3	When setting 0 to the INT_VALUE bit in TDMA_CTR1 register, the interrupt is not generated.	When using the interrupt by TDMA_CTR1, set the value other than 0 to the INT_VALUE bit.
4	When Transmit Timestamp Capture Overflow occurs, Transmit Timestamp Capture Overflow interrupt may not be generated.	Do not use Transmit Timestamp Capture Overflow interrupt. Instead, use Transmit Timestamp Capture interrupt and obtain the captured timestamp before overflow occurs.
5	The IRQ_STAT bit in TSM_IRQ_STAT_ACK register does not show the TSM interrupt pending status correctly.	When checking TSM interrupt pending status, do not use the IRQ_STAT bit in TSM_IRQ_STAT_ACK register but the TSM_INT bit in the INT_STAT_ACK register.
6	When reading MDIO related registers (MDIO_CFG_STATUS, MDIO_COMMAND and MDIO_DATA), the read value from MDIO related registers may be incorrect.	When accessing statistic counter register between 0x8012_0300 to 0x8012_033C, perform dummy read to the 0x8012_0310 after the access.

30. EtherCAT Slave Controller (ESC)

30.1 Overview

The EtherCAT slave controller (ESC) uses an EtherCAT Slave Controller IP Core made by Beckhoff Automation GmbH, Germany. The ESC handles EtherCAT communications as an interface between the EtherCAT field bus and slave applications.

Table 30.1 Specification of the EtherCAT slave controller

Item		Description
Number of ports		3
FMMU		8
SyncManager		8
Process data RAM [KB]		8
Distributed clocks		64 bits
EBus		No
Process data interfaces (PDI)	Digital I/O	No
	SPI slave	No
	Host MPU interface	On-chip bus

Figure 30.1 shows a block diagram of the EtherCAT slave controller.

This section describes the function of the registers and modules in white. The registers and modules in gray are described in section 27, Ethernet Subsystem, section 28, Ethernet MAC (GMAC), and section 29, Ethernet Switch (ETHSW). Refer to the related sections regarding the registers and modules which are needed to operate the EtherCAT slave controller.

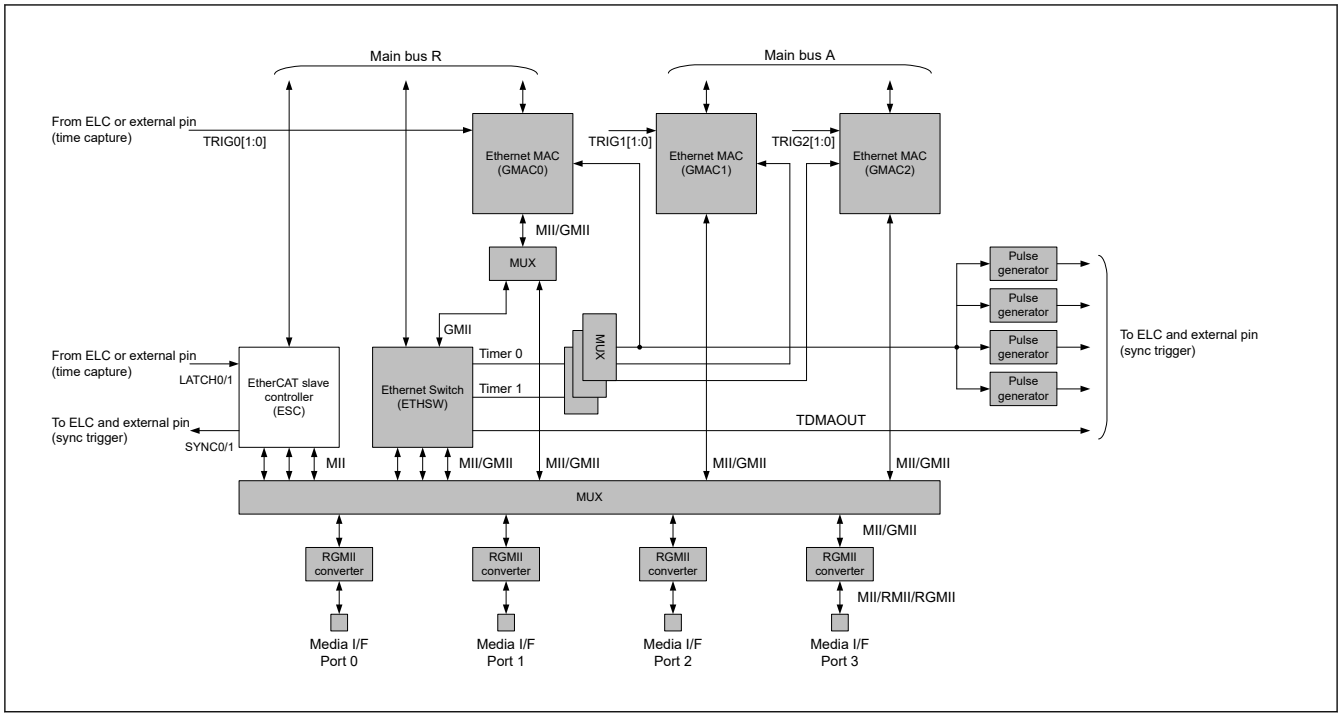

Figure 30.1 Block diagram of the EtherCAT slave controller

Table 30.2 lists the input/output pins of the EtherCAT controller.

Table 30.2 Input/Output pins of the EtherCAT slave controller (excluding PHY MII pins) (1 of 2)

Pin name	I/O	Function	Active
ESC_LEDRUN	O	EtherCAT RUN LED signal output pin	High

Table 30.2 Input/Output pins of the EtherCAT slave controller (excluding PHY MII pins) (2 of 2)

Pin name	I/O	Function	Active
ESC_IRQ	O	EtherCAT IRQ signal output pin	High
ESC_LEDSTER	O	EtherCAT Dual-color State LED signal output pin	High
ESC_LEDERR	O	EtherCAT Error LED signal output pin	High
ESC_LINKACT0	O	EtherCAT link/Activity LED signal output pin (port 0)	High
ESC_LINKACT1	O	EtherCAT link/Activity LED signal output pin (port 1)	High
ESC_LINKACT2	O	EtherCAT link/Activity LED signal output pin (port 2)	High
ESC_SYNC0	O	EtherCAT SYNC0 signal output pin	High
ESC_SYNC1	O	EtherCAT SYNC1 signal output pin	High
ESC_LATCH0	I	EtherCAT LATCH0 signal input pin	Rise/Fall (Both Edge)
ESC_LATCH1	I	EtherCAT LATCH1 signal input pin	Rise/Fall (Both Edge)
ESC_RESETOUT#	O	EtherCAT reset output pin	Low
ESC_I2CCLK	O	EtherCAT EEPROM I2C clock output pin	—
ESC_I2CDATA	I/O	EtherCAT EEPROM I2C data signal I/O pin	—
ESC_PHYLINK0	I	EtherCAT PHY0 link status signal input pin	High*1
ESC_PHYLINK1	I	EtherCAT PHY1 link status signal input pin	High*1
ESC_PHYLINK2	I	EtherCAT PHY2 link status signal input pin	High*1
ESC_MDC	O	Management data clock output pin	—
ESC_MDIO	I/O	Management data I/O pin	—

Note 1. ESC_PHYLINKn (n = 0 to 2) active level is controlled by PHYLNK register.

