the frame is mirrored.
- MAC Egress SA Match
  When the Egress Port Number match succeeded (see above) and the MAC source address matches the MIRROR_ESRC_0 and MIRROR_ESRC_1, the frame is mirrored.
- MAC Egress DA Match
  When the Egress Port Number match succeeded (see above) and the MAC destination address matches the MIRROR_EDST_0 and MIRROR_EDST_1, the frame is mirrored.

In addition, a counter is implemented (register MIRROR_CNT) that allows specifying that only every Nth (N: count value) frame that matches any of the specified criteria is mirrored. If the counter is set to 1 or 0, every frame that matches any of the specified criteria is mirrored.

(6) Congestion Resolution

(a) Overview

The congestion resolution function is used whenever an output port is not available and data must be sent to that port. An output port is defined to be available if the port is enabled (bit n in register PORT_ENA.TXENA is 1, n = 0 to 3) and its output queue is not full. If a port is deasserted (bit n in register PORT_ENA.TXENA is 0), the port is not available and frames cannot be switched to that port.

The congestion resolution function determines whether the frame should be processed further or discarded according to the following rules.

(b) Unique Destination (One Input to One Output)

If the output port is enabled and can accept, the frame is forwarded normally.

In any other case, the frame is discarded.

(c) Multiple Destinations (Flooding)

After broadcast/flooding resolution, a frame is switched to multiple output ports.

- Output disabled:
  All disabled ports are removed from the list of outputs.
- Output congestion:
  If any of the outputs cannot accept a frame (as indicated by the output queue management for the port), it is removed from the list of outputs also.

If after the removal, no output port is left in the list of outputs, the frame is read from the input and discarded. This event is counted in the port specific ODISCn statistics counter.

(7) Bridge Protocol Frame Resolution

To implement bridge control protocols like the Spanning Tree protocol, the following control functions are performed by the Bridge Protocol Frame Resolution function.

(a) Management Frame (BPDU) Identification

Bridge Protocol Frames are identified by its destination address being any of the following:

- 01-80-c2-00-00-00 to 01-80-c2-00-00-0F (Spanning Tree, IEEE 802.1D, Table 7-9)
- 01-80-c2-00-00-10 (Bridge Management Address, IEEE 802.1D, Table 7-10)
- 01-80-c2-00-00-20 to 01-80-c2-00-00-2F (Generic Attribute Registration Protocol, IEEE 802.1D, Table 12-1)

In addition, the following features are available to define a frame as Bridge Protocol frame which then experiences the same treatment as any other BPDU within the switch.

- Custom Address:
  To support other protocols and standards, the switch allows defining four additional addresses (see registers MGMT_ADDR0_lo/hi through MGMT_ADDR3_lo/hi) which are treated identically to the above, marking a frame as a Management (BPDU) frame.

To support IEEE 802.1X authentication, the destination address 01-80-c2-00-00-03 is used by EAPOL frames and can be treated differently from BPDU frames (see section 29.4.8. Port Based Access Control (802.1X)).

(b) Input Port Blocking

The input port blocking function is used to avoid forwarding of frames after address learning. The firmware can program the register INPUT_LEARN_BLOCK and if a frame is received on a port n which should be blocked (blocking bit n = 1) and the frame is not a bridge protocol frame, the frame is marked for discard and is not forwarded to any output port.

(c) Input Port Learning Disable

To reduce processing load from the firmware, a port can be configured for exclusion from learning (see section 29.3.1.8. INPUT_LEARN_BLOCK : Input Learning Block Register). When learning is disabled on a port, no source address extraction happens for incoming frames.

Incoming BPDU frame source addresses are never extracted and not forwarded to the learning process independent from this setting. The application must add source addresses from received BPDUs to the lookup table for example, as static entries as required.

(d) Management Frame Forwarding

If a frame is coming from any port except the management port and is marked as a management frame (BPDU frame) and the management port is enabled (see section 29.3.1.9. MGMT_CONFIG : Management Configuration Register), the frame is forwarded to the management port only, ignoring any destination address lookups.

If the management port itself receives management frames (host CPU sends management frames to switch), they are forwarded according to the port mask defined in the section 29.3.1.9. MGMT_CONFIG : Management Configuration Register. A handshaking mechanism is implemented that can be used by the protocol software to configure the destination port mask on a frame by frame basis for management frames.

In addition, the port mask given in MGMT_CONFIG can include ports that are disabled for normal traffic (configured in register PORT_ENA.TXENA) allowing transmitting management frames on ports that are disabled for normal traffic.

When forced forwarding is used, management frames are forwarded to the ports given in the forced forwarding mask and the port mask given in MGMT_CONFIG is ignored.

Note: VLAN domain verification/discard (see section 29.3.1.5. VLAN_VERIFY : Verify VLAN Domain Register) should be switched off for the management port to avoid that the switch discards management frames.

MGMT_CONFIG.MGMT_EN must be set to 0 to allow forwarding of BPDU frames from the management port without a management tag.

(8) Forced Forwarding

When the forced forwarding is used, it overrides any forwarding decision and a frame is forwarded to all ports given in the forced forwarding mask by management tagging fields.

This includes forwarding to disabled ports (overriding PORT_ENA) when the force filtering by management tagging fields is disabled (0). Only the port where the frame was received from is removed from the port mask automatically (it is not possible to transmit a frame to where it was received from).

Mirroring and Snooping functions may continue to inspect forced forwarded frames.

(9) Cut Through Forwarding

The switch normally operates in so-called store & forward mode. All frames are received and stored completely before they are forwarded to any output port. This allows error detection and discards of erroneous frames within the switch as well as communication between links of different speeds.

Alternatively, the switch can operate in cut through mode, where a frame is forwarded and transmitted at an output port before it is completely received. This allows for reduced latency and is independent of the frame size. However as the frame is forwarded before error checks can be done, erroneous frames are transmitted (the switch ensures to mark them erroneous and sends it with an invalid CRC).

Cut Through operation is configurable on a per-port basis with register MODE_CONFIG. It allows to define a group of ports for cut through and have other ports using normal store & forward.

When cut through forwarding is enabled, a frame is forwarded using cut through only if the following conditions are all valid. Otherwise, the frame is forwarded using store & forward:

- The source and destination ports both have their cut through mode bit set
- It is not a broadcast, not a BPDU, not an IEEE 1588 PDELAY_REQ frame (auto-response)
- The destination ports operate at the same or slower link speed than the source port
- The frame is not received as a preemptable frame (with an SMD-Sx as a frame delimiter)

A frame can be sent as cut-through to some destination ports and store & forward to other ports if the cut-through criteria are not met.

The cut through forwarding delay depends on link speed and the switch operating clock frequency. For a switch operating clock of up to 200 MHz, the following forwarding delays are possible.

See section 29.4.22.1. Cut-Through Frame Forwarding Delay.

When using cut-through operation the register CT_DELAY must be programmed as indicated in section 29.3.6.17. CT_DELAY_Pn : Port n Cut-Through Delay Indication Register (n = 0 to 2) to prevent frame underflows.

The control bit COMMAND_CONFIG.TX_TRUNCATE can be set to 1 so frames received with errors that started transmission in cut-through mode are shortened by the switch. The shorting is marginal (between 8 to 12 bytes) but it allows the frame to be progressively shortened over network hops, eventually forcing it to be discarded when it becomes less than 64 bytes.

(10) Switching

After the output ports are determined, the switch control enables the corresponding path through the switch matrix and the frame is forwarded to the output queues.

In a similar fashion, if a frame should be switched to multiple ports (broadcast), the switch control enables the corresponding paths through the switch matrix and the frame is forwarded to all the destination output ports.

Duplication is eventually done by the output ports reading the same frame from memory multiple times.

29.4.3.11 Broadcast Storm Protection

To avoid network and memory congestion caused by a broadcast storm, the switch engine can be programmed to limit the number of broadcast frames over a certain time period.

A counter is implemented on each receive port, which increments whenever a broadcast frame is received. The counters of all ports are cleared each time the timeout expires.

When the counter of a port reached the limit, further broadcast frames received at this port are discarded.

The register BCAST_STORM_LIMIT is used to set the periodic timeout and the counter limit for all ports.

29.4.3.12 Multicast Storm Protection

To avoid network and memory congestion caused by a multicast storm, the switch engine can be programmed to limit the number of multicast frames over a certain time period.

The behavior is identical to the broadcast storm protection, however, implements its own per port counters.

The register MCAST_STORM_LIMIT is used to set the counter limit for all ports. The periodic timeout from BCAST_STORM_LIMIT is used to reset the counters.

29.4.3.13 Output Frame Queuing

Figure 29.23 shows a conceptual output queue management function supporting multiple queues.

The implementation offers 8 queues numbered 0 to 7 where 0 is lowest and 7 is highest priority.

The output queues (FIFOs) are implemented separately for each output port. After input processing has completed, the frame is stored in a queue within the corresponding output port, based on the priority resolution result for the frame (classification, see (4) Priority Resolution).

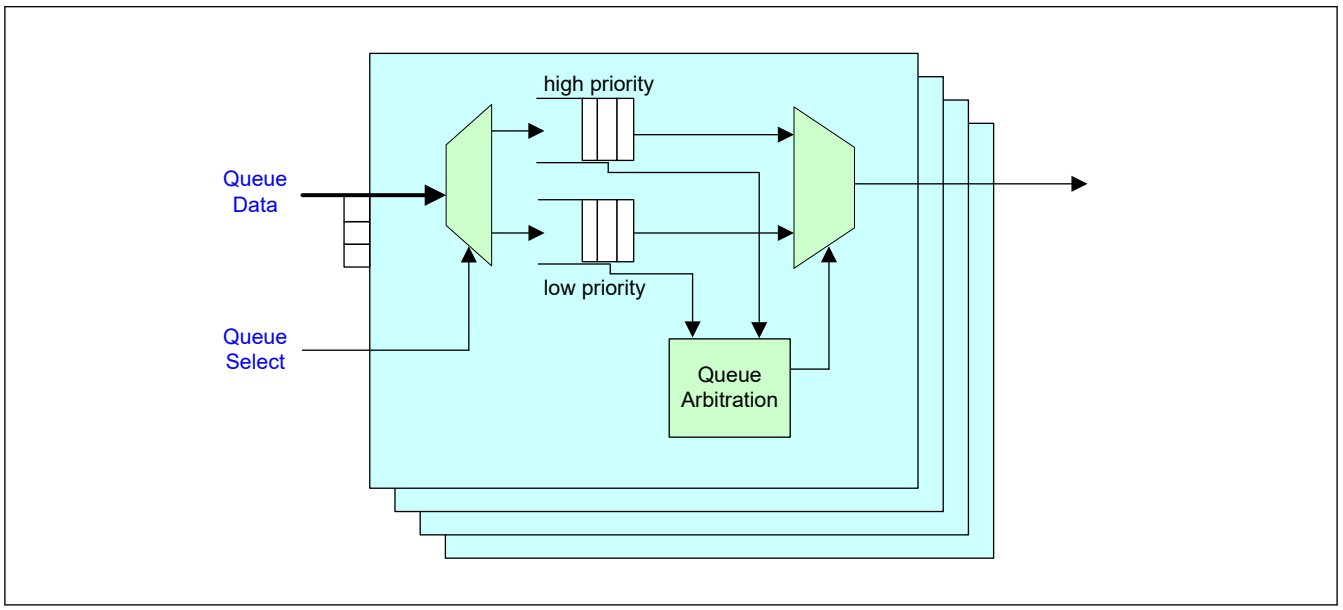

Figure 29.23 Output queuing

The queue arbitration selects the appropriate queue and indicates data availability to the output interface, which eventually transmits the frame. A higher queue number takes precedence over a lower queue number.

The queue arbitration implements a strict priority selection. Weighted fair queuing is also available (see section 29.3.1.41. IMC_CONFIG : Input Memory Controller Configuration Register).

In addition, the optional TDMA scheduler influences arbitration by allowing read from a queue only at specific times (see section 29.4.15. TDMA Operation).

The queues can be configured to transmit express or preemptable traffic. By default, all queues are express queues.

When some queues are configured for preemptable traffic, all express queues have priority over the preemptable queues when preemption is enabled and operational. See section 29.4.18. IEEE 802.3br Traffic Interspersing for details on traffic interspersing and preemption configuration.

29.4.3.14 Output Port Congestion Management

Depending on the output queue management method, a congestion indication is generated to the switch (internally) when a queue becomes full. When a frame must be forwarded to a congested queue, the frame is discarded and the associated error counter (section 29.3.9.5. ODISCn : Port n Discarded Outgoing Frame Count Register (n = 0 to 3)) is incremented.

(1) Tail Drop

By default, frame discard occurs only when a queue becomes full, or if the shared switch memory is exhausted. Frames are dropped as long as the congestion situation persists.

The implementation allows to store up to 58 frames per queue per port. This is independent of the frame size.

(2) Random Early Detection

As an alternative to Tail Drop, the Random Early Detection (RED) active queue management following RFC 2309 is available (see section 29.4.23.3. References, (1)). It can be enable per queue (only queue 0 to 3) but only globally for all ports (see registers QMGR_RED_MIN4*1/MAX4*2/CONFIG*3).

The RED algorithm averages the fill level of a queue over time. Depending on the current average a drop probability is calculated and frames are dropped before the queue becomes full. When filled completely, tail drop occurs. The early dropping of frames may help higher protocols (mainly TCP) to better adapt to the available link bandwidth. The algorithm is configured using two thresholds defining a window where frames are dropped before the queue capacity is reached. No drop occurs below the minimum threshold and all frames are dropped when the maximum is reached (resulting in tail drop behavior). Between minimum and maximum, the probability for dropping a frame increases. That is, the more the queue is filled the more frames are dropped which ideally, avoids reaching the maximum which causes continuous frame drops.

When the current queue fill level drops below the calculated average, the average is immediately set to the current level of the queue. This prevents a delayed reaction where the queue is already emptied again while the average still indicates a higher fill level causing unnecessary dropping of frames.

Note 1. See section 29.3.1.34. QMGR_RED_MIN4 : RED Minimum Threshold Register.
Note 2. See section 29.3.1.35. QMGR_RED_MAX4 : RED Maximum Threshold Register.
Note 3. See section 29.3.1.36. QMGR_RED_CONFIG : RED Configuration Register.

Figure 29.24 shows the behavior.

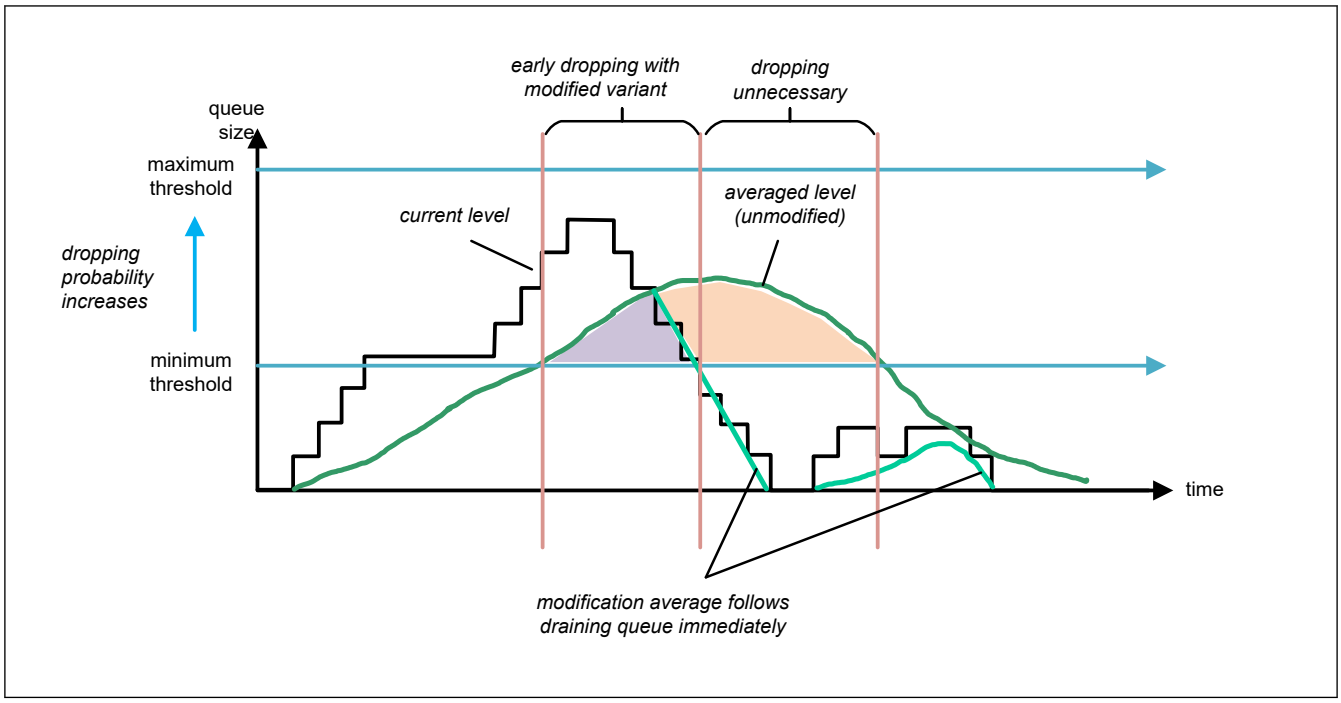

Figure 29.24 Random early detection algorithm implementation

The algorithm avoids dropping of frames when the queue is draining which means the output rate is higher than the input rate and therefore, dropping of frames should not occur. This allows to absorb a short peak in the queue size making use of the available storage capacity, ideally without (unnecessary) dropping activity.

29.4.4 Timestamping Functions (TSM)

29.4.4.1 Overview

The timer and timestamping module (TSM) implements the following functions:

- Collects a timestamp for received frames on all line ports.
- Collects a timestamp for transmitted frames on all line ports with interrupt generation.
- Processes IEEE 1588 Layer 2 event frames updating on the fly (1 step) the correction field with the transient time.

- Up to 2 adjustable timers allowing synchronizing the local time of the timer to a remote master clock through some protocol specific application software to implement, for example, the IEEE 1588 Precision-Time-Protocol (PTP).

29.4.4.2 IEEE 1588 Message Header Structure

Note: The following is provided as a brief reference only. Refer to the standard documents for details and usage scenarios.

An IEEE 1588 message can be transported with various encapsulation protocols for example within an Ethernet frame (L2) payload or a UDP/IP payload. Table 29.16 shows the message header, which is common to all IEEE 1588 version 2 messages. The MAC allows updating the correction field during transmission when using Layer 2 frames which are identified by Ethernet type field being 0x88F7. Other encapsulations are not supported. Correction field updates only occur in event messages (messageId < 4).

All fields follow the network byte order which is the first byte transmitted is the most significant byte (leftmost) of a multi byte field. Table 29.16 and Table 29.17 provide a short overview. For details of any of the fields, refer to the IEEE 1588 specification document (see section 29.4.23.3. References, (2)).

Table 29.16 IEEE 1588v2 message header (PTPv2)

Bits								Octets	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageId				1	0
reserved				versionPTP = 0x2				1	1
messageLength								2	2
domainNumber								1	4
reserved								1	5
flags								2	6
correctionField								8	8
reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
control								1	32
logMeanMessageInterval								1	33
further message specific fields may follow								n	34

The type of message is encoded in the field messageId (informal) as follows:

Table 29.17 PTPv2 message type identification

messageId	Message name	Message
0x00	SYNC	event message
0x01	DELAY_REQ	event message
0x02	PDELAY_REQ	event message
0x03	PDELAY_RESP	event message
0x04 - 0x07	—	reserved
0x08	FOLLOW_UP	general message
0x09	DELAY_RESP	general message
0x0A	PDELAY_RESP_FOLLOW_UP	general message
0x0B	ANNOUNCE	general message
0x0C	SIGNALING	general message
0x0D	MANAGEMENT	general message

29.4.4.3 Timestamp Processing

(1) Receive Timestamp Processing

When a port receives a frame, the timestamp, based on the current time from the timer, is captured when the start of frame delimiter (SFD) is detected at the PHY interface. The timestamp is forwarded together with the frame throughout the switching engine and can be accessed by the management port to implement, for example, the Precision-Time-Protocol (PTP).

The receive timestamp is encapsulated in the proprietary tag information for frames forwarded to the management port (see section 29.4.5. Management Port Specific Frame Tagging).

Only the timestamp from one timer can be encapsulated with the frame. The timer to be used is determined by (from lower to higher priority):

1. The default timer of the port based on the port selection, configured in the COMMAND_CONFIG_Pn register, TIMER_SEL field (see section 29.3.6.2. COMMAND_CONFIG_Pn : Port n Command Configuration Register (n = 0 to 3)). Each port can be configured to select the default timer to use for timestamping frames on receive (and on transmit).
2. PTP auto response timer selection based on the domainNumber of the frame (see section 29.3.2.3. PTP_DOMAIN : Domain Number of PTP Frame) or a default value per-port if no match against domainNumber programmed in the PTP Auto Response register (see section 29.3.6.10. PTPAUTORESPONSE_Pn : Port n PTP Auto Response Register (n = 0 to 2)).
   See section 29.4.4.6. Automatic Response to Peer Delay Request Messages for more information on PTP auto response.
3. An override using the pattern matchers. The pattern matchers can override the default timer to use based on fields on the frame. See section 29.4.14. Receive Pattern Matcher for details on the pattern matchers.
   See section 29.4.22.3. Frame Timestamp Interface Delay for details on how the timestamp captured by the port must be corrected to obtain a precise value. This correction accounts for the delay between the timestamp point and the MII/GMII interface.

(2) Transmit Timestamp Processing

When a frame is transmitted to the PHY on a port, the timestamp is also captured. The outgoing timestamp can be stored in a per-port FIFO to be read by software later using the registers TS_FIFO_READ_CTRL (see section 29.3.2.7. TS_FIFO_READ_CTRL : Transmit Timestamp FIFO Read Control Register) and TS_FIFO_READ_TIMESTAMP (see section 29.3.2.8. TS_FIFO_READ_TIMESTAMP : 32-bit Timestamp Value Read from FIFO). Each port is capable of storing up to 16 timestamps.

The management port, through its management port specific frame tagging has the capability to identify frames for outgoing timestamp capture, as timestamps must only be captured for dedicated event frames, not for all frames, as well as to indicate the timer to use for the timestamp operation and a 7-bit unique ID that gets stored together with the timestamp for further correlation. See section 29.4.5.4. Receive Processing (CPU to Switch) for details on the management tag control bits.

Similarly to the receive timestamp processing, the timer to use for timestamping a frame is determined by (from lowest to highest priority):

1. The default timer of the port based on the port selection, configured in the COMMAND_CONFIG_Pn register, TIMER_SEL field (see section 29.3.6.2. COMMAND_CONFIG_Pn : Port n Command Configuration Register (n = 0 to 3)). Each port can be configured to select the default timer to use for timestamping frames on receive (and on transmit).
2. PTP auto response timer selection based on the domainNumber of the frame (see section 29.3.2.3. PTP_DOMAIN : Domain Number of PTP Frame) or a default value per-port if no match against domainNumber programmed in the PTP Auto Response register (see section 29.3.6.10. PTPAUTORESPONSE_Pn : Port n PTP Auto Response Register (n = 0 to 2)).
   See section 29.4.4.6. Automatic Response to Peer Delay Request Messages for more information on PTP Auto response.
3. Override from the pattern matchers. See section 29.4.14. Receive Pattern Matcher for details on the pattern matchers.
4. Indication from the management port using the management tag (section 29.4.5.4. Receive Processing (CPU to Switch)).

Note: A limitation to the timestamping logic is that when the timer selection is the default of the port and the transmitted frame is a multicast frame, all ports utilize the timer indicated by the port with the lowest index in the destination port mask. For instance, if a frame from the management port is transmitted to ports 0 and 1, both ports timestamp the frame using the timer selection value of port 0.

See section 29.4.22.3. Frame Timestamp Interface Delay for details on how the timestamp captured by the port must be corrected to obtain a precise value. This correction accounts for the delay between the timestamp point and the MII/GMII interface.

29.4.4.4 Transparent Clock Support

(1) General

The hardware implements the necessary functions to implement transparent clocks (TC) in both the end-to-end variant and the peer-to-peer variant.

The end-to-end transparent clock is the default behavior when the register PEERDELAY is set to 0.

When a peer-to-peer transparent clock is implemented, the PTP software must determine the peer delay at the port where the master is connected to (where it receives SYNC messages). This value is then programmed into the PEERDELAY register. The setting must be updated when a new peer measurement has been done or whenever the master port changes.

(2) Implementation of Correction Field Update

The implementation is capable of updating the correction field within Layer 2 PTP frames only (frames with type 0x88F7). PTP messages within UDP/IP frames are not considered.

The update module only processes event messages, which it automatically detects from the messageId type field found within the PTP header (type < 4). This means that it does not process follow-up frames (which are not event frames), hence any correction field updates are found in the corresponding SYNC frame. This allows supporting one step as well as two step-master and -slave nodes connected to the switch.

For an end-to-end transparent clock implementation, the correction field of SYNC and DELAY_REQ messages is updated with the transient time (output time − input time).

For a peer-to-peer transparent clock implementation, the correction field update includes adding the value set in the PEERDELAY register of the port where the frame was received to the transient time. The hardware always implements the addition of this value, hence it only depends on configuring the PEERDELAY to define whether an end-to-end (PEERDELAY = 0) or peer-to-peer (PEERDELAY > 0) behavior is selected. It is the responsibility of the PTP software to exchange the PDELAY_REQ/PDELAY_RESP messages on every port to determine the peer delay values accordingly.

Correction field updates occur only on frames that are exchanged between external (line) ports. Any frame from and to the management port is not modified.

Figure 29.25 shows the operations when a frame is forwarded between line ports.

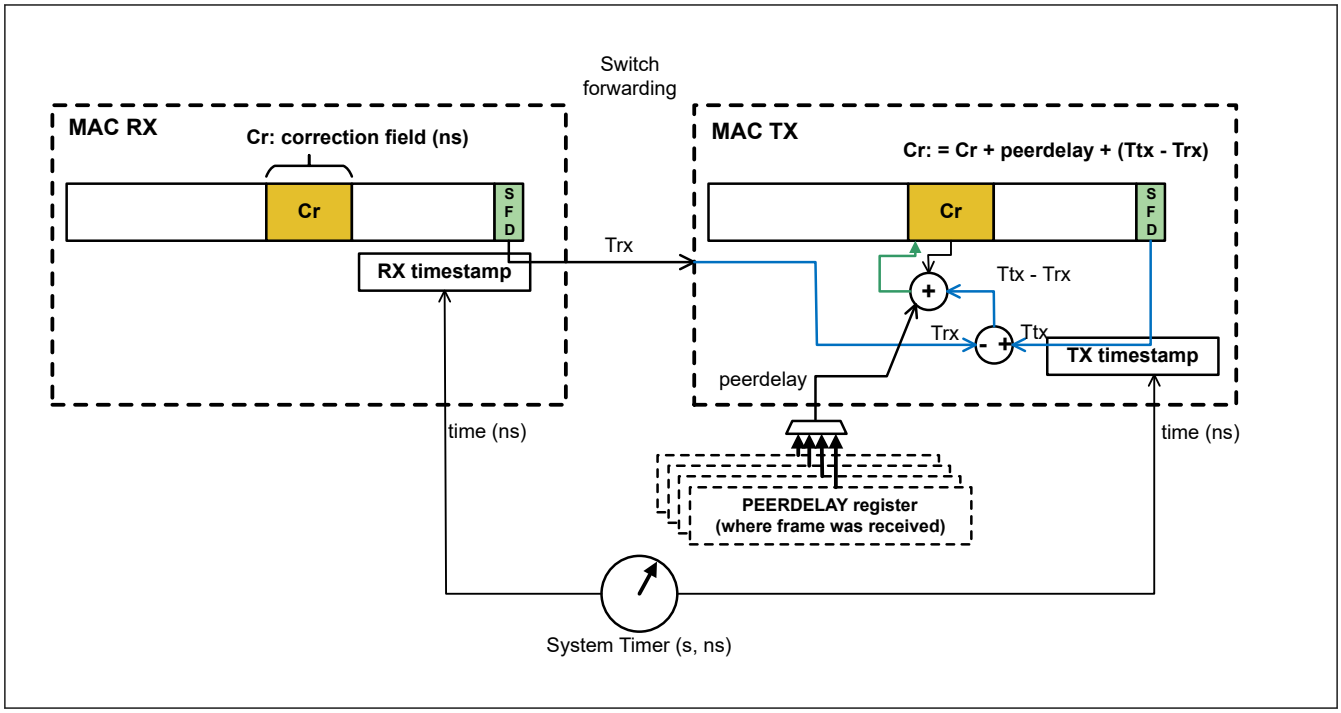

Figure 29.25 One-step correction field update

Note: No specific configuration is necessary (aside from PEERDELAY register and having a correctly running timer). The function is always active and automatically detects IEEE 1588v2 Layer 2 event frames for processing.

Using multiple timers for updating of the correction field of more than one time domain has limited functionality. If the same path is used for multiple domains, a pattern matcher for each extra domain is needed to select a different hardware timer to use.

29.4.4.5 Using One Step Update at the Management Port

When sending frames through the management port to the switch, the normal correction field updates are not available as there is no notion of a received timestamp at this interface.

However, to allow master or boundary clock implementations that uses one-step precise timestamping for CPU generated event frames such as SYNC messages, the management tag one step update feature can be used (see section 29.4.5.4. Receive Processing (CPU to Switch), ControlData[4]).

To use this function, an event frame requires special preparation by the application: The correction field must be set to the same value as nanoseconds value of the originTime field. When preparing a frame for one-step update, the application must perform the following steps:

- Read out the current time (seconds, nanoseconds) from the hardware timer.
- Prepare the event frame (such as SYNC message) and copy the time values retrieved from the timer into the originTime field of the frame. The originTime field contains seconds and nanoseconds fields.
- Set the correction field nanoseconds value of the frame the same as nanoseconds value of the originTime field (seconds are not relevant to the correction field).
- Transfer the frame to the switch using the management tag feature and setting ControlData[4] to 1 (see section 29.4.5.4. Receive Processing (CPU to Switch)) and selecting the corresponding hardware timer.

The MAC transmitter when transmitting the frame rewrites the correction field with the difference of the transmit timestamp and the value in the correction field. This function does not add to the correction field, it reads the value, subtracts it from the transmit time, and writes the result back into the correction field (after performing a 1 second modulo). Any PEERDELAY register settings are ignored. Figure 29.26 shows the principle of operations.

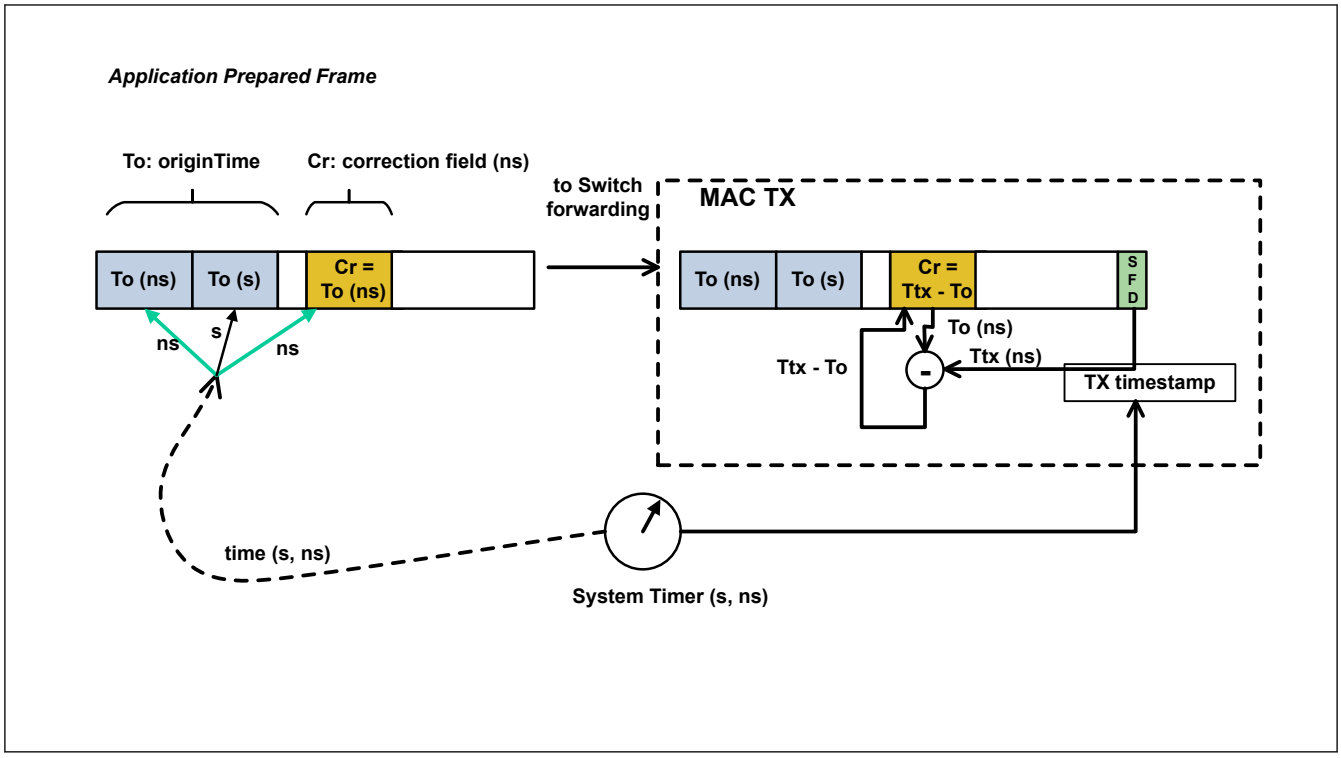

Figure 29.26 Management port one-step transmit feature

A receiver always adds the correction field value to the originTime field value and therefore, can get the precise transmit time of the frame as:

$T = To + Cr$ which is $To + Ttx - To = Ttx$.

Note: As the update function does not modify the seconds value within the frame, the application must ensure the time delay from reading the hardware timer value and the actual frame transmission at the switch output port is less than one second.

29.4.4.6 Automatic Response to Peer Delay Request Messages

(1) General

Each line port MAC can be configured to automatically respond to incoming peer delay request (PDELAY_REQ) messages. These are used in peer-to-peer clock implementations to measure the link delay between neighbor nodes. Both nodes of a link periodically transmit the PDELAY_REQ message to each other to allow both nodes to determine the link delay.

A node when receiving a PDELAY_REQ message responds with a PDELAY_RESP message. This enables the requesting device to calculate the path delay.

The switch management application periodically issues PDELAY_REQ messages to determine the link delay on each of its line ports to set PEERDELAY register of each port. The PEERDELAY register is used by the transparent clock when forwarding SYNC frames through the switch (see section 29.4.4.4. Transparent Clock Support).

In addition, the switch receives PDELAY_REQ from all its connected neighbor nodes and must respond with PDELAY_RESP messages, individually per port. The management application can be used to create such response messages, but as incoming requests have no relevance to the local system, this only represents additional processing overhead.

(2) Response Generation

To reduce overhead, each line port MAC can be instructed to automatically answer with a PDELAY_RESP message to incoming PDELAY_REQ messages. The incoming request is converted to a response and routed through the switch, however it is transmitted only at the port where it was received (emulating a MAC local response). This function can be enabled in the PTPAUTORESPONSE_Pn register.

When auto response is enabled, the following functions are performed:

- A PDELAY_REQ message is identified by an IEEE 1588v2 Layer2 frame (type 0x88F7) with messageId = 2 (first octet in PTP header, see section 29.4.4.2. IEEE 1588 Message Header Structure) and the hardware timer to use is selected by matching the domainNumber in the PTP frame against the values programmed in the PTP_DOMAIN register. If no match is found, a default value per-port is used for PTP functions, programmed in the PTPAUTORESPONSE_Pn register.

The next steps occur only when a PDELAY_REQ has been identified:

- If the destination address of the frame is unicast, the source address of the incoming frame is copied into the destination address of the frame. Otherwise, the destination address is not modified (if the neighbor sends the request with multicast the response returns to the same multicast).
- The source address of the frame is set to the MAC address (MAC_ADDR_0_Pn/MAC_ADDR_1_Pn registers) of the port.
- Address lookup and learning are suppressed for the frame. The frame is transferred to the switch but is marked for exclusive forwarding to the same port (this is an exception of the normal forwarding rules which do not forward to the same port). Therefore, normal statistics occur as with any other frame.
- When the frame is forwarded, it is converted into a one-step PDELAY_RESP by the MAC transmitter according to section 29.4.23.3. References, (2), as follows:
  - The messageId is changed to 3 (PDELAY_RESP).
  - The twoStepFlag bit within the flags field of the header is cleared (bit 1 of first octet, see section 29.4.23.3. References, (2)), to indicate a one-step response.
  - Adds the transient time (not considering the PEER_DELAY register value of the port) to the correction field.
  - The sourcePortIdentity is set according to the values from registers PTPCLOCKIDENTITY1_Pn, PTPCLOCKIDENTITY2_Pn, and PTPAUTORESPONSE_Pn. See Table 29.18.
  - The requestReceiptTimestamp field (10 octets at offset 34) is set to 0.
  - The original sourcePortIdentity field of the frame is copied into the requestingPortIdentity field (10 octets at offset 44).
  - All other bits/fields of the request are left unchanged and therefore are copied unmodified into the response message.
  - The CRC of the message is replaced accordingly.

Table 29.18 PTP auto response header sourceportIdentity mapping

Register[Octet]	Octet offset in PTP header, name
PTPCLOCKIDENTITY1_Pn.CLK_IDENTITY0[7:0]	20, portIdentity.ClockIdentity[0]
PTPCLOCKIDENTITY1_Pn.CLK_IDENTITY1[7:0]	21, portIdentity.ClockIdentity[1]
PTPCLOCKIDENTITY1_Pn.CLK_IDENTITY2[7:0]	22, portIdentity.ClockIdentity[2]
PTPCLOCKIDENTITY1_Pn.CLK_IDENTITY3[7:0]	23, portIdentity.ClockIdentity[3]
PTPCLOCKIDENTITY2_Pn.CLK_IDENTITY4[7:0]	24, portIdentity.ClockIdentity[4]
PTPCLOCKIDENTITY2_Pn.CLK_IDENTITY5[7:0]	25, portIdentity.ClockIdentity[5]
PTPCLOCKIDENTITY2_Pn.CLK_IDENTITY6[7:0]	26, portIdentity.ClockIdentity[6]
PTPCLOCKIDENTITY2_Pn.CLK_IDENTITY7[7:0]	27, portIdentity.ClockIdentity[7]
PTPAUTORESPONSE_Pn.PORTNUM0[7:0]	28, portIdentity.PortNumber[0] (msb)
PTPAUTORESPONSE_Pn.PORTNUM1[7:0]	29, portIdentity.PortNumber[1] (lsb)

(3) Usage Notes

- Auto response generation is available only for Layer 2 frames (not with UDP/IP).
- Auto response forces the MAC RX to strip the CRC. The TX appends a new CRC.

- When using the recommended PTP multicast destination address (01-80-c2-00-00-0e), the register MGMT_CONFIG must have management enabled bit (MGMT_EN) set, or at least the management frame discard bit (MGMT_DISC) cleared. Otherwise, the frame is discarded as this is a BPDU address.
- The normal priority resolution functions apply to the frame when forwarding. The PRIORITY_TYPE1 and PRIORITY_TYPE2 registers can be used to set the priority of Layer 2 PTP messages.
- The destination MAC address change is performed at the MAC RX. Hence if mirroring is active, it would show the frame with the already modified destination address.
- Although not required by PTP, a single VLAN tag is supported for PTP messages.
- If the port has VLAN input/output manipulation functions active, those settings are ignored for the response generation.
- The default timer to use for auto response generation is configured in the register PTPAUTORESPONSE_Pn.

29.4.4.7 Adjustable Timer

(1) Overview

The Adjustable Timer implements the Free Running Counter (FRC). The switch has two hardware timers. These timers are used for:

- Generating the timestamps for received and transmitted frames
- Being the time reference for the TDMA scheduler
- Providing a hardware time accessible to software using registers

Through dedicated correction logic, the timer can be adjusted allowing synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed period of time to allow synchronization of software timers or perform other synchronized system functions.

The timer is usually used to implement a period of 1 second, hence its nanoseconds value ranges from 0 to $1 \times 10^9 - 1$. The period event can trigger an interrupt and software can then maintain time values or timed actions as required.

These two hardware timers of the switch are connected to four units of PTP Pulse generators (see section 29.4.20. PTP Pulse Generator) whose outputs are connected to external pins (see Figure 29.1).

The timer is programmed via the host interface. section 29.4.22.4. Timer Configuration Delay describes the delays relevant for programming the timer with higher precision, assuming that the system is able to also characterize the delay to the host interface of the switch.

(2) Adjustable Timer Implementation

The adjustable timer consists of a programmable counter/accumulator and two correction counters. The periods of the counters and its increment rate are freely configurable allowing very fine tuning of the timer.

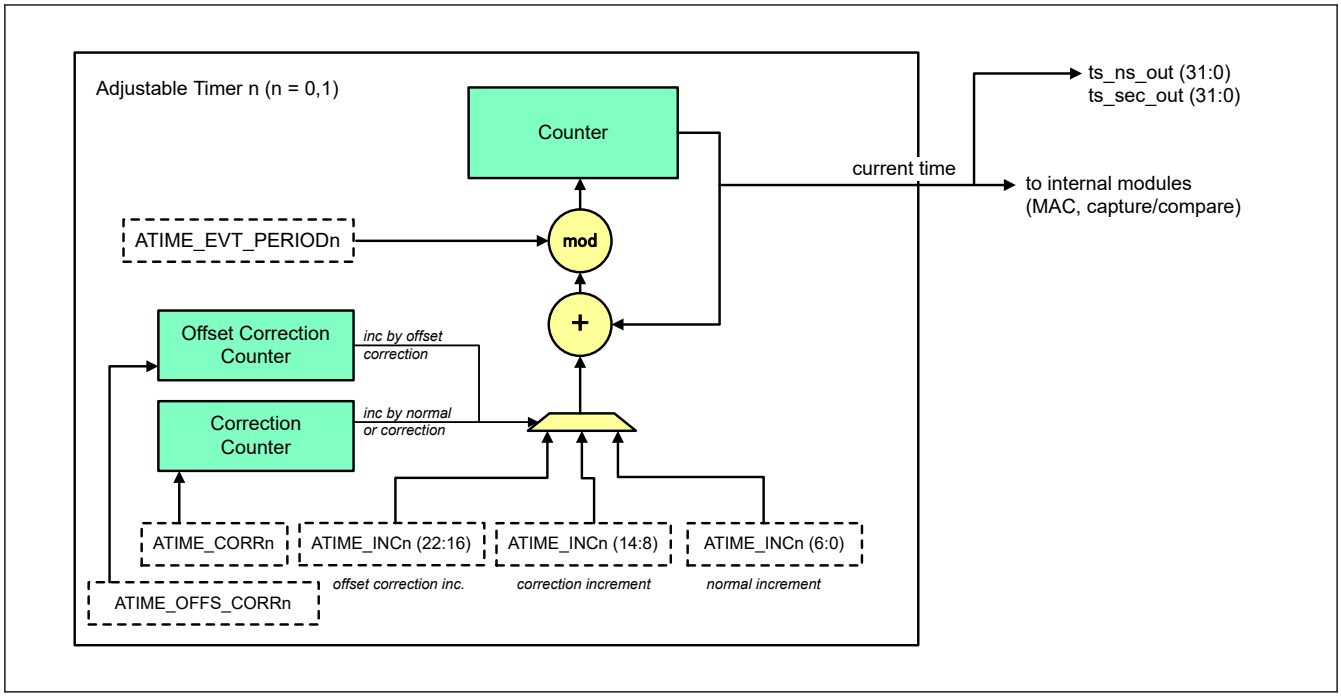

Figure 29.27 Adjustable timer implementation detail

(3) Normal Timer Operation

The counter (timer) is producing the current time. Each clock cycle is ts_clk: Timer module clock. The timer module can operate independently from all other clock domains. A constant value is added to the current time as programmed in the ATIME_INCn register. The ts_clk operates at 125 MHz, so the increment is to set to 8 representing 8 ns.

The period, configured in register ATIME_EVT_PERIODn, defines the modulo when the counter has to wrap around. In a typical implementation, the period is set to 1×10^9 so the counter wraps every 1 second and hence all timestamps represent the absolute nanoseconds within the 1 second period. When the period is reached, the counter wraps to start again according to the period modulo. This means it does not necessarily start from 0 but instead the counter is loaded with the value (current + inc − 1×10^9) assuming the period was set to 1×10^9.

(4) Drift Correction

The correction counter operates fully independently and increments by 1 with each clock cycle (ts_clk). When it reaches the value configured in ATIME_CORRn, it restarts and instructs the timer once to increment by the correction value, instead of the normal value. The normal and correction increments are configured in register ATIME_INCn. To speed up the timer the correction increment would be larger than the normal increment value. To slow down the timer, the correction increment is smaller than the normal increment value. The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections (and hence low jitter) happening in the range of 1 ns independently from the chosen clock frequency.

(5) Offset Correction

The offset correction counter operates fully independently and decrements by 1 with each clock cycle (ts_clk), when loaded. It can be loaded with a value by writing register ATIME_OFFS_CORRn. The timer does not start until an offset correction has been written into ATIME_OFFSETn (the ATIME_OFFS_CORRn must be written before writing the ATIME_OFFSETn value). When a value is written into ATIME_OFFSETn, the offset correction counter is loaded with ATIME_OFFS_CORRn and starts. When it reaches 0, it decrements the ATIME_OFFSETn value and applies the offset correction increment as defined in ATIME_INCn to the time counter. If the ATIME_OFFSETn value is not 0 after it was decremented, the counter is reloaded with ATIME_OFFS_CORRn and the cycle repeats. This repeats until the value in ATIME_OFFSETn reaches 0, after which no more corrections are performed. With this correction, it is possible to shift the timer to another time without causing an immediate jump in time. When the offset correction has completed, the ATIME_OFFSETn register reads out 0 and the offset event interrupt can optionally be triggered.