30.2 Functional Overview

Typical functions of the EtherCAT slave controller and supported functions by this LSI are shown in Table 30.3. Regarding the detailed specification of EtherCAT and ESC, refer to the documentation (ETG.1000 EtherCAT Specification) provided by EtherCAT Technology Group (ETG) and the EtherCAT Slave Controller IP Core (v2.04) data sheet provided by Beckhoff Automation.

Table 30.3 Typical functions of EtherCAT slave controller and supported functions by this LSI (1 of 3)

Features	Functions	Support
EtherCAT protocol	Handling the following frames: ● Ethernet frames with Ether type 0x88A4 ● EtherCAT frames encapsulated in UDP/IP ● EtherCAT frames with VLAN tag ● Normal Ethernet frames	✓
Addressing modes	Device addressing ● Auto increment address ● Configured station address ● Broadcast address	✓
	Logical addressing	✓
Working counter	Counting the number of read/write from/to the device	✓
EtherCAT command type	Processing the command that master requests slaves to address each addressing mode	✓
Loop control	Loop control and loop state in ESC	✓
Shadow buffer	Shadow buffers function when register is read/written	✓
Circulating frames	Processing of circulating frames during the failure	✓

Table 30.3 Typical functions of EtherCAT slave controller and supported functions by this LSI (2 of 3)

Features	Functions	Support
Link detection	Link MII signal (PHY link signal) (monitoring the PHY register through the management interface)	✓
	MI Link detection and configuration	—
	Enhanced link detection (monitoring the state of transfer by MII RX error monitor)	✓
FIFO size reduction	RX FIFO size reduction because of reduction of propagation delay	✓
Ethernet physical layer	MII	✓
	EBUS	—
	Back-to-Back MII connection	✓
	MII management interface	✓
	Read/write of the PHY register through MII management interface	✓
	PHY address offset	✓
	Manual TX shift compensation	✓
	Automatic TX shift compensation See Table 30.4 for enabling condition.	✓
FMMU	Mapping between logical address and physical address	✓
SyncManager	Buffer mode	✓
	Mailbox mode	✓
	Interrupt and latch event generation when a buffer was completely and successfully written or read.	✓
	Repeating mailbox communication	✓
	SyncManager deactivation by the PDI	✓
Distributed clocks	Clock synchronization considering propagation delay and drift compensation	✓
	Generation of synchronous output signals (SYNC0 and 1 signals) ● Cyclic mode ● Single shot mode ● Cyclic acknowledge mode ● Single shot acknowledge mode	✓
	Precise time stamping of input events (LATCH0 and 1 signals) ● Single event mode ● Continuous mode ● SyncManager event mode (for debugging)	✓
	Generation of synchronous interrupts	✓
	Synchronous digital output updates / Synchronous digital input sampling	—
	Exclusive control for the SYNC and LATCH signals of the ECAT and PDI	✓
	System time control by the PDI	—
	Communication Timing ● Free run ● Synchronized to output event ● Synchronized to SYNC signal	✓
EtherCAT state machine	Control of state machine/indication of the status and error code	✓
	Device emulation	—
SII EEPROM	SII EEPROM commands	✓
	SII EEPROM error indication	✓
	SII EEPROM access interface	✓
	EEPROM size selection	✓
	EEPROM emulation	—

Table 30.3 Typical functions of EtherCAT slave controller and supported functions by this LSI (3 of 3)

Features	Functions	Support
Interrupt	AL event request (PDI interrupt)	✓
	ECAT event request (ECAT interrupt)	✓
Watchdog	Process data watchdog	✓
	PDI watchdog	✓
Error counters	Port error counters	✓
	Forwarded RX error counter	✓
	ECAT processing unit error counter	✓
	PDI error counter	✓
	Lost link counter	✓
	Watchdog counter process data	✓
	Watchdog counter PDI	✓
LED signals	RUN LED signal	✓
	ERR LED signal	✓
	STATE LED and STATE_RUN LED signals	✓
	LINK/ACT LED signals	✓
	Port error LED signal	—
	RUN/ERR LED override	✓
Process data interface (PDI)	Digital I/O	—
	SPI slave	—
	8-bit/16-bit synchronous/asynchronous microcontroller interface	—
	On-chip bus	✓
	General purpose I/O	—
Write protection	Write protection for the register area (0x0000 to 0x0FFF)	✓
	Write protection for the whole area including the user RAM and process data RAM (0x0000 to 0x2FFF)	✓
ESC reset	ESC reset from the master or PDI	✓

Table 30.4 Configuration of TX shift function

PHYSEL bit in SCKCR register	ETHn_TXCLK	
	Connected	Not connected
0 (ETHn_REFCLK is based on PLL)	Valid (Automatic TX shift is enabled)	Valid (Manual TX shift may be needed)
1 (ETHn_REFCLK is based on Main OSC or external clock input)	Valid (Automatic TX shift is enabled)	Invalid (This combination is prohibited)

30.4 ESC Auxiliary Registers

30.4.1 ECATOFFADR : EtherCAT PHY Offset Address Setting Register

Base address: ESC_INI = 0x8011_0200

Offset address: 0x0_0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	OADD[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	OADD[4:0]	PHY Offset Address Setting Set the offset address of PHY of using the EtherCAT.	R/W
31:5	—	The read values are undefined. The write value should be 0.	R/W

Note: This register can only be written when protection is unlocked by the specific sequence using the Ethernet Protect register (PRCMD). For the protection unlock procedure, see section 27.3.1. PRCMD : Ethernet Protect Register. The special sequence is not necessary when reading the value of this register.

The ECATOFFADR register sets the offset address of the Ethernet PHY in case of using the EtherCAT. This register can be read/written in 32-bit units.

30.4.2 ECATOPMOD : EtherCAT Operation Mode Register

Base address: ESC_INI = 0x8011_0200

Offset address: 0x0_0004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EEPROMSIZE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EEPROMSIZE	EEPROM Memory Size Specification Sets the size of the EEPROM memory of the EtherCAT. 0: 16 Kbits or less 1: 32 Kbits to 4 Mbits	R/W
31:1	—	The read values are undefined. The write value should be 0.	R/W

Note: This register can only be written when protection is unlocked by the specific sequence using the Ethernet Protect register (PRCMD). For the protection unlock procedure, see section 27.3.1. PRCMD : Ethernet Protect Register. The special sequence is not necessary when reading the value of this register

The ECATOPMOD register sets the EEPROM memory size in case of using the EtherCAT. This register can be read/written in 32-bit units.