Alternatively, instead of distributing the offset correction over time using the offset correction timer, it is possible to immediately change the current time by the offset amount. This leads to a jump of the timer to the time current time + offset.

Setting ATIME_OFFS_CORRn to 0 and then writing the offset into ATIME_OFFSETn achieves this. A positive or negative value can be written to adjust the timer accordingly. The value written to ATIME_OFFSETn must be corrected by adding 2 × ts_cyc (timer clock period) to account for an internal delay in the timer update logic.

29.4.5 Management Port Specific Frame Tagging

To support the CPU through a normal networking interface (GMII), some special side band information required for implementing management protocols requires the addition of such information into frames exchanged between the CPU and the switch. This function is available only on the dedicated management port.

Management frames are frames that are identified by their destination address or type such as Bridge Protocol Data Units (BPDU) as defined in (7) Bridge Protocol Frame Resolution (destination 01-80-c2-00-00-xx).

Instead of only affecting management frames, the function can be optionally configured to include the side band information into all frames transferred from the switch to the CPU.

The CPU has the flexibility to insert control information into any frame it transfers to the switch. The hardware inspects all frames received at the management port and remove the extra data as necessary.

29.4.5.1 Tagged Frame Format

The additional control information is added following the frame source address marked by a programmable (proprietary) Ether type (ControlTag). If the tag exists, it is always the very first in the frame (before any VLAN tags).

The following information is added:

- ControlTag:
  An identifier that the control data is present within the frame (default: 0xE001)
- ControlData:
  2 octets following the ControlTag with control information
- ControlData2:
  4 additional octets used to carry 32-bit frame timestamps or destination port masks depending on transmit or receive.

All data following the ControlData2 are from the original frame. For example, any VLAN tags are found in this portion of the frame. The control tag, if present, is always the very first tag of a frame.

Table 29.19 Management port frame tagged frame format

7 octets	PREAMBLE
1 octet	SFD
6 octets	DESTINATION ADDRESS
6 octets	SOURCE ADDRESS
2 octets	ControlTag (default: 0xE001)
2 octets	ControlData
4 octets	ControlData2 (timestamp, portmask)
2 octets	Type/Length
0 to 1500/9000 octets	PAYLOAD DATA
0 to 42 octets	PAD
4 octets	FRAME CHECK SEQUENCE

The frame is extended by 8 bytes and the receiving MAC must be enabled to accept such enlarged frames as necessary.

29.4.5.2 Byte Order

The first octet of ControlData is the MSByte (bits [15:8]) and the 2nd octet of Control Data is the LSByte (bits [7:0]) of the 16-bit data field.

The first octet of ControlData2 is the MSByte (bits [31:24]) and the 4th octet of ControlData2 is the LSByte (bits [7:0]) of the 32-bit data field.

29.4.5.3 Transmit Processing (Switch to CPU)

When the switch forwards a frame to the management port to the host CPU, the following information is added into management (or all) frames.

Table 29.20 Management frame transmit tagging

Field	Bit#	Description
ControlData	[1:0] [3:2] Reserved, unused	Port number where the frame was received from. Ports are enumerated starting from 0 to 2.
	[4]	Timer used for timestamping the frame. This field contains the hardware timer used for timestamping the frame. 0: Timer 0 1: Timer 1
	[5]	Reserved, unused
	[6]	RED period indication. When this bit is 1, indicates whether the start of frame was received during the RED period (as indicated by the TDMA engine).
	[15:7]	Reserved, unused
ControlData2	[31:0]	Received timestamp of the frame. The 32-bit nanoseconds value when the Start Frame Delimiter (SFD) was detected at the port where the frame was received.

29.4.5.4 Receive Processing (CPU to Switch)

When the CPU sends a frame to the switch, the tagging function checks the frame and removes the optional control tag information from the frame if present. The CPU is free to add the tag to a frame as necessary or leave it out for normal frames that do not need special treatment.

When the tagging function detects the control tag (set by MGMT_TAG_CONFIG.TAGFIELD), it removes all 8 octets from the frame before it hands the frame over to the switch.

The control tag information for received frames provides the following information.

Table 29.21 Management frame receive tagging fields (1 of 2)

Field	Bit#	Description
ControlData	[0]	Forced Forwarding If set to 1, the frame is forwarded to all ports as defined in the destination port mask defined in ControlData2[2:0]. If set to 0, the destination port mask is ignored and the frame is forwarded normally.
	[1]	Forced Forwarding, include filtering. If set to 1 together with forced forwarding, normal filtering of the destination port mask applies (disabled ports are removed from the list). If set to 0, the frame is forwarded also to disabled ports. This applies to BPDU frames only. Normal frames are always filtered, meaning it can never be transmitted to disabled ports.
	[2]	Forced Forwarding, use management priority. If set to 1 together with forced forwarding, the priority of the frame is taken from the section 29.3.1.9. MGMT_CONFIG : Management Configuration Register, otherwise, the frame is prioritized as any other frame based on VLAN, IP.
	[3]	Mark frame for transmit timestamping. When set to 1, the frame transmit timestamp is latched into the corresponding transmit timestamp register of the port when the frame is transmitted. See section 29.4.4. Timestamping Functions (TSM) for details on timestamping functions.
	[4]	Mark frame for special one-step correction field update. When enabled, the correction field of the frame is subtracted from the TX timestamp on transmission and the result replaces the correction field. The application needs to prepare the frame specifically to use this update method as described in section 29.4.4.5. Using One Step Update at the Management Port.
	[5]	Suppress PRP trailer append. If set to 1, suppresses the switch adding a redundancy control trailer (RCT) when sending the frame at a port defined in the PRP group (bypassing the RedBox function). The bit has no effect if transmission occurs at a ports other than PRP group. If set to 0, the switch can append the RCT as needed. Must be 0 if ControlData[6] = 1.
	[6]	Force PRP trailer append. If set to 1, indicates that the transmitter must append a redundancy control trailer (RCT) when sending the frame at a port defined in the PRP group. This enforces trailer append, even if the frame is not duplicated to both redundant networks. Depending on bit 7, either the switch generates a sequence number, or the application can provide the sequence number that should be used. The bit has no effect if transmission occurs at a ports other than PRP group. If set to 0, no trailer append request is given. The bit has an effect only, if ControlData[5] = 0 and is ignored otherwise.
	[7]	Use provided sequence number for the PRP trailer. If set to 1, indicates that the sequence number for the frame to be used when appending the RCT is found in ControlData2[31:16]. If set to 0, the switch automatically generates a sequence number when forwarding the frame to the PRP ports. This requires that the source address of the frame is stored in the MAC address table (either a dynamic or static entry). The bit has an effect only, if ControlData[6] = 1 and is ignored otherwise. When using a provided sequence number (bits [7:6] = 11b), the sequence number/history memory is not updated. Therefore, if a following frame is sent without this method, an arbitrary/ older sequence number from the memory is added (this may be useful for testing out of sequence error scenarios).
	[8]	Reserved, (write 0 always).
	[9]	If set to 1, override destination queue. The destination queue is taken from bits [12:10] and any priority resolution is ignored.
	[12:10]	Destination queue. When bit [9] is set this queue is used and any priority resolution is ignored.
	[13]	If set to 1, override timer selection. Enables overriding the timer to be used for timestamp operations with the value in bit [14].
	[14]	Timer selection. These bits indicate the timer to use for timestamp operations when bit [13] is set to 1. 0: Timer 0 1: Timer 1
	[15]	Reserved, (write 0 always).

Table 29.21 Management frame receive tagging fields (2 of 2)

Field	Bit#	Description
ControlData2	[2:0]	Destination port mask. Relevant only if ControlData forced forwarding bit 0 is set. It then presents the list of ports where the frame should be forwarded to. One bit per port. A bit set to 1 causes the frame being forwarded to that port. Bit 0 = port 0, Bit 1 = port 1, and so on.
	[8:3]	Reserved, set 0.
	[15:9]	Transmit timestamp ID. When the frame is marked for transmit timestamping, these bits are a user-defined value that gets stored with the timestamp. This serves as a way of correlating a timestamp to a frame for the software layer.
	[31:16]	When ControlData[7] = 1, the 16-bit sequence number for use with the frame when appending the redundancy control trailer (RCT). Reserved otherwise.

29.4.5.5 Module Configuration

The tagging module is configured by the register MGMT_TAG_CONFIG.

The module can either insert the control information into every frame sent to the host CPU or only into dedicated management frames (BPDUs).

In addition to BPDU frames, two types (PRIORITY_TYPE1/2) can be defined that cause the tag being inserted if it should not be done on all frames. When using this feature, the type field compare can be done only for the first type field in the frame (it cannot skip VLAN tags at this point in the data path where the decision for the tag insertion is done).

When the CPU sends a frame to the switch, it can insert the control information as needed, every frame can be treated individually and software can decide for the best implementation on a frame-by-frame basis.

29.4.5.6 Usage notes

The MAC of the management port removes the management tag but counts the bytes of the management tag in the statistics counters. If the frame from the CPU including the management tag is between 64 and 71 bytes, the resulting frame after the management tag removal is less than 64 bytes. This frame is padded when transmitted by the transmit MACs.

Note that padding bytes added automatically are not always zero value. If non-zero value padding is not desirable, prepare the frame more than 71 bytes including management tag by software.

29.4.6 MAC EEE Support

29.4.6.1 Overview

Energy Efficient Ethernet (EEE) is defined in IEEE 802.3az. It defines energy saving modes for backplane applications allowing the PHY device to power down the link during idle times.

The MAC Core implements the necessary functionality to signal Low Power Idle (LPI) to the PHY and provides the necessary handshaking signals to the (external) user application (LPI Client Application).

The MAC includes the necessary timers and a control register to allow for the following usage scenarios:

1. Fully autonomous operation:
   The MAC integrated timers detect idle and initiate LPI transmission to power down the link when the idle time is reached. It also automatically wakes up and performs the Tw_sys_tx wake up delay before transmitting traffic.
2. Software controlled operation:
   A control register (EEE_CTL_STAT_Pn) within the MAC allows controlling the transmission of LPI (lpi_req) and holding the transmitter during wakeup (lpi_txhold). This allows software to implement idle detection and wake up timers.

Figure 29.28 shows the implementation of the MAC core.

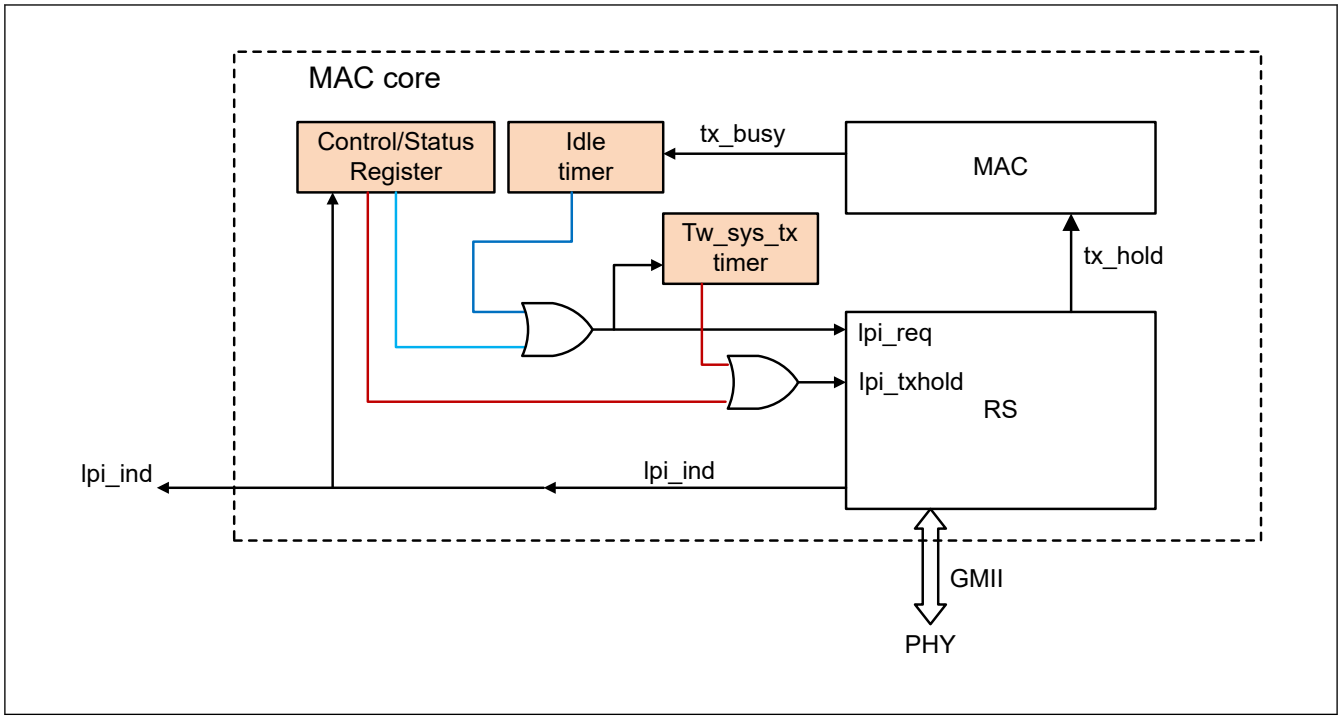

Figure 29.28 MAC extension for autonomous EEE operation

The following three functions are integrated with the MAC core on every line port:

- A control/status register. Allows software to configure the mode of operation (full autonomous with timers, or software controlled) and inspect the received LPI indication status.
- An idle timer. This timer asserts lpi_req when the MAC does not transmit any data for the configured amount of time. It causes the RS layer to transmit LPI.
- A wakeup timer (Tw_sys_tx). This timer prevents the MAC transmitter from transmitting traffic for a certain period after waking up. It keeps the lpi_txhold signal asserted after lpi_req deasserted.

All timers are programmable through registers under software control.

29.4.6.2 PHY Interface Encodings for EEE

The MAC general purpose PHY interface allows interconnecting to any PHY interface using a PHY interface converter as needed. Table 29.22 and Table 29.23 list the encodings for standard GMII and MII to allow transferring the Low Power Idle (LPI) sequences between MAC and PHY.

(1) GMII Encodings for EEE

Table 29.22 shows the interface encodings. When no frame is transferred on the interface, specific idle sequencing can be encoded on the GMII asserting the error signal while data valid is kept low.

Table 29.22 GMII encodings for EEE

rxdv/txen	rxer/txer	rxd/txd[7:0]	Description
1	x	0xXX	Normal frame transfer
0	0	0xXX	Normal interpacket gap (idle)
0	1	0x01	Low Power Idle indication
0	1	0x0F / 0x1F	Carrier Extend / Error during half-duplex operation only (not supported)
0	1	others	Reserved

(2) MII Encodings for EEE

Table 29.23 shows the interface encodings. When no frame is transferred on the interface, specific idle sequencing can be encoded on the MII asserting the error signal while data valid is kept low.

Table 29.23 MII encodings for EEE

rxdv/txen	rxer/txer	rxd/txd[3:0]	Description
1	x	0xX	Normal frame transfer
0	0	0xX	Normal interpacket gap (idle)
0	1	0x1	Low Power Idle indication
0	1	others	Reserved

29.4.7 MAC Transmit Rate Control

29.4.7.1 General

Every MAC implements a rate control function to allow reducing the average transmitted traffic load on the link. When enabled, the transmission bandwidth can be configured to use from 1% to 80% of the available link bandwidth. When disabled, 100% link bandwidth is used.

The implemented algorithm uses the credit based shaper as defined in section 29.4.23.3. References, (3). The algorithm maintains a credit counter for the traffic being transmitted by the MAC. The counter is incremented whenever a frame is waiting for transmission, or if the current count is negative. It decrements when a frame is transmitted. A frame can be transmitted only when the credit counter has a value of ≥ 0. If no frame is waiting and the credit counter is > 0, it is reset to 0.

The increment rate of the counter is defined by the idle slope. The decrement rate of the counter is defined by the send slope. The idle slope is configurable to define the bandwidth that can be allocated for the traffic. The send slope is defined by the link speed.

29.4.7.2 Configuration Settings

The send slope depends on the transmission speed of the link (10 or 100 or 1000 Mbps) and is defined by the current mode of operation of the MAC. The idle slope is defined by configuration (see section 29.3.6.16. IDLE_SLOPE_Pn : Port n MAC Traffic Shaper Bandwidth Control (n = 0 to 3)) depending on the (relative) bandwidth that should be allocated for the traffic.

The idle slope can be configured with a granularity of 1/64 bit. That is, the credit counter increments by 1 byte when the increment has reached 512 (8 × 64). The implementation may have restrictions on the granularity depending on byte to clock ratio of the interface, however, the calculations are always based on the 1/64-bit steps. This means the idle slope allows to specify bandwidth usage in steps of 0.2% (1 / (1 + 512)) of the link capacity. Using an 11-bit value allows to configure the bandwidth allocation from 0.2% to 80%.

The resulting bandwidth is calculated as:

bandwidth [%] = 1 / (1 + 64 / IdleSlope × 8) = 1 / (1 + 512 / IdleSlope)

IdleSlope = (512 × bandwidth) / (1 − bandwidth)

Table 29.24 Credit based shaper bandwidth setting examples (1 of 2)

IdleSlope Value	Allocated Bandwidth	Notes
2	1 / (1 + 32 × 8) = 0.4%	Counter decrements 8-bit per byte transmitted. During idle, it increments 2/64 bit per byte clock → requires 32 × 8 bytes clock cycles to increment by 1 byte.
4	1 / (1 + 16 × 8) = 0.77%	During idle, it increments 4/64 bit per byte clock → requires 16 × 8 bytes clock cycles.
6	1 / (1 + 10.6 × 8) = 1.1%	During idle, it increments 6/64 bit per byte clock → requires 10.6 × 8 bytes clock cycles.

Table 29.24 Credit based shaper bandwidth setting examples (2 of 2)

IdleSlope Value	Allocated Bandwidth	Notes
64	1 / (1 + 8) = 11%	Counter decrements 8-bit per transmit clock cycle. During idle, it increments 1 bit per transmit clock cycle hence requires 8 clock cycles.
57	~ 1 / 10 = 10%	—
73	~ 1 / 8 = 12.5%	—
170	~ 1 / (1 + 3) = 25%	—
256	1 / (1 + 0.25 × 8) = 33%	—
512	1 / (1 + 1) = 50%	—
1536	1 / (1 + 0.04 × 8) = 75%	—
2046	80%	—

29.4.8 Port Based Access Control (802.1X)

29.4.8.1 General

The IEEE 802.1X specification defines procedures to allow a port of the switch to be removed from the network until it is authorized by a higher layer authentication function.

Use of IEEE 802.1X is fully controlled by the application (software) usually connected through the management port. The application exchanges authentication messages through the switch with the devices that connect to the switch line ports. The switch does not interpret the messages aside from detecting the authentication relevant frames (EAPOL) and restricting forwarding if a port is configured as unauthorized.

Authentication of a port is controlled for each port individually through its configuration register AUTH_PORTn.

29.4.8.2 Terms & Definitions

- PAE:
  Port Access Entity — An entity associated with a port that implements the authentication protocols of interest.
- EAP:
  Extensible Authentication Protocol — Messages for encapsulation in frames for exchange between PAEs.
- EAPOL:
  EAP Over LAN — Encapsulation of EAP frames is defined in IEEE 802.1X:
  - Destination MAC address is either the PAE group address 01-80-c2-00-00-03 or the defined unicast address of the port configured in the MAC of the port
  - The Ether type is set to the PAE Ethernet Type: 0x888E
  - The frame shall not be VLAN tagged (VID ≠ 0) but may be priority tagged
- Port Controlled Direction — A port, while unauthorized, can operate with controlled direction in or both:
  - When using controlled direction in, the port only restricts incoming traffic but allows other ports to forward traffic to it for transmission. In controlled direction mode both, forwarding traffic from other ports is not allowed.
  - An exception from this rule is the dedicated EAPOL management port, which must be allowed to forward EAPOL (or other) frames even to ports that have controlled direction both to implement the necessary authentication protocol.

29.4.8.3 Functions

When a port is configured as unauthorized, the MAC/switch port receives behavior changes as follows:

- Accept EAPOL frames and forward them exclusively to a defined port (such as EAPOL port, which is typically the management port)
- Non-EAPOL frames can either be discarded or be allowed for limited forwarding to a specific group of ports (guest VLAN). For example, allowing DHCP before authentication

- Allow or discard non-EAPOL frames received from other ports to be forwarded for transmission on the port (controlled directions in or both)
- Allow or discard BPDU frames

When a port is configured as authorized, normal destination lookup and forwarding resolution occur with additional filtering of unauthorized destination ports which are configured in controlled direction both.

29.4.8.4 Forwarding Decision

The following decision is implemented in each port receive data path to determine the destination ports of a frame or discard it depending on authentication status of a port.

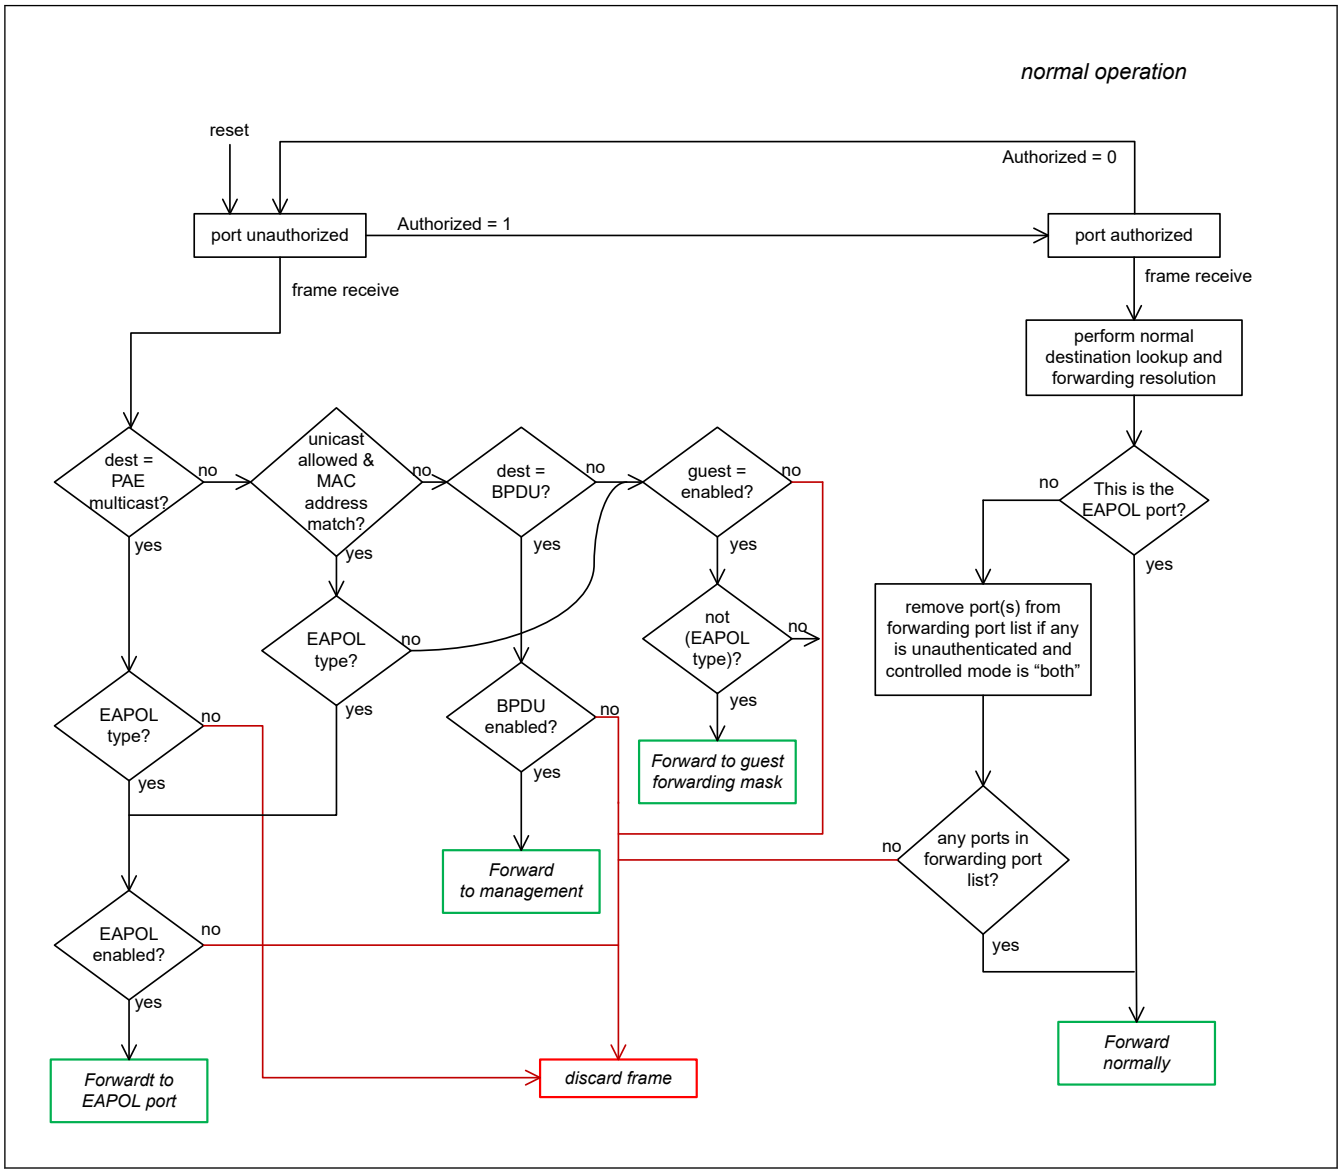

Figure 29.29 IEEE 802.1X forwarding decision flow

29.4.8.5 Usage aspects

The following points should be considered when implementing the authorization application:

- Source address learning should be disabled for an unauthorized port (see section 29.3.1.8. INPUT_LEARN_BLOCK : Input Learning Block Register) to avoid invalid addresses entering or overwriting the MAC address table (MAC address spoofing). The authorization application must enter the address into the MAC address table once the remote device is authenticated.

- With learning disabled and guest traffic allowed for an unauthorized port, the source address is not entered into the address table of the switch. Therefore, all traffic sent to such unauthorized port from another (answering) port is flooded. Flooding is limited to either the guest port mask of the (answering) port if it is unauthorized or the usual U/M/BCast flooding masks if the port is authorized. An exception is the management port, which can use forced forwarding to direct the frame to the intended port only.
- To enable EAPOL reception, the management port functionality must be enabled. That is, register MGMT_CONFIG bit 6 (enable) must be 1 and bit 7 (discard) must be 0. Otherwise, frames are discarded before EAPOL checking can be done.
- If a port is unauthorized, its cut through bit should be cleared to avoid any invalid frames entering the switch. Cut Through should be enabled only on authorized ports.

29.4.9 Interrupts

Global interrupt signal (ETHSW_INTR) and individual module interrupt signals are available.

For global interrupt, the following interrupt sources are available and can be individually enabled through the INT_CONFIG register.

The INT_STAT_ACK register allows inspecting interrupt status and acknowledging the individual pending interrupts by writing a bit with 1 to clear the interrupt latch except sources that have individual configuration and status and acknowledge registers.

Sources that have individual registers need to write individual registers.

Table 29.25 Global Interrupt (ETHSW_INTR) sources

Source	Bit symbol of INT_CONFIG register	Description	Individual Config register	Individual Status/Ack register	Individual interrupt signal
MDIO	MDIO1	MDIO master transaction completion	—	—	—
Lookup Source	LK_NEW_SRC	A frame with an unknown source MAC address was received.	—	—	—
PHY Link Change	IRQ_LINK[2:0]	Change on any of the PHY link status	—	—	—
TX Timestamps	TSM_INT	Per Line Port indication that outgoing frame timestamp is available.	TSM_CONFIG	TSM_IRQ_STAT_ACK	—
MAC EEE	IRQ_MAC_EEE[2:0]	The MAC integrated functions for managing Energy-Efficient Ethernet (EEE) can trigger interrupts from changing power states.	—	—	—
DLR Module	DLR_INT	Events generated by the Device Level Ring (DLR) module	DLR_IRQ_CONTROL	DLR_IRQ_STAT_ACK	ETHSW_DLR
PRP Module	PRP_INT	Events generated by the redundancy network support functions (PRP).	PRP_IRQ_CONTROL	PRP_IRQ_STAT_ACK	ETHSW_PRP
Hub Module	HUB_INT	Events generated by the Hub module.	HUB_IRQ_CONTROL	HUB_IRQ_STAT_ACK	ETHSW_IHUB
Pattern Matcher Module	PATTERN_INT	Events generated by the Pattern Matcher module.	PATTERN_IRQ_CONTROL	PATTERN_IRQ_STAT_ACK	ETHSW_PTRN[11:0]
TDMA Scheduler Module	TDMA_INT	Events generated by the TDMA Scheduler module.	TDMA_IRQ_CONTROL	TDMA_IRQ_STAT_ACK	—
Address Filter	SRCFLT_WD_INT	MAC Address Source Filtering Watchdog	—	—	—
Extended Frame Parser	EFP_INT	Events generated by Extended Frame Parser	*1	*1	—

Note 1. See section 29.4.19.11. Interrupt Source.

Additionally, TDMA_GPIO signals generated in TDMA scheduler module and PTPOUT signals generated in PTP pulse generators are available as interrupts for GIC, DMAC, and ELC as well as external signals.

29.4.10 PHY Management Interface (MDIO Master)

29.4.10.1 Overview

The MDIO management interface is a two wire Management Interface. It provides a standardized method to access PHY device internal management registers. The IEEE 802.3 Clause 22 defines the bus protocol.

29.4.10.2 MDIO Frame Format

A complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC signal).

Table 29.26 MDIO frame formats (Read/Write)

Type	PRE	Command				TA	Data MSB LSB	Idle
		ST MSB LSB	OP MSB LSB	Addr1 MSB.LSB	Addr2 MSB.LSB			
Read	0xFFFFFFFF	01b	10b	xxxxxb	xxxxxb	Z0b	xxxxxxxxxxxxxxxxb	Z
Write	0xFFFFFFFF	01b	01b	xxxxxb	xxxxxb	10b	xxxxxxxxxxxxxxxxb	Z

Table 29.27 MDIO frame fields description

Name	Description
PRE	Preamble: 32 bits of logical 1 sent prior to every transaction
ST	Start indication: 01b
OP	The opcode defines whether a read or write operation is performed: 1. If set to 10b, a read operation is performed. 2. If set to 01b, a write operation is performed.
Addr1	The PHY device address (PHYAD). Up to 32 devices can be addressed.
Addr2	Register Address. Each PHY can implement up to 32 registers.
TA	Turnaround time. Two bit-times are reserved for read operations to switch the data bus from write to read for read operations. The PHY device will present its register contents in the data phase and drives the bus from the 2nd bit of the turnaround phase.
Data	16 bits of data written to the PHY or read from the PHY.
Idle	Between frames, the MDIO data signal is tri-stated.

29.4.10.3 Turnaround Signalling

For Read operations, the addressed PHY has to drive the data bus. This direction change is done during the two bit-times TA phase of the frame.

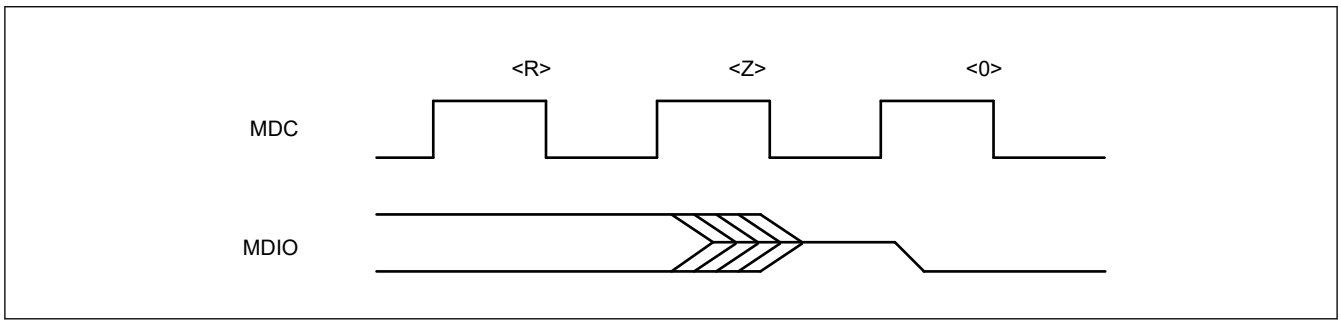

Figure 29.30 MDIO turnaround sequence

When the last bit before the TA phase (<R> in above figure) has been transmitted to the PHY, the transmitter will switch its MDIO data signal into tristate (<Z>). One clock cycle later, the PHY starts driving the MDIO data signal to 0 (<0>) and then shifts out its 16 bits of data from the addressed register. After all 16 data bits have been transferred by the PHY, it again tri-states MDIO.

29.4.10.4 MDIO Control Registers

The configuration register MDIO_CFG_STATUS is used to set the operation parameters for all MDIO transactions and must be initialized before any transactions can occur.

29.4.10.5 Transaction Types

The MDIO provides two transactions. A read transaction and a write transaction. The transactions contain the PHY device address and the register address allowing to address up to 32 devices on the bus with up to 32 registers.

The transactions can occur after the MDIO_CFG_STATUS has been initialized.

(1) Read Transaction

To read a register from the PHY the following sequence is used:

1. Setup MDIO_COMMAND with the PHY device and register address of interest and set bit 15 to trigger the read transaction.
2. Wait for transaction complete (inspecting MDIO_CFG_STATUS.BUSY).
3. Read data from MDIO_DATA.

(2) Write Transaction

To write into a PHY register, the following sequence is used:

1. Setup MDIO_COMMAND with the PHY device and register address of interest.
2. Write data into MDIO_DATA. This triggers the write transaction.
3. Wait for transaction complete (inspecting MDIO_CFG_STATUS.BUSY).

29.4.11 DLR Extension Module

29.4.11.1 Overview

The Device Level Ring (DLR) extension offers beacon frame processing on receive for the two line-ports (0 and 1) of the switch implementation.

The DLR extension module operates between the MAC receive and switch input of a port. Beacon frames are detected and the frame parameters are interpreted and stored locally for software access.

The switch forwards the beacon frames normally (possibly using cut through if available). Using a static address entry in the MAC address table allows limiting beacon frame forwarding to the two DLR enabled ports only. This prevents any beacon traffic sent to the management port or other line ports of the switch avoiding unnecessary processing load.

In addition, a loop filter is inserted into each receive data path to detect if the incoming frame's source address equals the local station MAC address. Such frames are discarded to avoid cycling of frames sent by the local device into the ring during reconfiguration times. The local node's MAC address can be configured with the DLR_LOC_MAClo/hi registers.

Any ring status change for beacon based node implementation is notified to the processor through the interrupt status. It is possible to read the received beacon frame parameters at any time. Statistics counters are implemented counting beacon frames processed.

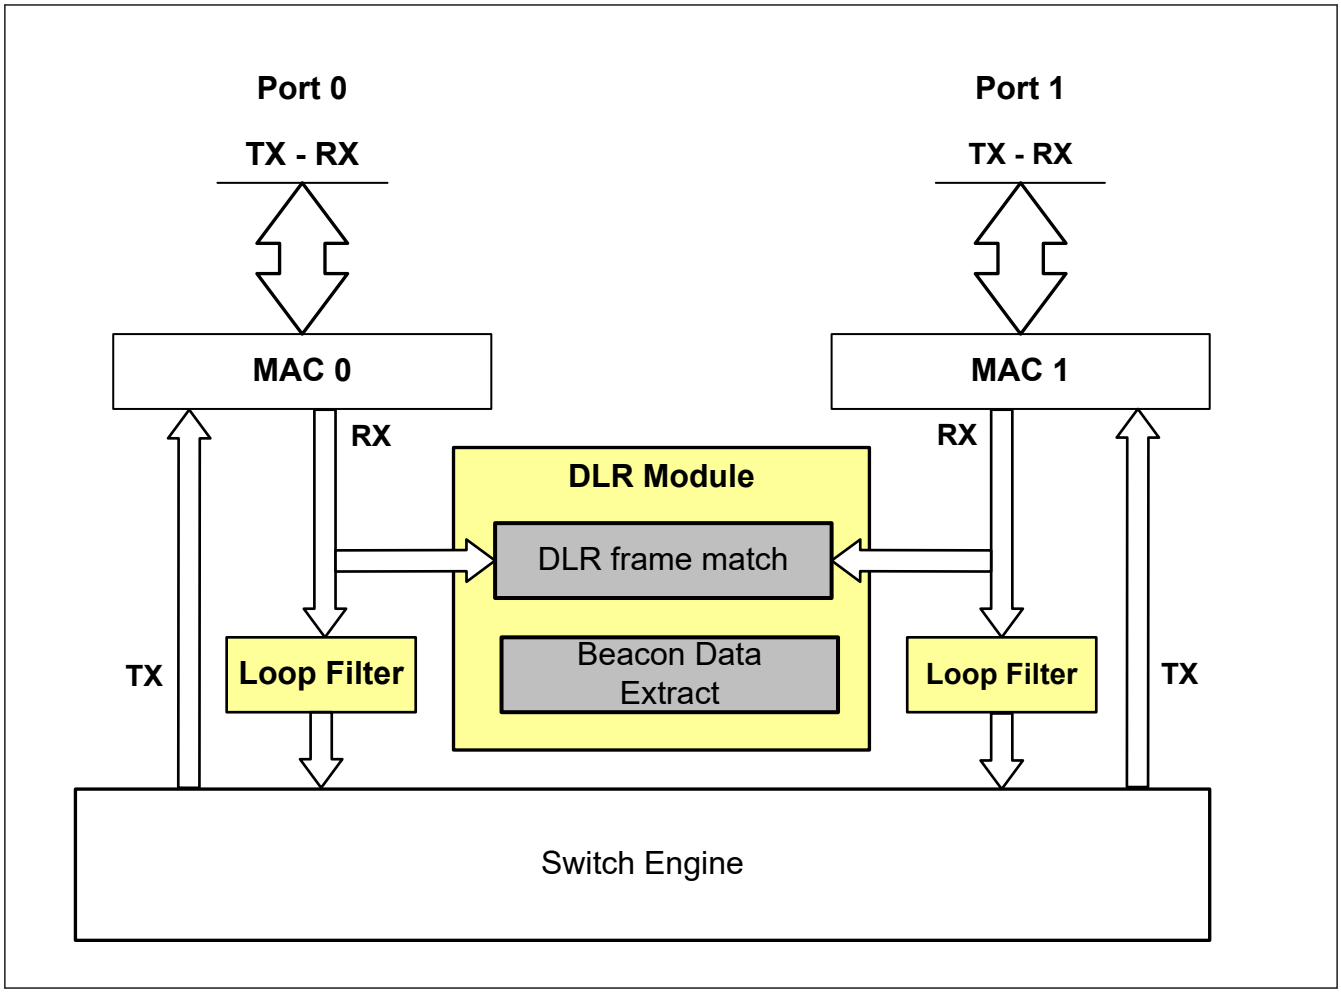

Figure 29.31 Switch with DLR extension

29.4.11.2 Beacon Frame Format

Within a DLR Network, the active ring supervisor transmits beacon frames through both of its Ethernet ports once per beacon interval (400 microseconds by default). DLR frames are using the frame format of 802.1Q. Frames are transmitted with highest priority (7). Beacon frames are DLR frames with a length of 64 bytes, excluding the preamble and the SFD bytes. Beacon frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Six bytes Destination MAC address of 01-21-6C-00-00-01
- Six bytes Source MAC address
- TPID (0x8100) and VLAN Info
- Ring Ether Type of 0x80E1
- Ring Subtype 0x02
- Ring protocol version 0x01
- Frame type 0x01
- Source port 0x00
- Source IP address
- Sequence ID
- Ring state
- Supervisor precedence

- Beacon interval
- Beacon timeout
- Frame check sequence (CRC value)

Table 29.28 Beacon frame format

Frame Length	Common DLR Protocol Header	7 octets	PREAMBLE
		1 octet	SFD
		6 octets	DESTINATION ADDRESS
		6 octets	SOURCE ADDRESS
		2 octets	TPID (0x8100)
		2 octets	VLAN info (0xE000 + VLAN ID)
		2 octets	Ring Ether TYPE (0x80E1)
		1 octet	Ring Sub Type (0x02)
		1 octet	Ring Protocol Version (0x01)
		1 octet	Frame Type (0x01)
		1 octet	Source Port (0x00)
		4 octets	Source IP Address (0x00 if source has no IP address)
		4 octets	Sequence ID
		1 octet	Ring State
		1 octet	Supervisor precedence
		4 octets	Beacon Interval
		4 octets	Beacon Timeout in microseconds
		20 octets	Reserved
		4 octets	Frame Check Sequence

Beacon frames are processed and parameters are stored locally for the software access. The following table shows the beacon frame fields.

Table 29.29 Beacon frame field definitions (1 of 2)

Term	Description	Related register
Destination Address	The destination MAC address for the beacon frame is fixed multicast address of 01-21-6C-00-00-01. This is an exclusive MAC address used only for beacon frames. Hence cut-through forwarding could be used based on this address match.	DLR_DSTlo/hi
Source Address	Source MAC address of the supervisor. 48-bit address is stored in two separate registers.	DLR_SUPR_MAClo/hi
TPID	DLR messages contain 2 octets TPID (0x8100) after the source MAC address according to IEEE 802.1Q.	—
VLAN Info	16-bit information field contains the priority field and the VLAN ID. VLAN ID is configured at the ring supervisor and received by the ring nodes. The default value for the VLAN ID is 0 when there is no VLAN ID available. The default VLAN ID does not need to be changed unless a commercial switch is being used within the ring.	DLR_STATE_VLAN (VLANINFO[15:0])
Ring Ether Type	Ether type for DLR frame is 0x80E1	DLR_ETH_TYP
Ring Sub Type	Ring Sub type value is always 0x02 for the DLR messages	DLR_ETH_STYP_VER (SUBTYPE[7:0])
Ring Protocol Version	Protocol version for the DLR messages	DLR_ETH_STYP_VER (PROTVER[7:0])
Frame Type	Frame Type value for the beacon frame is always 0x01	—

Table 29.29 Beacon frame field definitions (2 of 2)

Term	Description	Related register
Source Port	Source port value is always 0x0 for the beacon frame	DLR_ETH_STYP_VER (SPORT[7:0])
Source IP Address	IP address of the Supervisor. The default value for the IP address is 0 when there is no IP address available.	DLR_SURR_IPADR
Sequence ID	Sequence identification number of the frame	DLR_SEQ_ID
Ring State	State of the Ring network transmitted by the ring supervisor.	DLR_STATE_VLAN (RINGSTAT[7:0])
Supervisor Precedence	The Ring Supervisor Precedence value contains the user assigned precedence value to the ring supervisor. When multiple supervisors are enabled, the precedence value enables the user to select a single supervisor with highest precedence. The ring supervisor's precedence value can be any value within a range 0-255, with numerically higher values indicating higher precedence.	DLR_SUPR_MAChi (PRECE[7:0])
Beacon Interval	Interval in microsecond at which the ring supervisor sends beacon frames. Valid value is in a range between minimum 100 microseconds and maximum 100 milliseconds. Typical value is 400 microseconds.	DLR_BEC_INTRVL
Beacon Timeout	Amount of time in microsecond, nodes shall wait before timing out reception of beacon frames and taking appropriate action. Valid value is in a range between minimum 200 microseconds and maximum 500 milliseconds. Typical value is 1960 microseconds.	DLR_BEC_TMOUT
Frame Check Sequence	CRC value for the frame	—

29.4.11.3 Ring Node Functional Description

Beacon frames are detected and interpreted by the hardware so that the processor is not burdened with processing the beacon frames for ring node implementation. Any ring status change for beacon based node implementation is notified to the processor through the interrupt status. It is also possible to read the received beacon frame parameters at any time. Statistics counters are also implemented to view the number of beacon frames processed.

(1) Configuration

Following are the steps to configure the DLR Module:

- Enter the beacon destination address (01-21-6C-00-00-01) into the MAC address table as a static entry having only bits 0, 1 set in the portmask (see also section 29.4.3.8. Layer 2 Look Up Engine Operational Description). This ensures beacon frames are forwarded only between the two DLR capable ports within the switch.
- Set the beacon destination address (01-21-6C-00-00-01) within the DLR module to allow its detection (see also (2) Beacon Frame Detection):
  - Set register DLR_DSTlo = 0x006C2101 which is also the reset value.
  - Set register DLR_DSThi = 0x0100 which is also the reset value.
- Set the MAC address of the local device which is used by the loop filter.
  - Set the first 4 bytes of the MAC address in register DLR_LOC_MAClo.
  - Set the last 2 bytes of the MAC address in register DLR_LOC_MAChi.
- Set the DLR Ethernet type value of 0x80E1 to the register DLR_ETH_TYP which is also the reset value.
- Enable and control the DLR module through the DLR_CONTROL register. It also defines the timer constant (cycles required to count 1 µs) used by the timeout counters.
- Configure the destination address for Neighbor_Check_xxx and Sign_On messages (01-21-6C-00-00-02) to ensure it is always forwarded to the management port only and not forwarded between any of the line ports. There are 2 alternatives to achieve this:
  - Configure the address into the additional BPDU register MGMT_ADDRn_lo/hi.
  - Add it as static address into the address table with the portmask having only the bit of the management port set to 1.
- Any interrupt bit can be enabled/disabled through the register DLR_IRQ_CONTROL as required.

(2) Beacon Frame Detection

Received frames are inspected by the DLR module only if they match the following rules. Otherwise, the frame is ignored by the DLR module.

- Destination address must match the address provided in DLR_DSTlo/hi registers.
- Ethernet type must match the value given in register DLR_ETH_TYP.

If above rules both match, learning of the source address of the frame is suppressed, even if the port has learning enabled (to avoid the address table is constantly updated with alternating entries for the ring supervisor).

The accepted DLR frame is then forwarded to the beacon frame processing function (within the DLR module), which inspects the frame payload further to extract beacon information. However, this function accepts a frame only if the following rule matches:

- The DLR payload Frame Type field (3rd byte in payload) must have a value of 0x01.