30.4.3 ECATDBGC : EtherCAT Debug Control Register

Base address: ESC_INI = 0x8011_0200

Offset address: 0x0_0008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TXSFT2[1:0]		TXSFT1[1:0]		TXSFT0[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	TXSFT0[1:0]	Set the delay time for ETH0_TXEN and ETH0_TXDn of the EtherCAT 0 0: 0 ns 0 1: 10 ns 1 0: 20 ns 1 1: 30 ns	R/W
3:2	TXSFT1[1:0]	Set the delay time for ETH1_TXEN and ETH1_TXDn of the EtherCAT 0 0: 0 ns 0 1: 10 ns 1 0: 20 ns 1 1: 30 ns	R/W

Bit	Symbol	Function	R/W
5:4	TXSFT2[1:0]	Set the delay time for ETH2_TXEN and ETH2_TXDn of the EtherCAT 0 0: 0 ns 0 1: 10 ns 1 0: 20 ns 1 1: 30 ns	R/W
31:6	—	The read values are undefined. The write value should be 0.	R/W

Note: This register can only be written when protection is unlocked by the specific sequence using the Ethernet Protect register (PRCMD). For the protection unlock procedure, see section 27.3.1. PRCMD : Ethernet Protect Register. The special sequence is not necessary when reading the value of this register.

The ECATDBGC register controls the delay time of TXEN and TXDn. This register can be read/written in 32-bit units.

30.4.4 ECATTRGSEL : EtherCAT DC Latch Trigger Select Register

Base address: ESC_INI = 0x8011_0200

Offset address: 0x0_000C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TRGSEL1	TRGSEL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TRGSEL0	Select DC Latch Trigger 0 for ESC 0: Select LATCH0 input from ELC 1: Select LATCH0 input from external	R/W
1	TRGSEL1	Select DC Latch Trigger 1 for ESC 0: Select LATCH1 input from ELC 1: Select LATCH1 input from external	R/W
31:2	—	The read values are undefined. The write value should be 0.	R/W

Note: This register can only be written when protection is unlocked by the specific sequence using the Ethernet Protect register (PRCMD). For the protection unlock procedure, see section 27.3.1. PRCMD : Ethernet Protect Register. The special sequence is not necessary when reading the value of this register.

The ECATTRGSEL register selects the source to LATCHn (n = 0, 1) inputs to ESC. This register can be read/written in 32-bit units.

30.4.5 ECATRESOUT : EtherCAT Reset Out Control register

Base address: ESC_INI = 0x8011_0200

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RESOUT_EN	FORCE_RESET
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
0	FORCE_RESET	Force ESC_RESETOUT# pin state 0: Do not force reset state 1: Force reset state (Low level output)	R/W
1	RESOUT_EN	Specify whether Reset out from ESC is output to ESC_RESETOUT# pin or not. 0: Reset out from ESC is not output to ESC_RESETOUT# pin 1: Reset out from ESC is output to ESC_RESETOUT# pin	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written when protection is unlocked by the specific sequence using the Ethernet Protect register (PRCMD). For the protection unlock procedure, see section 27.3.1. PRCMD : Ethernet Protect Register. The special sequence is not necessary when reading the value of this register.

The ECATRESOUT register controls ESC_RESETOUT# pin state.

30.5 ESC Information Register

In the tables, ECAT indicates access by the EtherCAT master controller and PDI indicates access by the local CPU.

30.5.1 TYPE : Type Register

Base address: ESC = 0x8013_0000

Offset address: 0x0000

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TYPE[7:0]							
Value after reset:	1	0	1	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TYPE[7:0]	Type of the EtherCAT slave controller	R

The TYPE register indicates the type of the EtherCAT slave controller.

30.5.2 REVISION : Revision Register

Base address: ESC = 0x8013_0000

Offset address: 0x0001

Bit position:	7	6	5	4	3	2	1	0
Bit field:	REV[7:0]							
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
7:0	REV[7:0]	Revision of the EtherCAT slave controller	R

The REVISION register indicates the revision of the EtherCAT slave controller.

30.5.3 BUILD : Build Register

Base address: ESC = 0x8013_0000

Offset address: 0x0002

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BUILD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	BUILD[15:0]	Build number of the EtherCAT slave controller	R

The BUILD register indicates the build number of the EtherCAT slave controller.

30.5.4 FMMU_NUM : FMMU Supported Register

Base address: ESC = 0x8013_0000

Offset address: 0x0004

Bit position:	7	6	5	4	3	2	1	0
Bit field:	NUMFMMU[7:0]							
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
7:0	NUMFMMU[7:0]	Number of FMMU channels supported in the EtherCAT slave controller	R

The FMMU_NUM register indicates the number of FMMU channels supported in the EtherCAT slave controller.

30.5.5 SYNC_MANAGER : SyncManager Supported Register

Base address: ESC = 0x8013_0000

Offset address: 0x0005

Bit position:	7	6	5	4	3	2	1	0
Bit field:	NUMSYNC[7:0]							
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
7:0	NUMSYNC[7:0]	Number of SyncManager channels supported in the EtherCAT slave controller	R

The SYNC_MANAGER register indicates the number of SyncManager channels supported in the EtherCAT slave controller.

30.5.6 RAM_SIZE : RAM Size Register

Base address: ESC = 0x8013_0000

Offset address: 0x0006

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RAMSIZE[7:0]							
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
7:0	RAMSIZE[7:0]	Process data RAM size supported in the EtherCAT slave controller (unit: KB)	R

The RAM_SIZE register indicates the process data RAM size supported in the EtherCAT slave controller in KB.

30.5.7 PORT_DESC : Port Descriptor Register

Base address: ESC = 0x8013_0000

Offset address: 0x0007

Bit position:	7	6	5	4	3	2	1	0
Bit field:	P3[1:0]		P2[1:0]		P1[1:0]		P0[1:0]	
Value after reset:	0	0	1	1	1	1	1	1

Bit	Symbol	Function	R/W
1:0	P0[1:0]	Port 0 configuration Fixed to the setting for MII connection (11b) in this LSI. 0 0: Not implemented 0 1: Not configured (SII EEPROM) 1 0: EBUS 1 1: MII	R
3:2	P1[1:0]	Port 1 configuration Fixed to the setting for MII connection (11b) in this LSI. 0 0: Not implemented 0 1: Not configured (SII EEPROM) 1 0: EBUS 1 1: MII	R
5:4	P2[1:0]	Port 2 configuration Fixed to the setting for MII connection (11b) in this LSI. 0 0: Not implemented 0 1: Not configured (SII EEPROM) 1 0: EBUS 1 1: MII	R
7:6	P3[1:0]	Port 3 configuration This LSI does not implement port 3. Fixed to 00b. 0 0: Not implemented 0 1: Not configured (SII EEPROM) 1 0: EBUS 1 1: MII	R

The PORT_DESC register indicates the port configuration.

30.5.8 FEATURE : ESC Features Supported Register

Base address: ESC = 0x8013_0000

Offset address: 0x0008

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	FSCONFIG	RWSUPP	LRW	DCSYNC	FCS	LINKDECMII	—	—	DCWID	DC	—	FMMU
Value after reset:	x	x	x	x	0	0	0	1	1	1	x	x	1	1	x	0

Bit	Symbol	Function	R/W
0	FMMU	FMMU Operation 0: Bit oriented 1: Byte oriented	R
1	—	The read value is undefined.	R
2	DC	Distributed Clock 0: Not available 1: Available	R

Bit	Symbol	Function	R/W
3	DCWID	Distributed Clock Width 0: 32 bits 1: 64 bits	R
5:4	—	The read values are undefined.	R
6	LINKDECMII	Enhanced Link Detection in MII 0: Not available 1: Available	R
7	FCS	Separate handling of FCS errors 0: Not supported 1: Supported. Frames with wrong FCS and additional nibble will be counted separately in forwarded RX error counter.	R
8	DCSYNC	Enhanced DC SYNC activation 0: Not available 1: Available	R
9	LRW	EtherCAT LRW command support 0: Supported 1: Not supported	R
10	RWSUPP	EtherCAT read/write command support (BRW, APRW, FPRW) 0: Supported 1: Not supported	R
11	FSCONFIG	Fixed FMMU/SyncManager configuration 0: Variable configuration 1: Fixed configuration	R
15:12	—	The read values are undefined.	R

The FEATURE register indicates the features supported in the EtherCAT slave controller.

30.6 Station Address Registers

30.6.1 STATION_ADR : Configured Station Address Register

Base address: ESC = 0x8013_0000

Offset address: 0x0010

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	NODADDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	NODADDR[15:0]	Node Addressing Address Indication Address used for node addressing (FPxx commands) The access type from the EtherCAT master is R/W.	R

The STATION_ADR register indicates the address used for node addressing.

30.6.2 STATION_ALIAS : Configured Station Alias Register

Base address: ESC = 0x8013_0000

Offset address: 0x0012

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	NODALIADDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	NODALIADDR[15:0]	Alias Address Indication Alias address used for node addressing (FPxx commands). The use of this alias is activated by setting bit 24 of the ESC DL control register (ESC_DL_CONTROL at 0x0100) to 1. The access type from the EtherCAT master is R.	R/W

Note: The initial value, 0, is retained until the EEPROM is loaded. After that, the value becomes the value at address 0x0004 in the EEPROM. This value is only taken over from the EEPROM the first time the EEPROM is loaded after a power-on or reset.

The STATION_ALIAS register indicates the alias address used for node addressing (FPxx commands).

30.7 Write Protection Registers

30.7.1 WR_REG_ENABLE : Write Register Enable Register

Base address: ESC = 0x8013_0000

Offset address: 0x0020

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ENABLE
Value after reset:	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	ENABLE	Register Write Protection Unlock When registers are currently being protected against writing (bit 0 is 1 in the write register protection register, WR_REG_PROTECT, at 0x0021) and freely writing to registers of the given node is to be permitted, the operation to do so by writing to this register has to proceed in the same Ethernet frame and preceding the other desired writing to registers. Write protection will be reactivated once the frame period elapses (unless the value in the write register protection register is changed). The access type from the EtherCAT master is R/W.	R
7:1	—	The read values are undefined.	R

The WR_REG_ENABLE register is used to unlock the write protection temporarily while registers are write-protected.

30.7.2 WR_REG_PROTECT : Write Register Protection Register

Base address: ESC = 0x8013_0000

Offset address: 0x0021

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	PROTECT
Value after reset:	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	PROTECT	Register Write Protection Specification The access type from the EtherCAT master is R/W. 0: Protection disabled 1: Protection enabled	R
7:1	—	The read values are undefined.	R

The WR_REG_PROTECT register is used to protect registers against writing. The registers in the area 0x8013_0000 to 0x8013_0FFF are write-protected (except for the WR_REG_ENABLE register (0x0020) and ESC_WR_ENABLE register (0x0030)).

30.7.3 ESC_WR_ENABLE : ESC Write Enable Register

Base address: ESC = 0x8013_0000

Offset address: 0x0030

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ENABLE
Value after reset:	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	ENABLE	Register/Memory Write Protection Unlock When registers are currently being protected against writing by ESC write protection (bit 0 is 1 in the ESC write protection register, ESC_WR_PROTECT, at 0x0031) and freely writing to registers of the given node is to be permitted, the operation to do so by writing to this register has to proceed in the same Ethernet frame and preceding the other desired writing to registers. Write protection will be reactivated once the frame period elapses (unless the value in the ESC write protection register is changed). The access type from the EtherCAT master is R/W.	R
7:1	—	The read values are undefined.	R

The ESC_WR_ENABLE register is used to unlock the write protection temporarily while registers and memories are write-protected by ESC write protection.

30.7.4 ESC_WR_PROTECT : ESC Write Protection Register

Base address: ESC = 0x8013_0000

Offset address: 0x0031

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	PROTECT
Value after reset:	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	PROTECT	Register/Memory Write Protection Specification The access type from the EtherCAT master is R/W. 0: Protection disabled 1: Protection enabled	R
7:1	—	The read values are undefined.	R

The ESC_WR_PROTECT register is used to protect registers against writing. Registers and memories in the area 0x8013_0000 to 0x8013_2FFF including the process data RAM are write-protected (except for the WR_REG_ENABLE register (0x0020) and ESC_WR_ENABLE register (0x0030)).

30.8 Data Link Layer Registers

30.8.1 ESC_RESET_ECAT_W : ESC Reset ECAT Register for write

Base address: ESC = 0x8013_0000

Offset address: 0x0040

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RESET_ECAT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RESET_ECAT[7:0]	Software Reset Setting A reset is enabled after writing 0x52 ('R'), 0x45 ('E'), and 0x53 ('S') consecutively to this register. The access type from the EtherCAT master is R/W.	R

This register is used to reset the EtherCAT slave controller from the ECAT (master) by software.

30.8.2 ESC_RESET_ECAT_R : ESC Reset ECAT Register for read

Base address: ESC = 0x8013_0000

Offset address: 0x0040

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	RESET_ECAT[1:0]	
Value after reset:	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
1:0	RESET_ECAT[1:0]	Reset Progress Status The access type from the EtherCAT master is R/W. 0 1: After writing 0x52 1 0: After writing 0x45 (if 0x52 was written before) 0 0: Others	R
7:2	—	The read values are undefined. The access type from the EtherCAT master is R/W. In this case, the write value should be 0.	R

This register is used to reset the EtherCAT slave controller from the ECAT (master) by software.