If the DLR payload Frame Type is not matching, the frame is ignored by the beacon processing functions. However, source address learning will still not occur (as it does not depend on payload).

The switch will always process the frame normally (i.e. forwards it between port 0 and port 1), independent of the DLR module function inspecting the frame.

(3) Start Up

On start up ring node will be in IDLE_STATE and presumes the network in linear topology mode. The current state of the local ring node and other status bits are stored within the register DLR_STATUS.

Beacon frame received with invalid timer value will be ignored if ignore enabled through the DLR_CONTROL register. Invalid timeout timer value of the beacon frame will be always stored within the register DLR_INV_TMOUT irrespective of the ignore enable bit within the DLR_CONTROL register. An interrupt will be generated on receiving a beacon frame with invalid timeout timer value if enabled through DLR_IRQ_CONTROL.

On receiving a beacon frame through either port, the node shall transition to FAULT_STATE, which presumes the network in ring topology mode. An interrupt will be generated to the processor indicating a need for flushing the MAC address learning table and a change in state if enabled through the register DLR_IRQ_CONTROL. All ring supervisor parameters will be saved within register. Following parameters will be saved only during transition from IDLE_STATE to FAULT_STATE:

- Supervisor's MAC address and will be stored in the register DLR_SUPR_MAClo and DLR_SUPR_MAChi
- Supervisor's precedence value will be stored in the register DLR_SUPR_MAChi
- VLAN ID will be stored in the register DLR_STATE_VLAN
- Beacon timeout timer value will be stored in the register DLR_BEC_TMOUT

Supervisors IP address is accepted to change at any time. New IP address will always replace the old one and interrupt will be generated indicating the IP address change if enabled through the DLR_IRQ_CONTROL.

If beacon frame is received from a different supervisor with a higher precedence value or higher numeric value for MAC address with same precedence value, new beacon frame parameters will replace all the old values. An interrupt will be generated indicating change of supervisor if enabled through the register DLR_IRQ_CONTROL. Node will stay in FAULT_STATE.

If beacon frame is received from a different supervisor with a lower precedence value or lower numeric value for MAC address with same precedence value, beacon frame will be ignored. An interrupt will be generated indicating ignored beacon frame if enabled through the register DLR_IRQ_CONTROL. Node will stay in FAULT_STATE.

Ring supervisor is not expected to change parameters within the beacon frame. If parameters need to be changed, supervisor is expected to stop transmitting beacon frame for at least two beacon timeout periods before transmitting beacon frames with new parameters.

If the local node state changes back to IDLE_STATE due to beacon timeout timer expiration on both ports, it will generate interrupt if enabled through the register DLR_IRQ_CONTROL. Current interrupt status is available for software access showing beacon timeout timer asserted for both ports, need to flush MAC address learning table and state change within interrupt status register DLR_IRQ_STAT_ACK.

On receiving beacon frame through both ports and after receiving a beacon frame from active ring supervisor with ring state field set to RING_STATE_NORMAL on either one of its ports, Local node shall transition to NORMAL_STATE. Interrupt status bits will show the change in state, need to flush the unicast MAC address learning table and to stop neighbor check timeout timer when active within the software.

Note: Neighbor check time out timer (100 milliseconds) for neighbor check process (see section 29.4.23.3. References, (5)) should be implemented by the software. Software may take advantage of the stop neighbor check timeout timer bit of the interrupt status register to stop the timer.

(4) Fault Detection

One of several possible events shall cause the ring node to transition from NORMAL_STATE to other states:

- Receipt of beacon frame with state parameter set to RING_FAULT_STATE. Interrupt status will show a change in node state change and cause an interrupt if enabled.
- Receipt of beacon frame with different MAC address and higher precedence than the current active ring supervisor. In addition to state change, supervisor change bit will be asserted within the interrupt status register.
- Loss of beacon frame on both ports for a period specified by the beacon timeout period will cause the node to transition to IDLE_STATE. In addition to the state change, beacon timeout timer expire bits for both ports bit will be asserted within the interrupt status register.
- Loss of beacon frame on a single port for a period specified by the beacon timeout period will cause the node to transition to FAULT_STATE. In addition to the state change, beacon timeout timer expire bits for corresponding port bit will be asserted within the interrupt status register.

(5) Error Handling

DLR node module is able to handle several error conditions:

- Beacon frames with CRC error are detected and not interpreted for DLR node implementation and discarded before entering the switch. Beacon frame parameters are not stored for the error frame. Beacon frames with CRC error are counted and stored in the DLR statistics register DLR_RX_ERR_STAT0 and DLR_RX_ERR_STAT1 for the port 0 and port 1 respectively.
- Valid range for the beacon frame timeout timer value is between 200 microseconds to 500 milliseconds. Beacon frame from supervisor with invalid value of the beacon timeout will be ignored for processing (however are still forwarded normally) if configured through the DLR_CONTROL register. Beacon frames with invalid timeout timer are always detected irrespective of the DLR_CONTROL register configuration and invalid timeout value is stored within the register DLR_INV_TMOUT. An interrupt is also generated if enabled through the DLR_IRQ_CONTROL register.

(6) Beacon Frame Parameter Extraction

Parameters are transmitted by the Ring Supervisor through beacon frame and extracted by the node and stored within read only Registers. There are three types of beacon frame parameters depending on time of capture and store.

- Type1:
  Parameters that are not allowed to change during normal operation. This is done to avoid any unexpected change during normal operation. Parameters are always extracted and compared for the state machine evaluation but they are stored only during IDLE state or if the received beacon frame has higher precedence than the previously received beacon frame.
- Type2:
  Allowed to change at any time. Such parameters are always extracted and stored if the beacon frame is received from current Ring supervisor or node is in IDLE state or received beacon frame has higher precedence than previously received beacon frame.
- Type3:
  Always extracted from all beacon frames on any port and stored within the register. Does not have any dependency on state or supervisor or precedence. Useful for debugging purpose only.

(7) Link_Status Message Generation

When a DLR node detects a link failure a Link_Status message is generated to the other port to notify the active ring supervisor node. This feature can be automated by the switch with assistance from software using the queue trigger feature of the memory controller at the expense of sacrificing one output queue in the memory controller.

Each MAC port can enable a trigger event to the IMC for transmitting a frame on the event of a link loss via the register MAC_LINK_QTRIG_Pn. When the DLR ring is formed and the DLR state machine is in the NORMAL_STATE the ENABLE bit in MAC_LINK_QTRIG_Pn can be enabled to send the Link_Status frame in the event of a link loss.

The following steps must be performed to support Link_Status generation using the switch:

- Select a high priority queue for the Link_Status function in the DLR ports, namely QLS. This QLS can only be used for the Link_Status function and the switch must be configured to prevent frames from being sent to this queue.
- Gate the QLS queue using MMCTL_QGATE for the DLR ports by setting to 1 the bits corresponding to the DLR ports in PORT_MASK and setting QUEUE_GATE to 0x2 for the QLS queue.
- Enable the 1-frame mode (buffer mode) using the MMCTL_1FRAME_MODE_Pn for the DLR ports by setting the corresponding bits to the DLR ports in Q_1FRAME_ENA and Q_BUF_ENA. This causes the Link_Status frame to be stored in permanently in the memory.
- Preload the Link_Status frame in the QLS queue in both DLR ports by sending the Link_Status frame (or frames if they are distinct per port) from the firmware using forced forwarding (see section 29.4.5.4. Receive Processing (CPU to Switch).
- Wait until the DLR state machine is in the NORMAL_STATE (by reading the DLR_STATUS register, see section 29.3.11.2. DLR_STATUS : DLR Status Register.
- Enable the MAC link trigger function in MAC_LINK_QTRIG_Pn by setting the ENABLE bit to 1, setting to 1 the QUEUE_MASK to select the QLS queue, and programming the PORT_MASK with the "other" DLR port so the Link_Status frame is sent via the non-failed port.

(8) Dynamic Unicast L2 Entries Hardware Auto-Flush

The DLR can initiate a flush of the dynamic unicast entries in the L2 forwarding table by setting the AUTOFLUSH bit in the DLR_CONTROL register. The auto-flush feature executes whenever the following conditions occur:

1. The DLR state transitions from IDLE to FAULT
2. The DLR state transitions from FAULT to IDLE
3. The DLR state transitions from FAULT to NORMAL
4. The DLR state transitions from NORMAL to FAULT
5. The DLR state is FAULT and a beacon frame is received with a precedence higher than the active supervisor's precedence value.

The auto-flush function executes a lookup engine command LK_ADDR_CTRL.DEL_PORT with a mask (ADDR_MSK field) of 0x03 to delete all dynamic entries in the L2 table that are listed for forwarding to ports 0, 1 (i.e. it deletes all learned unicast that are located within the ring).

The interrupt "flush_macaddr" follows the conditions above as well so alternatively the hardware auto-flush can be disabled and the interrupt enabled to handle the flushing by the firmware.

29.4.12 Parallel Redundancy Protocol (PRP)

29.4.12.1 Overview

The switch can be used within a redundant network infrastructure according to IEC 62439-3 Clause 4 (section 29.4.23.3. References, (6)). The Parallel Redundancy Protocol (PRP) defines a network infrastructure consisting of two fully independent networks which are operated in parallel between all nodes. No communication occurs between the two networks and they are installed so that failure of one network does not affect the operation of the other network. Each network by itself is not aware of its role in a redundant infrastructure and is built from standard Ethernet networking equipment.

Each node that connects to the redundant network infrastructure uses two separate networking interfaces to connect to both networks at the same time. This is called a Double Attached Node (DAN). All DANs inject the same frame into both networks and append a Redundancy Control Trailer (RCT) which allows a receiving node to identify the redundant frames and only process one of the two frames. Hence if one of the networks experiences a failure the communication is not interrupted as all data still passes through the redundant network.

The infrastructure is held flexible to allow attachment of existing network components with only a single network interface (Single Attached Node, SAN) into the network. A SAN cannot benefit from the redundancy and can only communicate with other DAN or SAN on the same network.

If a SAN should also benefit from the redundant network infrastructure, it can be connected through a so-called Redundancy Box (RedBox) device which performs the necessary frame duplication functions to all traffic transferred between the SAN and the redundant networks. From the perspective of the network and all other nodes, a SAN behind a RedBox acts identical to a DAN and is called a virtual DAN (VDAN).

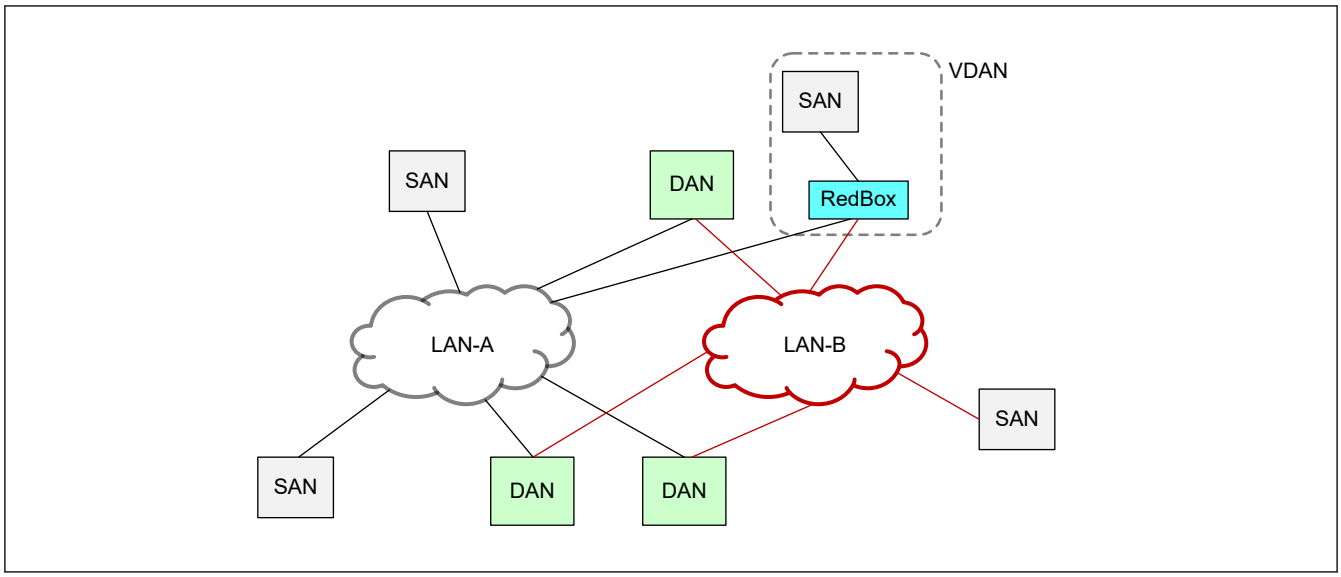

Figure 29.32 PRP network infrastructure overview

29.4.12.2 ETHSW Function Summary

The ETHSW allows implementing a very flexible device by combining two of its ports to a "PRP Group" to connect to such a redundant network infrastructure. All traffic to and from the PRP grouped ports will be subject to redundancy processing like frame duplication, trailer append, and duplicate detection. No traffic forwarding occurs between the PRP grouped ports.

At the same time, the other ports of the ETHSW can connect to regular SANs or other local (non redundant) networks and the switch will perform the function of a RedBox when forwarding traffic between the PRP Group and any other port. The following figure shows the different roles of the ETHSW within some mixed infrastructure example.

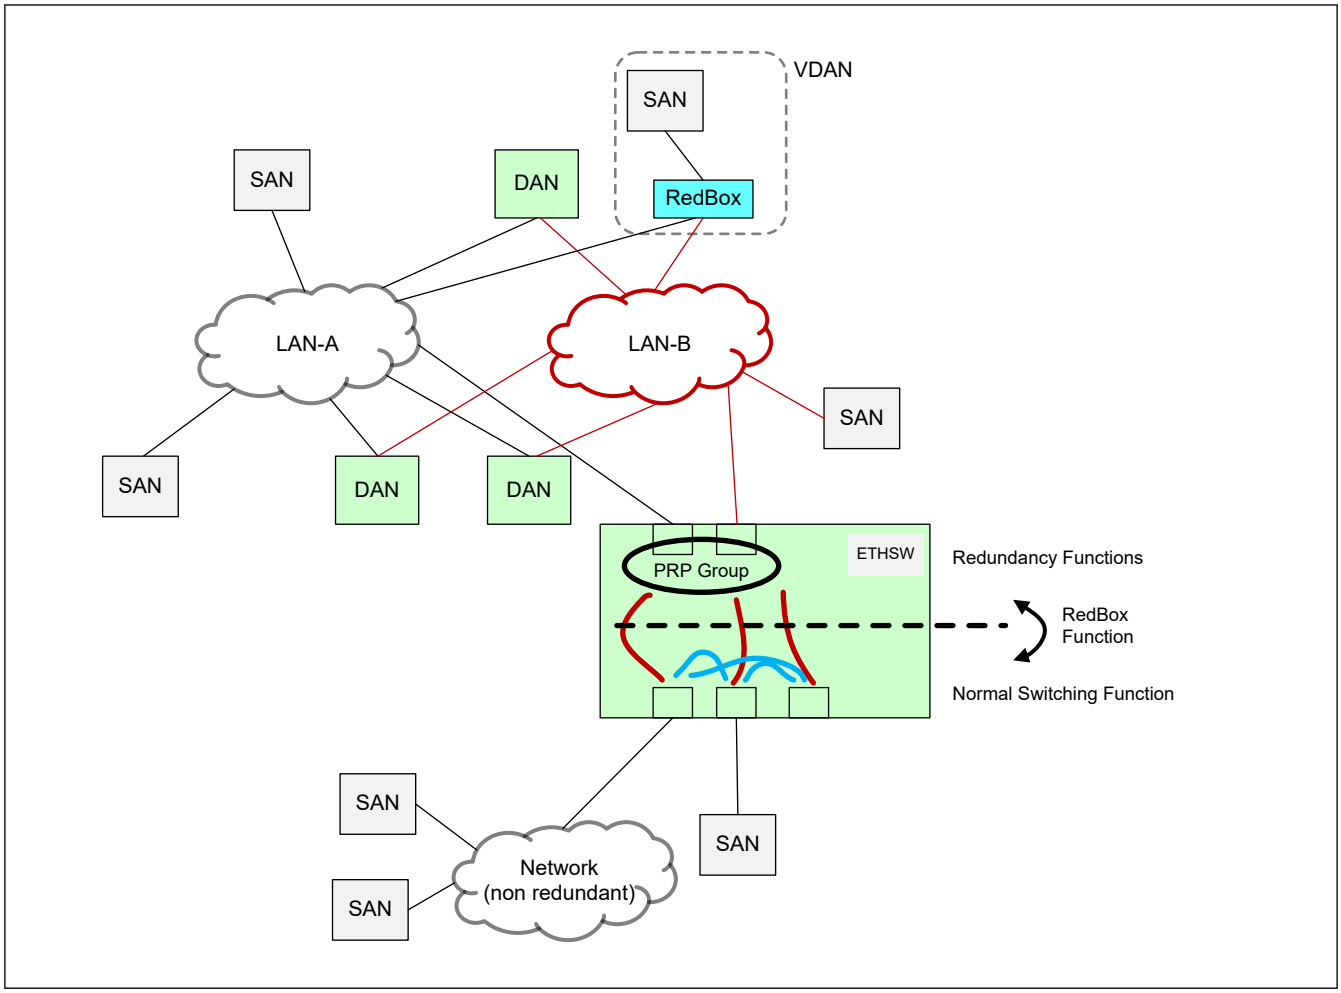

Figure 29.33 ETHSW within PRP infrastructure

The implementation is held flexible and enables the following functionalities:

- Any two ports of the line ports can be grouped for redundancy (one group can exist).
- Perform frame duplication and RCT append to frames directed to double attached nodes (DANs) when transmitting to the PRP group ports.
- Perform duplicate detection on frames received from the redundant networks with optional dropping of duplicates.
- Avoid frame duplication and RCT append if the destination is known to be a single attached node (SAN).
- The switch forwarding function distinguishes DANs and SANs fully automatically using its lookup table. A DAN has both ports of the PRP Group listed as its destination, whereas a SAN only has one of the ports of the PRP Group as its destination.
- The learning function is enhanced to automatically detect DANs when it receives redundant traffic from a node through the PRP grouped ports.
- Alternatively, management can setup the forwarding table to define DANs and SANs.
- Several options exist to configure trailer append and duplicate detection functionalities with optional automatic removal of the RCT when forwarding to non redundant ports.
- The special local switch management port (internal port) which connects the local node to the network(s) allows to operate the necessary network monitoring (software) and management services and can act itself as a DAN attached to the redundant networks.
- Traffic in between the PRP group ports is suppressed. SANs on one of the redundant networks cannot communicate with SANs on the other redundant network.
- Transparent RedBox functionality when forwarding traffic between the PRP grouped ports and the other switch ports.

29.4.12.3 Switch Forwarding Behavior

(1) Forwarding to Redundant Networks

Due to its flexible architecture and advantage of having a full switch in place, no dedicated redundancy layer exists. Instead, the existing switch forwarding mechanisms together with the capability to duplicate frames (used e.g. for broadcast or flooding) is used. When forwarding frames to the PRP grouped ports (as defined in register PRP_GROUP), the switch provides additional information with the frame to instruct the MAC transmitters to attach the redundancy trailer as needed. This allows transparent mixing of redundant and non redundant traffic on the networks. For example, link local traffic like BPDU management frames are forwarded without duplication and without redundancy trailer as are frames destined to SANs.

The following figure shows the flow of a frame and its respective actions along the path when forwarded from a non redundant port to the redundant ports. This effectively performs the RedBox functionality.

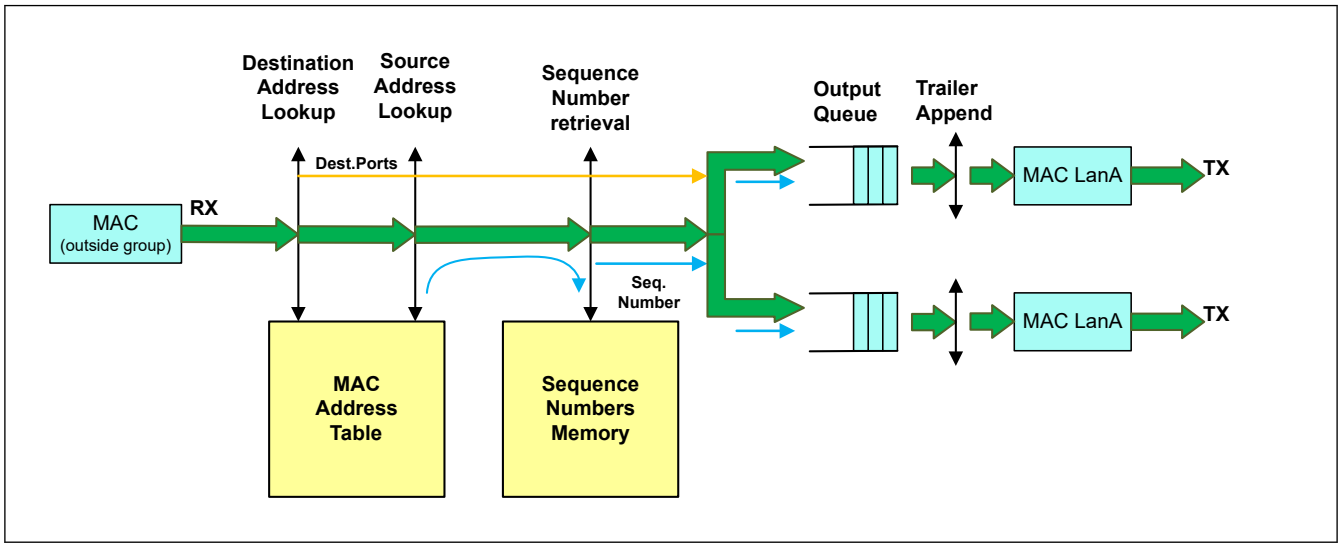

Figure 29.34 Forwarding to redundant ports (RedBox)

This also means that the switch's output queues are by itself already part of the redundant network infrastructure and sending of the duplicated frames into the redundant networks may not occur simultaneously. For example, if the queues of the redundant ports are filled to different levels because e.g. one port is transferring a frame to a SAN. Then the first of the two duplicates is sent immediately while the 2nd frame will have to wait for completion of the ongoing transmission at the other port.

To support automatic sequence number generation required to allow duplicate detection at the receiving DAN, the switch MAC address table is extended with a 2nd memory to store, for each MAC address, the current sequence number. The sequence number is automatically incremented whenever a frame from such a MAC address is forwarded from a non redundant port to the redundant ports and experiences duplication with trailer append. If the same source communicates with a SAN, the sequence number is not retrieved and stays unmodified.

(2) Receive from Redundant Networks

When receiving traffic from redundant networks optionally, a history memory is used to keep track of received sequence numbers. If the history memory shows that the same frame has been received from the same source already, it can be discarded. If it is the first of the two frames, it will be forwarded normally with the option to remove the redundancy control trailer.

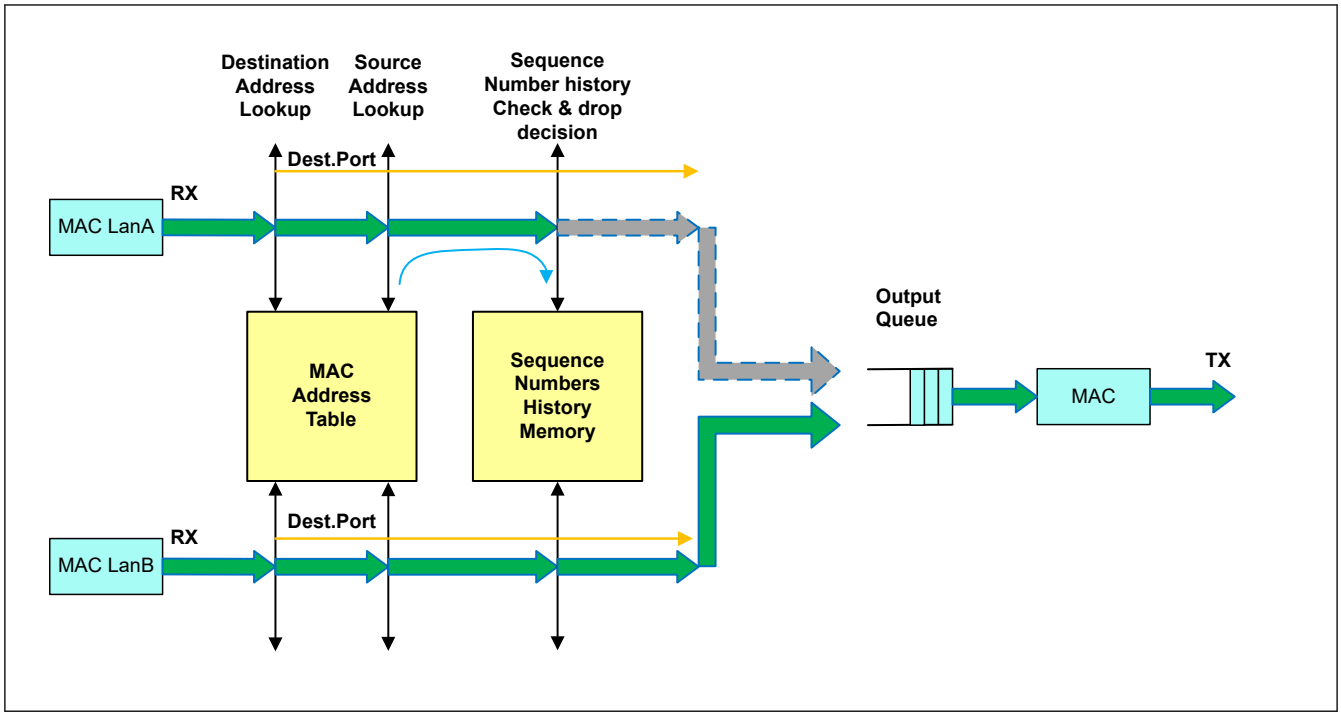

Figure 29.35 Receiving from redundant networks

The figure shows an example where the duplicate is dropped in the upper path (from MAC LanA). The sequence numbers history memory is consulted by every port when it receives frames to identify duplicates. The switch will then mark the frame for discard and not forward it.

The history memory provides specific atomic functions that guarantee that simultaneous reception of frames will always generate a consistent dataset in memory that allows a decision to drop one of the redundant frames only.

If sequence numbers are unknown or out of the expected range, the history is capable to manage, duplicates will not be detected and both frames will be forwarded to the output queue(s). The higher layer protocols therefore will need to be robust against receiving duplicated frames, as there is no guarantee that duplicates will be dropped. Rather in case of doubt the forwarding of both frames tries to ensure that no data is lost.

29.4.12.4 MAC Address Learning Enhancements

The hardware MAC address table management allows automatic learning of source addresses when receiving frames (see also (6) Automatic Learning / Migration). For supporting redundant networks, it is enhanced to allow the same source address to appear on both redundant ports. That is, when the same MAC address is found in the source address field of frames received on both redundant ports, the associated port mask of the entry in the table will contain the same two bits that were defined as a PRP group (register PRP_GROUP).

This causes the switch forwarding to duplicate the frames to both redundant ports when a frame is sent to a node attached to both redundant networks (DAN). This also ensures that no duplication is performed if the address entry would not show both bits within its table identifying the remote device as a SAN.

In addition, dynamic entries indicate reception of frames from either of the two ports in the (otherwise unused) bits 51 and 52. The hardware will only set the corresponding bit when receiving frames from the designated LAN A or LAN B port (as defined by register PRP_GROUP). It is up to the management (software) to deliberately clear those bits as necessary. This can be used to e.g. verify that traffic from a DAN is received on both ports allowing detection of network failures in one of the redundant networks.

The following figure shows the enhanced format of dynamic entries when redundancy operation is enabled (see also Figure 29.16). The normally unused bits 51 and 52 are used to indicate reception from the corresponding port of a redundant network.

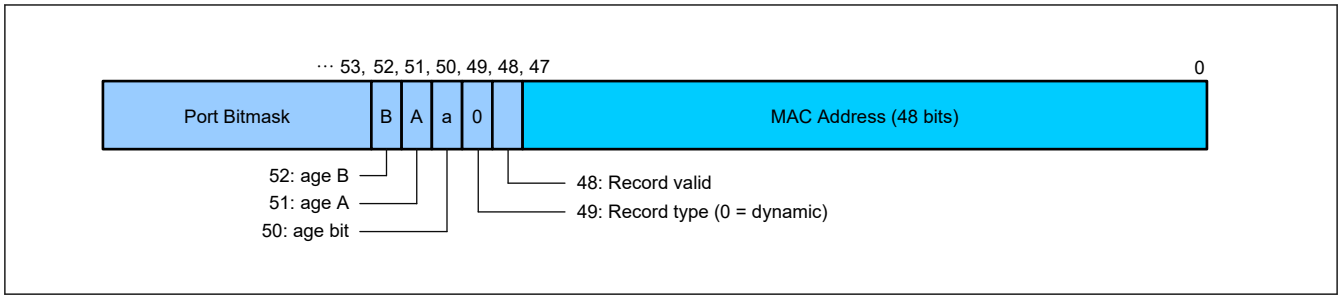

Figure 29.36 Dynamic address table entry with redundancy enhancement

By disabling the learning function (register LK_CTRL), software can control the address table in a static way. However, it should then still use dynamic entries (i.e. Bit 49 = 0) when adding addresses for DANs to enable the automatic updating of Bits 51, 52 for network monitoring purposes. The aging and migration functions can be disabled, hence dynamic entries will not be modified by the hardware except for updating (setting) those two bits of an entry.

Note: The normal age bit (bit 50) is also set always by the hardware independent of the port where the frame was received from.

PRP cannot be used together with memory reservations (see section 29.4.16.2. Memory Reservation). When enabling PRP memory reservations have to be disabled for all queues.

Table 29.30 PRP support relevant registers (1 of 2)

Register	Notes
PRP_GROUP	Defines which two of the line ports should be used to connect to redundant networks. The management port (internal Port 3 of ETHSW) cannot be assigned. When the switch forwards frames to the PRP group ports, it automatically performs frame duplication and appends the redundancy control trailer (RCT). A dedicated memory is used to store the current sequence number for each known (source) MAC address which is automatically incremented whenever such node sends frames to the redundant networks requiring duplication and trailer append. Frame duplication is controlled through the normal MAC address table entries (see section 29.4.3.7. Layer 2 Look Up Engine). If an address is inserted into the table, the port bitmask can be set to contain both ports to identify a DAN. The MAC transmitters use this information to determine if a trailer should be appended or not. On the other hand, if only one port is listed, frames are forwarded to any other port, no duplication occurs and no trailer is appended. Note: When using ports within a PRP group, the VLAN output manipulation function that relies on the per-VLAN tag mask cannot be used any more (i.e. Mode 3 as described in (d) Mode 3: VLAN Domain Mode / Transparent Mode is not available at the redundant ports).
PRP_CONFIG	Enables all redundancy functions and configures when to add redundancy trailer or perform duplicate detection with automatic removal of the trailer.
PRP_IRQ_CONTROL	Allows enabling several interrupts that may be of interest to the management application when implementing network monitoring functionalities.
RM_ADDR_CTRL	Access functions to read and write the history (rx) and sequence number (tx) memory entries for every MAC address. The memory has the same number of entries as the MAC lookup table memory (LK_ADDR_CTRL) allowing to store a sequence number or sequence number history for each individual MAC address. Which type of information is stored depends on the port(s) associated with a MAC address: If it is associated with the redundant ports (i.e. it is a source address of a DAN), a history is stored allowing duplicate detection. If the MAC address is associated with any other port of the switch, a sequence number is stored which is used when appending the RCT to frames forwarded to a DAN. Note: The history and sequence number memory is automatically updated and managed by the switch hardware. The application usually does not modify the entries. It may however decide to e.g. clear the table or perform modifications during initialization or network reconfiguration scenarios.

Table 29.30 PRP support relevant registers (2 of 2)

Register	Notes
LK_CTRL	The lookup function can be used to automatically learn addresses. This includes automatic detection of DAN and SAN within the redundant networks. Dynamic entries are enhanced to provide a (new) indication that allows if frames are received from a node through one or both of the redundant ports. Alternatively, management can set up the address table if the network configuration is known, or should be controlled by other measures. The management (software) then may choose to disable the global learning and aging functions (LK_CTRL bits 1, 2, 3) and can use the table management registers (LK_ADDR_CTRL) to add and remove addresses as needed. Even if using a static table setup, the entries for DANs and SANs should follow the format of dynamic entries (see Figure 29.16) as it allows the hardware to update the age A/B bits. The LAN A/B bits can be cleared by software and will be set by the switch hardware whenever the corresponding MAC source address is found in a frame received from any of the redundant ports. This method allows implementing a software controlled aging or additional monitoring for e.g. detecting faults within one of the networks connecting to a DAN.

29.4.13 Integrated HUB Module

29.4.13.1 Overview

The switch offers an integrated flexible Hub function. The Hub function emulates functionality similar to an IEEE 802.3 Clause 27 Class 2 repeater connecting multiple half-duplex ports to create a shared network infrastructure.

The basic task of the Hub function is to copy all frames cut through manner between all ports. Only one port can receive at any time and data is always copied to all other ports, allowing for half-duplex operation only. If multiple ports receive simultaneously, a collision occurs resulting in corrupted data.

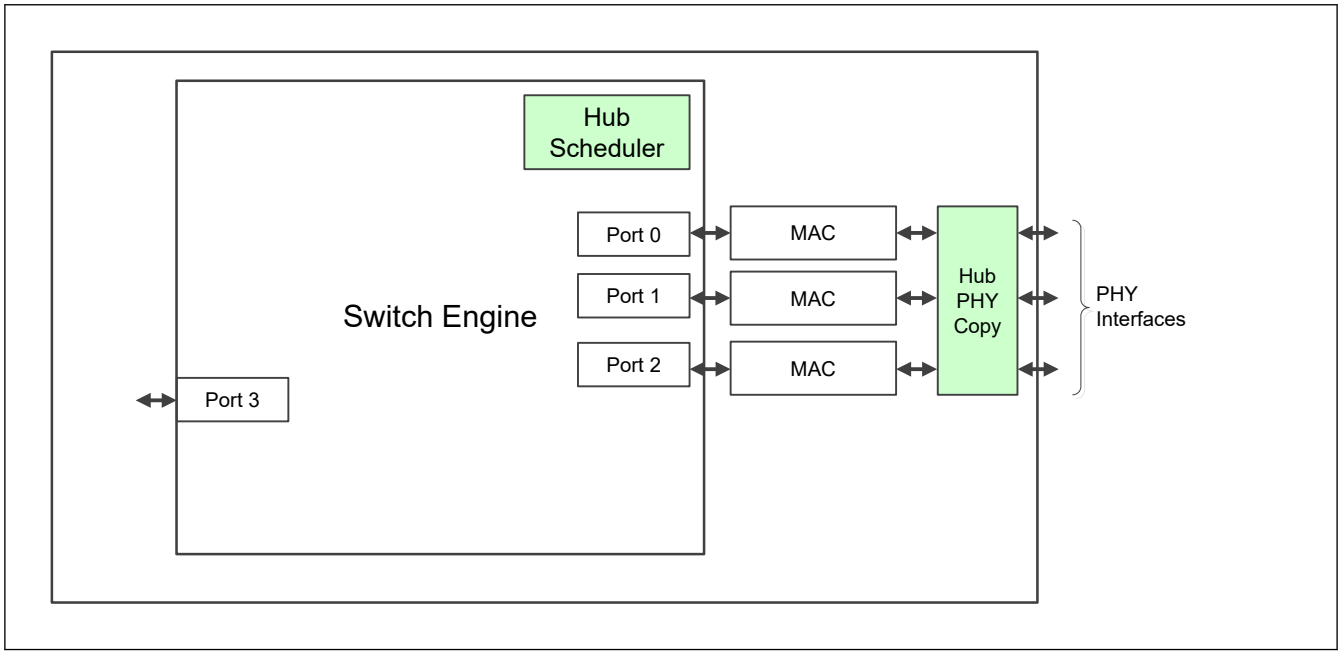

Figure 29.37 Integrated hub function overview

The switch integrated Hub function allows flexible assignment of any line port to create a so-called Hub Group. The Hub Group implements a copying layer inserted between MAC and PHY interfaces with the following functionalities:

- Copying of data in between all ports of the Hub Group at the PHY interfaces.
- Copying of MAC transmit data from a single MAC of the group to all Hub Group PHY interfaces.
- Data received at PHY interfaces is transparently received by the corresponding MAC port (i.e. is not copied to multiple MAC receivers).

Additional switch functionalities available when the hub mode is active are:

- Optional frame retransmission following collisions (when a MAC transmitted).

- Hub scheduler ensuring at all times only one MAC of the Hub group can transmit.
- Additional MAC transmit allowance controllable by application or from received frames (pattern matching).
- Regeneration of the preamble for transmitted frames ensuring that each frame has exactly 7 bytes of preamble plus 1 byte of SFD.

29.4.13.2 Functional Description

The switch can forward (transmit) to the Hub Group with any of the MACs of the Hub Group. When a MAC transmits into the Hub Group, its data is copied to all PHY interfaces of the group. Data received at any of the Hub Group's PHY interfaces is received by the switch through the port's connected MAC layer as normal (i.e. no copying into multiple MAC receivers occurs).

The switch forwarding is modified to allow only one of the Hub Group's MACs to transmit at any time. The MACs of the Hub Group must be configured for half-duplex operation.

(1) Dataflow Example

The following figure shows an example Hub Group configuration consisting of ports 0 and 1.

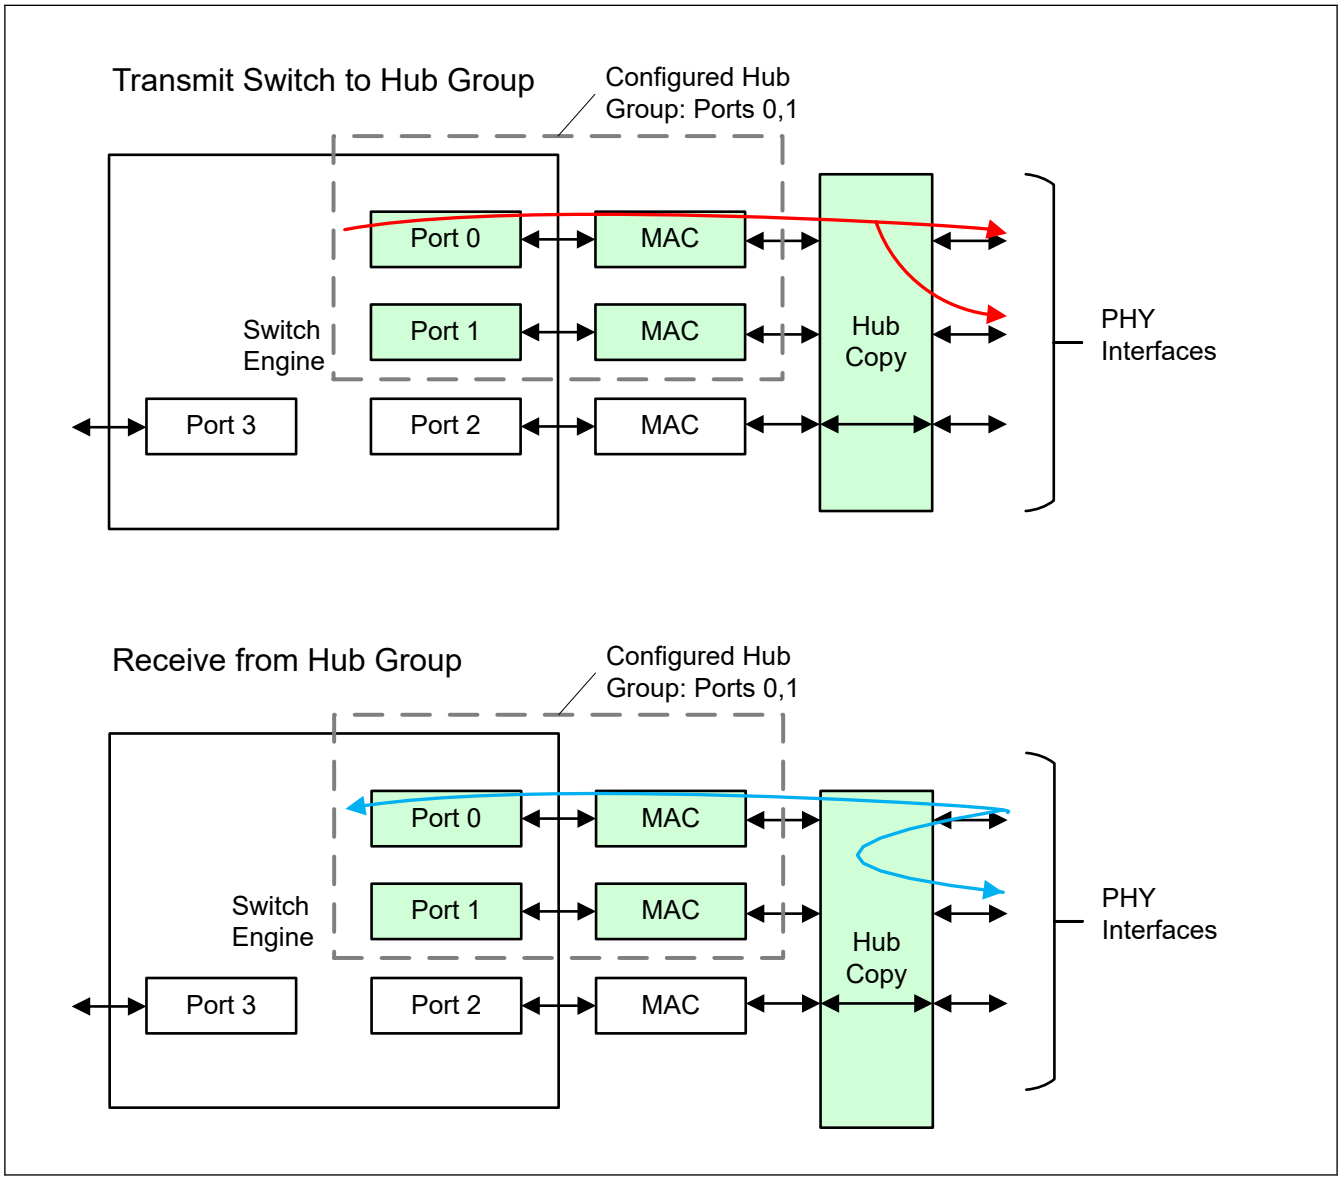

Figure 29.38 Integrated hub copy function examples

(2) Transmit into Hub Group

When a switch port (port 0 in above example) within the Hub Group transmits, its MAC transmit data is copied to all group's PHY interfaces simultaneously. Note that any MAC in the group can transmit independently into the group and be copied to all PHY interfaces. The hub scheduler function within the switch ensures that only one of the output ports can transmit at any time into the group to avoid collisions.

The ports which do not participate in the Hub Group are fully independent. Their PHY interfaces are directly connected to the corresponding MAC, bypassing the copy function, and may operate at different rates.

(3) Hub Group Receive

When a PHY interface within the Hub Group receives data, it is copied to all other PHY interfaces of the group, as well as to the corresponding MAC (i.e. PHY 0 to MAC 0, PHY 1 to MAC 1). The switch forwarding ensures that no frame received at a port of the Hub Group will be forwarded to the other ports of the Hub group to avoid frame duplication (and causing loops).

For learning, it means it will learn a MAC address from incoming frames at the port where it was received (same as normal switch mode). However, forwarding to a MAC learned on any of the Hub ports will still only use the dedicated (configured) Hub Group's default port.

29.4.13.3 Hub Specific Forwarding Rules

The switch forwarding decisions, when the Hub Group exists, needs special consideration for frames that are forwarded between the group and all other ports to avoid frame duplication. As every MAC within the Hub Group will transmit to all PHY interfaces of the group, frames would be sent multiple times if they are stored in multiple switch output ports (e.g. due to flooding or broadcast).

The switch forwarding decisions are modified to send frames always to only one MAC within the hub group (the default group port). When receiving frames from a port of the Hub group, the frame is never forwarded to any other port within the group (as this is already performed by the hub copy).

The following forwarding rules apply when the Hub is enabled:

- If frame received from within the Hub group
  - If isolate mode (HUB_CONFIG.HUB_ISOLATE = 1), set the management port as the only destination.
  - Otherwise, normal destination lookup defines the destination (incl. flooding) and all hub group ports are removed from final destination map.
- If frame received from the management port
  - If destination lookup fails or broadcast or BPDU: allow flooding only to the hub default port.
  - If destination lookup successful and a static entry: forward normally (can use static table entries to have full control to any hub group port, unfiltered!).
  - If destination lookup is successful and a dynamic entry:
    - If destination is a port of the hub group, forward to hub default port only;
    - Otherwise, forward normally (i.e. traffic to non hub ports).
  - Forced forwarding is unrestricted (application is responsible not to send to two ports within hub group).
- If frame received from another port (i.e. non hub group and not from management)
  - If destination lookup resolves non hub only, forward normally.
  - Otherwise, if destination is inside hub group (either from lookup or flooding),
    - If isolate mode: remove all hub group, add management port;
    - Otherwise, remove all hub group, add default hub port only.

The basic concept behind these rules is that all traffic from a port outside the Hub Group is sent only through the output port of a single MAC (the default hub port) into the hub infrastructure. Hence the other port(s) within the Hub group are not used for transmitting by default. They are however fully operable and the switch integrated hub scheduler will ensure that at any time only one of the MACs within the Hub Group will transmit into the hub infrastructure.

Those unused transmit MACs are available for use by the management port (application), which can use either forced forwarding or static address table entries to direct traffic to those ports.

For example, when used in a PowerLink environment, the default port would be used for all asynchronous traffic, while the management port can use the alternate port for all isochronous traffic and the protocol specific frames that require guaranteed response times.

Note: For Powerlink it is better to use one or more queues for isochronous traffic in the same port and to use the TDMA engine to trigger traffic from these queues, or to use the pattern matcher to trigger frames when requested by the controller.

29.4.13.4 HUB Group Clocking

When using Hub mode, set 100 Mbps and Half-duplex mode to CONVCTRLn register. (See section 27.3.5. CONVCTRLn : RGMII/RMII Converter n Control Register (n = 0 to 3)).