30.8.3 ESC_RESET_PDI_W : ESC Reset PDI Register for write

Base address: ESC = 0x8013_0000

Offset address: 0x0041

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RESET_PDI[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RESET_PDI[7:0]	Software Reset Setting A reset is enabled after writing 0x52 ('R'), 0x45 ('E'), and 0x53 ('S') consecutively to this register. The access type from the EtherCAT master is R.	R/W

This register is used to reset the EtherCAT slave controller from the PDI (slave) by software.

30.8.4 ESC_RESET_PDI_R : ESC Reset PDI Register for read

Base address: ESC = 0x8013_0000

Offset address: 0x0041

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	RESET_PDI[1:0]	
Value after reset:	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
1:0	RESET_PDI[1:0]	Reset Progress Status The access type from the EtherCAT master is R. 0 1: After writing 0x52 1 0: After writing 0x45 (if 0x52 was written before) 0 0: Others	R/W
7:2	—	The read values are undefined. The write value should be 0.	R/W

This register is used to reset the EtherCAT slave controller from the PDI (slave) by software.

30.8.5 ESC_DL_CONTROL : ESC DL Control Register

Base address: ESC = 0x8013_0000

Offset address: 0x0100

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	STAAL IAS	—	—	—	—	—	RXFIFO[2:0]		
Value after reset:	x	x	x	x	x	x	x	0	x	x	x	x	x	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	LP3[1:0]		LP2[1:0]		LP1[1:0]		LP0[1:0]		—	—	—	—	—	—	TEMP USE	FWDR ULE
Value after reset:	1	1	0	0	0	0	0	0	x	x	x	x	0	0	0	1

Bit	Symbol	Function	R/W
0	FWDRULE	Forwarding Rule The source MAC address is changed for every frame (SOURCE_MAC[1] is set to 1 (locally administered address)) regardless of the forwarding rule. The access type from the EtherCAT master is R/W. 0: EtherCAT frames are processed. Non-EtherCAT frames are forwarded without processing. 1: EtherCAT frames are processed. Non-EtherCAT frames are destroyed.	R
1	TEMPUSE	Temporary Use of Bits 15 to 8 Settings The access type from the EtherCAT master is R/W. 0: Permanent use 1: Use for about 1 second, then revert to previous settings	R
3:2	—	These bits are read as 0.	R
7:4	—	The read values are undefined.	R
9:8	LP0[1:0]	Loop Port 0 Configuration The access type from the EtherCAT master is R/W. 0 0: Auto 0 1: Auto close 1 0: Open 1 1: Closed	R
11:10	LP1[1:0]	Loop Port 1 Configuration The access type from the EtherCAT master is R/W. 0 0: Auto 0 1: Auto close 1 0: Open 1 1: Closed	R
13:12	LP2[1:0]	Loop Port 2 Configuration Port 2 is not available on this LSI. The access type from the EtherCAT master is R/W. 0 0: Auto 0 1: Auto close 1 0: Open 1 1: Closed	R

Bit	Symbol	Function	R/W
15:14	LP3[1:0]	Loop Port 3 Configuration Port 3 is not available on this LSI. The access type from the EtherCAT master is R/W. 0 0: Auto 0 1: Auto close 1 0: Open 1 1: Closed	R
18:16	RXFIFO[2:0]	RX FIFO Size Set the RX FIFO size. The transfer time can be reduced by reducing the FIFO size. The access type from the EtherCAT master is R/W. 0 x x: Shortened by 40 ns 1 1 1: Default Others: No change	R
23:19	—	The read values are undefined.	R
24	STAALIAS	Station Alias Status The access type from the EtherCAT master is R/W. 0: Ignore station alias 1: Alias can be used for all configured address command types such as FPRD, FPWR.	R
31:25	—	The read values are undefined.	R

Note:
- Changes to loop configurations are delayed until any current reception or transmission of a frame through the port is completed.
- Reducing the size of the RX FIFO depends on all masters and slaves connected to the same network as the EtherCAT having very precise clock sources. An RX FIFO size of 7 (default) is sufficient if the precision of all clocks is 100 ppm or better and RX FIFO sizes of 0 to 3 are possible if the precision is 25 ppm or better.

The ESC_DL_CONTROL register is used to control loop in the EtherCAT slave controller and configure the RX FIFO size and station alias.

30.8.6 PHYSICAL_RW_OFFSET : Physical Read/Write Offset Register

Base address: ESC = 0x8013_0000

Offset address: 0x0108

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RWOFFSET[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RWOFFSET[15:0]	Offset between Read and Write Addresses Offset of R/W commands (FPRW, APRW) between read address and write address. When read, RD_ADR = ADR (the given address is read) When write, WR_ADR = ADR + R/W offset (writing is to the address obtained by adding the offset set in this register to the given address) The access type from the EtherCAT master is R/W.	R

The PHYSICAL_RW_OFFSET register is used to set the offset between read address and write address in the R/W commands.

30.8.7 ESC_DL_STATUS : ESC DL Status Register

Base address: ESC = 0x8013_0000

Offset address: 0x0110

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	COMP 3	LP3	COMP 2	LP2	COMP 1	LP1	COMP 0	LP0	PHYP 3	PHYP 2	PHYP 1	PHYP 0	—	ENHLI NKD	PDIW DST	PDIOP E
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	x	1	0	0

Bit	Symbol	Function	R/W
0	PDIOPE	PDI/EEPROM Load State Indication 0: EEPROM not loaded, the PDI not operational (process data RAM is not accessible) 1: EEPROM loaded correctly, the PDI operational (process data RAM is accessible)	R
1	PDIWDST	PDI Watchdog Timer Status 0: Timeout of the watchdog timer 1: Watchdog timer reloaded	R
2	ENHLINKD	Enhanced Link Detection Indication This bit is set to the value of bit 9 at address 0x0000 in the EEPROM the first time the EEPROM is loaded after power is initially supplied or after a reset. 0: Deactivated for all ports 1: Activated for at least one port	R
3	—	The read value is undefined.	R
4	PHYP0	Port 0 Link State Indication Physical link on port 0. 0: No link 1: Link detected	R
5	PHYP1	Port 1 Link State Indication Physical link on port 1. 0: No link 1: Link detected	R
6	PHYP2	Port 2 Link State Indication Port 2 is not available on this LSI. 0: No link 1: Link detected	R
7	PHYP3	Port 3 Link State Indication Port 3 is not available on this LSI. 0: No link 1: Link detected	R
8	LP0	Loop Port 0 State Indication 0: Open 1: Closed	R
9	COMP0	Port 0 Communication State Indication 0: No stable communication 1: Communication established	R
10	LP1	Loop Port 1 State Indication 0: Open 1: Closed	R
11	COMP1	Port 1 Communication State Indication 0: No stable communication 1: Communication established	R
12	LP2	Loop Port 2 State Indication Port 2 is not available on this LSI. 0: Open 1: Closed	R
13	COMP2	Port 2 Communication State Indication Port 2 is not available on this LSI. 0: No stable communication 1: Communication established	R
14	LP3	Loop Port 3 State Indication Port 3 is not available on this LSI. 0: Open 1: Closed	R
15	COMP3	Port 3 Communication State Indication Port 3 is not available on this LSI. 0: No stable communication 1: Communication established	R

Note: Reading this DL status register from the ECAT clears bit 2 of the ECAT event request register (ECAT_EVENT_REQ at 0x0210). Avoid reading DL Status register from PDI.

The ESC_DL_STATUS register indicates the state of the EtherCAT slave controller.

30.9 Application Layer Registers

30.9.1 AL_CONTROL : AL Control Register

Base address: ESC = 0x8013_0000

Offset address: 0x0120

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	DEVICEID	ERRINDACK	INISTATE[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	1

Bit	Symbol	Function	R/W
3:0	INISTATE[3:0]	Change the state transition of the device state machine. The access type from the EtherCAT master is R/W. 0x1: Initial state request 0x2: Pre-operational state request 0x3: Bootstrap state request 0x4: Safe-operational state request 0x8: Operational state request Others: Reserved	R
4	ERRINDACK	Error Indication Acknowledge (Response) The access type from the EtherCAT master is R/W. 0: Error Indication in AL status register is not acknowledged 1: Error Indication in AL status register is acknowledged	R
5	DEVICEID	Device ID Request The access type from the EtherCAT master is R/W. 0: No request is present 1: A request is present	R
15:6	—	The read values are undefined. The access type from the EtherCAT master is R/W. In this case, the write value should be 0.	R

Note: The PDI has to read the AL control register after the ECAT has written it. Otherwise, the ECAT cannot write again to the AL control register. Reading the AL control register from the PDI clears bit 0 of the AL event request register (AL_EVENT_REQ at 0x0220).

The AL_CONTROL register is used to change the state transition of the device state machine and to acknowledge error indication.

30.9.2 AL_STATUS : AL Status Register

Base address: ESC = 0x8013_0000

Offset address: 0x0130

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	DEVICEID	ERR	ACTSTATE[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	1

Bit	Symbol	Function	R/W
3:0	ACTSTATE[3:0]	State Machine State Indication Actual state of the device state machine The access type from the EtherCAT master is R. 0x1: Initial state 0x2: Pre-operational state 0x3: Request bootstrap state 0x4: Safe-operational state 0x8: Operational state	R/W
4	ERR	Error State Indication The access type from the EtherCAT master is R. 0: The device is in the state as requested or flag was cleared by command 1: The device has not entered the requested state or the state was changed as a result of local action	R/W
5	DEVICEID	Device ID Load State Indication The access type from the EtherCAT master is R. 0: Loading failed 1: Loading was successful	R/W
15:6	—	The read values are undefined. The write value should be 0.	R/W

Note: Reading this AL status register from the ECAT clears bit 3 of the ECAT event request register (ECAT_EVENT_REQ at 0x0210). Avoid reading DL Status register from PDI.

The AL_STATUS register indicates the state of slave application.

30.9.3 AL_STATUS_CODE : AL Status Code Register

Base address: ESC = 0x8013_0000

Offset address: 0x0134

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	STATUSCODE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	STATUSCODE[15:0]	AL status code The access type from the EtherCAT master is R.	R/W

The AL_STATUS_CODE register indicates an error code from slave application.

30.9.4 RUN_LED_OVERRIDE : RUN LED Override Register

Base address: ESC = 0x8013_0000

Offset address: 0x0138

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	OVERRIDEEN	LEDCODE[3:0]			
Value after reset:	x	x	x	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	LEDCODE[3:0]	LED Code Indication (FSM state: Bits [3:0] of the AL Status register, AL_STATUS) 0x0: Off (FSM: 1-Init) 0xD: Blinking (FSM: 2-PreOp) 0xE: Flickering (FSM: 3-Bootstrap) 0xF: On (FSM: 8-Op) Others: Flash 1x - 12x (FSM: 4-SafeOp 1x)	R/W

Bit	Symbol	Function	R/W
4	OVERRIDEEN	Override Setting 0: Override disabled 1: Override enabled	R/W
7:5	—	The read values are undefined. The write value should be 0.	R/W

Note: Changing the value of the AL status register to an appropriate value will clear bit 4 (override enable).
Normally RUN LED is controlled by the AL status register (AL_STATUS at 0x0130) automatically. It is not necessary to override RUN LED in order to indicate the state of a general state machine.
For example, this register can be used to run special lighting patterns that indicate the positions of specific slaves.

The RUN_LED_OVERRIDE register is used to override control of the RUN LED pin.

30.9.5 ERR_LED_OVERRIDE : ERR LED Override Register

Base address: ESC = 0x8013_0000

Offset address: 0x0139

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	OVERRIDEEN	LEDCODE[3:0]			
Value after reset:	x	x	x	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	LEDCODE[3:0]	LED Code Indication 0x0: Off 0xD: Blinking 0xE: Flickering 0xF: On Others: Flash 1x to 12x	R/W
4	OVERRIDEEN	Override Setting 0: Override disabled 1: Override enabled	R/W
7:5	—	The read values are undefined. The write value should be 0.	R/W

Note: Bit 4 (override enable) will be cleared if a new error occurs.
The ESC automatically controls an error LED under the conditions below. Regarding other errors, the error LED should be controlled by application using this register.

- SII EEPROM load error
- PDI watchdog timeout

The ERR_LED_OVERRIDE register is used to override control of the error LED pin.

30.10 PDI Registers

30.10.1 PDI_CONTROL : PDI Control Register

Base address: ESC = 0x8013_0000

Offset address: 0x0140

Bit position:	7	6	5	4	3	2	1	0
Bit field:	PDI[7:0]							
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PDI[7:0]	Process Data Interface. In this LSI, the following value is indicated. 0x80: On-chip bus	R

This register indicates the type of PDI.

30.10.2 ESC_CONFIG : ESC Configuration Register

Base address: ESC = 0x8013_0000

Offset address: 0x0141

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ENLP3	ENLP2	ENLP1	ENLP0	DCLATCH	DCSYNC	ENLALLP	DEVEMU
Value after reset:	0	0	0	0	1	1	0	0

Bit	Symbol	Function	R/W
0	DEVEMU	Device emulation (control of AL status) 0: The AL status register must be set by the PDI 1: The AL status register is set to a value written to the AL control register	R
1	ENLALLP	Sets enhanced link detection for all ports 0: Disabled (if bits 15 to 12 of address 0 in the EEPROM = 0) 1: Enabled at all ports	R
2	DCSYNC	Sets the SYNC output unit for distributed clocks (fixed to 1 in this LSI) 0: Disabled (power saving) 1: Enabled	R
3	DCLATCH	Sets the latch input unit for distributed clocks Fixed to 1 in this LSI. 0: Disabled (power saving) 1: Enabled	R
4	ENLP0	Port 0 Enhanced Link Detection Setting 0: Disabled (if bit 9 of address 0 in the EEPROM = 0) 1: Enabled	R
5	ENLP1	Port 1 Enhanced Link Detection Setting 0: Disabled (if bit 9 of address 0 in the EEPROM = 0) 1: Enabled	R
6	ENLP2	Port 2 Enhanced Link Detection Setting Port 2 is not available in this LSI. 0: Disabled (if bit 9 of address 0 in the EEPROM = 0) 1: Enabled	R
7	ENLP3	Port 3 Enhanced Link Detection Setting Port 3 is not available in this LSI. 0: Disabled (if bit 9 of address 0 in the EEPROM = 0) 1: Enabled	R

The ESC_CONFIG register indicates configuration of the EtherCAT slave controller.