The hub copy logic operates in the switch operating clock domain. It is required that all Hub ports generate at least a valid tx_clk at a rate consistent with the port speed (either 100 Mbps or 10 Mbps) even when the link is down. If the clock is disabled, then the port must also be configured to not be in the Hub group. The frame data is first copied over to the switch operating clock domain and there it is replicated to all the other Hub member ports.

29.4.13.5 PHY Requirement

A PHY that should be used with a port that is intended for use within a Hub Group requires the following functionality for proper operation when hub mode is active.

1. The PHY, when operating in half-duplex, must not return transmit data to its receive interface.
2. The carrier sense (CRS) signal must assert for any traffic activity (standard behavior).
3. The PHY must operate in 10 Mbps or 100 Mbps at all times. Especially, when it has no link, it must be avoided that it would fall back to operate at 10 Mbps. A misconfigured speed on a port can prevent the hub from becoming operational hence affecting all ports of the group (see also section 29.3.13.9. HUB_STATUS : HUB Status Register).
4. The PHY must report link-up to the switch via the input ETHSW_PHYLINKn (n = 0 to 2) input pin.

Note that the first two requirements are general requirements for any PHY that is used for half-duplex operation attached to any of the switch ports.

29.4.13.6 Usage Information

- The Hub Group can be enabled at any time, however due to the changing clocking requirements special care on possible reset sequences and PHY initialization may be needed.
- A Hub Group should not use ports used in other grouping modes at the same time (e.g. DLR, PRP grouped ports).
- All ports used within the Hub Group must be configured for 10 Mbps or 100 Mbps and half-duplex operation (COMMAND_CONFIG_Pn).
- A frame transmitted by a port in the Hub Group will regenerate the preamble and SFD, ensuring that exactly 7 bytes of preamble plus one byte of SFD are transmitted with every frame, regardless of the number of preamble bytes on the received frame.

29.4.14 Receive Pattern Matcher

The switch has 12 pattern matchers that can be used to match against fields in the frame to perform override actions on the normal forwarding process.

The pattern matchers support fixed pattern matching and a 2-byte matching at an offset of up to 256-bytes after the frame's source address field. The fixed mode is limited to up to 12 bytes following the frame's source address field.

29.4.14.1 Functional Description

(1) Fixed Pattern Matcher

Every port implements additional receive pattern matchers which allow pattern search within up to 12 bytes following the frame's source address field.

The pattern comparison starts at the 13th byte of a frame and can inspect up to the 24th byte (not considering Preamble/SFD). Hence it covers the length/type field of the frame and up to 10 bytes of payload (see also Figure 29.3 for frame formats). For each byte an individual compare value and bit mask is available to define individual length patterns.

A pattern defines a compare value (see registers PTRN_CMP) and a mask value (see registers PTRN_MSK). The mask value is AND-ed with the frame's data and the result compared with the compare value to determine a match. Hence all bits that should be treated as not relevant must have a 0 in the mask as well as in the compare value itself.

The pattern matchers can be used in combination with the integrated hub module (see section 29.4.13. Integrated HUB Module) to allow triggering a MAC transmission when a specific frame is received. This allows implementation of protocols like e.g. Powerlink where a node's transmission into the network is controlled by receiving specific frames from a central master node.

However its use is not limited to the hub module but can be used for any applications.

(2) Flexible Pattern Matcher

These pattern matchers build on top of the fixed pattern matchers by having an additional mode selection between the following four operating modes:

1. Default 12-byte compare with mask (same as fixed pattern matcher).
2. 2-byte table look-up. Compares a single 2-byte field from the frame at a configurable offset with 8 possible values, with port and queue mask for frame triggering and optional Length/Type matching.
3. 2-byte range compare by using a minimum and maximum range, at a programmable offset, with port and queue mask for frame triggering and optional Length/Type matching.
4. 2-byte inverted range compare by using a minimum and maximum range, at a programmable offset, with port and queue mask for frame triggering and optional Length/Type matching. This is the same as the previous mode but a match is indicated if the range is outside the min/max.

Following Table depicts the utilization of the current compare and mask bits in the new modes. In addition, the following control bits need to be added to the PATTERN_CTRLn register (see section 29.3.15.2. PATTERN_CTRLn : RX Pattern Matcher Function Control for Pattern n (n = 0 to 11)).

- MODE: Selects the operating mode between modes 1, 2, 3, and 4 above.
- HUBTRIGGER: Triggers a frame from the ports enabled in PORTMASK (only one port must be enabled). This generates a transaction to the output memory controller to output a single frame from one of the enabled queues. The queues must be in the closed state for this to have any effect. This trigger goes to the integrated HUB module.
- IMC_TRIGGER: Triggers a frame from the ports indicated in PORTMASK and from the queues indicated by QUEUESEL. A single frame per-port among the selected queues is triggered. This request goes to the memory controller.
- IMC_TRIGGER_DLY: Same as IMC_TRIGGER but the event is delayed by the value programmed in MMCTL_DLY_QTRIGGER_CTRL. This allows a response frame to be delayed by a defined value before being transmitted.
- FORCE_FORWARD: Forwards the frame to the ports enabled in PORTMASK.
- MATCH_RED: Enables the matcher only if in the Profinet IRT RED period.
- MATCH_NOT_RED: Enables the matcher only if not in the Profinet IRT RED period.
- QUEUESEL (4-bit): A queue selector which selects the queue to trigger a frame. Can be set to 0x8 to select all queues.
- TIMER_SEL: Selects a timestamp from the specified timer when TIMER_SEL_OVR is set to 1.
- TIMER_SEL_OVR: Enables overriding the timer selection by TIMER_SEL when set to 1.
- LEARNING_DIS: Disables MAC source address learning when set to 1.
- MATCH_LT: Applicable to modes 2, 3 and 4. Compares the Length/Type field with value in the COMPARE register (See table below: length_type[15:0]). The offset is counted after the Length/Type if it matches.
- VLAN_SKIP: Applicable to modes 2, 3 and 4. When set to 1, the first 2 bytes after the MAC Source Address are compared against 0x8100. If this matches a VLAN tag is assumed and the Length/Type is checked after the tag if enabled. If MATCH_LT is not enabled then 4 bytes are added to the programmed offset to bypass the VLAN tag.

- SWAP_BYTES: Applicable to modes 2, 3 and 4. Control the byte order for comparison: when 0 the first byte received is the least significant byte (index 0), and vice versa when 1.

Table 29.31 Flexible pattern matcher PTRN_CMP and PTRN_MSK functionality

2-byte lookup		2-byte range compare	
Field	**Maps to**	**Field**	**Maps to**
cmp0[15:0]	PTRN_CMP_30[15:0]	min[15:0]	PTRN_CMP_30[15:0]
cmp1[15:0]	PTRN_CMP_30[31:16]	max[15:0]	PTRN_CMP_30[31:16]
cmp2[15:0]	PTRN_CMP_74[15:0]	<unused>	PTRN_CMP_74[15:0]
cmp3[15:0]	PTRN_CMP_74[31:16]	<unused>	PTRN_CMP_74[31:16]
cmp4[15:0]	PTRN_CMP_118[15:0]	<unused>	PTRN_CMP_118[15:0]
cmp5[15:0]	PTRN_CMP_118[31:16]	<unused>	PTRN_CMP_118[31:16]
mask[15:0]	PTRN_MSK_30[15:0]	mask[15:0]	PTRN_MSK_30[15:0]
length_type[15:0]	PTRN_MSK_30[31:16]	length_type[15:0]	PTRN_MSK_30[31:16]
offset[7:0]	PTRN_MSK_74[7:0]	offset[7:0]	PTRN_MSK_74[7:0]
<unused>	PTRN_MSK_74[15:8]	<unused>	PTRN_MSK_74[15:8]
and_mask[15:0]	PTRN_MSK_74[31:16]	and_mask[15:0]	PTRN_MSK_74[31:16]
cmp6[15:0]	PTRN_MSK_118[15:0]	<unused>	PTRN_MSK_118[15:0]
cmp7[15:0]	PTRN_MSK_118[31:16]	<unused>	PTRN_MSK_118[31:16]

The functions of the fields from Table 29.31 are:

- cmp[15:0] – Compare value
- min[15:0], max[15:0] – Minimum and maximum length to compare the 2 bytes at the offset. The match is successful is the value is within the range of min and max for MODE 3, or when not within the range of min and max for MODE 4.
- mask[15:0] – Masks bits set to 0 from the range comparison. Can be used to do a 1-byte range check by setting mask[15:0] to 0x00FF. The logical comparison done by the pattern matcher is:
  range_match = ((frame_2bytes & mask) ≥ min) & ((frame_2bytes & mask) ≤ max)
  When using a mask other than 0xFFFF, the minimum and maximum values must be programmed so the logic expression above yields the intended result.
- length_type[15:0] – Value to compare against the frame's Length/Type when MATCH_LT is set in the config register. If VLAN_SKIP is set and the frame contains a VLAN tag with a Length/Type field of 0x8100, the value in length_type[15:0] is compared against the next Length/Type after the VLAN tag.
- offset[7:0] – Byte offset to do the match after the MAC source address of the frame. If VLAN_SKIP is set and the frame contains a VLAN tag with a Length/Type field of 0x8100, the offset is internally incremented by 4 bytes to skip over the tag. In this case the maximum value valid for offset[7:0] is 251 bytes.
- and_mask[15:0] – Indicates that this pattern matcher matches if its own matching conditions match AND the pattern matchers which have their bits set to 1 in and_mask[15:0] also match. The action performed is that of the pattern matcher with the highest index. For example:
  - if pattern matchers 2 and 3 have both and_mask[15:0] set to 0x0C, then a match occurs only if both pattern matcher's matching conditions succeed, and the action performed is the one programmed for pattern 3.
  - if pattern matcher 3 has and_mask[15:0] set to 0x0C, then a match occurs only if pattern matcher 2 and pattern matcher 3 succeed, and the action of pattern matcher 3 is performed. If only pattern matcher 3 matches, then the match fails. If only pattern matcher 2 matches, then the action of this pattern matcher is performed.

Note: and_mask[15:12] is reserved.

29.4.14.2 Usage Information

- The pattern matcher module is configured with registers shown in section 29.3.15. RX Pattern Matcher Registers.
- Up to 12 patterns are globally available (see registers PTRN_CMP_xx, PTRN_MSK_xx and PATTERN_SEL).

- The executed function if a pattern matches a received frame, is configured with the per pattern control register PATTERN_CTRLn (n = 0 to 11).
- If and which pattern(s) is applied to traffic received at a specific port can be configured individually per port with the port specific RXMATCH_CONFIGn (n = port) register. Multiple patterns can be enabled for a port. When multiple pattern matchers succeed and report a match, the pattern matcher with the highest index is executed (i.e. 0 is the lowest priority pattern matcher and 11 is the highest priority).
- For each pattern an interrupt can be generated when a match occurs. This is globally per pattern, not per port, however still requires that a pattern is enabled at any one port at least. The pattern interrupts are enabled with the module's specific PATTERN_IRQ_CONTROL and PATTERN_IRQ_STAT_ACK registers.
- When using modes 2, 3, or 4 in the flexible pattern matcher the offset can be configured up to 255. However, if memory reservations are enabled then the offset must be limited to less than 82 without VLAN skipping (VLAN_SKIP set to 0), or 78 bytes with VLAN skipping (VLAN_SKIP set to 1).
- When a port is configured as blocked (via register INPUT_LEARN_BLOCK) the pattern matcher results are ignored except for BPDU frames. BPDU frames that are received by the external ports can have their port mask overridden using the pattern matchers. This can be used for instance to redirect MRP TEST frames to be forwarded to the other port when received on a blocked port.
- See section 29.4.22.6. Pattern Matcher Delayed Frame Trigger Delay for details on the delay when using the delayed frame trigger function (IMC_TRIGGER_DLY). This delay should be accounted for when programming the time offset to ensure a more precise event.

29.4.15 TDMA Operation

29.4.15.1 Overview

To support network infrastructures that define a time multiplexed access to reserve bandwidth for different traffic classes, the switch can be configured to operate some or all ports in a TDMA (Time Division Multiple Access) fashion.

Typical usage of such a scheduling is to reserve bandwidth and define times (time slot) for transmitting e.g. real-time or delay sensitive traffic. Other traffic can use the network only at other times. This allows implementation of isochronous (real-time) traffic channels with deterministic delays while sharing the network with other best-effort traffic.

Proper operation of such an infrastructure requires that all nodes and switches connected in the network operate with synchronized clocks (e.g. using IEEE 1588) and agree on the time slot assignments through some network management protocol.

The TDMA scheduler is controlled by a sequence table which determines the sequence of events programmed in a data table, as shown in following figure. A Time Control Vector (TCV) is the combination of a sequence and data vector that generates an event or change in the switch. Multiple sequence entries can refer to the same data entry, allowing for more flexibility in defining the tables sizes.

The TDMA scheduler operates in cycles. The cycle duration is determined by the application and programmed in the register TDMA_CYCLE. When the scheduler is operating the sequence table is read in order up to a maximum programmable entry. Each TCV has an associated offset in the TCV data entry which determines the event execution point relative to the start of the cycle.

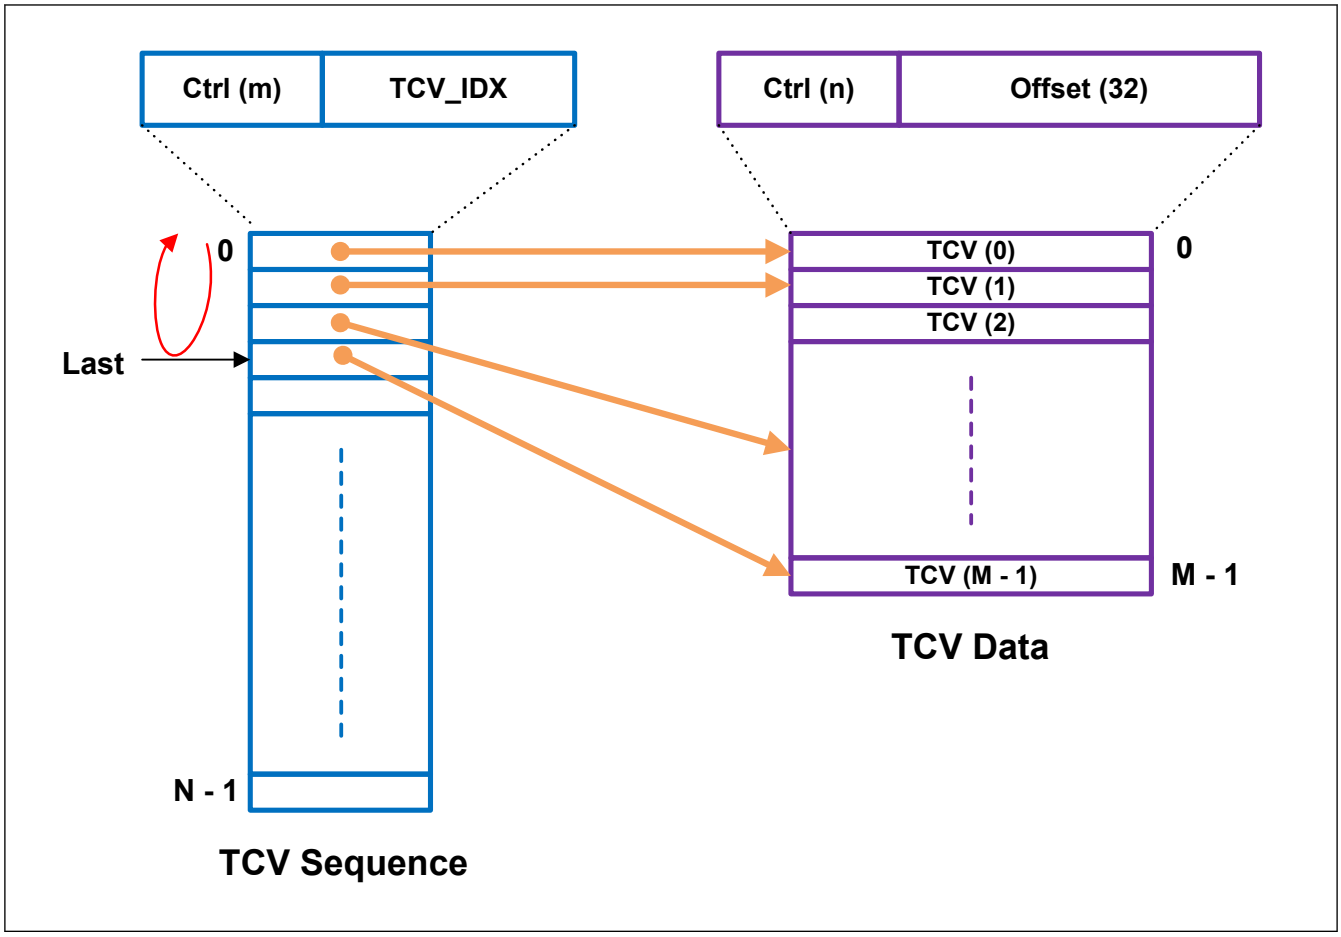

Figure 29.39 TDMA TCV control structure

Following tables below describe the TCV sequence and TCV data fields respectively. The size of TCV Sequence table is 4096 and the size of TCV Data table is 512.

Table 29.32 TDMA timer control vector sequence table

Bits	Field Name (size)	Description
0	START (1)	When set identifies this TCV to be a cycle start vector. The OFFSET in the TCV is taken as the offset after the next cycle starts. The offset value can be zero. This bit should be always set to 1 for entry 0.
1	INT (1)	When set to 1, an interrupt is generated to the CPU when this TCV is executed (after the indicated OFFSET relative to the cycle start).
10:2	TCV_D_IDX (9)	Index in the TCV Data Table. Selects which entry in the TCV data to use for the time offset and control information.
18:11	GPIO	Output value for the output pins ETHSW_TDMAOUTn. The value of these bits is propagated to ETHSW_TDMAOUTn when the vector is executed. The output pin can be configured for level, toggle, or strobe operation with the TDMA_GPIO register.

Table 29.33 TDMA timer control vector data table (1 of 2)

Bits	Field Name (size)	Description
31:0	OFFSET (32)	Time offset from the TDMA Cycle Start. Defines the activation of this TCV as an offset from the current cycle start. The units are nanoseconds (maximum value is ~ 4 ms). A value of 0 can be used to perform back to back operations, limited to the speed at which the TCV sequence and data tables can be read and commands executed. If the TCV sequence table has the START bit set to 1, the activation time is at OFFSET time from the next cycle start.

Table 29.33 TDMA timer control vector data table (2 of 2)

Bits	Field Name (size)	Description
32	INC_CTR0 (1)	Increments counter 0. This counter can be used to keep track of the number of cycles since the start of the TDMA operation. For Profinet, it tracks the SendClock number so it is possible for software to recover the current state after a lock up or software reboot. This may not be needed as the current cycle number can be determined by reading the current absolute time.
33	INC_CTR1 (1)	Increments counter 1. This is a smaller counter that can trigger periodic interrupts. For Profinet it can be used to keep track of the Phase when the Reduction Ratio is greater than 1.
34	RED_PERIOD (1)	Indicates to the ingress RED_GUARD and MAC bridge functions that the RED period is active. This control is passed to the pattern matchers. Set this bit to 0 if period color identification is not required.
35	OUT_CT_ENA (1)	Enables cut-through operation in the output memory read controller. This can be used to disable CT in the YELLOW period and initiate the YELLOW port byte counter. When GATE_MODE and TRIGGER_MODE are both 0 and OUT_CT_ENA is set to 1, the cut-through state for each port is set to the value in PMASK (1: cut-through enabled; 0: cut-through disabled). If GATE_MODE is set to 1 then the cut-through state is changed for the ports selected in PMASK(P) to the value in OUT_CT_ENA. If GATE_MODE is set to 0 and TRIGGER_MODE is set to 1 the cut-through state is not changed. Set this bit to 1 if control on the Cut-Through mode of the switch is not required.
36	IN_CT_ENA (1)	Allows changing the ingress cut-through state in the input frame receiver. The IN_CT_ENA flag is effective when GATE_MODE and TRIGGER_MODE are both 0. When GATE_MODE and TRIGGER_MODE are both 0, and IN_CT_ENA is set to 1, the ingress cut-through state is changed for all ports to the values in PMASK(P), where a 1 enables cut-through, and 0 disables it. Set this bit to 1 if control on the Cut-Through mode of the switch is not required.
37	TRIGGER_MODE (1)	When set to 1, QGATE causes a single-frame transmission between the closed queues selected QGATE on the ports selected by PMASK. GATE_MODE must be set to 0 for trigger operation.
38	GATE_MODE (1)	When set to 1, changes the state of the queues indicated in QGATE for the ports selected by PMASK.
39	HOLD_REQ (1)	When set to 1, a hold request operation (see section 29.4.18.7. MM_CTL.request (hold_req)) can be generated for the ports selected in PMASK. TRIGGER_MODE must be set to 0 for HOLD_REQ to be executed.
47:40	QGATE (8)	Bit mask that controls which queues are gated or triggered in the current time slot. A value of 0 closes (disables) the queue when GATE_MODE is 1. A value of 1 opens (enables) the queue if GATE_MODE is set to 1, or triggers a frame if TRIGGER_MODE is 1 and GATE_MODE is 0. PMASK selects which ports are affected.
50:48	PMASK (3)	Bit mask (one per output port) that controls which ports' queues are gated or triggered, hold request generation and which ports change their CT mode setting. A value of 1 enables the port.

29.4.15.2 Output Queue Scheduling

The main use of the TDMA scheduler is to control the transmission from the output queues. Each TCV can define via a port mask (PMASK) and queue mask (QGATE) which queues in which ports are allowed to transmit in every time slot. Two modes of controlling the queues are supported:

- Queue gating (GATE_MODE set to 1): In this mode the QGATE and PMASK control which queues in the enabled ports are allowed to transmit frames. Among the enabled queues the selected priority algorithm is used to select the next frame.
- Queue triggering (TRIGGER_MODE set to 1): In this mode the QGATE and PMASK control from which queues in the enabled ports a single frame is transmitted. The queue must be in the closed state (gated) and among the selected queues in QGATE a single frame per selected port in PMASK is transmitted.

Note that receive is not restricted in any way when TDMA is active. Frames can arrive completely asynchronously at the switch but will be stored and sorted into timeslots for transmission according to their classification (i.e. priority resolution).

29.4.15.3 Other functions in the TDMA scheduler

Other functions supported in the TDMA scheduler are listed below:

- Interrupt generation: every TCV sequence entry can optionally interrupt the CPU.
- Two hardware counters incremented via TCV control. This allows for a hardware tracking of the current cycle and sub-cycle. Counter 0 is a 32-bit counter which can be initialized by software. Counter 1 is an 8-bit counter, also initialized by hardware, but also capable of generating interrupts on a specific value and with a configurable maximum value.
- RED period indication: This is specific for Profinet IRT. It indicates to the pattern matchers and the MAC IPG calculation logic the current Profinet period color. It can be used however to indicate enable pattern matchers in certain time periods more generically.
- Output Cut-Through enable: Also for Profinet IRT, allows switching from Store-and-Forward in the YELLOW period for the ports enabled in PMASK. This feature requires also that the ports and queues enable the CTFL (Cut-Through Frame Length) function (see section 29.4.16.3. Egress Cut-Through Selection).
- Input Cut-Through enable: Controls the input cut-through enable function. Overrides the default enable for Cut-Through on the receive data path for the ports enabled in PMASK.
- Hold request generation for 802.3br frame preemption (see section 29.4.18.7. MM_CTL.request (hold_req)). This allows generating a hold request to a port with traffic interspersing enabled and operational. The hold request state can be cleared via the TDMA_CONFIG register.
- Second shadow table: To allow atomic for software reconfiguration the TCV sequence table can be split into two logic tables using the register TDMA_TCV_START. The register TDMA_TCV_START indicates the first entry on the TCV sequence table to be executed when a cycle starts (either when the TDMA is first enable, or after the last TCV sequence is executed, as defined by TCV_SEQ_LAST). A second table can thus be created by logically partitioning the TCV sequence and changing TDMA_TCV_START to the start of each table to switch between them. This way a table is effectively "online" while the other table is "offline".
- Gate control for CQF and GPIO pins. See section 29.4.15.7. Gate Control and GPIO Pins.

29.4.15.4 Scheduling Example: Profinet IRT

The following figure shows an example of configuring the TDMA scheduler for Profinet IRT. In this example the switch is defined to have 4 queues, and queues 3 and 2 are reserved for Profinet isochronous traffic (RTC3). Queues 1 and 0 are used for all other traffic. The cycle is divided in three periods: RED where only isochronous traffic is allowed, GREEN where non-isochronous traffic is transmitted in Cut-Through, and a YELLOW period where non-isochronous traffic is transmitted only if the frame can be finished before the start of the next cycle (this is a guard time for the next RED period).

Note: This example does not consider other switch configurations required for Profinet operation.

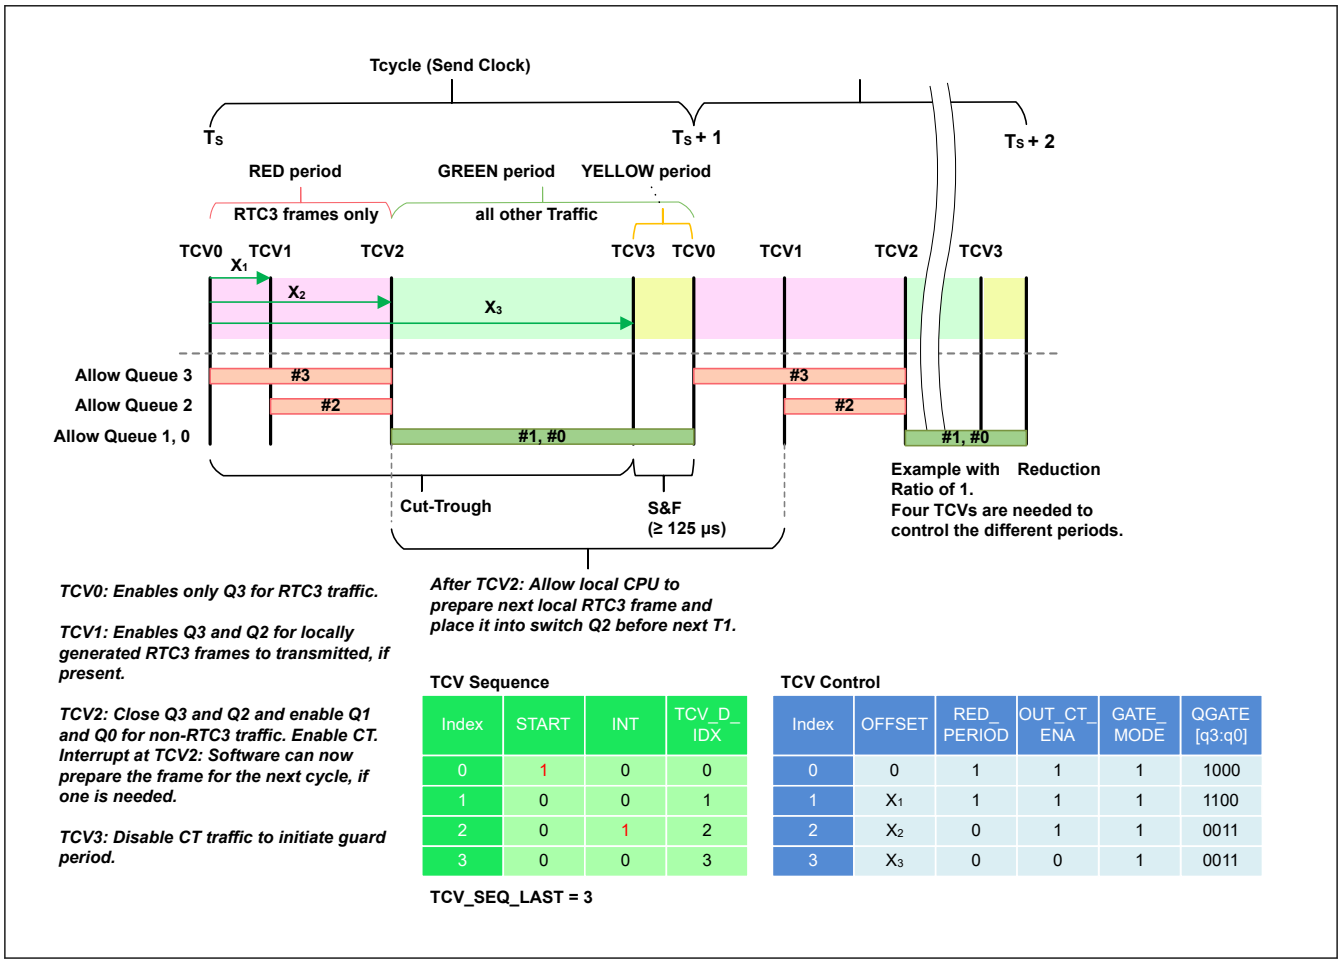
The figure defines a single cycle using 4 TCV. The first TCV enables traffic only from queue 3. The START bit in the TCV sequence entry is set to 1 and the offset in the TCV data entry is programmed to 0 so it is executed on every cycle start.

The second TCV (TCV1) enables a second queue within the RED period. Queues 1 and 0 are kept disabled as this is the isochronous phase. Queue 2 is used in this case to transmit a locally generated frame at a precise time within the RED period. If more frames would need transmission more TCVs can be provisioned for this purpose, and the TRIGGER function can be used to trigger a single frame from one queue instead of enabling the queue.

On TCV2, the third TCV, the GREEN period begins where non-isochronous traffic is generated. The queue gating is inverted (queues 3 and 2 are closed, and queues 1 and 0 are enabled). Also, an interrupt is generated to software to indicate that the traffic from Queue 2 is finished, and more frames can be scheduled if needed.

Finally, TCV3 starts the YELLOW guard period by setting OUT_CT_ENA to 0. Frames here are transmitted from the non-isochronous queues but only if their length is within the remaining of the YELLOW period (MMCTL_YELLOW_BYTE_LENGTH_Pn register in the memory manager configures at the start of this period the number of bytes that can be transmitted).

When TCV3 is executed, TCV0 is read again as the last vector from the sequence table is TCV3. Since TCV0 has the start bit set to 1 the scheduler will wait until the cycle finishes to execute this TCV again.



Index	START	INT	TCV_D_IDX
0	1	0	0
1	0	0	1
2	0	1	2
3	0	0	3

Index	OFFSET	RED_PERIOD	OUT_CT_ENA	GATE_MODE	QGATE [q3:q0]
0	0	1	1	1	1000
1	X_1	1	1	1	1100
2	X_2	0	1	1	0011
3	X_3	0	0	1	0011

Figure 29.40 TDMA scheduling example for Profinet IRT

For more details on the configuration see section 29.3.14. TDMA Scheduler Registers. The initial state of the queues can be configured from the application using the action registers in the management controller (see section 29.4.16.4. Egress Queue Controls, and section 29.3.10.8. MMCTL_QGATE : Queue Gate State Register.

29.4.15.5 Startup Sequence

When the application has determined all information for the cycle and slots to use and the system timer has been locked to some master clock within the network infrastructure (and hence runs precise) it can start the TDMA scheduler.

The hardware timer to use for the scheduler must be selected in TDMA_CONFIG.TIMER_SEL. To start the TDMA scheduler the application defines the absolute time when to begin with the first cycle setting register TDMA_START. It then enables the scheduler writing register TDMA_CONFIG (bit 0 = 1).

Note: The application must ensure to write the TDMA_CONFIG before the value in TDMA_START can be reached by the timer. If it would enable the scheduler after the timer has already passed the start value, the scheduler will wait until the timer wraps around and reaches the value again one full timer period later, which may not be intended.

This will cause the TDMA scheduler to begin its operation as soon as the timer reached the configured start time. While waiting for the first cycle the queues can be enabled or disabled (open or gated) via the register MMCTL_QGATE.

When the first cycle has started, the interrupt occurs if the INT bit is enabled in the corresponding TCV sequence entry (See Table 29.32) and interrupts are also enable (see register TDMA_IRQ_CONTROL).

The TDMA scheduler can be disabled at any time by clearing the TDMA_CONFIG register. This has an immediate effect and will enable all queues in the current state. The queues' states can be checked via register MMCTL_QCLOSED_STATUS_P0_3 and changed using the register MMCTL_QGATE.

If two logic tables are used, a reconfiguration can be done on the table which is offline, and once the reconfiguration is done the tables can be switched by writing the proper TCV sequence entry in TDMA_TCV_START.

29.4.15.6 Usage Information

- The TDMA scheduler is configured through registers given in section 29.3.14. TDMA Scheduler Registers.
- When using the TDMA scheduler, the strict priority selection scheme must be configured (see section 29.3.1.41. IMC_CONFIG : Input Memory Controller Configuration Register). Other schemes are not allowed and may yield unpredictable results.
- The MAC rate limiter for all TDMA enabled ports must be disabled to avoid delaying transmissions unexpectedly (see section 29.3.6.16. IDLE_SLOPE_Pn : Port n MAC Traffic Shaper Bandwidth Control (n = 0 to 3)).
- To classify received traffic into corresponding output queues several methods can be used and combined (see (4) Priority Resolution):
  - Classification based on settings per port with register PRIORITY_CFGn.
  - Define mapping of VLAN priorities per port with register VLAN_PRIORITYn.
  - Using the Pattern Matcher to define priority for a matching frame.

  As classification occurs at frame reception, all ports of the switch must be configured consistently, not only the TDMA enabled ports.
- The transmit MAC has a small buffer to compensate for the latency from the Input Memory Controller (IMC) to the transmit MAC data path. Due to this buffer the time between a queue gating event and the queue actually stopping can be imprecise. The control bit TDMA_PREBUF_DIS in the COMMAND_CONFIG_Pn allows disabling this buffering to increase the precision of the event. However, setting this control bit can cause the minimum IPG on the transmit MAC to be greater than the programmed value in TX_IPG_LENGTH when operating at gigabit speeds.
- See section 29.4.22.5. TDMA Action Delays for details on the delays in the event execution internally and how to correct the time offsets to ensure a more precise operation.

29.4.15.7 Gate Control and GPIO Pins

To monitor the TDMA a set of output pins are provisioned: ETHSW_TDMAOUTn. The number of pins is 8. These pins are controlled via the TCV sequence table (see Table 29.32) in a one to one match (i.e. bit 0 of the TCV.GPIO field controls the output pin ETHSW_TDMAOUT0). The value in the TCV sequence entry is applied when the vector is executed (i.e. at the time programmed in the TCV control vector).

The output pins can be used to monitor the current cycle. For instance in IRT, they can be used to indicate the start of cycle and whether the period is red, green or yellow. The period can be encoded into two bits also and a fourth pin used to indicate the start of the phase (i.e. when the reduction ratio is > 1).

The output behavior of the pin is configured in the register TDMA_GPIO (see section 29.3.14.18. TDMA_GPIO : TDMA GPIO Register). Each pin can be independently configured to operate as:

- Level mode: the output pin changes according to the value in the TCV sequence GPIO field, and holds the value until the next sequence is executed.
- Strobe mode: the output pin changes to 1 if the value in the TCV sequence GPIO field is 1, and holds the value for 16 switch operating clock cycles, and then returns to 0.
- Toggle mode: the output pin toggles its value when the value in the TCV sequence GPIO field is 1, and holds the value until the next TCV sequence with a value of 1 for the GPIO pin is executed.

In the same TDMA_GPIO register the value of the ETHSW_TDMAOUTn (n = 0 to 7) pins can be read.

These pins are also used for Cyclic Queuing and Forwarding (CQF) (see section 29.4.17. Cyclic Queuing and Forwarding (CQF) and Annex T in IEEE 801.Q). When used for CQF the same GPIO pins can be selected via per-port registers in the MMCTL_CQF_CTRL_Pn as the gate control for selecting the ODD/EVEN queue.

29.4.16 Memory Controller

The switch memory is architected as a single unit that is shared among all ports. The memory size is 128 KB. The memory is used as an egress memory buffer for all ports. The memory can store frames of arbitrary size from multiple

sources to multiple destinations (ports). The memory controller offers a set of time-multiplexed write input ports and time-multiplexed output ports with the capability to perform virtual frame duplication on the output ports (multiple reads of a single instance). The memory is partitioned in cells to balance efficiency between administration resources (linked lists pointers) and inefficiencies due to unused space, particularly for small frames.

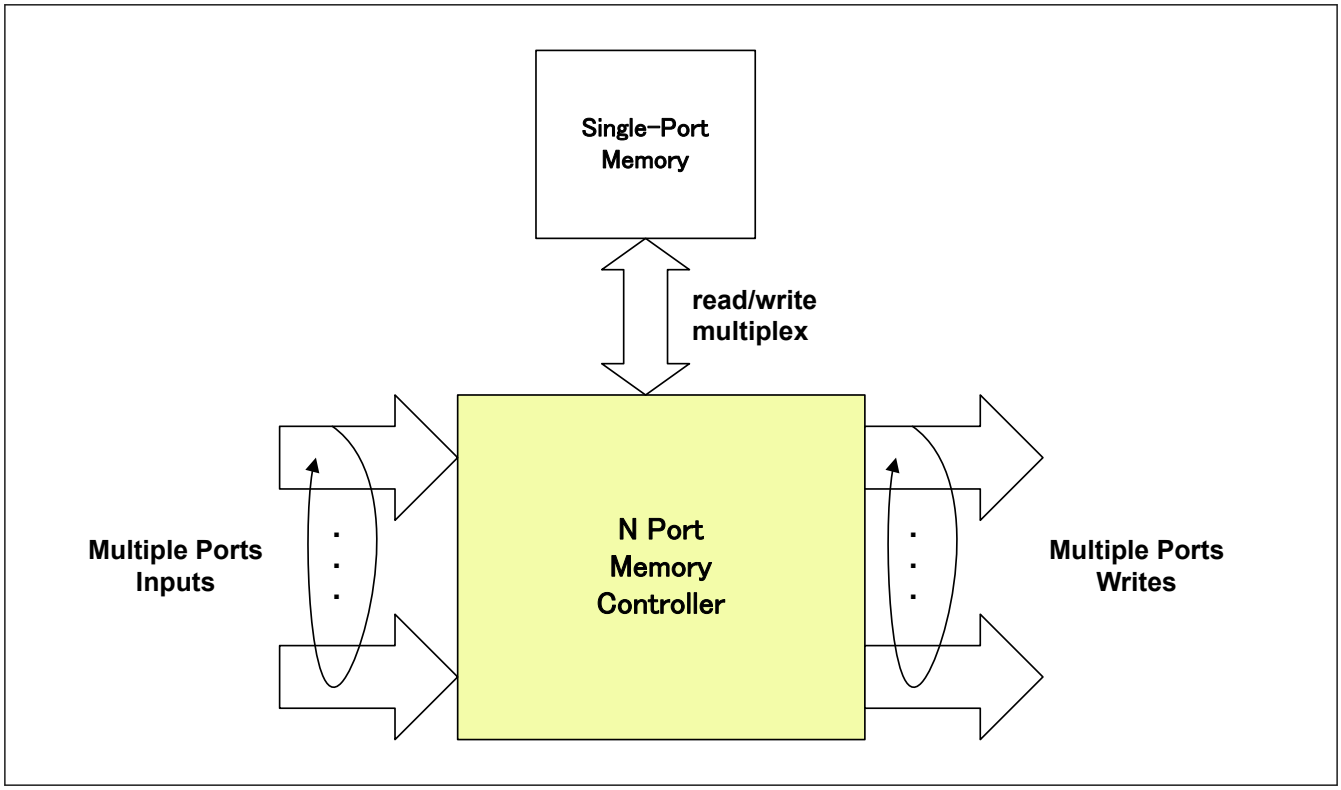


Figure 29.41 Memory controller overview

29.4.16.1 Cells and Output Queues

The complete shared memory is partitioned in 128 byte cells. The total number of cells is 1024. Incoming frames are stored partitioned in 128 byte blocks (cells) within the shared memory. The cell number (cell #) of the first cell of a frame identifies the frame and is passed to the destination queues to be stored in a FIFO to ensure orderly transmission of frames.

Each cell has metadata associated which includes a pointer to another cell (next-cell), number of output queues where the cell is listed (use-count), and whether the cell is the last cell of a frame (end-of-packet) and bytes used in that cell (modulo). As shown in following figure, a frame is tracked via its first cell number in the output queue FIFOs, and successive cells of a frame are linked via the next-cell pointer. The last cell provides end-of-packet indication and modulo information.

Cells can be anywhere within the shared memory, and therefore a single frame must not necessarily be stored in consecutive cells but instead can be scattered over the complete memory at arbitrary cells as shown in following figure.

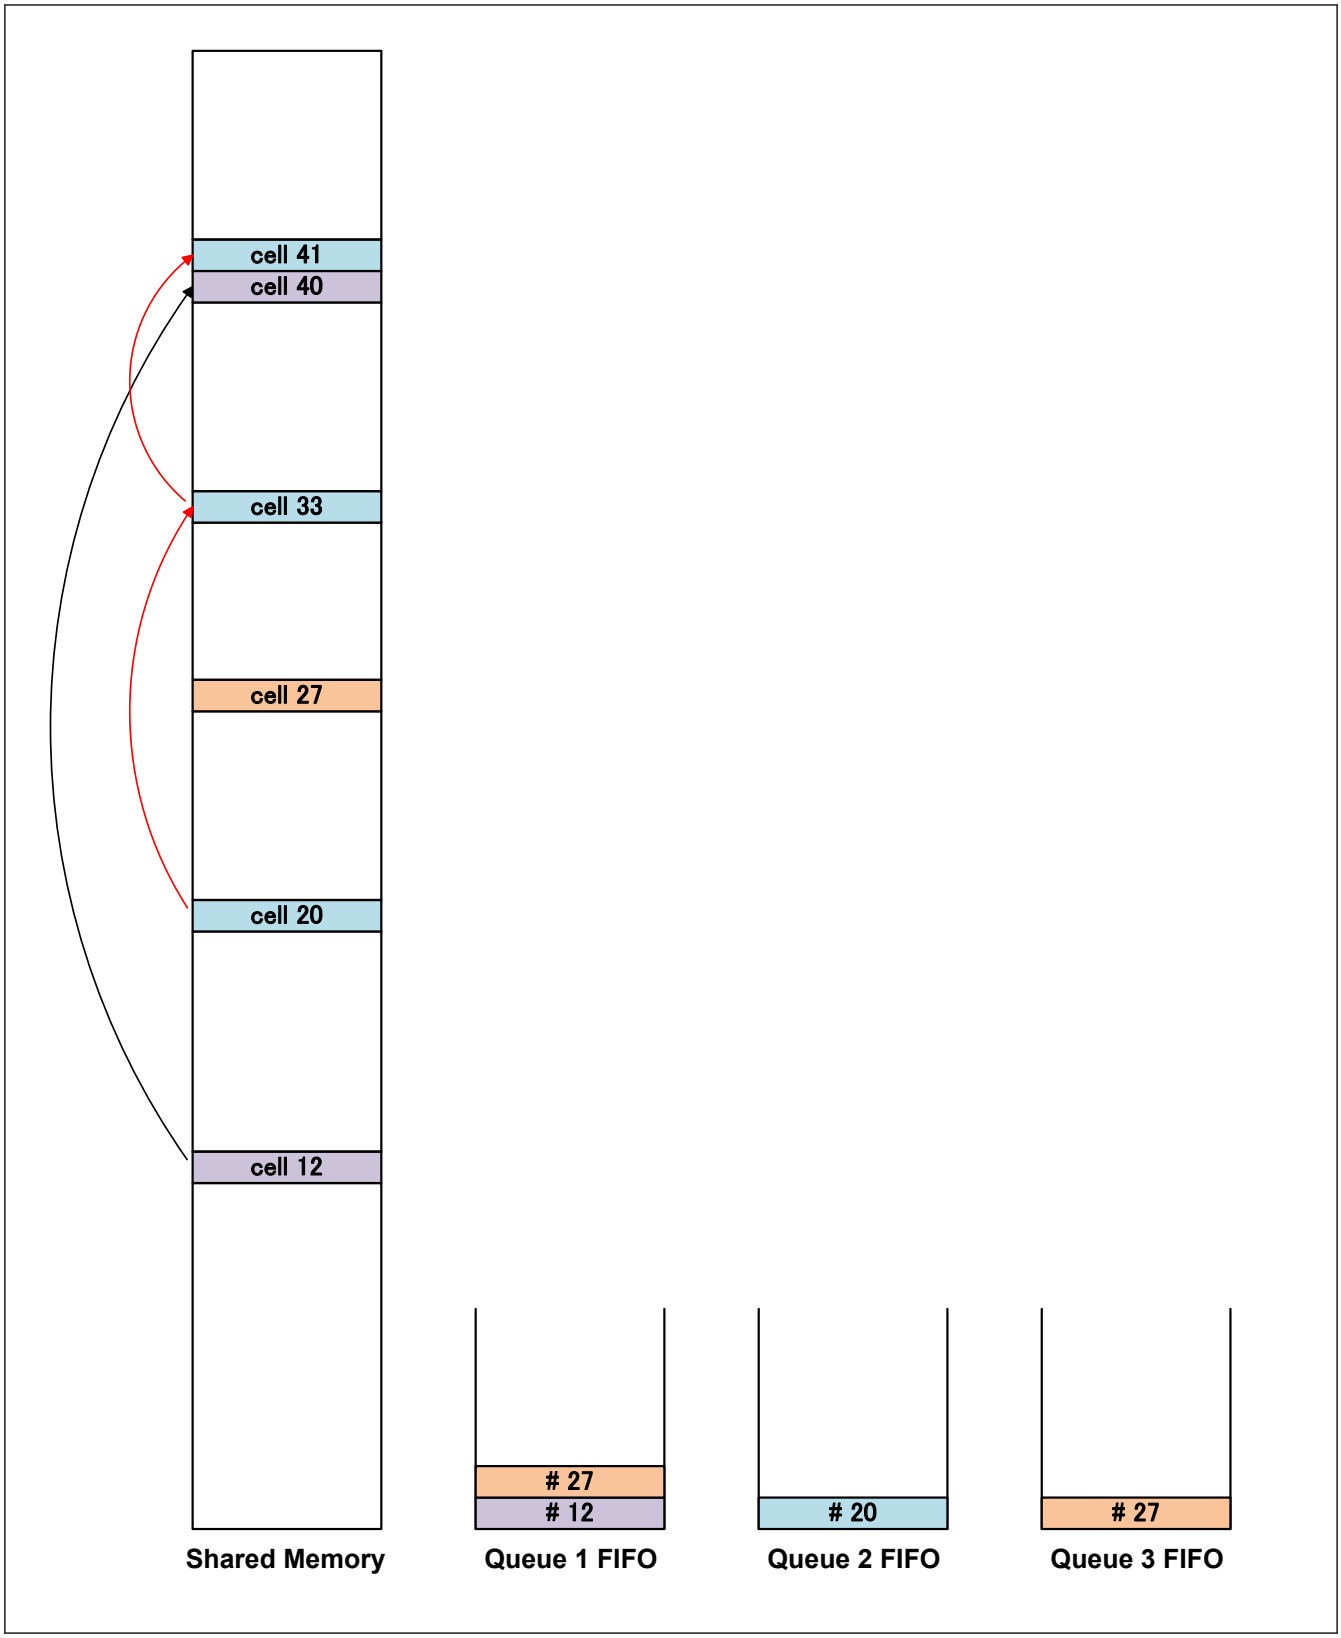

Figure 29.42 Cell storage concept

A central part of the memory controller is the cell allocation and de-allocation functions. When a frame is starting to be received, the allocation module selects a free cell to initiate the storage of the frame from a free-cells tracking FIFO. As each frame has a list of destinations determined by the forwarding function, the cell number of the first cell (which identifies the frame in the system) is stored in each of the output queue FIFOs to where the frame is destined, and the number of queues using the frame is tracked in the use-count. As frames are transmitted by the output ports, the de-allocation function

receives the indication for deallocating the frame from memory. Once the use-count is zero, meaning all ports completed transmission of the frame, the cells used by that frame are returned to the free-cells tracking FIFO for reuse.