30.10.3 PDI_CONFIG : PDI Configuration Register

Base address: ESC = 0x8013_0000

Offset address: 0x0150

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ONCHIPBUS[2:0]			ONCHIPBUSCLK[4:0]				
Value after reset:	0	1	0	0	0	1	0	0

Bit	Symbol	Function	R/W
4:0	ONCHIPBUSCLK[4:0]	On-Chip Bus Clock Indication Indicate the frequency of the on-chip bus clock. In this LSI, the value is always 0x04 (corresponding to 100 MHz).	R
7:5	ONCHIPBUS[2:0]	On-Chip Bus Type Indication Indicate the type of on-chip bus. In this LSI, the value is always 010b.	R

The PDI_CONFIG register indicates configuration of the PDI.

30.10.4 SYNC_LATCH_CONFIG : SYNC/LATCH PDI Configuration Register

Base address: ESC = 0x8013_0000

Offset address: 0x0151

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SYNC 1MAP	SYNC LAT1	SYNC1OUT[1:0]		SYNC 0MAP	SYNC LAT0	SYNC0OUT[1:0]	
Value after reset:	1	1	1	0	1	1	1	0

Bit	Symbol	Function	R/W
1:0	SYNC0OUT[1:0]	SYNC0 Output Driver and Polarity Indication Indicate the SYNC0 output driver/polarity. In this LSI, the value is always 10b (push-pull and active-high).	R
2	SYNCLAT0	SYNC0/LATCH0 Indication Indicates the SYNC0/LATCH0 configuration. In this LSI, the value is always 1.*1 0: LATCH0 input 1: SYNC0 output	R
3	SYNC0MAP	SYNC0 State Mapping Indication Indicates enabling or disabling of mapping of the SYNC0 state to bit 2 of the AL event request register (AL_EVENT_REQ at 0x0220). This is always enabled in this LSI, so the value indicated is always 1 (enabled). 0: Disabled 1: Enabled	R
5:4	SYNC1OUT[1:0]	SYNC1 Output Driver and Polarity Indication Indicate the SYNC1 output driver/polarity. In this LSI, the value is always 10b (push-pull and active-high).	R
6	SYNCLAT1	SYNC1/LATCH1 Indication Indicates the SYNC1/LATCH1 configuration. In this LSI, the value is always 1.*1 0: LATCH1 input 1: SYNC1 output	R
7	SYNC1MAP	SYNC1 State Mapping Indication Indicates enabling or disabling of mapping of the SYNC1 state to bit 3 of the AL event request register (AL_EVENT_REQ at 0x0220). This is always enabled in this LSI, so the value indicated is always 1 (enabled). 0: Disabled 1: Enabled	R

Note 1. Latch input is available though the value indicates SYNC output. Use the MPC function in order to switch SYNC output to LATCH input and vice versa.

The SYNC_LATCH_CONFIG register indicates the configuration of SYNC output and LATCH input.

30.10.5 EXT_PDI_CONFIG : Extended PDI Configuration Register

Base address: ESC = 0x8013_0000

Offset address: 0x0152

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DATABUSWID[1:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
1:0	DATABUSWID[1:0]	PDI Data Bus Width Indication Indicate the data bus width of the PDI. In this LSI, the value is always 00b (4 bytes). 0 0: 4 bytes 0 1: 1 byte 1 0: 2 bytes 1 1: Reserved	R
15:2	—	The read values are undefined.	R

The EXT_PDI_CONFIG register indicates configuration of the PDI.

30.11 Interrupt Registers

30.11.1 ECAT_EVENT_MASK : ECAT Event Mask Register

Base address: ESC = 0x8013_0000

Offset address: 0x0200

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ECATEVMASK[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ECATEVMASK[15:0]	Event Request Mask Setting The access type from the EtherCAT master is R/W. 0: The corresponding bit of the ECAT Event Request register (ECAT_EVENT_REQ at 0x0210) is not mapped 1: The corresponding bit of the ECAT Event Request register is mapped	R

The ECAT Event Request (ECAT interrupt) is used to transmit the slave event to the EtherCAT master. This register is used to set mask to each event of the ECAT Event Request register (ECAT_EVENT_REQ at 0x0210). The logical AND of each effective bit in the ECAT Event Request register and the corresponding bit of this register is taken and the result produces the interrupt signal.

30.11.2 AL_EVENT_MASK : AL Event Mask Register

Base address: ESC = 0x8013_0000

Offset address: 0x0204

Bit position:	31																													0
Bit field:	ALEVMASK[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0	0	1	1	1	1

Bit	Symbol	Function	R/W
31:0	ALEVMASK[31:0]	Event Request Mask Setting The access type from the EtherCAT master is R. 0: The corresponding bit of the AL Event Request register (AL_EVENT_REQ at 0x0220) is not mapped 1: The corresponding bit of the AL Event Request register is mapped	R/W

The AL event request (PDI interrupt) is used to transmit the ESC interrupt to the slave application. This register is used to set mask to each event of the AL Event Request register (AL_EVENT_REQ at 0x0220). The logical AND of each effective bit in the AL Event Request register and the corresponding bit of this register is taken and the result produces the interrupt signal.