29.4.16.2 Memory Reservation

The memory controller is capable of limited memory reservation for guaranteeing that certain traffic classes can have a guaranteed minimum memory portion. This is useful for applications where it is known that some memory reservation is required for the operation of a protocol. One specific example is Profinet IRT where the isochronous traffic requires the use of dedicated queues that must be able to operate during the isochronous phase without interference from non-isochronous traffic.

The memory reservation is achieved by using "pools" of memory cells that are assigned for use on specific queues across all ports. The limitation in the reservation capabilities is that reservations are shared among all ports, but this should be sufficient for applications like Profinet IRT and other forms of isochronous traffic where congestion is not expected.

The memory controller implements to kinds of pools:

- A global shared pool that is used by all queues first if there are cells available.
- Two dedicated pools that can be assigned for use by one or more queues.

The global shared pool allows efficient sharing of a bigger portion of the memory, while the dedicated pools allows for memory guarantees for a traffic class or traffic priority. Each dedicated pool can be assigned to one or more queues, and not all dedicated pools need to be used.

For details on the registers for configuring the memory reservations see section 29.3.10. Memory Controller Extended Registers. The configuration procedure in general can be outlined as follows (after having defined by the particular application the traffic classes requiring memory reservation):

1. Enable memory reservations by writing to RSV_ENA in the register IMC_CONFIG.
2. For each traffic class requiring memory reservations, select one memory pool Pi (i: pool number).
3. In the register MMCTL_POOL_QMAP assign the queues Qi (i: queue number) destined for the traffic class to the memory pool Pi.
4. Program the number of cells reserved in MMCTL_POOLn_CTR, where "n" is the register for configuring pool Pi.
5. Repeat steps 1. through 3. for other traffic classes requiring memory reservations.
6. The remaining memory which is shared among all traffic classes minus one block per input port is programmed in MMCTL_POOL_GLOBAL.

Following figure illustrates the concept of the memory reservation. Each pool is basically a counter for the number of cells utilized. Each counter tracking each pool's utilization is decremented when a cell is requested by the memory writer on allocation, and incremented when a frame is completed and the cells are no longer needed.

Note: It is not possible to reconfigure the memory reservations while the memory is in use.

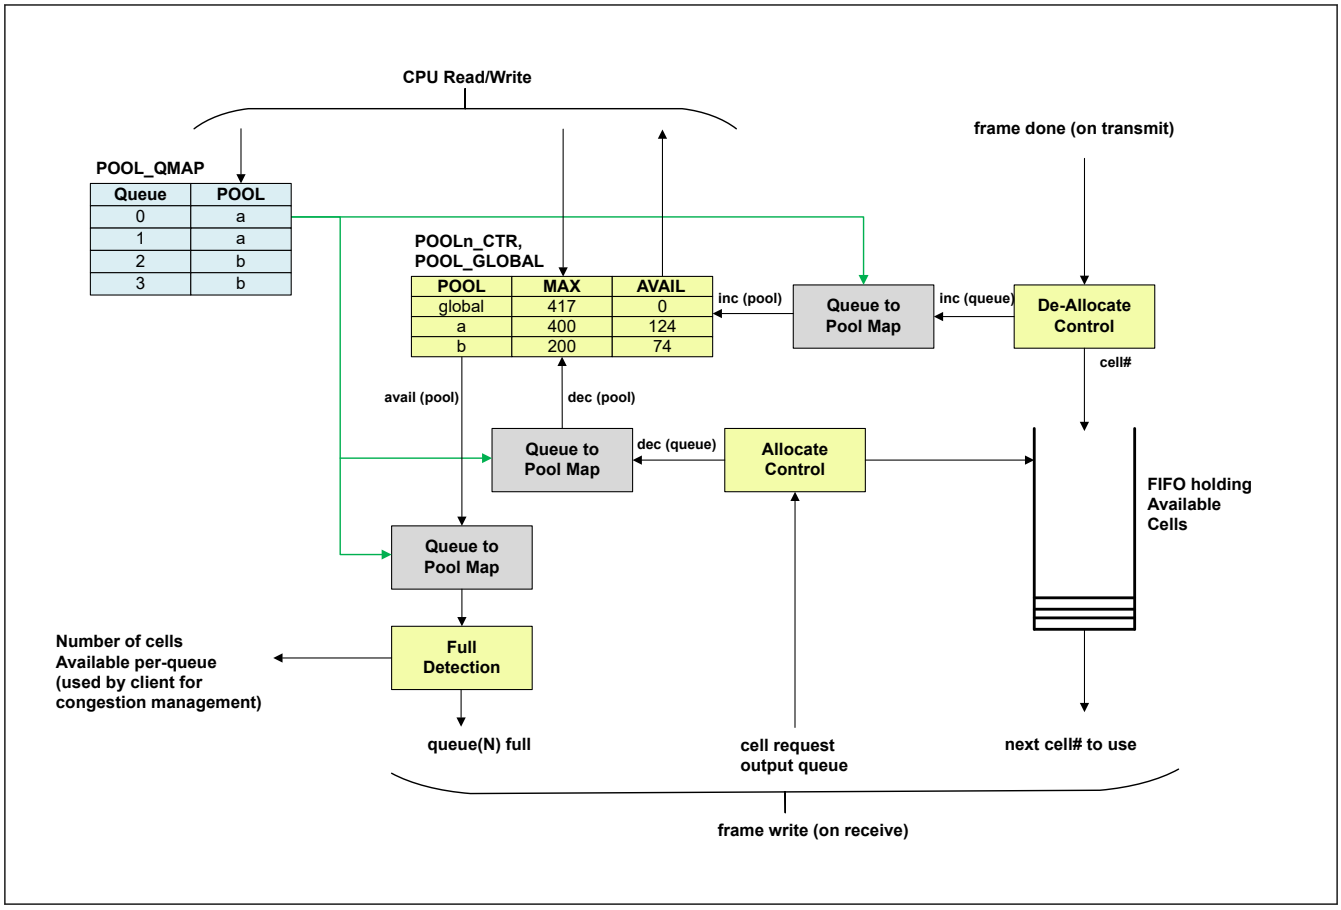

Figure 29.43 Memory reservation functional description

Note: Memory reservations cannot be used if PRP is enabled.

29.4.16.3 Egress Cut-Through Selection

Each port in the switch can be configured for Cut-Through operation which reduces the bridging latency. However, some protocols like Profinet IRT require when switching between non-isochronous to isochronous phases that the non-isochronous phase does not interfere with the isochronous phase, that is, all traffic from the non-isochronous phase must have terminated. A guard-band is then provision sufficiently large to allow a maximum-length frame to be transmitted, and the switch is required to switch into Store-and-Forward mode to ensure that the frame length is known prior to initiating a transmission in this guard-band phase.

The switch between Cut-Through (CT) to Store-and-Forward (SF) can be done at the memory controller when starting a frame transmission by enabling the "Cut-Through Frame Length" (CTFL) feature for the queues which must switch between CT and SF dynamically.

The CTFL feature is enabled via MMCTL_CTFL_P0_3_ENA (see section 29.3.10.2. MMCTL_CTFL_P0_3_ENA : Cut-Through Frame Length Enable Register). Every queue in every port where this feature is required must be enabled via these registers. When enabled a special structure is used for storing the frame length of Cut-Through frames so once the queue is switched into SF mode the frame is held from transmission until the frame length information is known.

The switch between CT and SF can be controlled by the TDMA scheduler (see section 29.4.15.3. Other functions in the TDMA scheduler) or from software via the register MMCTL_OUT_CT (see section 29.3.10.1. MMCTL_OUT_CT : Cut-Through Register).

The CTFL is a limited resource shared between all ports and queue that have it enabled. When a frame is received and there is no space in this table, the switch can be configured to act in either of two ways via the register IMC_CONFIG.CTFL_EMPTY_MD (see section 29.3.1.41. IMC_CONFIG : Input Memory Controller Configuration Register):

1. Receive the frame in the memory as store-and-forward frame (CTFL_EMPTY_MD set to 0).

2. Receive the frame in the memory indicating that the frame length information is not available but still in cut-through mode if the other cut-through requirements are met (CTFL_EMPTY_MD set to 1). In this case the frame may not be transmitted if the YLEN_EN control is set to 1 (see section 29.3.10.3. MMCTL_YELLOW_BYTE_LENGTH_Pn : Port n Yellow Period Byte Length Register (n = 0 to 2)).
   The frame will not be transmitted until CT mode is enabled again (via the TDMA or the register MMCTL_OUT_CT), or the control YLEN_EN is set to 0. Note that a frame in this state will potentially cause a head-of-the-line blocking in the queue, so this mode is only recommended when SF mode is used for short periods (such as with cyclic networks like Profinet IRT).

29.4.16.4 Egress Queue Controls

The memory controller provisions mechanisms to control the state of a queue and its mode of operation. This is useful for protocols like Profinet and Powerlink. The controllability of the queues comes from three sources:

1. From the application via register controls (see section 29.3.10. Memory Controller Extended Registers).
2. From the TDMA scheduler (see section 29.4.15.1. Overview)
3. From the receive pattern matchers (see section 29.4.14. Receive Pattern Matcher)

(1) Queue Gating

A queue gate control allows enabling and disabling (gating) the queue for transmission. While the queue is disabled (gated) the output queue FIFO is not selected for transmission by the queue selection algorithm. Frames can be stored in the queue while the queue is gated.

section 29.4.22.7. Transmit Frame Selection to Frame's FB Delay describes the delay from a queue transitioning from closed to open and the frame transmitted on the MII/GMII interface.

(2) Queue Triggering

Queue triggering allows transmitting a single frame from a group of queues. When a triggering operation is performed, a port and a queue mask are given to the memory controller, and the queue selection algorithm in every selected port will transmit one frame among the indicated queues which are in the gated (disabled) state. This allows for protocols like Powerlink to trigger a frame from an output queue via the pattern matchers when a send request from the controller is received, and Profinet IRT to transmit isochronous RTC3 frames at a deterministic time.

section 29.4.22.7. Transmit Frame Selection to Frame's FB Delay describes the delay from a queue trigger event (queue ready) to the frame transmitted on the MII/GMII interface.

(3) Queue Flushing

Queue flushing allows for flushing the port queues. The basic application is to clear the frames stored in memory under software control, but it can be also be used for implementing special protocols where frames need to be discarded (like PowerLink and Profinet IRT). The following flushing modes are supported:

- Flushing disabled: normal operation when no frame discarding is required.
- Flushing on close: flush the frames queued in the output queue when the queue state transitions from open (enabled) to closed (disabled) until the output queue FIFO is empty, and then flushing is disabled and more frames can be queued up.
- Flushing when closed: flush all the frames in the output queue when the queue state transitions from open (enabled) to closed (disabled) and keeps flushing until the queue state transitions back to open.
- Trigger flush: flushes all frames in the output queue until empty, and then stops flushing, regardless of the queue state.

Whether a queue is flushing frames or not can be read in the registers MMCTL_P0_3_FLUSH_STATUS.

(4) 1-Frame and 1-Frame-Buffer Modes

This mode is static and can only be configured via registers (see section 29.3.10.12. MMCTL_1FRAME_MODE_Pn : Port n 1-Frame Mode Configuration Register (n = 0 to 2)).

The 1-frame mode limits the number of frames queued to 1. If a new frame is received while another frame is still queued, the oldest frame is discarded. Note that a frame may have initiated transmission while a second frame is queued. In this case this second frame is not discarded.

The 1-Frame-Buffer mode also limits the number of frames queued to 1, but on frame transmission the frame is not removed from the queue. If a new frame is received, the old frame is removed from the queue. To use this mode the queue must be in the closed state (disabled, otherwise the frame would be transmitted infinitely). This mode is applicable for instance in implementing Powerlink, where a response can be kept queued at all times so the controller can poll it at any time, and when a newer response is ready, the frame can be sent from software and it will automatically replace the current frame in the egress queue.

29.4.16.5 Cyclic Queuing and Forwarding Configuration

The control register MMCTL_CQF_CTRL_Pn controls per-port the operation of CQF. The configuration is done on a per-egress port to allow configuring only the ports that participate in CQF. For details on CQF refer to section 29.4.17. Cyclic Queuing and Forwarding (CQF).

To enable CQF in an egress port the field PRIO_ENABLE0 must be programmed with a '1' for each of the priorities that will be used for CQF. The priority of a frame is determined as described in section 29.4.3.5. Frame Classification and Priority Resolution. It is recommended that the resolved priority for CQF traffic matches one of the two queues used for CQF, and that the priority for non-CQF traffic is never a priority corresponding to a CQF queue. More than 2 priorities can be enabled for CQF but because all are queued in the same egress queue the transmission order is the order in which they are enqueued, and not their relative priority. It is recommended also to use the two highest-priority queues for CQF to avoid non-CQF traffic to cause interference.

The queues use for CQF are programmed in QUEUE_SEL0. The two CQF queues are always contiguous with the lowest queue number programmed in QUEUE_SEL0.

The control or gating signal for determining which is the buffering queue is selected via GATE_SEL0, and each port and CQF group can use a different gate signal. Moreover, the control bit REF_SEL0 configures whether the gate signal used is the value in GATE_SEL0 for the egress port(s) or for the ingress port. These signals are generated by TDMA scheduler, which can produce up to 8 independent signals. And these are the same source for the output pins ETHSW_TDMAOUTn (n = 0 to 7). For CQF the gate signal must be a level indication (i.e. not strobing) and be kept stable for the duration of the CQF cycle. For details on configuring the TDMA refer to section 29.4.15. TDMA Operation.

Finally, the queuing function can be configured to select the buffering queue with the start of frame or with the end of frame via USE_SOP0. The end of frame is the default behavior and the one specified in 802.1Q. The start of frame is allowed for flexibility, but it should not be used for standard operation.

29.4.17 Cyclic Queuing and Forwarding (CQF)

CQF is described in Annex T of the IEEE 802.1Q-2018 specification. CQF is intended to allow delivery of time-sensitive traffic in a deterministic latency that is dependent only on the number of hops through the network. To remove the hop-to-hop latency and switching delay, each intermediate device is required to buffer the frames received in a time period, while transmitting frames that were received the period before. This results in a hop-to-hop latency equal to one cycle if the network and switch delay allows for the frames to be fully transmitted and received within the time period.

CQF is implemented by selecting two egress queues as CQF queues and alternating their state between "buffering" and "transmitting" as shown in the figure below. This figure shows a simple example where two queues in an egress port alternate between these two states in periodic cycles named EVEN and ODD. Frames received during the EVEN cycle indicated by the control signal (called gate signal as well) being "low" are not transmitted immediately and queued up in Queue A, while frames received during the ODD cycle indicated by the control signal being "high" are queued up in Queue B. When a queue is in the "transmitting" state the frames which were received during the previous cycle are now transmitted in the order they were received (and not their original priority).

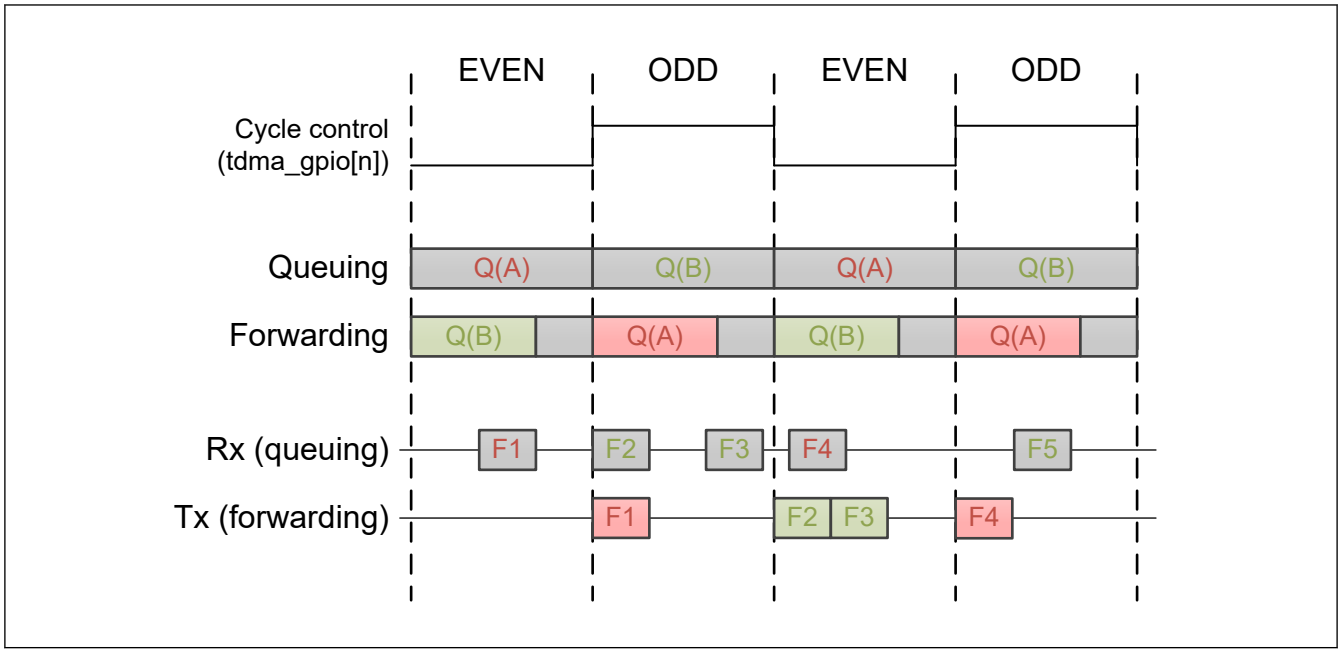

Figure 29.44 Cyclic queuing and forwarding (CQF) using 2 egress queues

To use the switch with CQF the process can be viewed as two separate functions: queueing and forwarding. Queuing determines based on the current cycle, frame priority and register configuration in which queue the frame will be placed, while forwarding controls which queue is allowed to transmit during each cycle. The figure below shows a functional diagram where the two functions are depicted, description of each function follows in the sections below.

The configuration for CQF is mostly configured via the register MMCTL_CQF_CTRL_Pn. Both functions are controlled by the TDMA scheduler which generates the control signal (ETHSW_TDMAOUT) that determines which CQF queue is used in each cycle, and the open/close queue controls to select the queue that is in the forwarding state (see section 29.4.15. TDMA Operation for details on the TDMA operation). section 29.4.17.3. CQF Configuration Example shows a brief example where the switch is configured for CQF.

CQF also requires that the priority resolution is configured so time-sensitive traffic is mapped to the CQF queues, and prevent other traffic from being queued into the CQF queues.

CQF time-sensitive traffic can coexist with non-CQF best-effort traffic. To ensure timely forwarding of the time-sensitive traffic CQF must be configured to use the highest priority queues to ensure timely forwarding of these frames in the corresponding time period.

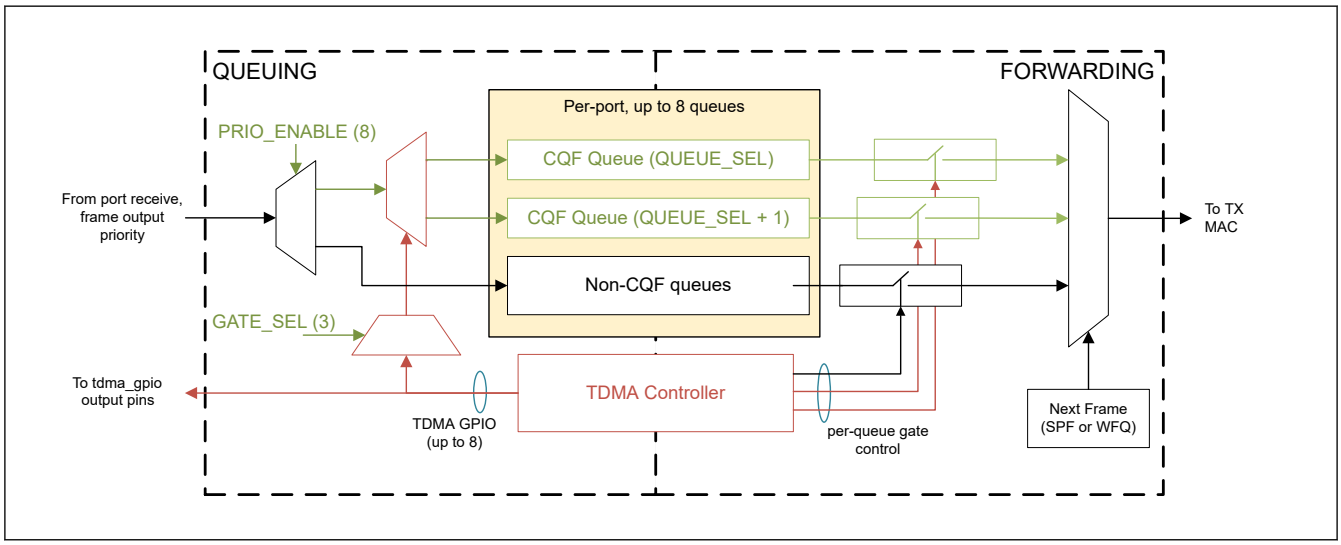

Figure 29.45 Cyclic queuing and forwarding functional diagram

29.4.17.1 Frame Queuing Function

The frame queueing function is based on the resolved priority in the frame receive data-path (section 29.4.3.5. Frame Classification and Priority Resolution). The resolved priority is the result of port configuration, the frame's VLAN priority, the DSCP if present, and it can also be modified via the pattern matchers or by the management port specific tag when the frame is sourced by the local CPU.

In normal operation when CQF is disabled the priority is used directly to select the egress queue for the frame. Enabling CQF via MMCTL_CQF_CTRL_Pn.PRIO_ENABLE0 causes that the frames matching the enabled priorities to be queued in the CQF queues selected via MMCTL_CQF_CTRL_Pn.QUEUE_SEL0, while frames whose priorities are not enabled for CQF are queued in the directly corresponding egress queue.

Note: It is important then to be aware that the hardware provides no protection when the CQF queues match priorities that are not enabled for CQF in MMCTL_CQF_CTRL_Pn.PRIO_ENABLE0. If a frame is received in such priority it will be queued in the corresponding queue.

The CQF queue to use is determined by the selected control signal from the TDMA scheduler (ETHSW_TDMAOUT) via MMCTL_CQF_CTRL_Pn.GATE_SEL0. The programming of the TDMA must ensure that the selected signal is periodic and does not wiggle during the cycle. This can be achieved by programming the signal to operate in either level or toggle modes (details in section 29.4.15.7. Gate Control and GPIO Pins). When the control signal is "low", the CQF queue used is MMCTL_CQF_CTRL_Pn.QUEUE_SEL0, and when "high" frames are queued into QUEUE_SELx + 1. The control MMCTL_CQF_CTRL_Pn.REF_SEL0 controls for each ingress port whether the gate signal used is the one programmed for the egress port(s) or for the ingress port.

To synchronize the CPU the TDMA scheduler the interrupts from the TDMA scheduler can be used to wait for a cycle to being. The state of the gate signals can then be read from the TDMA_GPIO register.

29.4.17.2 Frame Forwarding

Frame forwarding for CQF is controlled also by the TDMA scheduler using the queue gating function to open and close the CQF queues in an alternating fashion such that the buffering queue is in a closed state and the forwarding queue is in an open state as shown in the table below. This is decoupled from the queueing function to provide more flexibility in case guard bands need to be added.

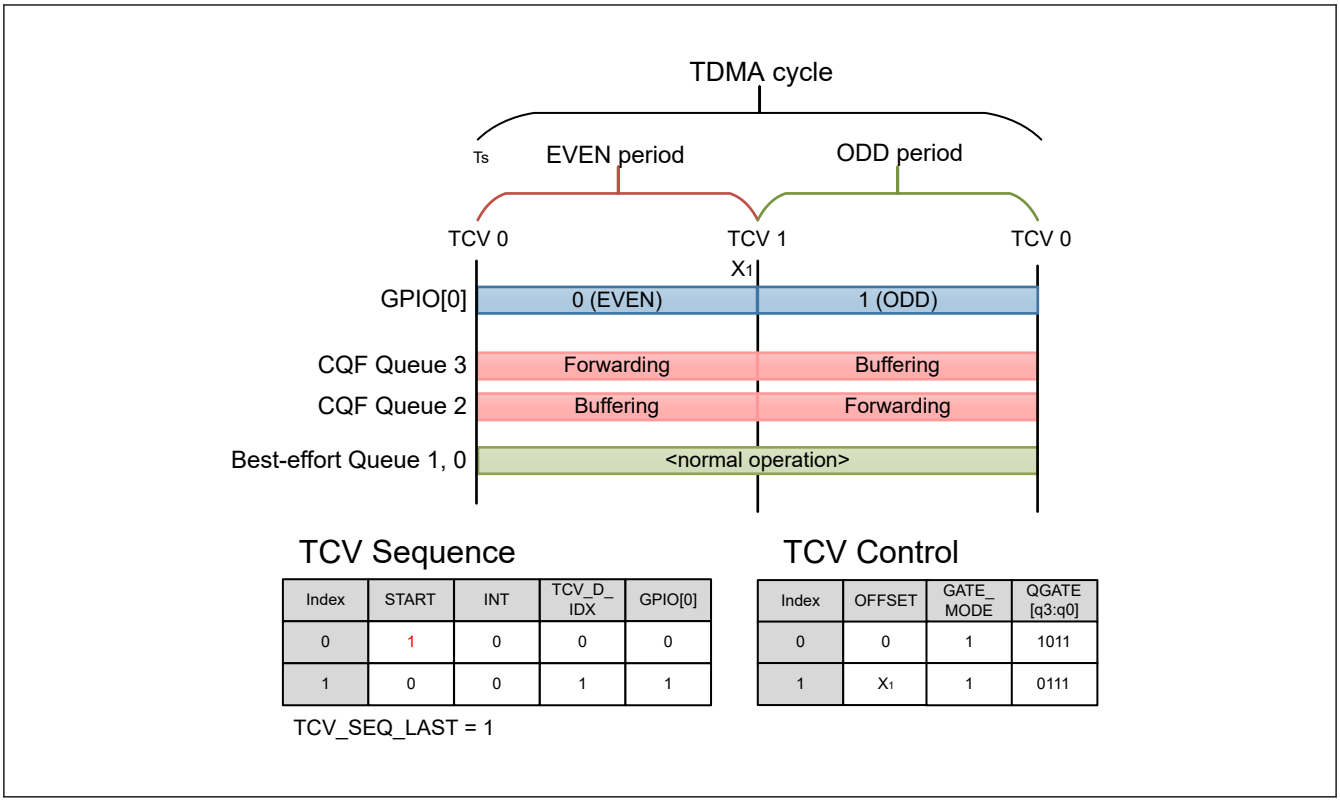
Table 29.34 Queue state programming for CQF

Cycle	CQF Queue A	Queue A State	CQF Queue B	Queue B State
EVEN	Buffering	Closed	Forwarding	Open
ODD	Forwarding	Open	Buffering	Closed

For a proper operation, all traffic received in a cycle must be forwarded in the following cycle such that by the end of the cycle the CQF queue is empty. It is the job of the firmware to configure the TDMA scheduler appropriately and provide enough margins to ensure this. For debugging, the register MMCTL_P0_3_QCLOSED_NONEMPTY can be used to monitor when a queue is closed with frames still in the queue.

29.4.17.3 CQF Configuration Example

The following example illustrates the use of the TDMA scheduler to configure the switch for CQF. The example uses 4 egress queues for frame queueing per port in total and uses only ports 0 and 1 for CQF. Queues 3 and 2 are configured as CQF queues, and queues 1 and 0 are used for best-effort traffic. The figure below show the queue states in both CQF cycles. The best-effort queues are always enabled since the CQF queues are of higher priority, so they are always given precedence over best-effort queues.



Index	START	INT	TCV_D_IDX	GPIO[0]
0	1	0	0	0
1	0	0	1	1

Index	OFFSET	GATE_MODE	QGATE [q3:q0]
0	0	1	1011
1	X1	1	0111

Figure 29.46 CQF configuration example

(1) Priority Classification

The switch must be properly configured to resolve the egress priority of the received frames into the enabled egress queues. To ease the configuration, the priority resolves to queues 0 or 1 for best effort traffic, and queues 3 and 4 for CQF traffic. See section 29.4.3.5. Frame Classification and Priority Resolution for details on frame priority resolution.

Table 29.35 CQF configuration example – Priority resolution

Register	Value	Description
VLAN_PRIORITYn (n = 0 to 3)	o33221100 (octal)	Remap VLAN priorities into the 4 egress queues. Both ports are configured the same.
IP_PRIORITYn (n = 0 to 3)	Map all to queue 0-3	Ensure all possibly used IP TOS/COS field mappings are cleared. If TOS/COS field priorities should be used, the application must ensure they map only to queues 0-3.
PRIORITY_CFGn (n = 0 to 3)	0x01	Enable VLAN priority resolution (bit 0) to respect above VLAN_PRIORITY. Also set the default priority to 0 to avoid interference with CQF traffic. If required by the application it may choose to also enable other additional priority resolutions here ensuring they only map into queues 0-3.

(2) TDMA Scheduler

The TDMA scheduler needs to be configured to toggle the ETHSW_TDMAOUT[0] signal as shown in Figure 29.46 and to open and close queues 2 and 3 to match the forwarding state in the same figure. For the configuration example a cycle time of 4 ms is assumed.

Table 29.36 CQF configuration example TDMA scheduler (1 of 2)

Register	Value	Description
TDMA_CONFIG	0x04, 0x05	TDMA scheduler enable (bit 0 = 1) and timer selection (bit 2 = 1). This register must be written last after all other configuration registers are set correctly.
TDMA_ENA_CTRL	0x3	Indicate that ports 0 and 1 will use the TDMA functions and that the memory controller shall not do any frame prefetching.
TDMA_START	40,000,000	Set a time value of 40 ms for the start (this is arbitrarily chosen here).

Table 29.36 CQF configuration example TDMA scheduler (2 of 2)

Register	Value	Description
TDMA_MODULO	1,000,000,000	Set timer modulo of 1 second. Assumes the local system's timer wraps around every 1 second.
TDMA_CYCLE	8,000,000	Set the cycle time to 8 ms, which is twice the CQF cycle time
TCV_SEQ_LAST	0x1	Last entry in the TCV sequence table. As shown in Figure 29.46, only two entries are used.
TDMA_GPIO	0x0	Configure the GPIO signals to operate in level mode. Here only gpio[0] is used, so the other signals can be configured as required.

Table 29.37 CQF configuration example – TCV sequence

Entry	TCV_SEQ_CTRL	Notes
0	0x00000001	START (bit 0) = 1 INT (bit 1) = 0 TCV_D_IDX (bits [10:2]) = 0x000 GPIO[0] = 0 Set the START bit to 1 so this TCV is executed when a new cycle starts. GPIO[0] is set to 0 here. This is the first CQF cycle.
1	0x00400004	START (bit 0) = 0 INT (bit 1) = 0 TCV_D_IDX (bits [10:2]) = 0x001 GPIO[0] = 1 Second CQF cycle. Toggle GPIO[0].

Table 29.38 CQF configuration example – TCV Data

Entry TCV_D_ADDR	TCV_D_OFFSET[i]	TCV_D_CTRL[i]	Notes
0	0	0x00030B58	INC_CTR0 = 0 INC_CTR1 = 0 RED_PERIOD = 0 OUT_CT_ENA = 1 IN_CT_ENA = 1 TRIGGER_MODE = 0 GATE_MODE = 1 HOLD_REQ = 0 QGATE = 0xB PMASK = 0x3 Set queue 2 in closed state as it is buffering, and queue 3 in open state as it is forwarding
1	4,000,000	0x00030758	INC_CTR0 = 0 INC_CTR1 = 0 RED_PERIOD = 0 OUT_CT_ENA = 1 IN_CT_ENA = 1 TRIGGER_MODE = 0 GATE_MODE = 1 HOLD_REQ = 0 QGATE = 0x7 PMASK = 0x3 Set queue 2 in open state as it is forwarding, and queue 3 in closed state as it is buffering. This TCV is executed 4 ms after the TDMA cycle start.

(3) Memory Controller

The register MMCTL_CQF_CTRL_Pn configures per-port the queues and control signal to be used. Ports 0 and 1 are used for CQF with priorities 2 and 3 being used for time-sensitive traffic, and queues 1 and 0 for best-effort traffic. The following table shows the configuration for this example for ports 0 and 1. Other ports keep this register programmed to 0x0 to disable CQF.

Table 29.39 CQF configuration example – MMCTL_CQF_CTRL_Pn

Register	Value	Description
MMCTL_CQF_CTRL_P0	0x0000020C	Set priorities 2 and 3 for CQF in PRIO_ENABLE0. Program queue 2 to be the CQF base queue in QUEUE_SEL0. Select ETHSW_TDMAOUT[0] for selecting the buffering queue in GATE_SEL0.
MMCTL_CQF_CTRL_P1	0x0000020C	Set priorities 2 and 3 for CQF in PRIO_ENABLE0. Program queue 2 to be the CQF base queue in QUEUE_SEL0. Select ETHSW_TDMAOUT[0] for selecting the buffering queue in GATE_SEL0.

29.4.17.4 Additional Usage Notes

- When egress queues are enabled for CQF, these queues will have cut-through disabled. Frames are not allowed for transmission until the full frame is received. If a received frame results in the frame to be sent to a CQF queue in port A and a non-CQF queue in port B, for port B the frame can be transmitted in cut-through mode if possible.
- A frame received on a port that is time-sensitive can be forwarded to another port with CQF enabled and to a port without CQF (for instance, a copy to the local CPU). For the non-CQF enabled port the egress queue used is the priority indicated by the priority resolution process, while the CQF port will store the frame in the queue indicated by QUEUE_SEL0 and the state of ETHSW_TDMAOUT. This means that a frame can be queued up in different queues in each port. This is not a problem except when memory pools are enabled in any of the involved CQF queues. To ensure proper operation of memory reservations in this scenario, the priority resolution must be configured so all time-sensitive traffic intended for CQF has the same priority as the two CQF queues, and the memory pool must include both CQF queues.
- To implement something like traffic interleaving as described in T.5.2 of IEEE 802.1Q, the queueing function must be based on the ingress port. This is achieved by setting REF_SEL0 to 1 so the gate control signal is based on the input port. The forwarding function is independent of the gating signal and it is simply implemented by opening and closing the queues using the TDMA scheduler of each port independently.
- Guard-bands can be provided by using additional TCVs to shift the toggling of the ETHSW_TDMAOUT signals and queues closing and opening. These guard-bands can delay the switch of queues for a port to compensate for switch-to-switch delays.
- Traffic interspersing can be enabled in the best-effort queues. This reduces the interference caused by best-effort traffic when transitioning between CQF periods.
- The switch provides two flooding masks that can be used to prevent traffic from ports not participating in CQF to transmit into the CQF ports. If these ports need to generate traffic into the CQF ports care must be taken in the programming of the priority resolution so none of the frames forwarded into the CQF ports matches the CQF priorities.

29.4.18 IEEE 802.3br Traffic Interspersing

29.4.18.1 Overview

The switch supports traffic interspersing as defined by the IEEE 80.3br specification. The goal is to reduce the latency to the medium for latency-critical traffic (referred to as express traffic) on transmission by interrupting any best-effort frame (referred to as preemptable traffic) that is being transmitted.

Each port's next-frame selection controller monitors the availability of traffic in the up to 8 egress queues. These queues are configured via a control register into preemptable queues (low priority queues) and express queues (high priority queues). The controller then gives priority to the express queues over the preemptable queues, which is no different than using regular strict-priority arbitration. However, when traffic interspersing and preemption is enabled and operational, the controller can interrupt an active frame from a preemptable queue as needed to prioritize express frames. The controller will use strict-priority or weighted round-robin arbitration amongst the preemptable and express-defined queues but note that express queues have priority over preemptable queues regardless of its queue number.

The diagram in the figure below illustrates traffic transmission without interspersing. Two queues are represented with queued frames at different points, with each bar representing the frame transmission length and the additional queuing time as a shaded area. In this scenario the next-frame selection controller uses strict priority arbitration to select the next frame to be transmitted. The time it takes for high priority frames to be transmitted is greatly affected by the transmission time of lower priority frames that get selected when there are no high priority frames in the queue.

When traffic interspersing and frame preemption is enabled, the high priority traffic can access the media much faster as seen in Figure 29.48. The next-frame controller will preempt a preemptable frame when another express frame appears ready for transmission. The queueing times, and therefore the latency of the high priority frames is greatly reduced, as well as the jitter of such latency. The side effects are of course that the low priority traffic takes longer in being transmitted, and the link utilization goes slightly down as the low priority frames are divided in ethernet segments which must be each individually framed for transmission (IPG, preamble, SFD and FCS for each segment).

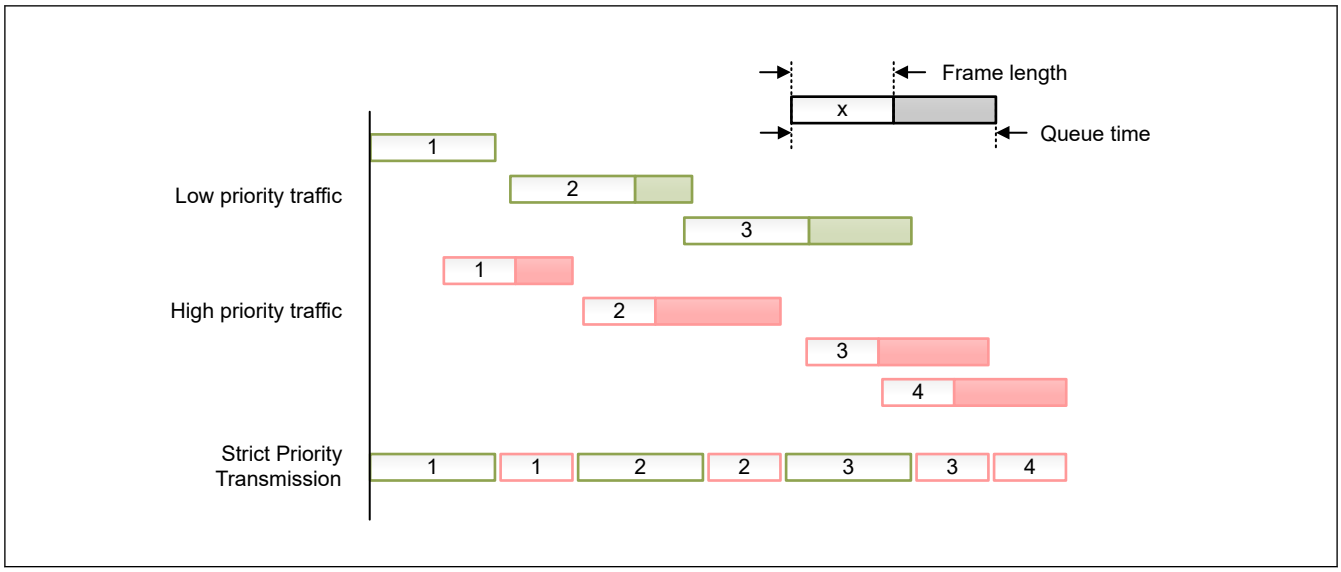


Figure 29.47 Transmission without traffic interspersing

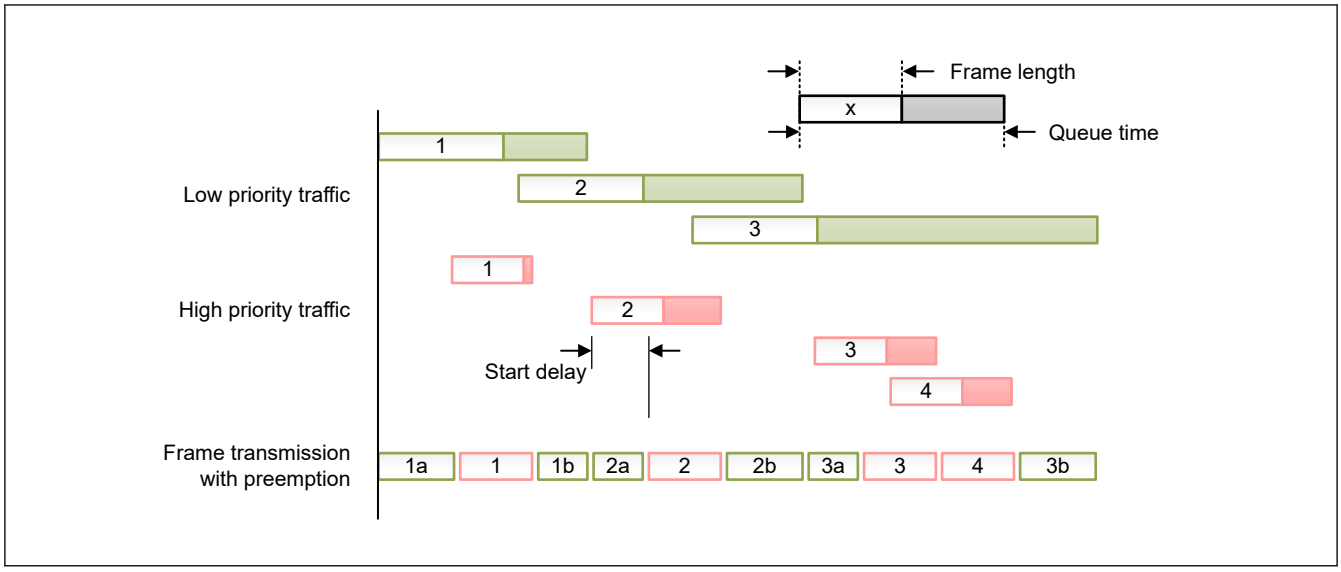

Figure 29.48 Transmission with traffic interspersing and frame preemption

On receive the traffic interspersing function performs the reassembly of preemptable frames. Once reassembled these frames are no different from express frames and they follow the standard forwarding process. One exception however is that reassembled frames are never forwarded in cut-through mode as a preemption event would cause an underrun. Express frames on the other hand have no special treatment as they are indistinct from normal Ethernet frames and can be forwarded cut-through if it is enabled.

The MAC also generates and receives response and verify frames to validate that both ports support preemption, as required by the IEEE 802.3br. This however can be overridden, and preemption can be forced to operate without this verification process.

Preemptable traffic can be stopped and preempted to allow an external agent application to generate an idle window for express traffic. This causes the transmission of preemptable traffic to stop even if there is no express traffic queued. This

action can be performed by the TDMA controller to allow periodic windows of express-only traffic, and from control registers to allow for direct control from the firmware.

29.4.18.2 Operation with Traffic Preemption Disabled (TX and RX)

Traffic preemption must be first enabled, and the verification process successfully completed or be disabled for it to operate. At a higher layer, the support for traffic preemption is auto-negotiated by communicating additional Ethernet capabilities using LLDP frames (see clause 79.3.7 of the IEEE 802.3br standard).

When traffic preemption is non-operational all queues are treated as express queues and the MAC sends all frames using the standard SFD (0xD5).

On receive preemptable frames are still accepted and reassembled even when preemption is disabled. This can be changed by setting the control bit BR_CONTROL_Pn.RX_BR_SMD_DIS to disable the acceptance of frame delimiters other than 0xD5. This can be useful to prevent spurious frame drops due to corruption of the preamble bits when preemption is not used.

The TDMA controller's hold_req function has no effect when preemption is disabled as all egress queues are configured as express queues.

29.4.18.3 Operation with Traffic Preemption Enabled (TX)

Traffic preemption is enabled via the register BR_CONTROL_Pn.PREEMPT_ENA. Enabling preemption must be done by a higher layer after having auto-negotiated it via LLDP (see clause 79.3.7 of the IEEE 802.3br standard), or if it is a closed network where it is known that the link partner supports traffic interspersing. Also, at least one queue must be programmed to transmit preemptable traffic via the control register MMCTL_PREEMPT_QUEUES. Note that a single register for all ports is provisioned, so all ports that have preemption enabled will use the same queues. The ports that have preemption disabled, or for which preemption is enabled but not operational will ignore the configuration in MMCTL_PREEMPT_QUEUES and treat all queues as express queues.

For frame preemption to operate the preemption verification process must successfully complete, or it must be disabled via the control register BR_CONTROL_Pn.VERIFY_DIS (see section 29.4.18.5. Preemption Verification Process). The verify process is a hardware mechanism to ensure that both peers can receive preemptable frames before transmitting preempted frames. The operational state of the port's preemption capability can be observed in the MAC STATUS_Pn.BR_VERIF_ST register.

The IEEE 802.3br standard specifies how the frames must be preempted. Since the frames must always be valid Ethernet frames when leaving the MAC, the minimum frame length must be respected. The Figure 29.49 shows an example where two express frames are interspersed in one long preemptable frame. The process is as follows:

1. A frame is queued in a preemptable queue and no frames in the express queues are available. The next-frame controller initiates the transmission of the preemptable frame.
2. The preemptable frame is started with SMD-Sx to indicate that this is a start of frame.
3. A frame is queued in an express queue.
4. The next-frame controller checks whether the number of bytes transmitted is greater than minFragLength = 64 × (1 + addFragSize) − 4 (4a) and whether the remaining bytes for the frame is ≥ 60 (4b). In this example it is, so current frame is preempted.
5. The MAC adds the mCRC to the frame to indicate that this is an mPacket and that more segments are remaining.
6. After the IPG, the express frame is transmitted.
7. The express frame uses the SMD-E as the identifier and the standard FCS for ethernet frames.
8. Once the express frame transmission is completed, the preempted frame resumes if there are no more frames queued in the express queues.
9. The continuation mPacket is identified with SMD-Cx to indicate that this is a continuation frame, and the fragment count is zero to indicate this is the first continuation mPacket for this frame.
10. Another frame is queued in an express queue, but preemption is not yet executed until the minFragLength is met.
11. After minFragLength bytes are transmitted and more than 60 bytes remain for the frame, the preemptable frame is preempted a second time.

12. The continuation mPacket is terminated by the MAC with an mCRC to indicate that there is still more data pending for this frame.
13. The second express frame is then transmitted after the IPG has elapsed. The same format as the previous express frame is used.
14. Once the express frame is transmitted, the preemptable frame resumes transmission.
15. The second continuation mPacket is identified by using SMD-Cx, and a fragment count of 1.
16. The final mPacket of the preemptable frame is terminated with the standard FCS so the receiving port can detect that there are no more segments remaining. The FCS may be bad if the frame must be discarded (or got corrupted during transmission), but as long as the FCS does not match the mCRC, the frame is deemed complete by the receiving port.

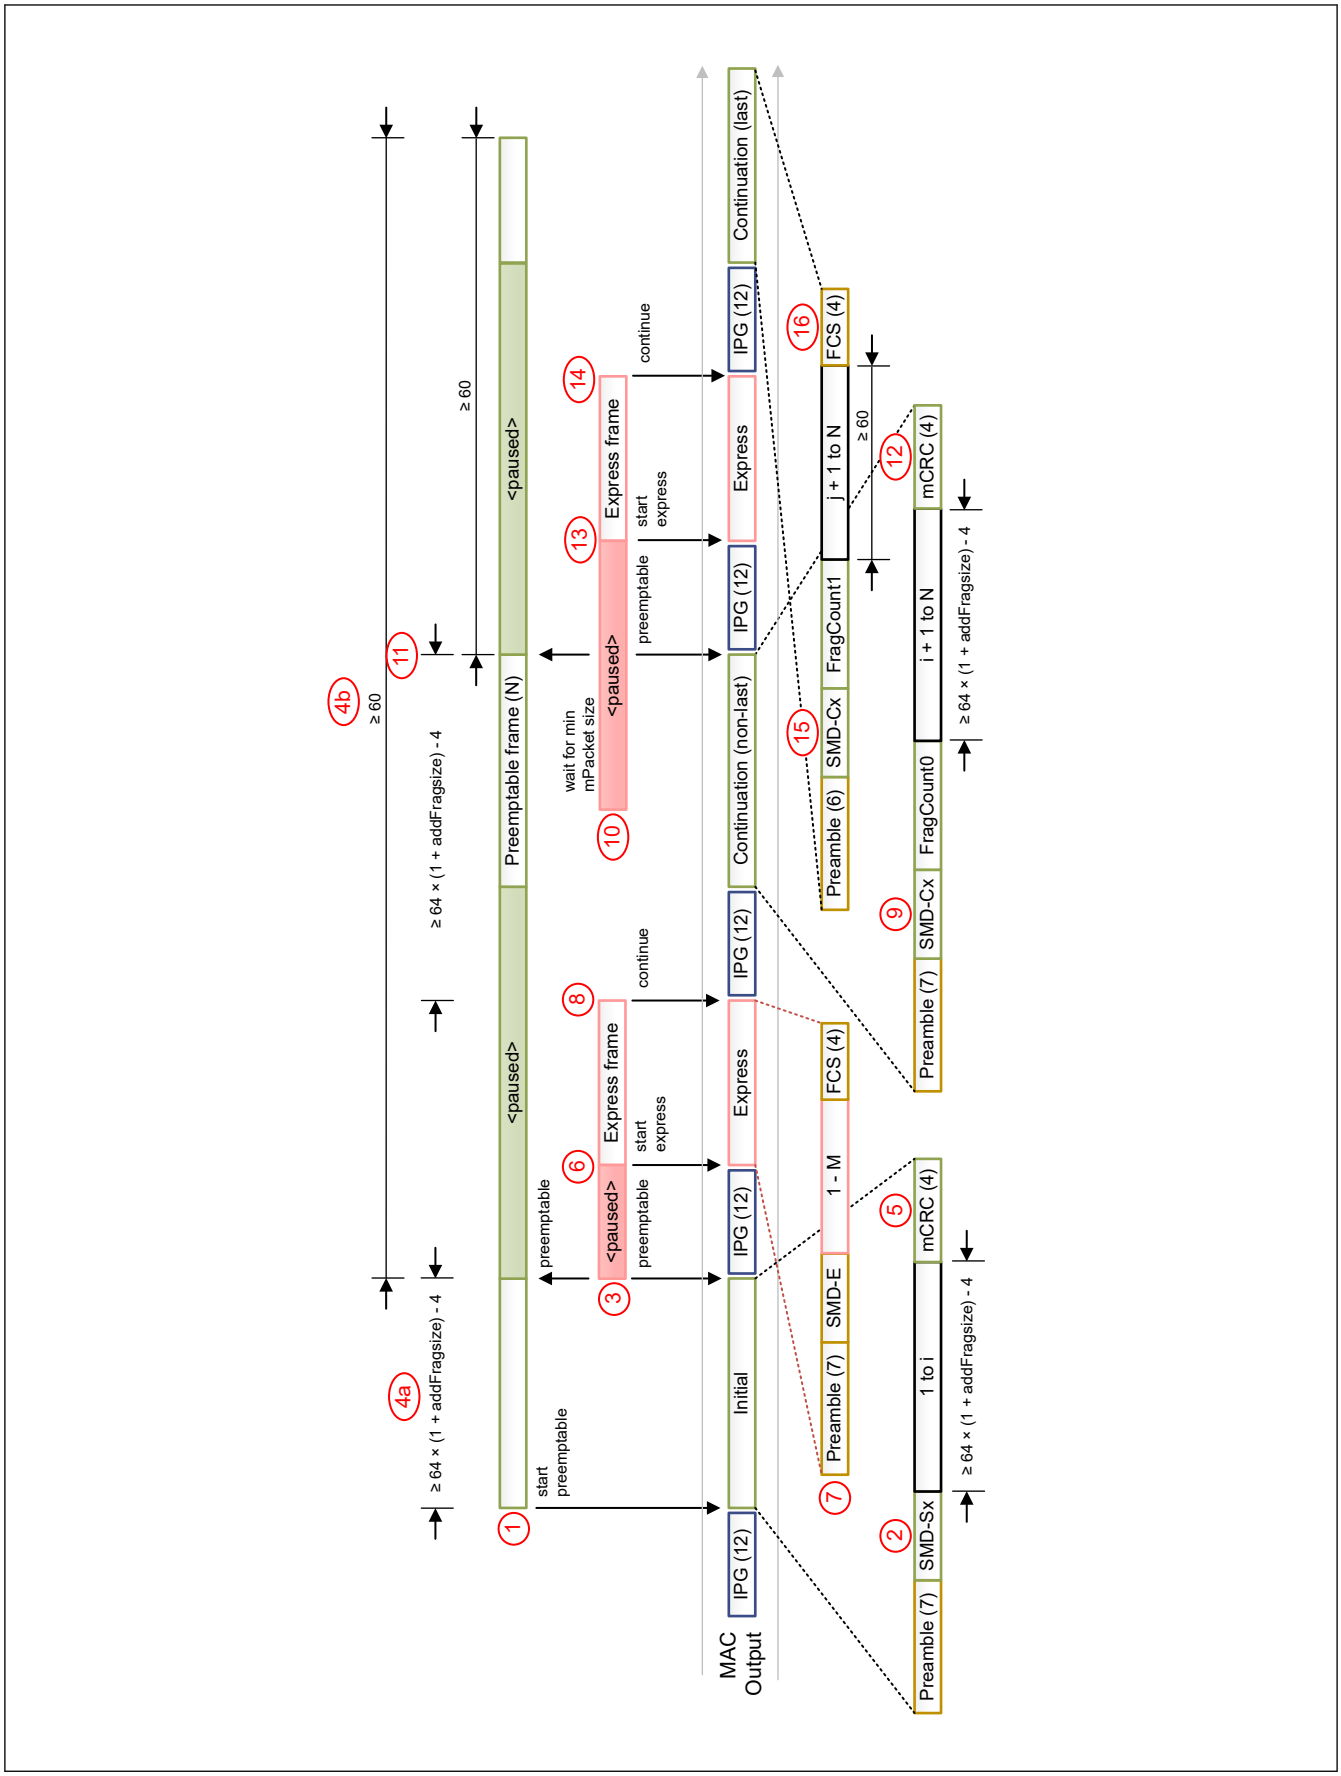

Figure 29.49 Example of frame preemption

In summary, these are the rules that govern how frames are transmitted once traffic preemption is enabled:

1. Express traffic has always precedence over preemptable traffic. The preemptable traffic is transmitted from the queues configured as such in the register MMCTL_PREEMPT_QUEUES. This supersedes the strict-priority arbitration done by the next-frame selection controller.
2. Express frames are transmitted as a single frame delimited by using SMD-E, which is identical to the SFD (0xD5). These mPackets are never interrupted and use the standard CRC32 FCS calculation.
3. Preemptable frames are transmitted with one or more mPackets (see Table 29.7 for SMD encodings).
   (a) The initial mPacket is delimited with SMD-Sx, where x goes from 0 to 3 and increments for every new packet.
   (b) The subsequent (continuation) mPackets are delimited with SMD-Cx, where x goes from 0 to 3 and is the same number as the initial mPacket SMD-Sx. Also, each continuation mPacket indicates the fragment count after SMD-Cx via the FRAG_COUNT field which encodes four different values (see Table 29.8).
   (c) mPackets for express frames use the standard Ethernet CRC32 FCS.
   (d) mPackets for preemptable frames which are not the final mPacket use an mCRC, which is the standard Ethernet CRC32 FCS from the first byte of the full frame up to the last octet of the current mPacket, but with an XOR mask of 0x0000FFFF (see clause 99.3.6 of the IEEE 802.3br specification).
   (e) The last mPacket for a preemptable frame (which can be also the first one if the preemptable frame is not preempted) uses the standard Ethernet CRC32 FCS calculated from the first octet of the full frame.
4. Preemptable frames can be preempted to transmit an express packet if the following conditions are true:
   (a) The current mPacket is at least minFragLength = 64 × (1 + addFragSize) − 4 octets. addFragSize is configured in BR_CONTROL_Pn.ADDFRAGSIZE.
   (b) The preemptable frame has at least 60 octets of data to be transmitted.
5. If tx_hold_req (mapped to MM_CTL.request (hold_req) in the IEEE 802.3br specification) asserts, preemptable traffic is stopped. If a preemptable frame is currently being transmitted and traffic preemption is enabled, the frame is preempted if the conditions in point 3 are met.

29.4.18.4 Operation with Traffic Preemption Enabled (RX)

The receive side processes the preamble of every frame to determine whether it is an express frame, an mPacket part of a preemptable frame, or a "verify" or "response" frame. The port must also be configured to accept SMD-xx as frame delimiters by setting the control bit BR_CONTROL_Pn.RX_BR_SMD_DIS to 0.

Express frames are passed directly to the forwarding processing. Preemptable frames are passed also to the forwarding process, but this process may be suspended if the frame is preempted. For "verify" and "response" frames the port discards these frames and uses them to advance the verification process as needed. Verify and Response frames are not counted in the standard MAC statistics. A separate set of counters track the receive (and transmit) of these frames (see section 29.4.18.8. Counters).

As part of the preamble processing, the port checks for preempted frames that the fragment sequencing is correct (indicated by FRAG_COUNT) for every received mPacket.

29.4.18.5 Preemption Verification Process

This process sends a "verify" frame to the link partner, and expects a "response" frame in return to validate that both ports support frame preemption (see section 29.4.1.6. Preemption Verify and Response Frames for more detail on the frames format, and clause 99.4.3 of the 802.3br IEEE standard).

When preemption is enabled, the MAC initiates the process by sending a "verify" frame to the link partner, and waits 10 ms (or the configured time, which can be between 1 ms to 127 ms in register BR_CONTROL_Pn.TX_VERIFY_TIME) for a "response" frame to be received. If no frame is received, the process is attempted two more times, and on the third failure the MAC stops attempting and inhibits frame preemption.

This process can be disabled via BR_CONTROL_Pn.VERIFY_DIS if it is known that the system supports preemption (i.e. a closed network). When verification is disabled the MAC will still respond to "verify" frames. Moreover, "verify" frames are always replied to unless BR_CONTROL_Pn.PREEMPT_ENA is set to 0 and BR_CONTROL_Pn.RESPONSE_DIS is set to 1.

The verification process is also automatically restarted when the link fails as indicated by the input phy_link.

Note: Setting BR_CONTROL_Pn.TX_VERIFY_TIME to less than 5 ms violates the 20% precision required by the 802.3br specification due to the timer implementation. The precision of the timer is +/− 1 ms.

29.4.18.6 PAUSE Operation with Traffic Interspersing

When PAUSE frames are enabled, the transmit MAC can be paused if a pause request is received from the peer port. When this happens the transmission of express and preemptable frames is stopped. If the pause causes the MAC to stop in the middle of a preempted frame, the frame does not resume transmission until after the PAUSE is cleared.

When the MAC is PAUSE it is still allowed to generate PAUSE frames, as well as Verify and Response frames.

29.4.18.7 MM_CTL.request (hold_req)

The IEEE 802.3br specification defines MM_CTL.request (hold_req) as a mechanism to allow the higher layers to stop the preemptable traffic in advance for express traffic, ensuring that the express traffic will have access to the media as soon as it gets to the output queues. The figure below details the operation of hold requests. When the tx_hold_req asserts (via the TDMA controller's hold_req function), a hold request is given to the next-frame controller, which causes it to stop the preemptable traffic (preempting the frame if needed). Afterwards, the link remains idle unless there are express frames queued for transmission. Express frames will have immediate access to the media, so they get transmitted with almost no delay as soon as they are queued for transmission. A hold request can also be issued by software via the control register MMCTL_HOLD_CONTROL. The preempted state and hold request indication can be checked in real-time via the register MMCTL_PREEMPT_STATUS.

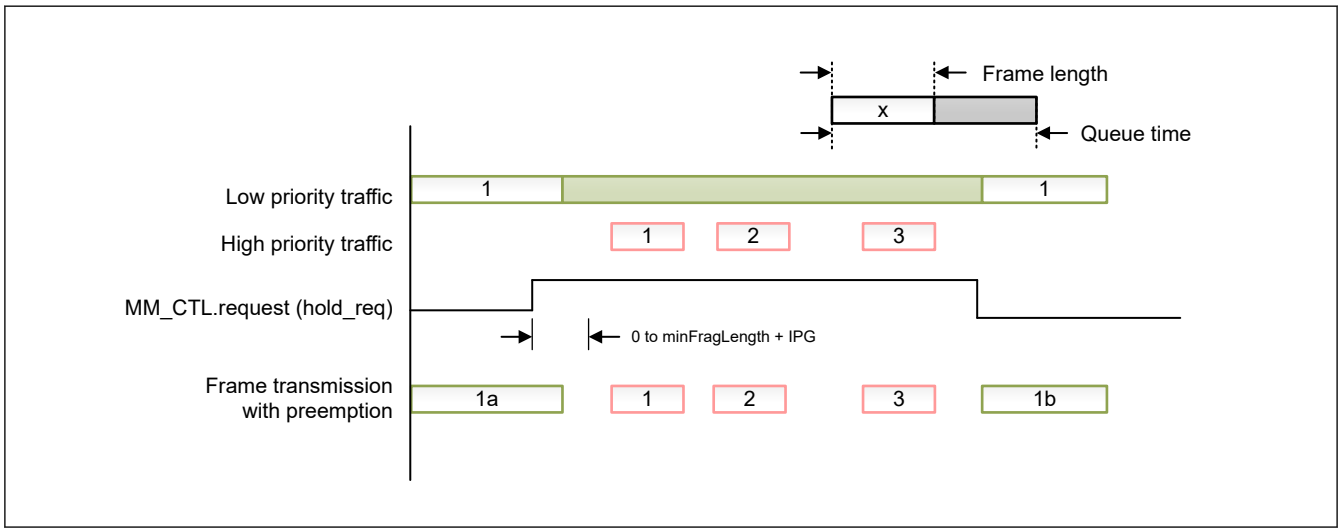

Figure 29.50 Operation of hold_req (MM_CTL.request (hold_req))

section 29.4.22.7. Transmit Frame Selection to Frame's FB Delay describes the delay relevant for hold_req transitioning from high to low and for a frame ready for transmission to be transmitted over the MII/GMII interface.

29.4.18.8 Counters

The table below lists the internal counters supported for 802.3br. Some of them are specified by the IEEE 802.3br standard, while others are custom and meant for debugging.

These counters are accessible in the global discard and 802.3br statistics memory page (see section 29.3.9. Global Discard and 802.3br Statistics Registers).

Table 29.40 Counters related to IEEE 802.3br (1 of 2)

Counter (width)	Counter Name	802.3br clause	Description
aMACMergeFragCountTx (32)	TX_FRAG_CNTn	30.14.1.12	Additional mPacket transmitted due to preemption.
aMACMergeFragCountRx (32)	RX_FRAG_CNTn	30.14.1.11	Increments for every continuation mPacket received.

Table 29.40 Counters related to IEEE 802.3br (2 of 2)

Counter (width)	Counter Name	802.3br clause	Description
aMACMergeFrameSmdErrorCount (16)	RX_SMD_ERR_CNTn	30.14.1.9	Received frame with an SMD-C when no frame is in progress.
aMACMergeFrameAssErrorCount (16)	RX_ASSY_ERR_CNTn	30.14.1.8	Assembly error seen (due to FRAG_COUNT)
aMACMergeFrameAssOkCount (32)	RX_ASSY_OK_CNTn	30.14.1.10	Frame successfully assembled.
aMACMergeHoldCount (32)	TX_HOLD_REQ_CNTn	30.14.1.13	Increments when hold_req transitions from FALSE to TRUE.
ResponseRxGoodCount (8)	RX_RESPONSE_OK_CNTn	N/A	Good Response frames received.
ResponseRxBadCount (8)	RX_RESPONSE_BAD_CNTn	N/A	Bad Response frames received.
VerifyRxGoodCount (8)	RX_VERIFY_OK_CNTn	N/A	Good Verify frames received.
VerifyRxBadCount (8)	RX_VERIFY_BAD_CNTn	N/A	Bad Verify frames received.
ResponseTxCount (8)	TX_RESPONSE_OK_CNTn	N/A	Response frames transmitted.
VerifyTxCount (8)	TX_VERIFY_OK_CNTn	N/A	Verify frames transmitted.

Note: When BR_CONTROL_Pn.RX_STRICT_BR_CTL is set to 1, the VerifyRxBadCount and ResponseRxBadCount will only increment for frames with the corresponding SMD, a length of 64 bytes, a frame content of all 0's, and a bad mCRC.

29.4.18.9 Limitations and Observations

- The IEEE 802.3br standard defines the minimum fragment length as minFragLength = 64 × (1 + addFragSize) − 4. However, this MAC uses the following size as the minimum length minFragLengthReal = 64 × (1 + addFragSize). The net effect is that the minimum fragment can be larger by 4 bytes than what the specification states, but this is not a violation since minFragLengthReal is greater than minFragLength.
- Frames received as express frames can be sent over preemptable queues due to the priority remapping process. If this is expected to happen then the CTFL function must be enabled, otherwise these frames will not be preemptable on transmission. The CTFL is a frame length storage table for frames that are received when cut-through mode is enabled as the frame length is not known until the frame is fully received.
- When a preemptable frame is transmitted without CRC (i.e. the MAC will insert the CRC), the minimum length of a continuation mPacket is 68 bytes. If the application is providing the CRC, then the minimum length of the last continuation mPacket is 64 bytes, but still 68 bytes for the initial or non-last continuation mPackets.
- IEEE1588 1-step PTP frames should never be preempted. The MAC requires these frames to be contiguous to properly update their fields. The application must ensure that PTP frames are transmitted as express traffic.
- When cut-through operation is enabled in the switch the CTFL table must be enabled when frame preemption is enabled. This is required as the CTFL stores the frame's length which is needed to determine preemption. If the CTFL is disabled it could yield to a live-lock condition as a frame of unknown length blocks the preemptable queues.

29.4.18.10 Additional 802.3br Options

The following options are provided as non-standard options that can be enabled or disable to provide additional robustness.

- Strict preamble
  This mode enables checking for the preamble bytes in the SFD detection logic. The mode is configured in the BR_CONTROL_Pn.RX_STRICT_PRE field. When set to 0, the SFD detection logic will look for the SFD or any of the SMD-xx characters to accept a frame. When set to 1, the frame will be ignored if a character other than 0x55 is received prior to an SFD or SMD-xx.
- Disable 802.3br SMD-xx decoding
  This control is set in BR_CONTROL_Pn.RX_BR_SMD_DIS. When set to 1, it instructs the SFD detection logic to accept frames only based on the standard SFD (0xD5). This can be enabled when preemption is not supported to avoid false frame acceptances due to preamble corruption. Note however that even if a false acceptance occurs, the CRC checker will mark the frame as bad as the frame's FCS will not be calculated correctly.

- 802.3 verify process disable
  The verify process required for operating in preemptable mode can be disabled with the register BR_CONTROL_Pn.VERIFY_DIS. This can be set to 1 in a closed system well it is known that the peer port supports preemption, or for debugging the port.
- Strict verify and response frame decoding
  This mode can be set via BR_CONTROL_Pn.RX_STRICT_BR_CTL. When set to 1, the Response and Verify frames must have a correct mCRC, a total length of 64-bytes and a payload of all 0x00. When set to 0, only the mCRC is checked to validate that the frame is a Verify or Response frame. A value of 0 is required to comply with IEEE 802.3br.

29.4.19 Extended Frame Parser (EFP)

29.4.19.1 Overview

It supports ingress filtering and Ethernet frame header manipulation according to the following standards:

- IEEE 802.1CB, Clause 6.6: Active Stream Identification
- IEEE 802.1Q, Clause 8.5 and 6.9: TCI.PCP remapping / TCI.VID assignment.
- IEEE 802.1Q, Clause 12.20.3: Priority Regeneration Override
- IEEE 802.1Q, 8.6.5 and MEF 10.3: Flow classification and metering

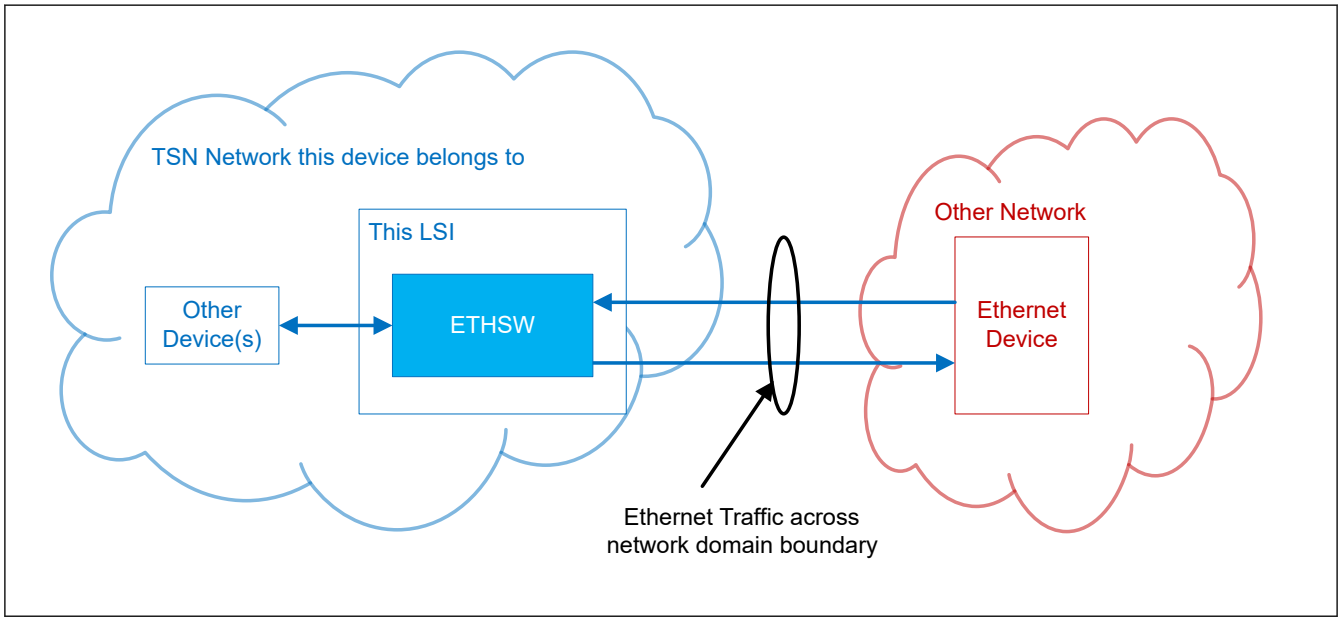

Figure 29.51 Network domain boundary

Configuration:

- 3 independent channels
  - one channel per ingress port of the switch
- 8 Filter per channel
- Priority regeneration 8; 8 per channel
- Active Stream Identification for 128 stream IDs (DA & VID & PCP) per channel
- Max SDU check per channel
- 8 Flow Meters per channel
  - Green Bucket only
  - Envelope Mode (concatenation) of meters for up to 3 buckets

If concatenating more than 3 buckets, overflow token may get lost.

29.4.19.2 Frame Processing Overview

This function processes only ingress frames of line ports (not for the management port). It shall handle incoming traffic from other network domains at the boundary ports of an industrial Ethernet/Profinet network domain (see Figure 29.51). The ingress processing has two purposes:

1. Protection of internal network resources from overflow due to excessive traffic from outside.
2. Header modification to align incoming frames to the internal traffic scheme.

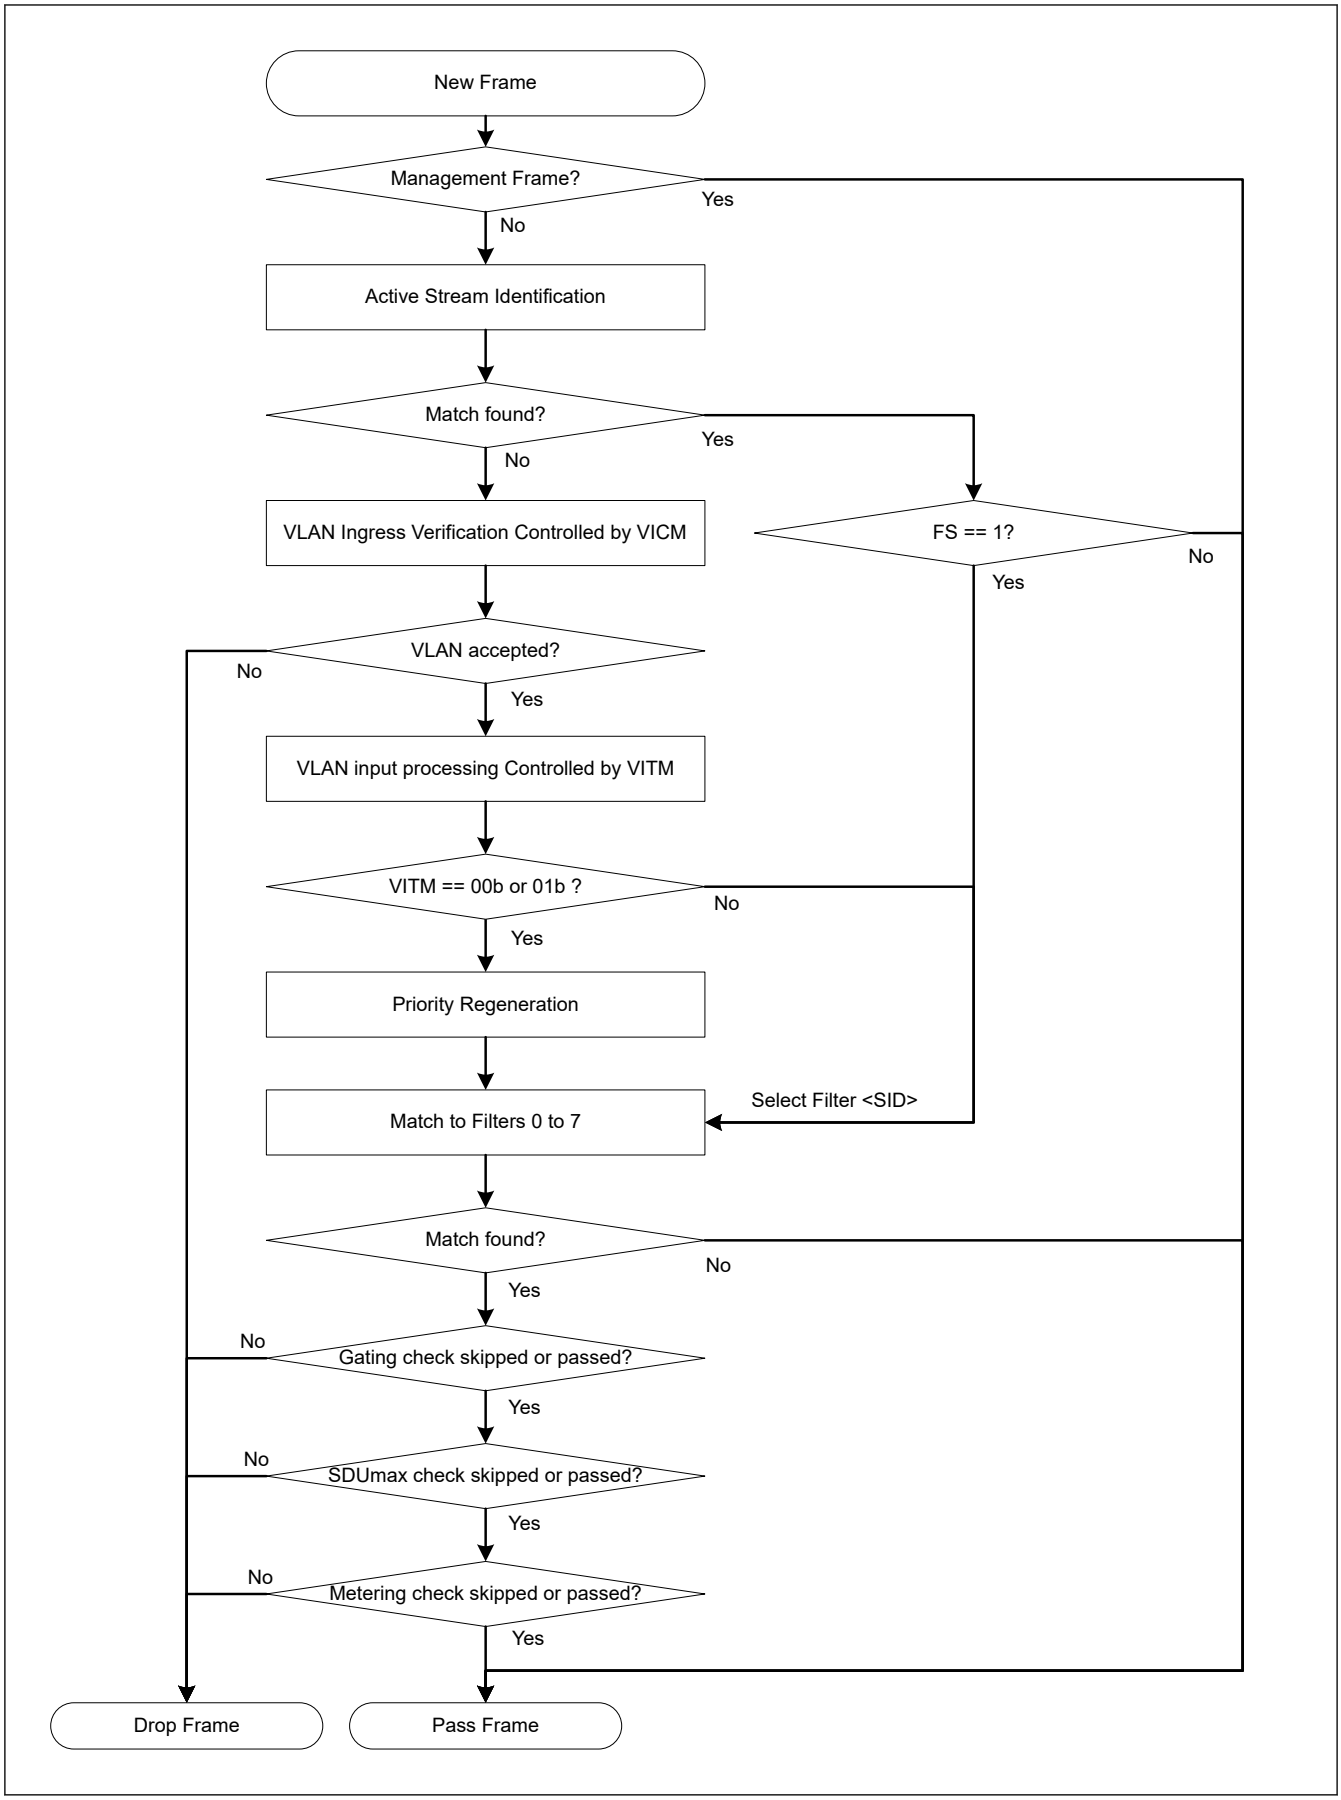

Figure 29.52 Frame processing flow

Figure 29.52: Frame processing flow shows the logical flow of frame processing. To stream processing of the frames, timing of the steps needs to be considered carefully. Features like pre-emption and cut-through cause technical limitations and corner cases for the function. Conditions like broken frames, i.e. cancellation of reception at any time, pre-emption without resuming rest of frame transmission, multiple pre-emptions of a frame (sequentially, not stacked) etc. shall be taken into account for a robust design. Software reset of the processing state machines shall be possible to recover function in case of deadlocks without full reset of the total system.

Timing wise the frame processing can be split into two sections:

1. Ethernet header based
   These processing steps operate on header information and immediately available information. For example, classification of the frame, VLAN tag modifications, active stream identification, gating check. All of these operations can be executed immediately after receiving the Ethernet header information, i.e. the first 14 octets of the frame. The maximum supported line rate is 1 Gbps. The minimum length of a valid Ethernet frame is 64 Octets. Considering preamble and inter frame gap of 8 octets each, this translates to approximately 640 ns for processing two frames back-to-back.
2. Ethernet frame length based
   These processing steps require the information about frame length. Since the frame length of an Ethernet II frame corresponds to the number of received octets, this information becomes available at the end of a frame reception. Consequently, forwarding or dropping decision of cut-through frames cannot be made depending on the frame length (SDUmax checking). However, frames exceeding the maximum length could trigger all consecutive frames of the same class to be dropped. This is an Ethernet header-based check as described above.

COMMAND_CONFIG.EFPI_SELECT must be set to 1 to process of frames. However, it can inspect ingress frames even if COMMAND_CONFIG.EFPI_SELECT is set to 0.

29.4.19.3 Frame Processing Details

(1) Management Frame Identification

Link local management frames are exchanged between neighbored bridges. They are only forwarded to the management port. Management frames are not automatically forwarded to other external ports of the switch. Management frames shall not be subject to ingress processing. According to IEEE802.1Q-2018 Table 8-1 management frames are identified by a Destination MAC Address (DMAC) in the range of 01-80-C2-00-00-00 to 01-80-C2-00-00-3F.

(2) Active Stream Identification

The Active Stream Identification function is defined in IEEE802.1CB-2017 Clause 6.6. It is executed first to determine if the frame is belonging to a defined TSN stream. If the frame matches to an entry in the Active Stream Identification table, the header information of the frame is updated as defined in IEEE802.1CB-2017 and the stream handle is derived from an entry of the Active Stream Identification table. This frame handle then directly refers into the filter table, it means bypassing the frame identification by the MAC/VLAN comparison in the filter entries. The frame conformance checking parameters of the respective filter entry are applied.

(3) VLAN Verification

In accordance with IEEE802.1Q-2018 section 6.9 this function checks the VLAN tag of the frame for conformance to the VLAN assignments of the port. Following settings are supported:

Table 29.41 VLAN input verification mode

Mode	Pn_VLAN_MODE.VICM	Description
0	00b	Disabled, all frames pass
1	01b	Admit Only VLAN-tagged frames
2	10b	Admit Only Untagged or Priority-tagged frames
3	11b	Do not use (drop all frames)

Note: VLAN verification is only done for frames not identified as TSN streams.

Note: This function is already implemented in Switch Function. But due to its functional linkage to the Active Stream Identification function, so use this function here.

(4) VLAN Ingress Processing

This process step manipulates the VLAN tags of ingress traffic. It is only performed, if the Active Stream Identification did not find a match for the ingress frame. Therefore, and since the VLAN tag may be subject to the following filters, the already existing VLAN processing function cannot be used here.

Table 29.42 VLAN input tagging mode

Mode	Pn_VLAN_MODE.VITM	Description
0	00b	Disabled, VLAN tag is neither added nor overwritten.
1	01b	Single Tagging with Passthrough / VLAN ID (VID) Overwrite. Insert Tag if untagged frame. Leave frame unmodified if tagged and VID > 0. If tagged with VID = 0 (priority tagged) then the VID will be overwritten with the VID from Pn_VLAN_TAG and priority is kept
2	10b	Single Tagging with Replace If untagged, add the tag Pn_VLAN_TAG, if single tagged, overwrite the tag.
3	11b	Tag always Insert a tag Pn_VLAN_TAG always. This results in a single tagged frame when an untagged is received, and a double tagged frame, when a single tagged frame is received (or triple tagged if double-tagged received etc.). Note: This mode is prohibited for switch ports running at 1 Gbps line rate.

(5) Priority Regeneration

In accordance with IEEE802.1Q-2018 clause 6.9.4 this function reassigns the PCP value of the VLAN tag. All 8 possible PCP values are replaced by the respective table entry. To bypass priority regeneration, replacement values are same as the input value (default setting after reset release).

(6) Filter Function (Match for Filters)

Supports Per-Stream Filtering and Policing (PSFP) function as defined in IEEE802.1Q-2018 clause 8.6.5.1.

In the Profinet TSN use-case, PSFP application is generalized from TSN streams to all classes of Ethernet frames like broadcast, multicast, and unicast traffic.

The filter function identifies Ethernet frames by their Destination MAC address (DMAC), Source MAC address (SMAC) or VLAN tag and assigns them to a SDUmax, flow gate and flow meter. Each channel provides 8 filters.

Each frame is matched against the filters sequentially starting at filter 0. The first matching filter determines the frame policing parameters. If no filter matches, the frame will be forwarded unconditionally, i.e. PSFP is not applied to the frame.

Frames identified and relabeled by the Active Stream Identification function can be assigned to one of these filters directly. The frame policing parameters of the respective filter are applied without prior frame re-identification by the filter.

Note: Frames processed by the Active Stream Identification function shall get a "frame handle" assigned as lookup value from the table. This frame handle shall be an index (0..7) to the Filter table.

By the frame handle, the respective entry of the filter table can be immediately selected for the respective frame without need to search and match the header information again. Since no new search is needed, the MAC/VLAN entry in the filter table may not match to the frame header. This is no functional limitation. Filtering is optional for these frames, it means, along with the stream ID, a control bit (FS) can enable/disable the PSFP function for these frames.

(7) Gating Check

The gating check is enabled by Pn_QSFTBLs.GAIDV set. The frame can pass the gate, if the tdma_gpio signal for switch selected in Pn_QSFTBLs.GAID is set to 1. In this case the Pn_QGPPC counter is incremented. If not, the frame is dropped, the error interrupt is signaled by the respective flag in Pn_QGEIS.QGMOIS and the counter of dropped frames Pn_QGDPCg is incremented.

If the Pn_QGMOD.QGMOD[g] bit for the respective gate is set and if the error interrupt flag Pn_QGEIS.GQMOIS[g] corresponding to the gate is set, all frames assigned to the respective gate are dropped independently. The software must clear the Pn_QGEIS.QGMOIS[g] flag to re-enable frames passing the gate.

(8) SDUmax Check

The SDUmax check is enabled by Pn_QSFTBLs.MSDUE set. The frame length (FL) is compared against the SDUmax value Pn_QSFTBLs.MSDU defined in the filter entry.

If the FL is less or equal to SDUmax, the frame passes the filter.

If the FL is higher than SDUmax

- The frame is dropped and the SDUmax error interrupt is generated
- If Pn_QSFTBLs.QSMSM is set, all consecutive frames matching this filter are dropped if the error interrupt flag is still set.

Note: The FL is known at the end of the frame. While frames in S&F mode can still be canceled, frames transmitted in cut-through mode cannot be prevented from transmission. However, for such frames the error interrupt and the optional permanent blocking function would be available.

29.4.19.4 Active Stream Identification

It provides a table with 128 entries per channel for Active Stream Identification. The table is organized as hashed table with 64 hashes with 2 entries per has value to mitigate hash collisions. The Address is a hash of lookup {DA, VID, 0000b (padding)}: CRC-7 Polynomial (IEC 60870-5) 0x65 = $x^7 + x^6 + x^5 + x^2 + 1$. It needed to be reset to 7'h3F on a SOP.

Note: The Active Stream Identification table is stored in RAM. This RAM is not initialized by the hardware. The software driver must initialize the memory before enabling the ingress policing function.

Table 29.43 Active Stream Identification table entry

Item	Width	Description
DMACI	48	DMACI/VIDI are the DMAC and VID of the incoming frame, which are matched to this table entry. A full match is required.
VIDI	12	
DMACO	48	If a frame matches this entry, its DMAC, VID, and PCP are replaced by these values. The DEI bit keeps its value.
VIDO	12	
PCPO	3	
SID	3	This is the frame handle assigned to the matched frame. In case of this implementation, it directly refers to a filter entry in the filter table.
FS	1	If set, the filter referenced by SID is applied. If cleared, no filtering is applied.
EV	1	If set, this table entry is valid. If cleared, this table entry shall be ignored.

Note: 16 bytes (128 bits) per entry

Table 29.44 Active Stream Identification table entry bit fields

DMAC Ingress	VID Ingress	DMAC Translate	VID Translate	PCP Translate	SID	FS	EV
Bit [127:80]	Bit [79:68]	Bit [67:20]	Bit [19:8]	Bit [7:5]	Bit [4:2]	Bit [1]	Bit [0]

The SID obtained from the active stream identification table is a direct index into the filter table. It is enabled by setting the FS bit. By this link, the gating and metering features can be utilized for each stream without specific MAC/VLAN filter definition in the filter table.

Note: For frames identified by the Active Stream Identification, as the further steps on VLAN verification, Priority Regeneration and Null stream identification are not applied. Gating, Metering and SDUmax checks are applied only by a linked filter entry.

Following is a flow of Active Stream Identification.

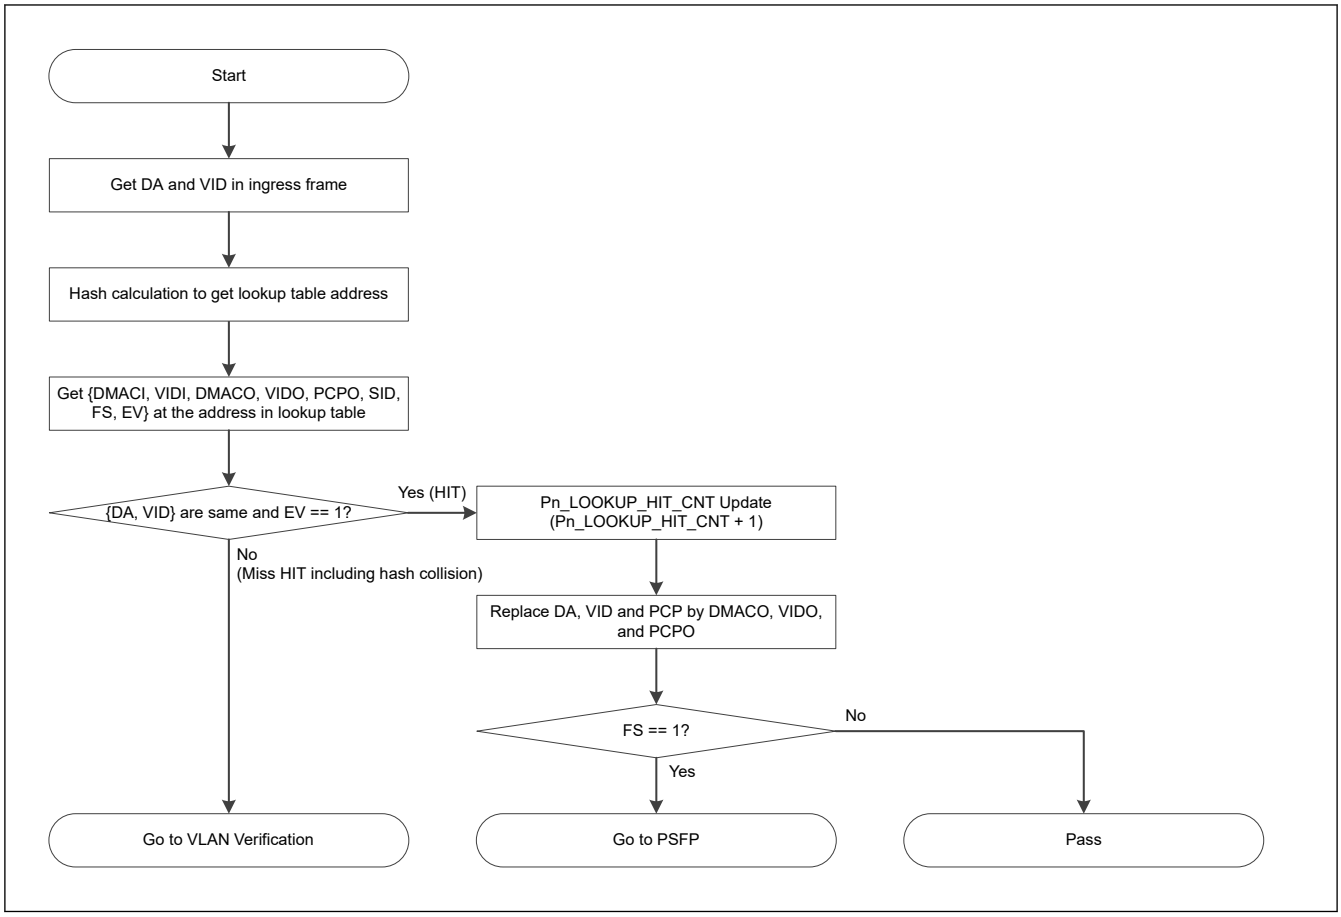

Figure 29.53 Active Stream Identification flow

Hash calculation and comparison image is as follows.

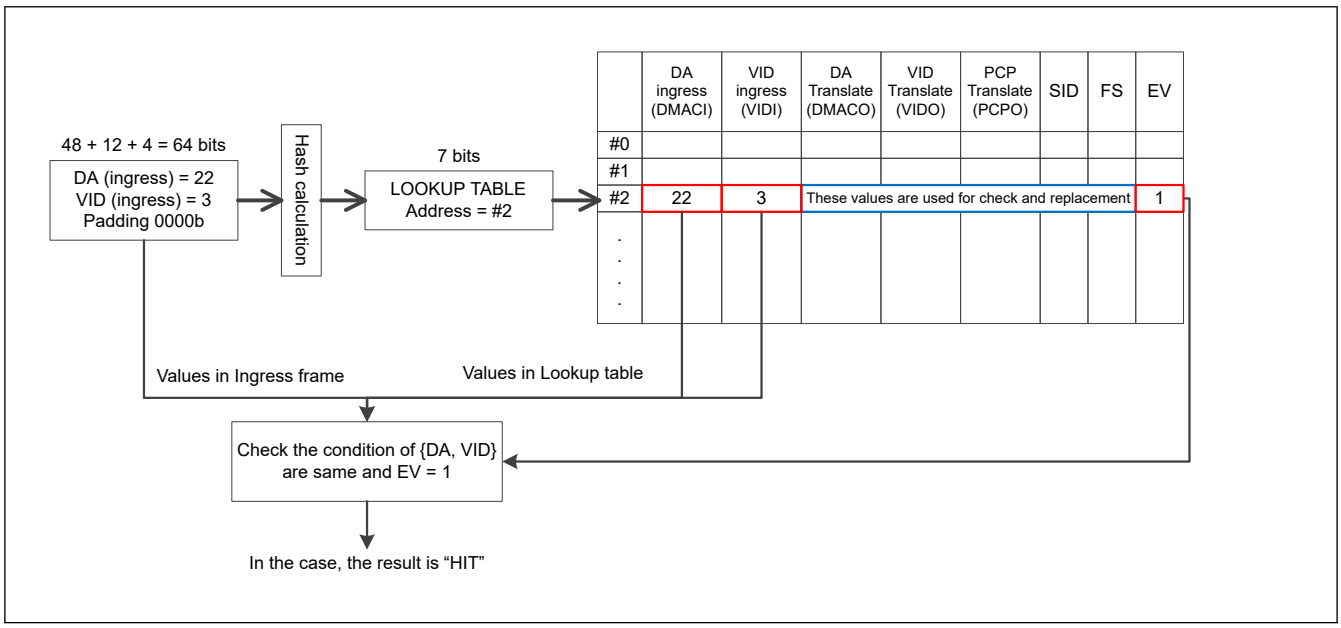

Figure 29.54 Hash calculation and comparison image

Before using the EFP functions, the Active Stream Identification Table should be initialized using the flow in Figure 29.55. This flow will initialize the Active Stream Identification tables of all three channels.

Note: The Active Stream Identification Table is not initialized by hardware function. Thus, it MUST be initialized before the respective channel operation is enabled by triggering the CHANNEL_ENABLE register bit of the respective channel.

Initialization of all three memories can be done in parallel, it means all three ASI_MEM_ADDR.MEM_REQ control bits can be set simultaneously.

Note: Initialization of the Active Stream Identification Table is mandatory. It cannot be skipped even this function is not used.

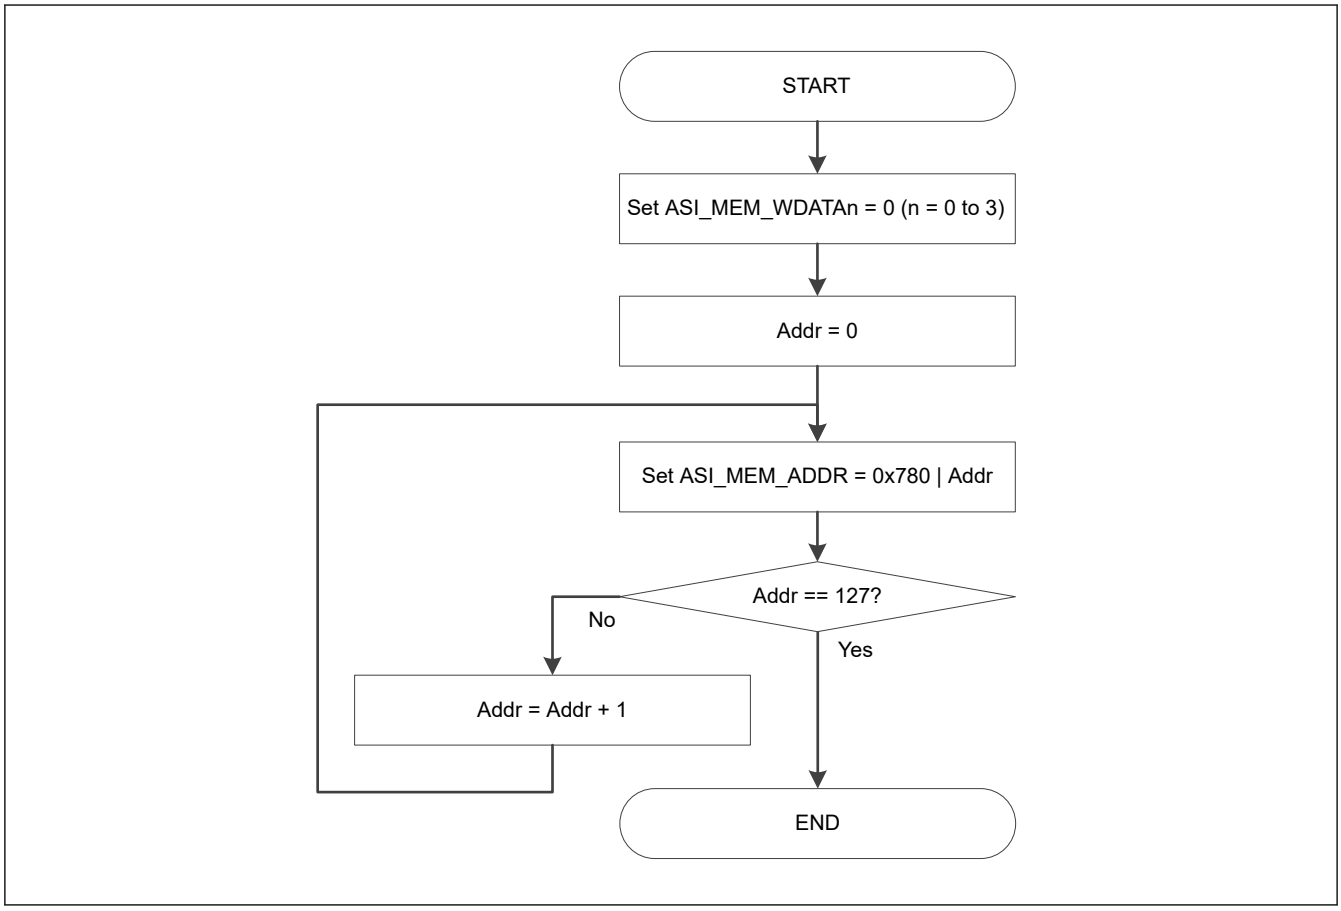

Figure 29.55 Active Stream Identification initialization

Setting an entry into the Active Stream Identification Table shall follow the flow in Figure 29.56.

Deleting an Entry shall follow the flow in Figure 29.57.

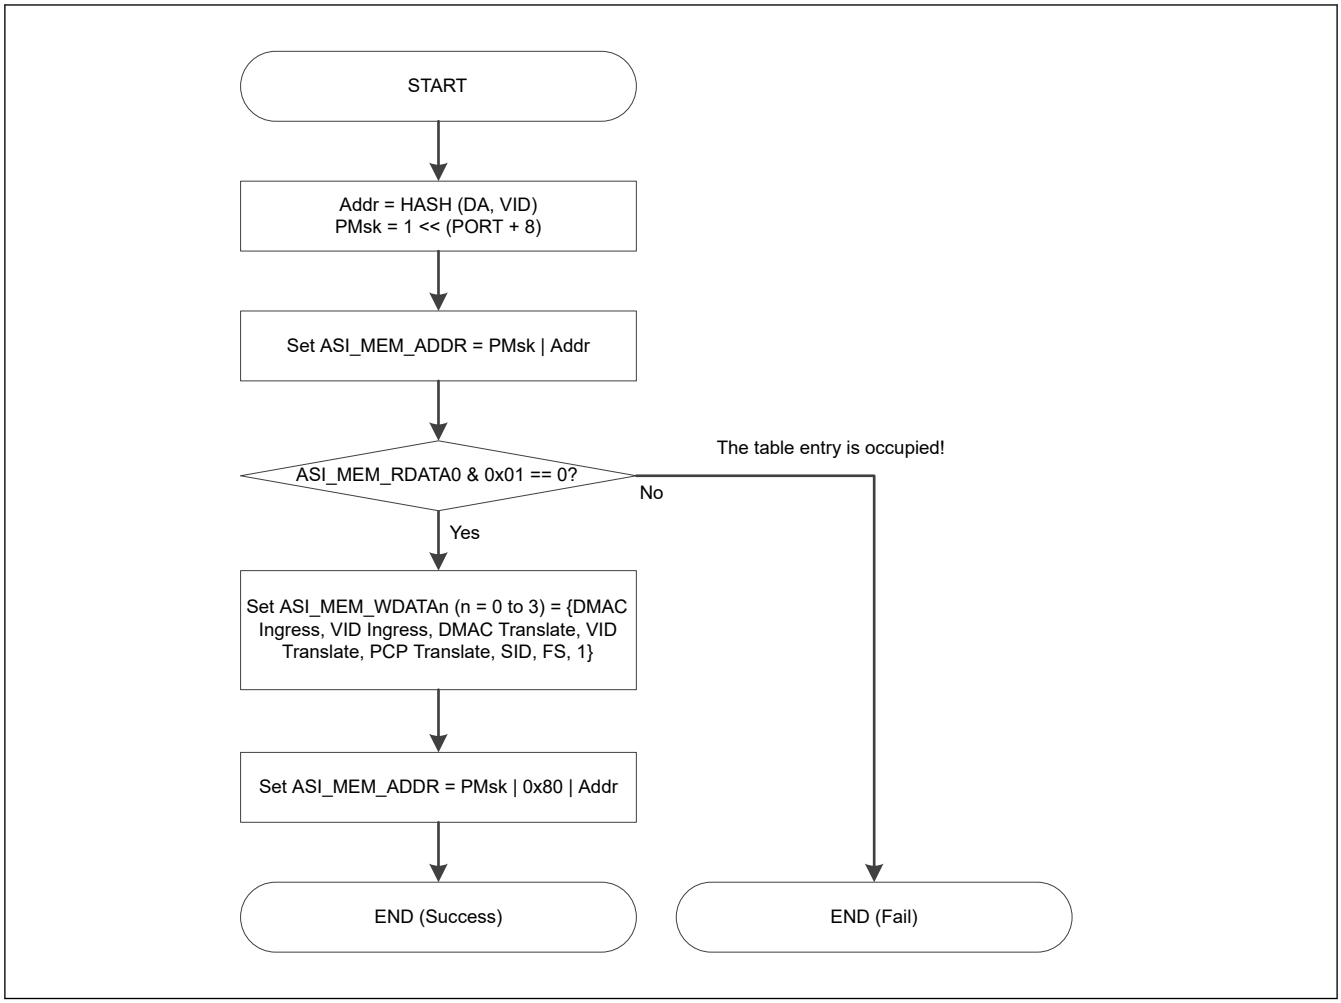

Figure 29.56 Active Stream Identification entry setting

Note: PMsk contains the respective ASI_MEM_ADDR.MEM_REQ bit of the port's memory set.

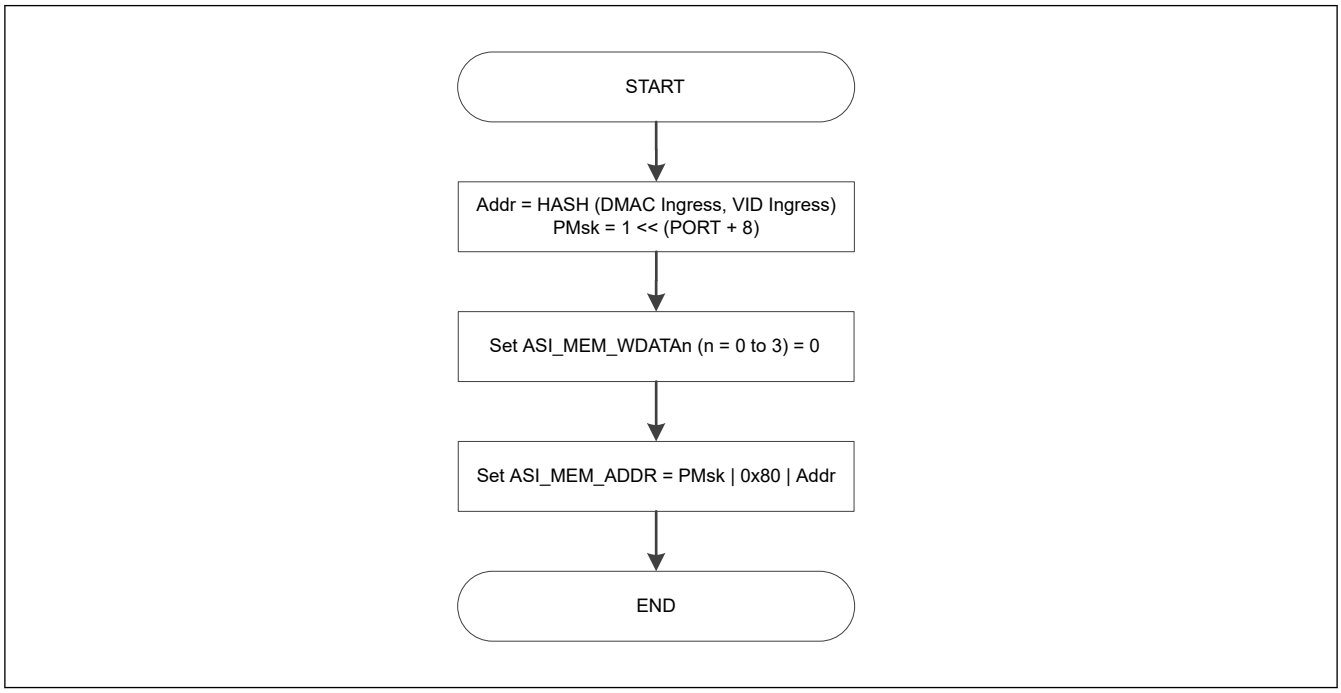

Figure 29.57 Active Stream Identification entry deletion

29.4.19.5 VLAN Ingress Verification

VLAN ingress verification checks presence of a VLAN tag and its VID of an incoming frame.

All frames violated the VLAN ingress verification check are dropped. Following is a flow of VLAN verification.

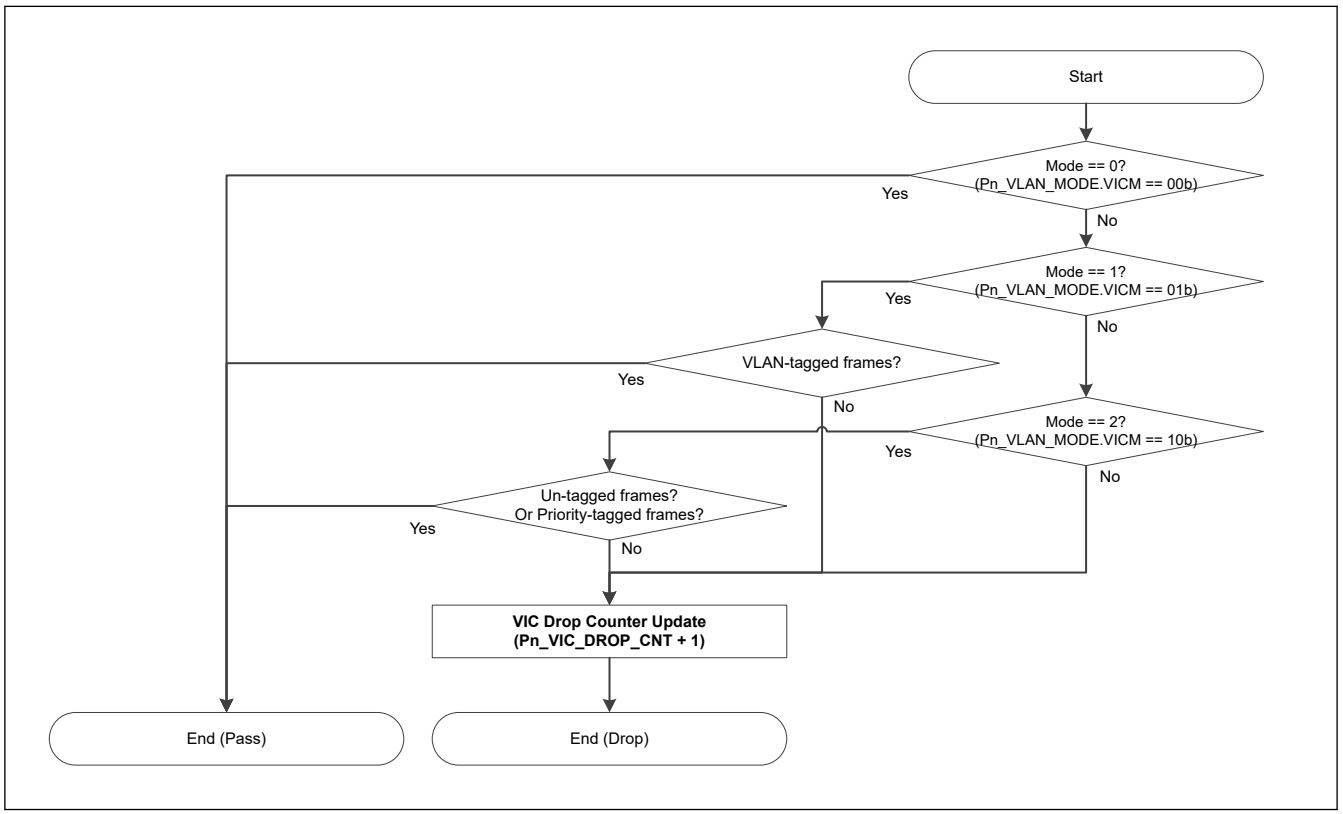

Figure 29.58 VLAN Verification flow

29.4.19.6 Priority Regeneration

The priority regeneration function reassigns PCP values of incoming, VLAN tagged frames. A 1:1 lookup table assigns a new PCP value for each incoming PCP value. The VID and DEI flag are not modified.

Priority regeneration is always executed for VLAN tagged ingress frames, which PCP values have not been changed by the VLAN processing (see VITM setting). However, by default the PCP replacement values correspond to the received PCP, thus the frame is effectively not changed.

The replacement table assigns a new PCP value [0..7] for each permitted PCP ingress value. The same PCP output value can be assigned for multiple PCP ingress values.

For configuration of PCP reassignment, write the respective PCP replacement values into Pn_PCP_REMAP.

Note: Priority regeneration will be skipped, if the PCP value has been assigned by the ingress VLAN tagging flow. See VITM setting in Pn_VLAN_MODE register:

- VITM = 00b or 01b: Priority regeneration is applied.
- VITM = 10b or 11b: Priority regeneration is skipped, PCP value set by Pn_VLAN_TAG is maintained.

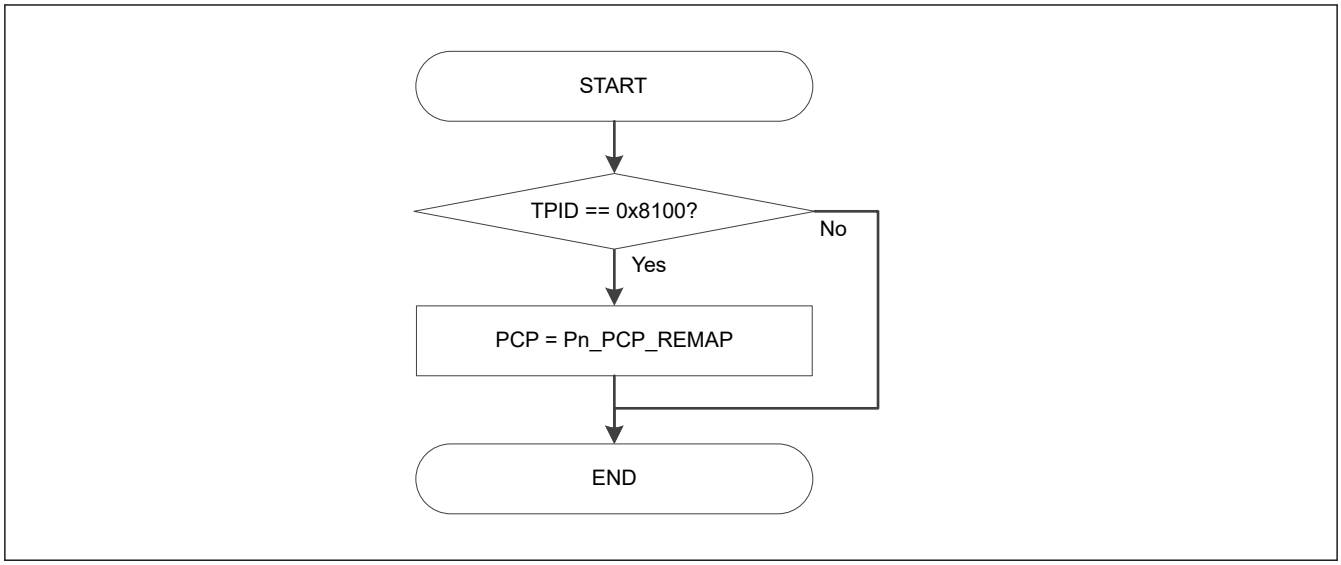

Figure 29.59 Priority Regeneration flow

29.4.19.7 Filtering Function

The filtering function matches the newly received frame against a table of 8 filter entries. The table entries are processed sequentially by comparing the new frame against the filter parameters. Once a match occurs, the comparison terminates and the further frame processing (gating check, SDUmax verification, Flow Metering) is determined by the parameters assigned to the respective filter entry <S>. A match could also be forwarded from the Active Stream Identification table, parameter SID.

If no match is found for a new frame, it means no filter entry matches the frame, the frame is forwarded without any further constraints.

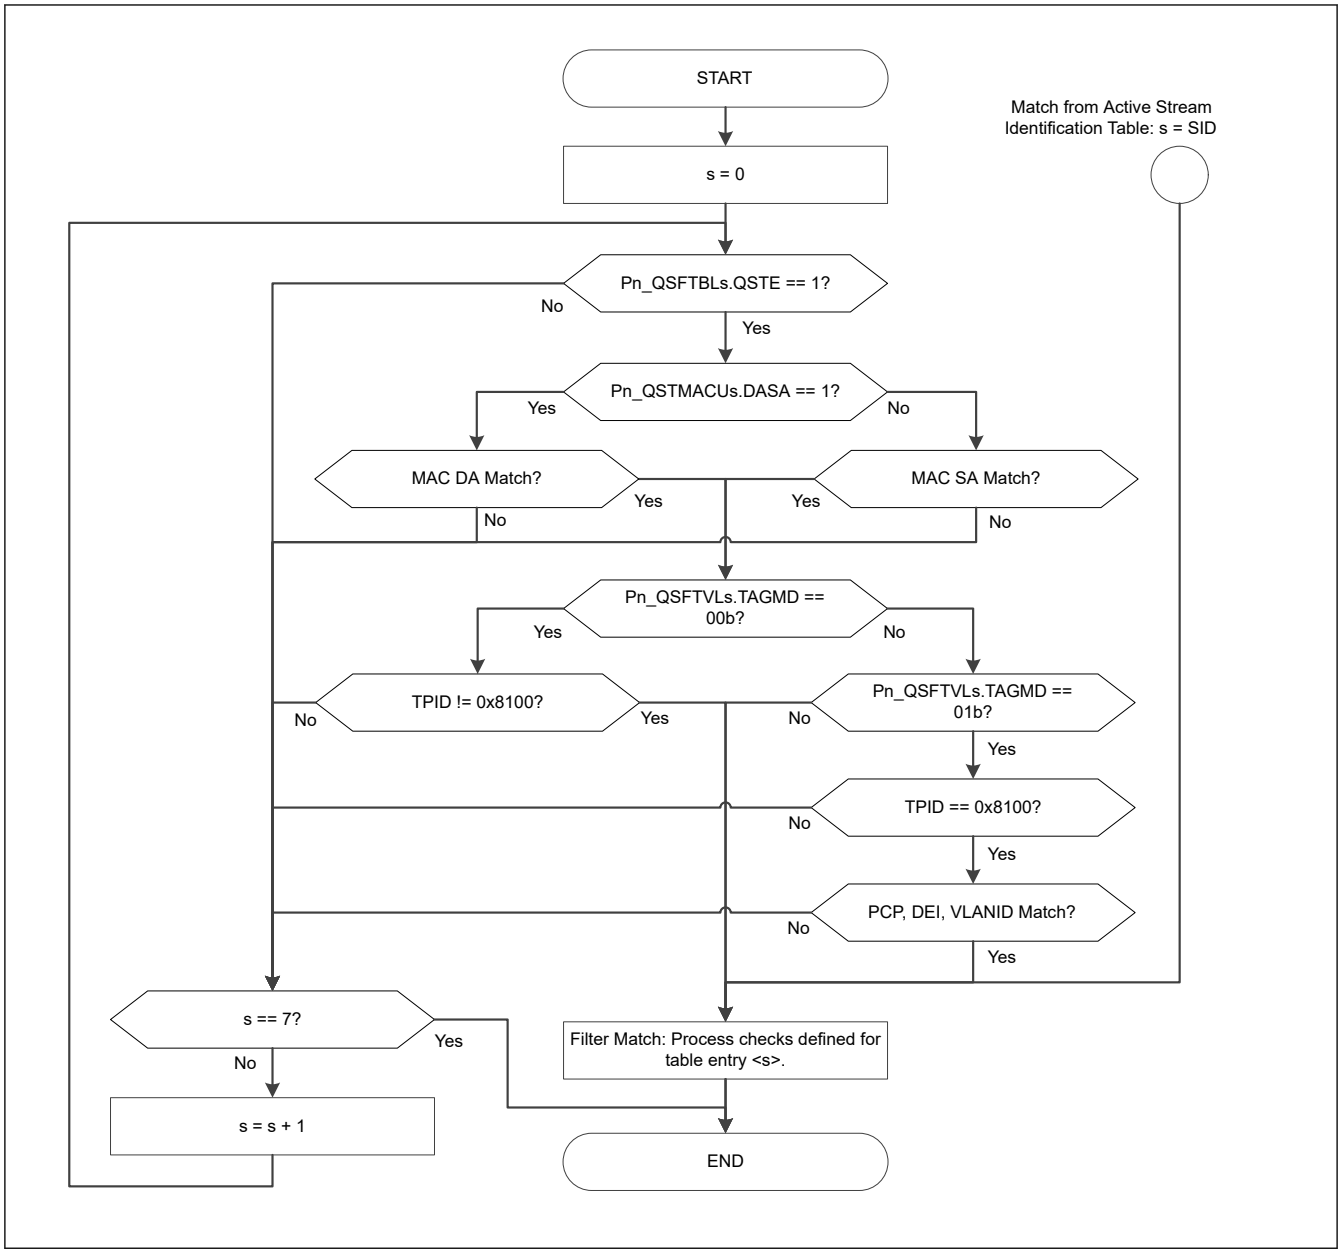

Figure 29.60 Qci filtering flow

Qci stream filter table setting flow is shown in Figure 29.61.

Be sure to set the corresponding Pn_QSTMACUs, Pn_QSTMACDs, Pn_QSTMAMUs, Pn_QSTMAMDs, Pn_QSFTVLs, and Pn_QSFTVLMs first and set Pn_QSFTBLs continuously.

If set in any other sequence, operation is not guaranteed.

Writing of Pn_QSTMACUs, Pn_QSTMACDs, Pn_QSTMAMUs, Pn_QSTMAMDs, Pn_QSFTVLs, Pn_QSFTVLMs, and Pn_QSFTBLs is reflected when is written.

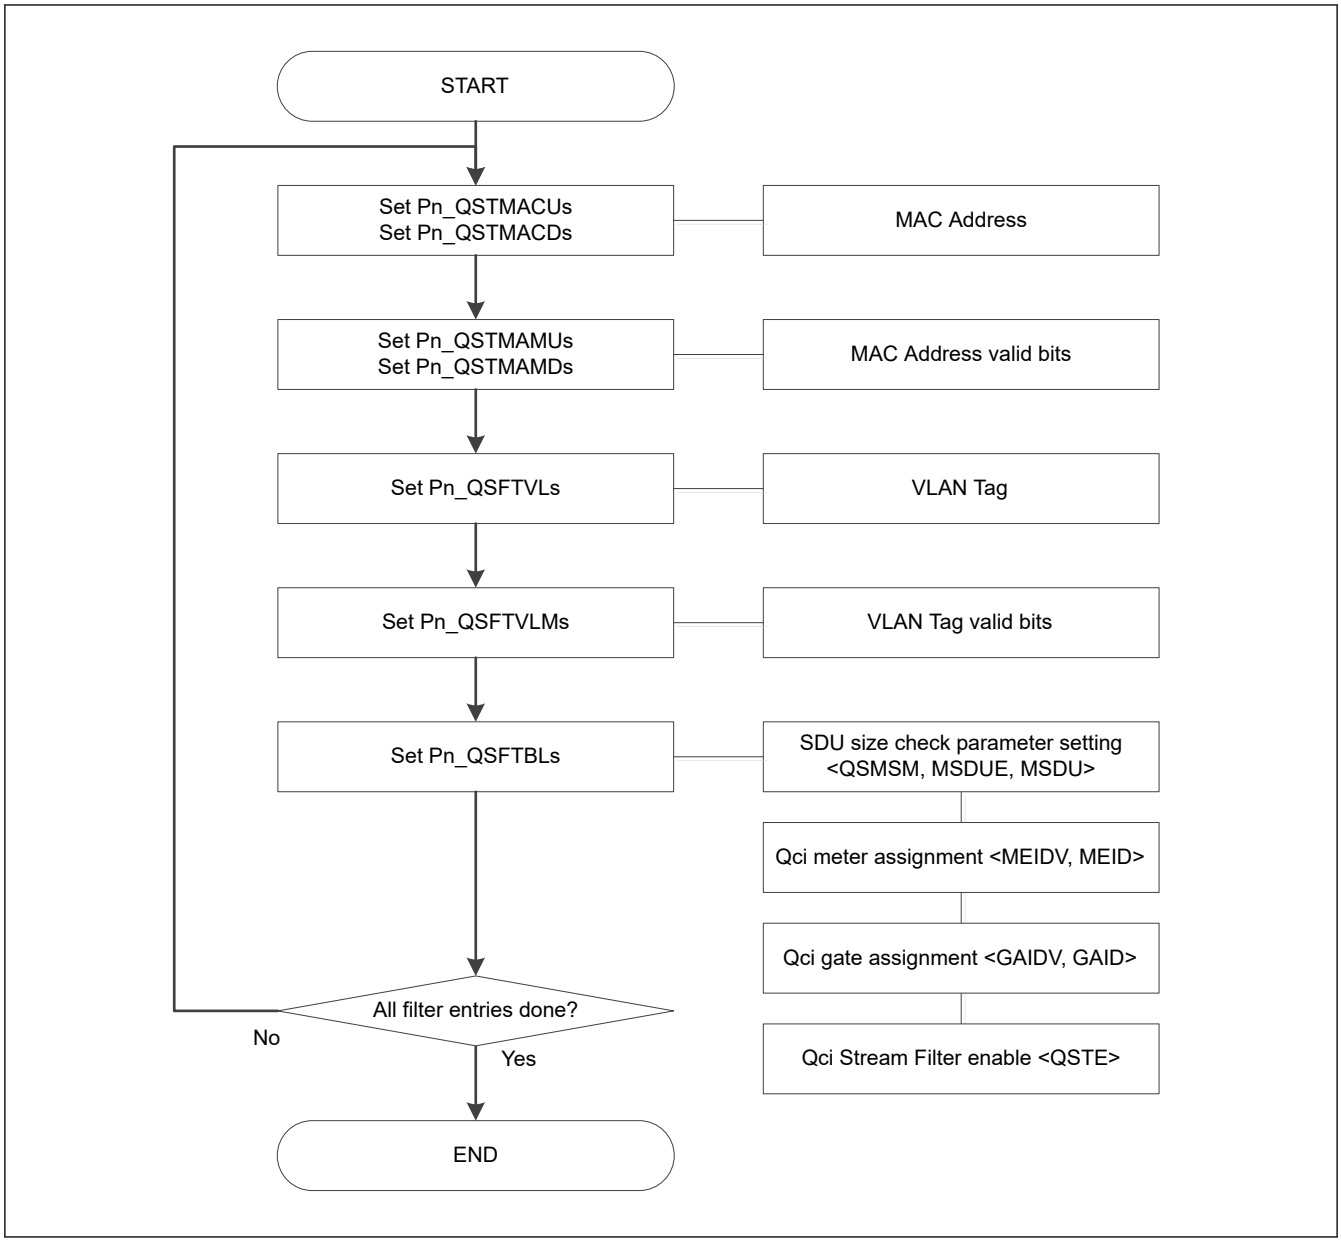

Figure 29.61 Qci stream filter table setting flow

Note: When reconfiguring a filter entry, be sure to set Pn_QSFTBLs.QSTE = 0 before starting to change any other setting of the respective filter entry.

29.4.19.8 Gating Check

A frame is applied for gating check, if the Pn_QSFTBLs.GAIDV control bit is set. In this case, Pn_QSFTBLs.GAID[2:0] determines, which of the tdma_gpio[7:0] signals should be checked. If the signal is low, the frame is dropped and the interrupt event is set.

Depending on the setting of Pn_QGMOD.QGMOD bit, the consecutive frames are not forwarded as long as gating event interrupt is pending.

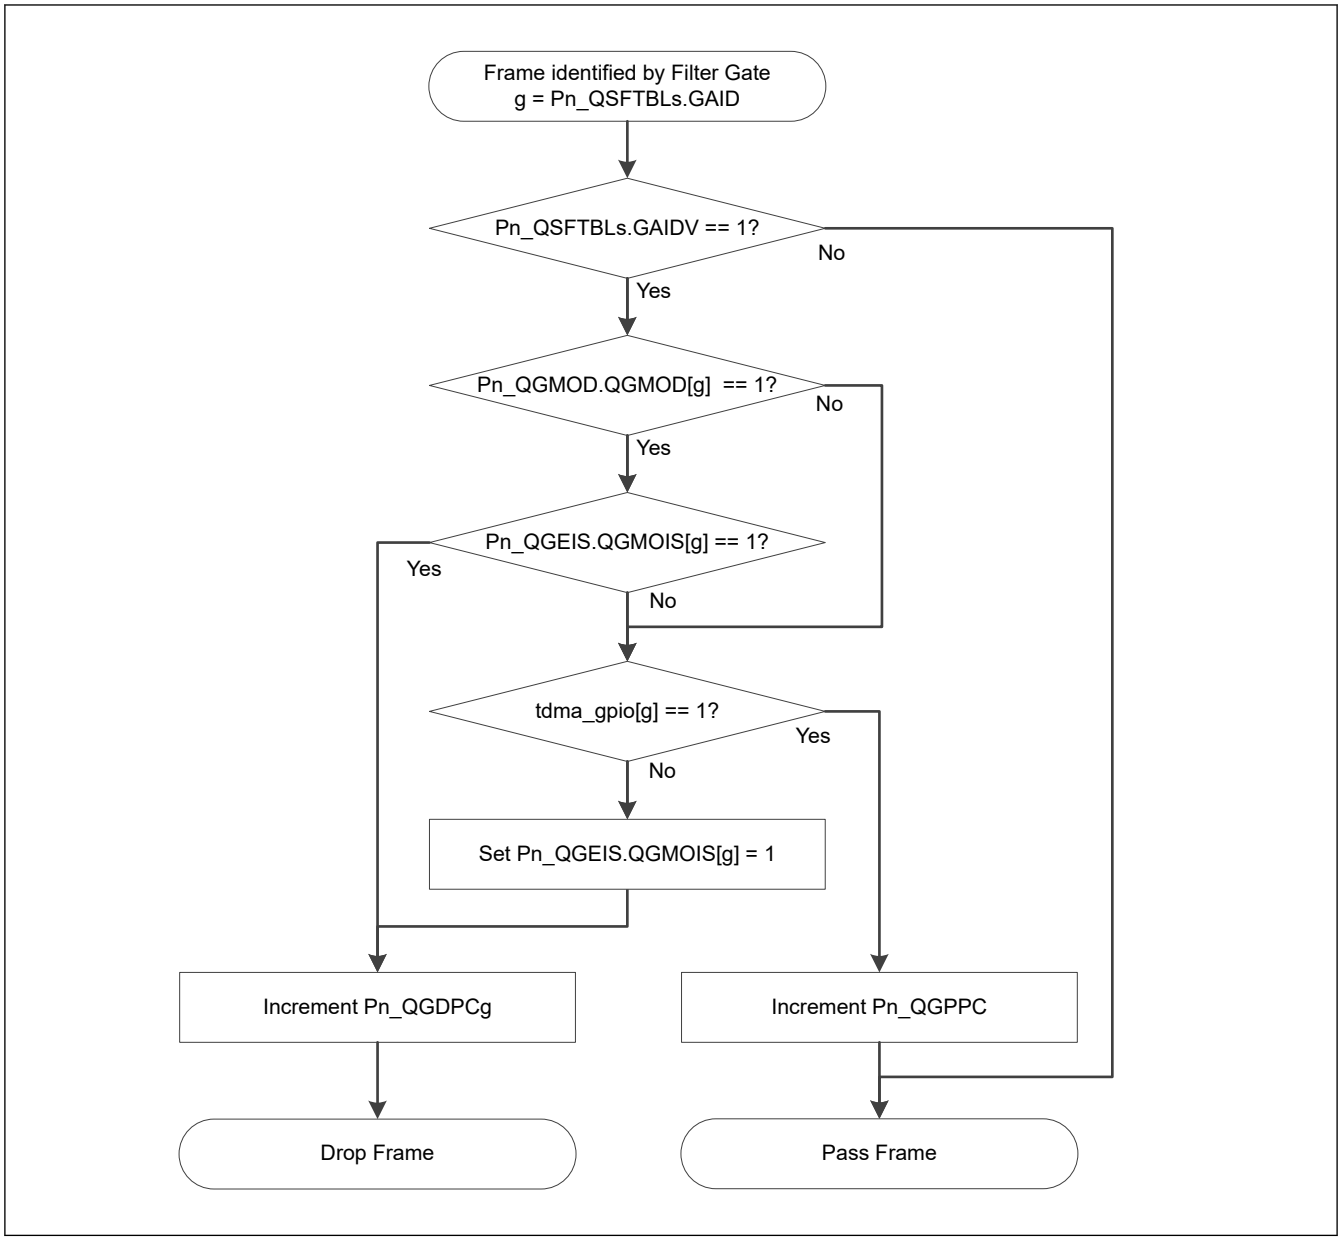

Figure 29.62 Gating check process flow

Set gating check mode by register Pn_QGMOD.

Set gating signals tdma_gpio[7:0] by the TDMA scheduler. See section 29.4.15. TDMA Operation for setting up the TDMA scheduler.

29.4.19.9 SDUmax Verification

After receiving the full frame, the maximum frame length is checked if the Pn_QSFTBLs.MSDUE bit is set. In this case, all frames longer than the value Pn_QSFTBLs.MSDU trigger an error event. The violating frame is dropped and the interrupt event is set.

Depending on the setting of Pn_QSFTBLs.QSMSM, the consecutive frames are not forwarded if SDU size event interrupt is pending.

Note: For checking the SDUmax length, the full frame has to be received. It means SDUmax check can be performed at the end of the frame transmission while most other checks can be applied at the beginning of a frame.

Note: Oversized cut-through frames cannot be stopped. But if the Pn_QSFTBLs.QSMSM bit is set, all consecutive frames mapped to the same filter will be dropped.

SDUmax verification parameters are set along with filter parameters. Refer to Pn_QSFTBLs register function and Figure 29.61 for details.

29.4.19.10 Flow Metering

The Flow meters use the algorithms described in MEF 10.3. Each channel uses the same metering submodule. The meters support two main functions:

1. Replenish tokens into the buckets
   Tokens are replenished into the buckets at a constant rate. The buckets can overflow into other buckets according to the algorithms defined in MEF 10.3.
2. Making acceptance check for frames
   A bucket can be checked for holding sufficient tokens corresponding to the length of a frame to be assessed. If the bucket contains enough tokens, an acceptance judgement is returned, and the corresponding number of tokens is removed from the bucket (frame is green). If the number of token is insufficient, an reject judgement is returned and the number of token in the bucket remains unchanged (frame is red). See Figure 29.65 for details.

The metering structure consists of 8 buckets, which can be cascaded to support the envelope mode.

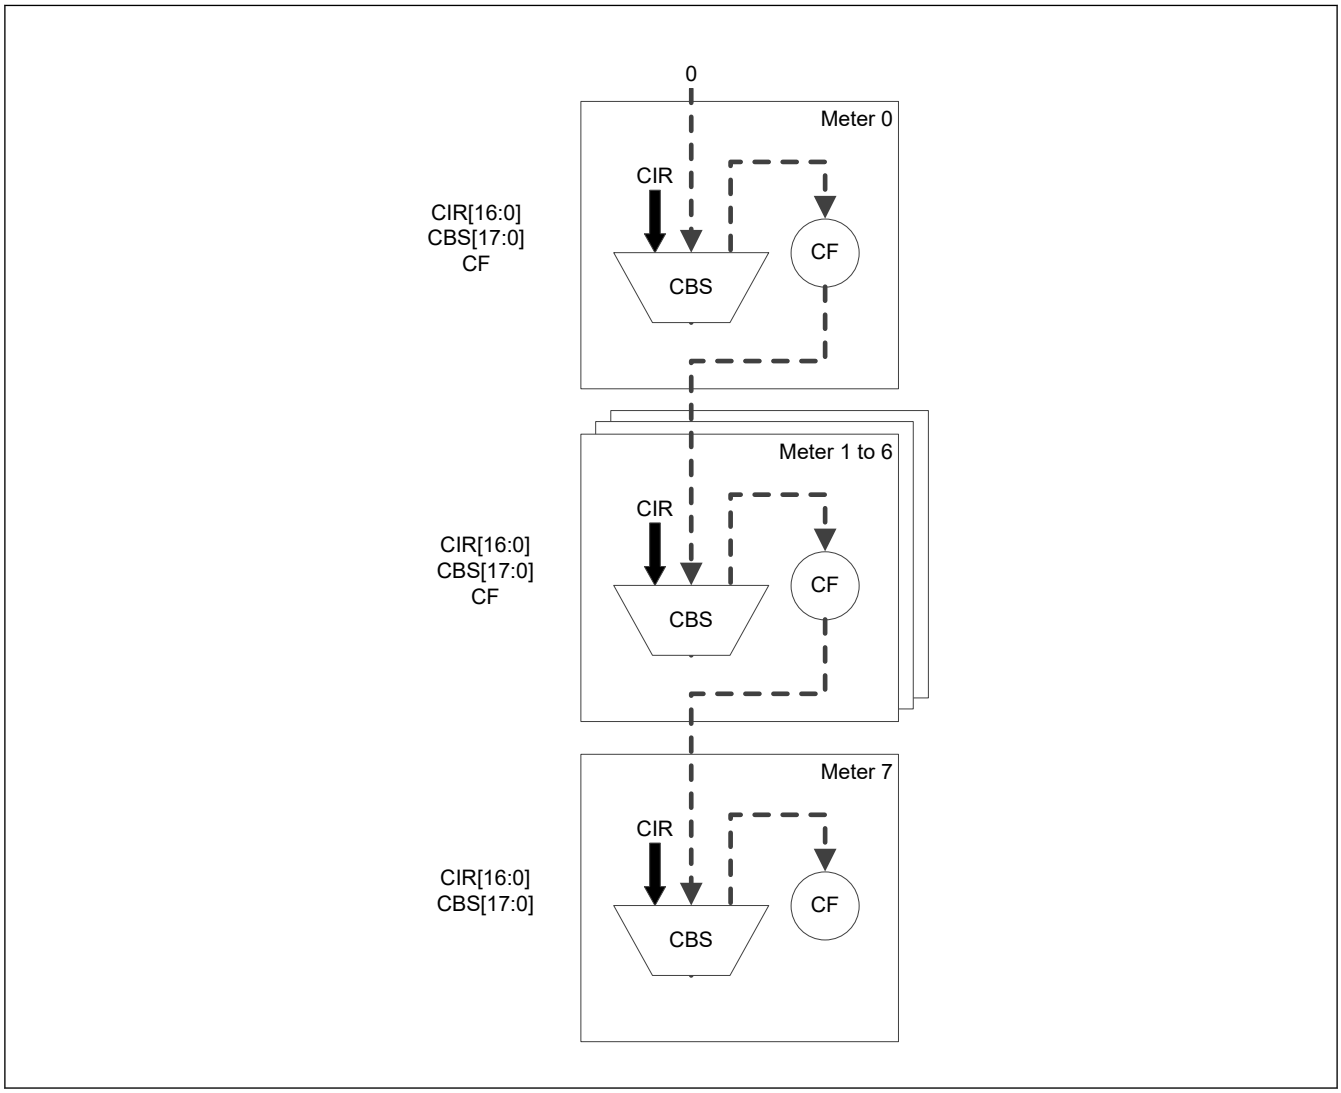

Figure 29.63 Configuration of flow meters

This function provides flow meters according to MEF10.3. Each flow meter provides a green token bucket, that can be configured to provide an envelope mode. Coupling is controlled by the Coupling Flags (CF).

Note: For checking bandwidth compliance by the assigned meter, the full frame has to be received. It means the meter check can be performed at the end of the frame transmission while most other checks can be applied at the beginning of a frame.

Note: Cut-through frames exceeding the bandwidth limit cannot be stopped. But if the Pn_QMDESCm.MM bit is set, all consecutive frames mapped to the same filter will be dropped until the software clears the error event.

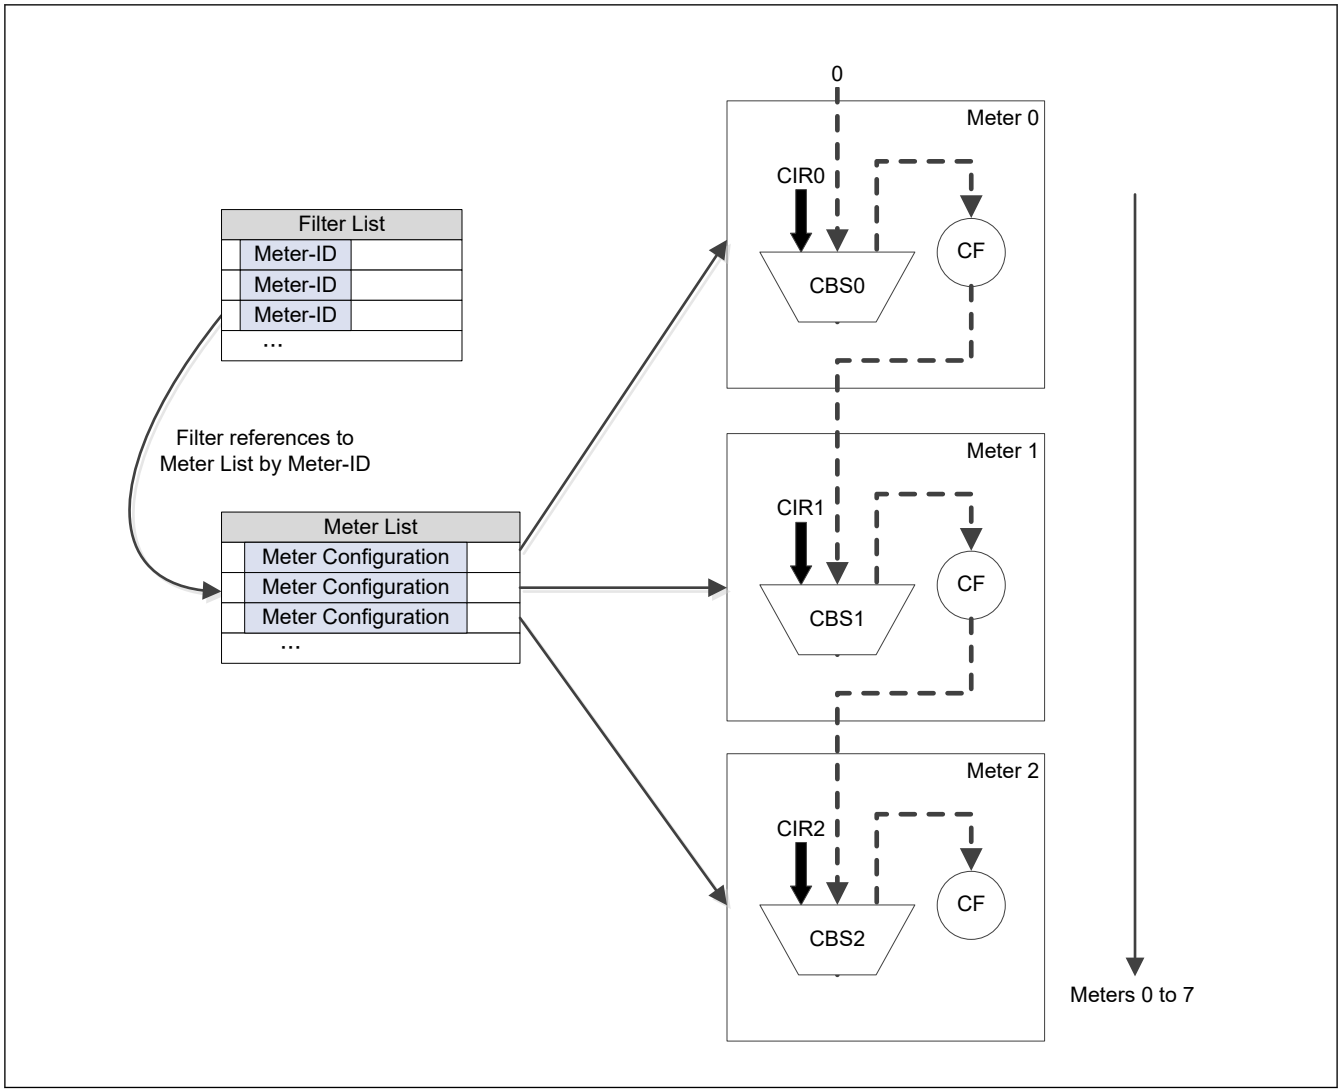

Figure 29.64 Flow meter architecture in EFP

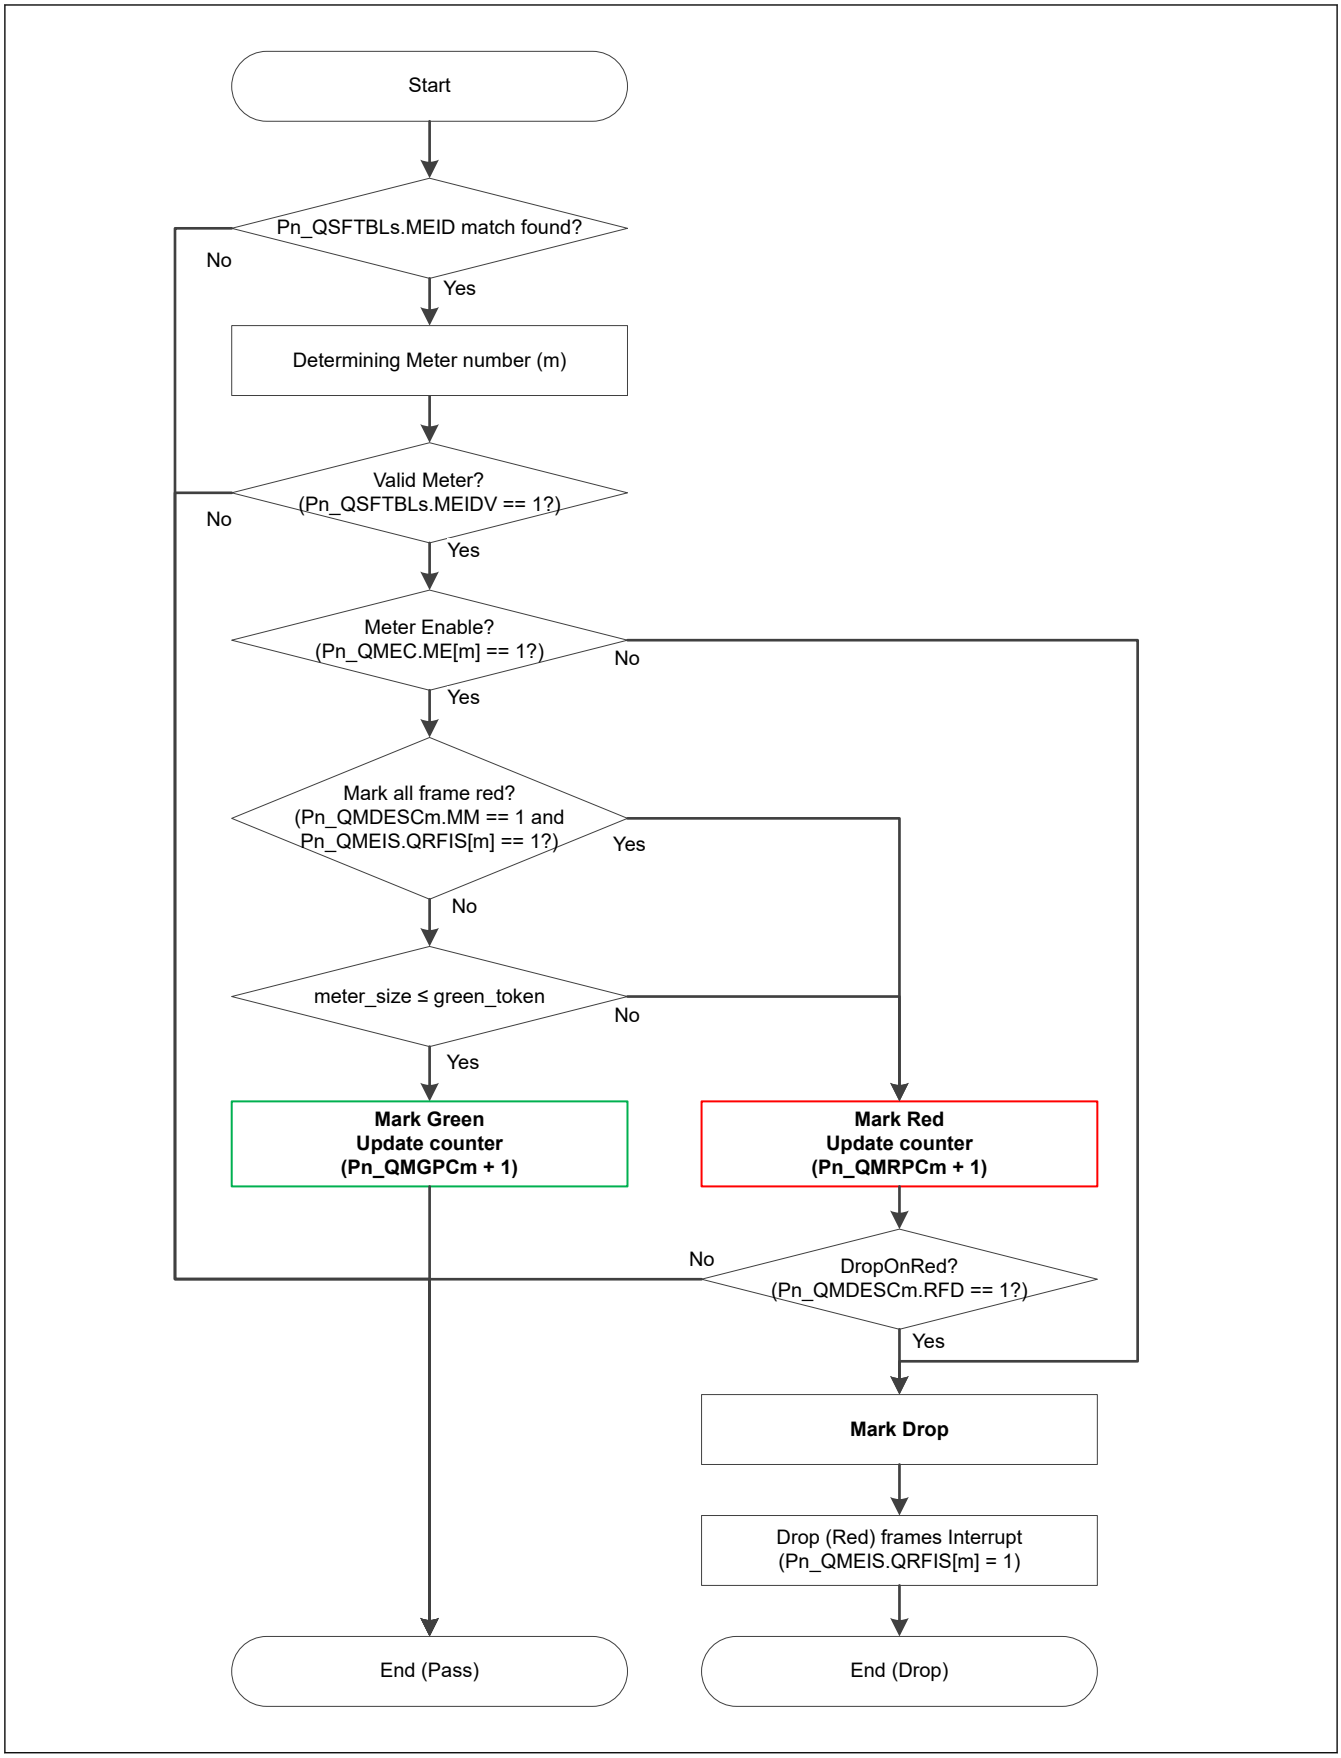

Figure 29.65 Flow meter flow in EFP

Flow Meter setting flow is shown in the figure below.

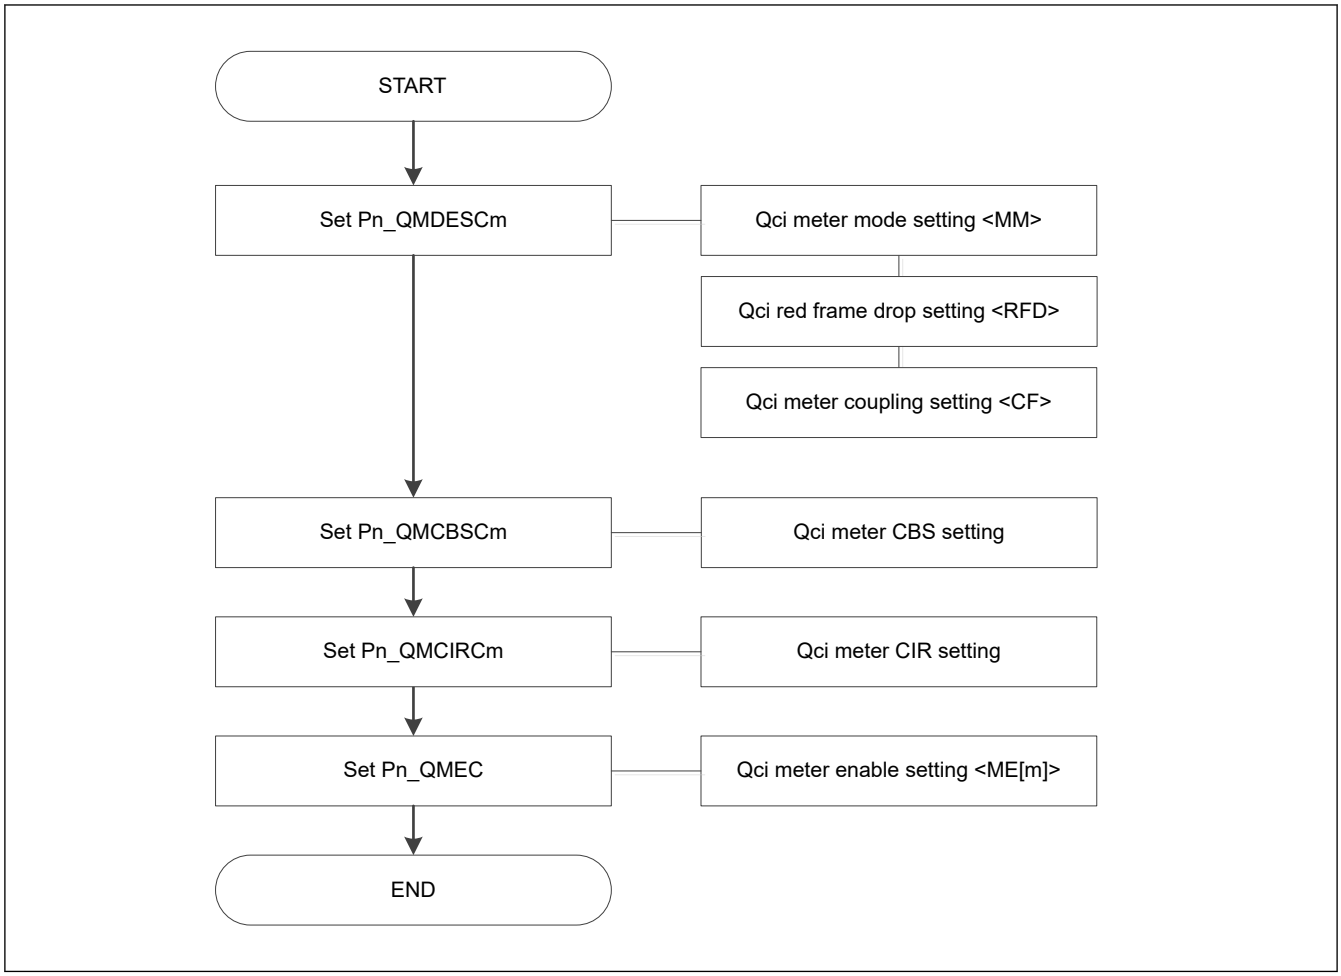

Figure 29.66 Flow Meter setting flow

- Bucket parameters
  - CIR
    CIR bits in Pn_QMCIRCm register is the information rate for replenishing the buckets. The maximum value is determined by the maximum line rate of the port. The minimum value is determined by the application requirement for minimum information rate.
    Max: 1 Gbps = 125 MBps = CIRmax
    Since the replenisher is running at 200 MHz → CIRmax = 0.625; only fractional part needed
  - CBS
    CBS bits in Pn_QMCBSCm register is the maximum token count in the buckets. The minimum value is determined by the maximum Ethernet frame size to be received. The maximum value is determined by the maximum burst length tolerated by the application.
    Min: Maximum frame size of an Ethernet Frame (2 kB).

29.4.19.11 Interrupt Source

Following table shows interrupt sources.

When any of the following interrupts occur, it becomes a global interrupt (INT_CONFIG.EFP_INT).

Table 29.45 Interrupt source for Extended Frame Parser (1 of 2)

Description	Individual Config register	Individual Status/Ack register
Qci stream filter error interrupt (max SDU over drop) (n = 0 to 2)	Pn_QSEIE/Pn_QSEID	Pn_QSEIS
Qci stream gate error interrupt (gating error drop) (n = 0 to 2)	Pn_QGEIE/Pn_QGEID	Pn_QGEIS
Qci meter error interrupt (flow meter drop) (n = 0 to 2)	Pn_QMEIE/Pn_QMEID	Pn_QMEIS

Table 29.45 Interrupt source for Extended Frame Parser (2 of 2)

Description	Individual Config register	Individual Status/Ack register
Frame parser error interrupt (runtime error) (n = 0 to 2)	Pn_ERROR_MASK	Pn_ERROR_STATUS

29.4.19.12 Restrictions

- Restrictions of metering function:
  - Metering function is not available for cut-through frames.
  - It introduces additional forwarding latency into the ingress path.
  - IEEE802.1Q-2018, 8.6.5 Flow classification and metering
    The DEI flag of forwarded frames cannot be modified according to the resulting color of the frame. The final color is determined after frame length is known, i.e. after reception of the full frame. Support of this function would need frame modification at egress process.
  - Supported color mode is color-blind only. EIR and EBS are not supported.
- Additional VLAN tag insert by VITM = 3 is not supported for 1 Gbps operation.
- For Bandwidth metering
  IEC61158-6-10 specifies support of envelope mode (bandwidth sharing) and has no requirement to support of color-awareness. These are the differences to IEEE802.1Q-2018, which is referring to MEF 10.3 without support of envelope mode.
- Forwarding frame dropped
  If the drop is given after the forwarding information has been passed to the memory controller, it will corrupt the frame's egress CRC to ensure that the receiving port will discard the frame. This has the side-effect of causing the port statistics of the receiving device to indicate CRC errors, which can lead to falsely interpret them as errors in the link.

29.4.20 PTP Pulse Generator

The 4 Pulse generators are implemented in ETHSW. These 4 Pulse generators can generate the pulses which have any of period and any of pulse width by utilizing Adjustable timers of the EtherSwitch (see section 29.4.4.7. Adjustable Timer). Selection of the Adjustable timer for these 4 Pulse generators is described in the register PTPMCTRL (see section 27.3.3. PTPMCTRL : PTP Mode Control Register).

This Pulse generator can be configured as following Table and following Figure by the register (see section 29.3.16. PTP Timer Pulse Control Registers).

Table 29.46 Parameter list of pulse signal generation (1 of 2)

Parameter	Registers	Description
Pulse generation enable	SWTMENn	Enables or disables to output pulse signal
Pulse output start time	SWTMSTSECn, SWTMSTNSn	Set the start time of the output signal in seconds and nanoseconds. After set the start time and set 1 to the SWTMEN register in order to enable to output the pulse signal, the pulse output starts when current time is over the start time set. If pulse output is enabled after the set start time, no pulse is output.
Pulse period	SWTMPSECn, SWTMPNSn	Set the pulse period of the output signal in seconds and nanoseconds. The value set in the SWTMPNS register must be larger than 16 × ATIME_INC[6:0] value (128 ns). The value must be set before pulse output is enabled.
Pulse width	SWTMWTHn	Set the pulse high level width in the cycle number of ts_clk (8 ns). Output pulse width is the set value × 8 (ns). If the pulse width set in the SWTMWTH register is greater than pulse period, output is fixed to high level. If the pulse width is set to 0, no pulse is generated and output is fixed to low level. The value must be set before pulse output is enabled.

Table 29.46 Parameter list of pulse signal generation (2 of 2)

Parameter	Registers	Description
Max nanosecond counter	SWTMMAXPn	This register sets the boundary value in nanoseconds to carry from the nanosecond field to the second field. When the nanosecond field reaches the set value of this register, the second field is carried up. This register is normally used with the initial value of 0x3B9ACA00 (= 10^9). In this case, the nanosecond field counts from 0 to 0x3B9AC9FF (= 10^9 - 1) and then carries to the second field. If 0 is set in this register, the boundary value for carrying to the second field is interpreted as 0x100000000 (= 2^{32}). In this case, the nanosecond field is fully counted from 0 to 0xFFFFFFFF (= 2^{32} - 1) and then carries to the second field. This register must always be set to the same value set in the ATIME_EVT_PERIOD register.
Pulse rising time latch	SWTMLATSECn, SWTMLATNSn	The pulse output rising time is latched into the registers. The value is updated whenever pulse output rises.

Note: n = 0 to 3

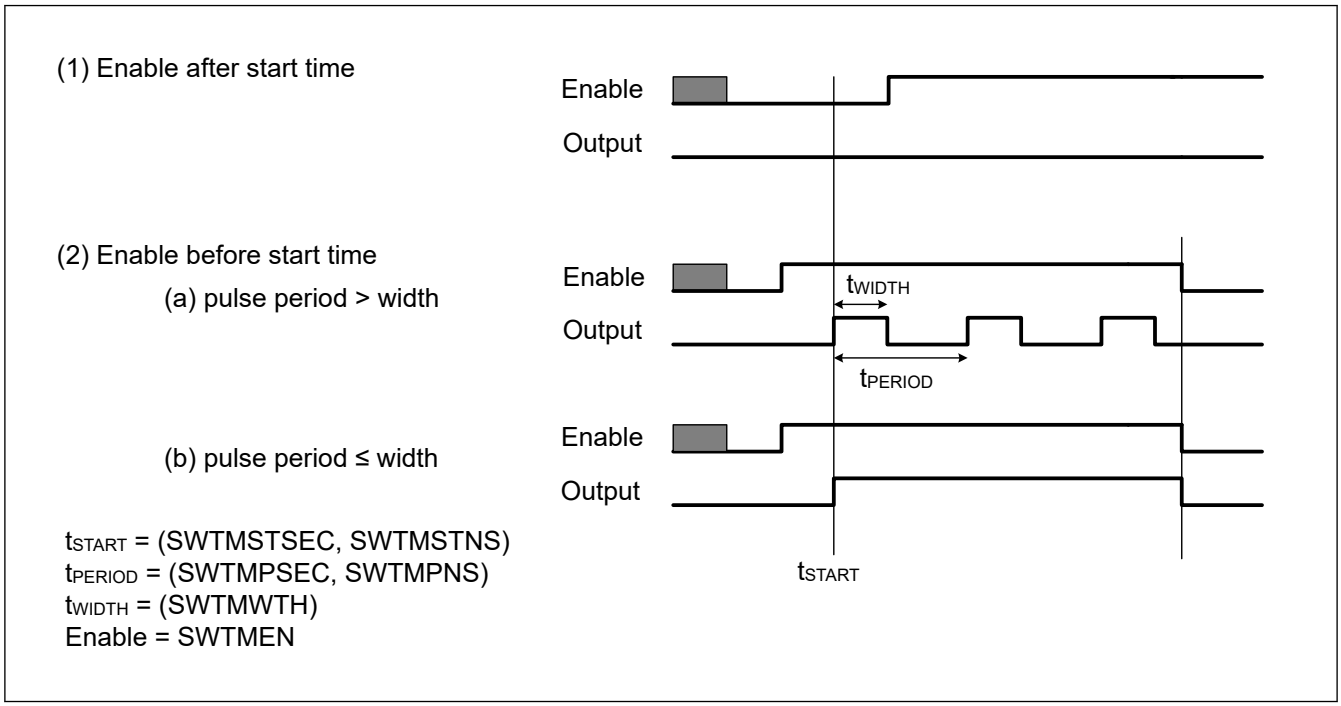

Figure 29.67 Timing chart of pulse generator function

29.4.21 Initializing ETHSW

The initializing sequence in this section is an example used for preparation of system environments for using ETHSW under configuration below.

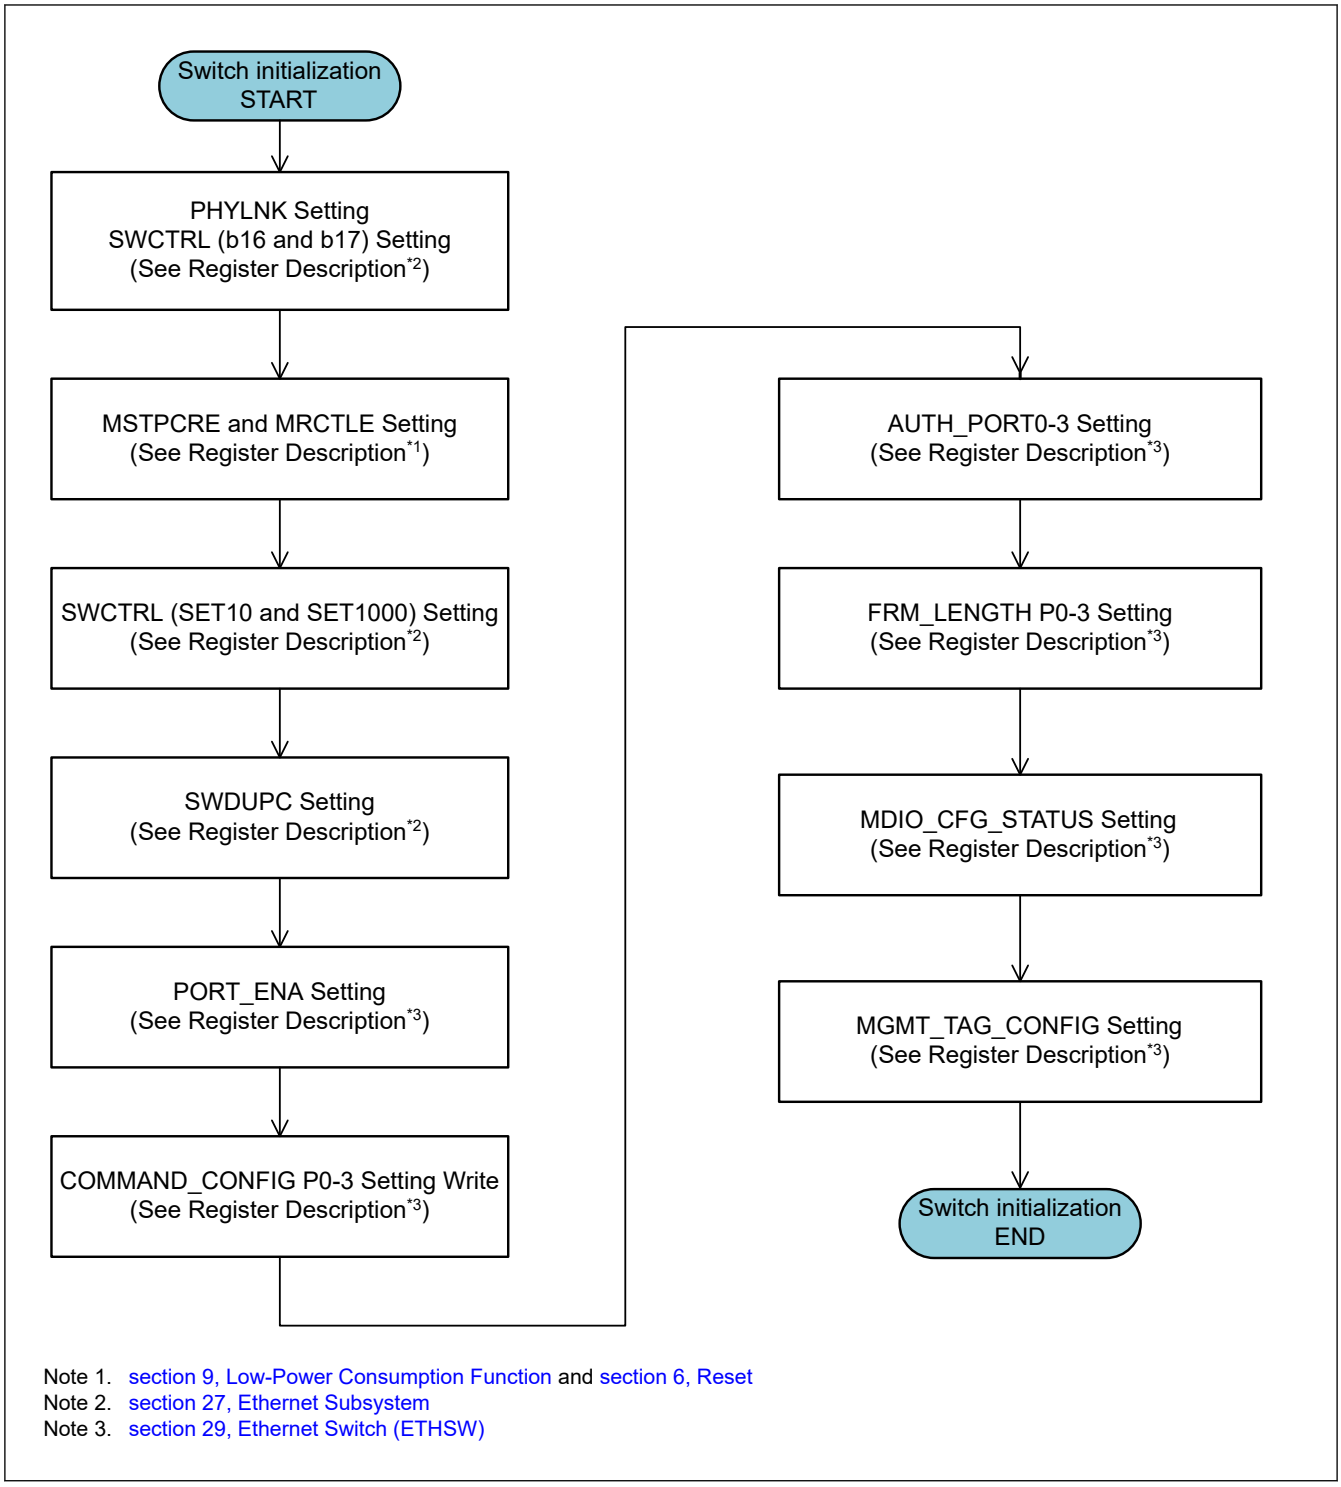

Figure 29.68 Initializing of ETHSW Flowchart

29.4.22 Timing Considerations

29.4.22.1 Cut-Through Frame Forwarding Delay

The forwarding delay is measured from the time of the first byte of the frame received at the phy receive interface in the switch (MII receive interface) to the same byte being transmitted on the phy transmission interface in the switch (MII transmit interface) for a single frame with no other activity in other ports. The delay shown is the expected minimum delay and it can be higher due to congestion in the forwarding tables and frame buffer.

The cut-through forwarding delay does not apply when the destination port is the management port as this port only receive frames in store-and-forward.

Table 29.47 Cut-through frame forwarding delay

Source port speed	Destination port speed	Delay (minimum)
10 Mbps	10 Mbps	44.4 µs
100 Mbps	10 Mbps	12.9 µs
100 Mbps	100 Mbps	3.96 µs
1000 Mbps	10 Mbps	10.8 µs
1000 Mbps	100 Mbps	1.50 µs
1000 Mbps	1000 Mbps	0.59 µs

Note: The measurements were made with the values for CT_DELAY register.

29.4.22.2 Store-and-Forward Frame Forwarding Delay

The forwarding delay is measured from the time of the first byte of the frame received at the phy receive interface in the switch (MII receive interface) to the same byte being transmitted on the phy transmission interface in the switch (MII transmit interface) for a single frame with no other activity in other ports. The delay shown is the expected minimum delay and it can be higher due to congestion in the forwarding tables and frame buffer.

Table 29.48 Store-and-forward frame forwarding delay

Source port speed	Destination port speed	Delay (minimum)
10 Mbps	10 Mbps	63.6 µs
10 Mbps	100 Mbps	54.5 µs
10 Mbps	1000 Mbps	53.6 µs
100 Mbps	10 Mbps	15.3 µs
100 Mbps	100 Mbps	6.60 µs
100 Mbps	1000 Mbps	5.70 µs
1000 Mbps	10 Mbps	10.8 µs
1000 Mbps	100 Mbps	1.81 µs
1000 Mbps	1000 Mbps	0.92 µs

29.4.22.3 Frame Timestamp Interface Delay

The frame timestamp interface delay is a value that needs to be added or subtracted from MAC captured timestamp in both receive and transmit directions. This value represents the delay between the internal frame timestamp point and the switch's MII interface. The timestamp is captured conceptually at the first bit of the frame after the SFD (i.e. the first bit of the destination address of the frame).

The correction is dependent on the timestamp clock frequency and the port rate. The values in the table below are given for a timer's clock frequency of 125 MHz. The port's receive and transmit frequencies depend on the rate: 2.5 MHz for 10 Mbps, 25 MHz for 100 Mbps, and 125 MHz for 1000 Mbps. The calculation column describes how to obtain the correction value for different clock frequencies.

The correction value has an uncertainty that is due to the clock-crossing of from/to the port's receive/transmit clock domain to/from the timer's clock domain, which can be reduced by using a faster timer's clock as well.

Table 29.49 Frame timestamp interface delay (correction offset) (1 of 2)

Correction value	Minimum	Typical	Maximum	Calculation
10 Mbps Receive Timestamp	-1216 ns	-1212 ns	-1208 ns	- (3 × rx_cyc + (1 to 2) × ts_cyc)
100 Mbps Receive Timestamp	-136 ns	-132 ns	-128 ns	- (3 × rx_cyc + (1 to 2) × ts_cyc)
1000 Mbps Receive Timestamp	-32 ns	-28 ns	-24 ns	- (2 × rx_cyc + (1 to 2) × ts_cyc)
Transmit Timestamp (all speeds, HUB disabled)	-16 ns	-12 ns	-8 ns	- ((1 to 2) × ts_cyc)

Table 29.49 Frame timestamp interface delay (correction offset) (2 of 2)

Correction value	Minimum	Typical	Maximum	Calculation
10 Mbps Transmit Timestamp (HUB enabled)	+2384 ns	+2388 ns	+2392 ns	+ (6 × tx_cyc – (1 to 2) × ts_cyc)
100 Mbps Transmit Timestamp (HUB enabled)	+224 ns	+228 ns	+232 ns	+ (6 × tx_cyc – (1 to 2) × ts_cyc)

Note: The correction value is given with a sign indicating that the value needs to be added (+) or subtracted (-) from the timestamp value. The ts_cyc is the cycle time for the timer's clock (fixed 8 ns); The rx_cyc and tx_cyc are the cycle times for the receive and transmit port's clocks respectively.

29.4.22.4 Timer Configuration Delay

The switch's internal timers are programmed via the register interface which has an inherent delay from the time when the register write operation is presented to the CPU host interface until the timer action is executed.

The table below describes the delay from the point of the CPU operation presented to the register interface (input pin hsel transitioning from 0 to1) to the action on the timer being executed. Two actions are relevant:

- Timer load: loading the timer with a new seconds and nanoseconds value via ATIME_SECn and ATIMEn. The delay indicated in the table should be added to the value in {ATIME_SECn, ATIMEn} to accurately program the timer to the desired time.
- Time capture: capturing the timer's current value using ATIME_CTRLn.CAPTURE or ATIME_CTRLn.CAPTURE_ALL. The captured time is read back in {ATIME_SECn, ATIMEn} and to this value the delay below should be subtracted to obtain the time at the point when hsel transitioned from 0 to 1.

Table 29.50 Timer configuration delay

Correction value	Minimum	Typical	Maximum	Calculation
Timer Load (using ATIMEn)	87 ns	93.5 ns	100 ns	3 × PCLKM_cyc + (5 to 6) × sx_cyc + (4 to 5) × ts_cyc
Timer Capture (using ATIME_CTRLn.CAPTURE)	68 ns	74.5 ns	81 ns	3 × PCLKM_cyc + (6 to 7) × sx_cyc + (1 to 2) × ts_cyc

Note: Condition is PCLKM_cyc is 8 ns, sx_cyc (switch clock) is 5 ns (fixed), and ts_cyc (timer clock) is 8 ns (fixed).

29.4.22.5 TDMA Action Delays

The following table lists the delays related to the TDMA actions. When the TDMA is operating there is a delay from the matching of the time in the TCV to the action indicated by the TCV being executed. There is also a minimum action time between events which limits the time between back to back actions.

For programming the TDMA we recommend to use a distance between vectors of at least the maximum value in the "minimum time between vectors" in the table below.

The delay values for state changes and gate/queue events must be subtracted to the time value programmed in the TCV vector to ensure a more precise execution. For instance, if the GPIO pin is to be toggled at 1000 ns after the period starts, the time offset to be programmed in the TCV should be (1000 - 43.5) = 956.5 ns.

Table 29.51 TDMA action delays

TDMA action	Minimum	Typical	Maximum	Calculation
GPIO change RED_PERIOD change OUT_CT_ENA change IN_CT_ENA change HOLD_REQ change	41 ns	43.5 ns	46 ns	2 × ts_cyc + (5 to 6) × sx_cyc
GATE close/open QUEUE trigger	51 ns	53.5 ns	56 ns	2 × ts_cyc + (7 to 8) × sx_cyc
Minimum time between vectors	115 ns	121.5 ns	128 ns	(5 to 6) × ts_cyc + (15 to 16) × sx_cyc

Note: Condition is that sx_cyc (switch clock) is 5 ns (fixed) and ts_cyc (timer clock) is 8 ns (fixed).

29.4.22.6 Pattern Matcher Delayed Frame Trigger Delay

The pattern matcher has a delayed frame trigger function (IMC_TRIGGER_DLY) which allows triggering a frame at a specified time after the trigger event occurs. Due to the logic doing the time comparison and generating the

event, there is a delay from the actual time programmed and the trigger event executing which could need to be accounted for. The table below describes this delay, and such delay should be subtracted to the value programmed in MMCTL_DLY_QTRIGGER_CTRL.

Table 29.52 Pattern matcher action delays

Pattern matcher action	Minimum	Typical	Maximum	Calculation
IMC_TRIGGER_DLY	51 ns	53.5 ns	56 ns	2 × ts_cyc + (7 to 8) × sx_cyc

Note: Condition is sx_cyc (switch clock) is 5 ns (fixed) and ts_cyc (timer clock) is 8 ns (fixed).

29.4.22.7 Transmit Frame Selection to Frame's FB Delay

The following table describes the delay from a queue becoming ready for transmission to the first byte being transmitted by switch at the MII/GMII interface. A queue becoming ready to transmit frames depends on various factors including:

- The queue being enabled by the firmware
- A frame queued-up for transmission (i.e. the output queue buffer going non-empty)
- A queue transitioning from closed to open
- A frame triggering action on a closed queue
- The hold request transitioning from 1 to 0 for a preemptable queue

The values in the table below are the minimum time, and this time can be slightly higher due to arbiters in the memory controller and clock crossing into the transmission port. The values also assume that the port is idle and all IPG has been transmitted for the previous frame when the queue becomes ready for transmission.

Table 29.53 Transmit frame selection to frame's FB delay

Port speed	Delay	Calculation
10 Mbps	10.1 µs	18 × sx_cyc + 25 × tx_cyc
100 Mbps	1.09 µs	18 × sx_cyc + 25 × tx_cyc
1000 Mbps	0.210 µs	18 × sx_cyc + 15 × tx_cyc

Note: The sx_cyc is the cycle time for the switch's clock; The tx_cyc is the cycle time for the transmit port's clock.

29.4.23 Usage notes

29.4.23.1 Restriction

1. If Ethernet ports are used as Hub mode, the ports must be configured to "RMII mode 10/100 Mpbs REF_CLK output" mode by CONV_MODE bits of "RGMII/RMII Converter n Control register (CONVCTRLn) (n = 0 to 2)" (see section 27, Ethernet Subsystem). Because PHYs connected with the Ethernet ports in Hub mode requires common clock supplied as REF_CLK.
2. To configure the port of ETHSW as half-duplex mode, it is necessary to clear PHY_DUPLEX[2:0] bits of "Switch Core Duplex Mode register (SWDUPC)" (see section 27, Ethernet Subsystem) and set HD_ENA bit of "Port n Command Configuration register (COMMAND_CONFIG_Pn)" (See section 29.3.6.2. COMMAND_CONFIG_Pn : Port n Command Configuration Register (n = 0 to 3)). Note that 1 Gbps is not supported at half-duplex mode.
3. For initialization of the Learning Table, wait until CLRTBL bit of LK_CTRL register is cleared.
4. IP Classify table is not initialized automatically, therefore it is necessary to initialize all areas by software. Refer to IP_PRIORITYn register (see section 29.3.1.48. IP_PRIORITYn : IP Priority Register n (n = 0 to 3)) description for an access procedure to IP Classify table.
5. The PHY, when operating in half-duplex, must not return transmit data to its receive interface.
6. The Parallel Redundancy Protocol (PRP) and 802.3br frame preemption should not use at the same time.
7. The following shows how to disable the MAC transmit function:
   (a) Disable the port via the control register PORT_ENA. This prevents frames to be forwarded to the port. The egress frames queued up can be flushed with the queue flush function via the control register MMCTL_QFLUSH, otherwise, the port becomes inactive once the queues are empty.

(b) Block the queues via the control register MMCTL_QGATE. The TDMA must be disabled for the port as well using TDMA_ENA_CTRL.PORT_ENA to prevent the TDMA from opening the queues again. The egress queues can be flushed via the control register MMCTL_QFLUSH if needed.

8. When using adjustment function other than immediate offset adjustment, the nanosecond time of the timer can glitch dependent on the difference between the normal increment value (ATIME_INCn[6:0]) and the adjustment value (ATIME_INCn[22:16] or ATIME_INCn[14:8]). ATIMEn and ATIME_SECn may output invalid value, for example, a transition from 24.4294967276 to 25.4294967292 and 24.999999980 to 25.1000000004. To mitigate these errors, consider two workarounds as below:

   (a) The firmware must monitor the timer with a frequency faster than twice every second using a time source that is different from the timer itself. This can detect an error in the seconds increment when a frame's timestamp needs to be processed. Subtract 1 from the seconds if occurred.

   (b) When using a progressive (offset) correction or continuous (drift) adjustment, program the values in ATIME_INCn[22:16] and ATIME_INCn[14:8] as similar as ATIME_INCn[6:0] (within 5 ns).

9. Setting ATIME_CTRLn[12] to 1 causes not only time capture from all the timers but also immediate timer correction from ATIME_INCn[14:8]. To avoid altering the timer value, consider below workaround:

   (a) The value in ATIME_INCn[14:8] must be programmed the same as ATIME_INCn[6:0] if continuous (drift) adjustments are not used. This ensures that a timer capture does not alter the timer value.

   (b) If continuous (drift) adjustments are needed, then prior to a capture ATIME_INCn[14:8] must be programmed the same as ATIME_INCn[6:0]. After the capture ATIME_INCn[14:8] can be returned to its original value. This can result in a small error in the timer if the period for the adjustments is short (ATIME_CORRn).

   (c) When a one-time small immediate adjustment is needed the value in ATIME_INCn[14:8] must be returned to be the same ATIME_INCn[6:0] after the adjustment is executed.

29.4.23.2 Known Issue and Workaround

There are known issues in ETHSW. Please consider workaround when using related function.

Table 29.54 Known issue and workaround

No.	Issues	Workaround
1	TX_RESPONSE_OK_CNT and TX_VERIFY_OK_CNT registers may be incremented count incorrectly.	No workaround. Do not use TX_RESPONSE_OK_CNT and TX_VERIFY_OK_CNT registers. Count the frame by software if needed.
2	When FRM_LENGTH register in port 3 (Management port) is set to very small value, the frame may be discarded since the frame length may be incorrectly detected as oversize.	Set FRM_LENGTH register in port 3 to more than or equal to the initial value. When you want to limit the frame length of the received frame, use FRM_LENGTH registers in port 0 to port2.