30.11.3 ECAT_EVENT_REQ : ECAT Event Request Register

Base address: ESC = 0x8013_0000

Offset address: 0x0210

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	SMSTA7	SMSTA6	SMSTA5	SMSTA4	SMSTA3	SMSTA2	SMSTA1	SMSTA0	ALSTA	DLSTA	—	DCLATCH
Value after reset:	x	x	x	x	0	0	0	0	0	0	0	0	0	0	x	0

Bit	Symbol	Function	R/W
0	DCLATCH	DC Latch Event State Indication This bit is cleared by reading DC latch event times from the ECAT for ECAT controlled latch units, so the latch 0 and 1 status registers (DC_LATCH_STAT0 and DC_LATCH_STAT1 at 0x09AE and 0x09AF) indicate no event. 0: No change on DC latch inputs 1: At least one change on DC latch inputs	R
1	—	The read value is undefined.	R
2	DLSTA	DL Status Event State Indication This bit is cleared by reading out the DL status register (ESC_DL_STATUS at 0x0110 or 0x0111) from the ECAT. 0: No change in DL status 1: DL status change	R
3	ALSTA	AL Status Event State Indication This bit is cleared by reading out the AL status register (AL_STATUS at 0x0130 or 0x0131) from the ECAT. 0: No change in AL status 1: AL status change	R
4	SMSTA0	Mirror value of SyncManager 0 Status Indication 0: No Sync channel 0 event 1: Sync channel 0 event pending	R
5	SMSTA1	Mirror value of SyncManager 1 Status Indication 0: No Sync channel 1 event 1: Sync channel 1 event pending	R
6	SMSTA2	Mirror value of SyncManager 2 Status Indication 0: No Sync channel 2 event 1: Sync channel 2 event pending	R
7	SMSTA3	Mirror value of SyncManager 3 Status Indication 0: No Sync channel 3 event 1: Sync channel 3 event pending	R
8	SMSTA4	Mirror value of SyncManager 4 Status Indication 0: No Sync channel 4 event 1: Sync channel 4 event pending	R
9	SMSTA5	Mirror value of SyncManager 5 Status Indication 0: No Sync channel 5 event 1: Sync channel 5 event pending	R
10	SMSTA6	Mirror value of SyncManager 6 Status Indication 0: No Sync channel 6 event 1: Sync channel 6 event pending	R
11	SMSTA7	Mirror value of SyncManager 7 Status Indication 0: No Sync channel 7 event 1: Sync channel 7 event pending	R
15:12	—	The read values are undefined.	R

The ECAT_EVENT_REQ register indicates the source of ECAT event requests (ECAT interrupts).

30.11.4 AL_EVENT_REQ : AL Event Request Register

Base address: ESC = 0x8013_0000

Offset address: 0x0220

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SMINT7	SMINT6	SMINT5	SMINT4	SMINT3	SMINT2	SMINT1	SMINT0	—	WDPD	—	SYNCACT	DCSYNC1STA	DCSYNC0STA	DCLATCH	ALCTRL
Value after reset:	0	0	0	0	0	0	0	0	x	0	x	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ALCTRL	AL Control Event State Indication This bit is cleared by reading the AL control register (AL_CONTROL at 0x0120 or 0x0121) from the PDI. 0: No change in the AL control register 1: The AL control register has been written	R
1	DCLATCH	DC Latch Event State Indication This bit is cleared by reading DC latch event times from the PDI for PDI controlled latch units, so the latch 0 and 1 status registers (DC_LATCH_STAT0 and DC_LATCH_STAT1 at 0x09AE and 0x09AF) indicate no event. 0: No change on DC latch inputs 1: At least one change on DC latch inputs	R
2	DCSYNC0STA	DC SYNC0 State Indication This bit is cleared by reading the SYNC0 status register (DC_SYNC0_STAT at 0x098E) from the PDI.	R
3	DCSYNC1STA	DC SYNC1 State Indication This bit is cleared by reading the SYNC1 status register (DC_SYNC1_STAT at 0x098F) from the PDI.	R
4	SYNCACT	SyncManager Activation Indication Change of the SyncManager activation register (SMn.ACT at 0x0806 + 0x8 × n) This bit is cleared by reading SyncManager activation registers from the PDI. 0: No change in any SyncManager 1: At least one SyncManager changed	R
5	—	The read value is undefined.	R
6	WDPD	Watchdog Process Data Indication This bit is cleared by reading the watchdog status process data register (WDS_DATA at 0x0440) from the PDI. 0: Valid 1: Timeout	R
7	—	The read value is undefined.	R
8	SMINT0	SyncManager 0 interrupt (bit 0 or 1 of the SyncManager status register (0x0805)) 0: No SyncManager 0 interrupt 1: SyncManager 0 interrupt pending	R
9	SMINT1	SyncManager 1 interrupt (bit 0 or 1 of the SyncManager status register (0x080D)) 0: No SyncManager 1 interrupt 1: SyncManager 1 interrupt pending	R
10	SMINT2	SyncManager 2 interrupt (bit 0 or 1 of the SyncManager status register (0x0815)) 0: No SyncManager 2 interrupt 1: SyncManager 2 interrupt pending	R
11	SMINT3	SyncManager 3 interrupt (bit 0 or 1 of the SyncManager status register (0x081D)) 0: No SyncManager 3 interrupt 1: SyncManager 3 interrupt pending	R

Bit	Symbol	Function	R/W
12	SMINT4	SyncManager 4 interrupt (bit 0 or 1 of the SyncManager status register (0x0825)) 0: No SyncManager 4 interrupt 1: SyncManager 4 interrupt pending	R
13	SMINT5	SyncManager 5 interrupt (bit 0 or 1 of the SyncManager status register (0x082D)) 0: No SyncManager 5 interrupt 1: SyncManager 5 interrupt pending	R
14	SMINT6	SyncManager 6 interrupt (bit 0 or 1 of the SyncManager status register (0x0835)) 0: No SyncManager 6 interrupt 1: SyncManager 6 interrupt pending	R
15	SMINT7	SyncManager 7 interrupt (bit 0 or 1 of the SyncManager status register (0x083D)) 0: No SyncManager 7 interrupt 1: SyncManager 7 interrupt pending	R
31:16	—	The read values are undefined.	R

The AL_EVENT_REQ register indicates the source of AL event requests (PDI interrupts).

30.12 Error Counter Registers

30.12.1 RX_ERR_COUNTn : RX Error Counter n Register (n = 0 to 2)

Base address: ESC = 0x8013_0000

Offset address: 0x0300 + 0x2 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RXERRCNT[7:0]								INVFRMCNT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	INVFRMCNT[7:0]	Invalid Frame Counter Value Indication Counter value of invalid frames for port n counting is stopped when 0xFF is reached. These bits are cleared if one of the RX error counters (RX_ERR_COUNTn, FWD_RX_ERR_COUNTn) is written. The access type from the EtherCAT master is R/W.	R
15:8	RXERRCNT[7:0]	RX Frame Error Counter Value Indication Counter value of RX errors for port n counting is stopped when 0xFF is reached. The number of RX errors of MII interface is counted. These bits are cleared if one of the RX error counters (RX_ERR_COUNTn, FWD_RX_ERR_COUNTn) is written. The access type from the EtherCAT master is R/W.	R

The RX_ERR_COUNTn register counts RX frame errors.

30.12.2 FWD_RX_ERR_COUNTn : Forwarded RX Error Counter n Register (n = 0 to 2)

Base address: ESC = 0x8013_0000

Offset address: 0x0308 + 0x1 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	FWDERRCNT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	FWDERRCNT[7:0]	Forwarded Error Counter Value Indication Counter value of forwarded RX error frames for port n counting is stopped when 0xFF is reached. These bits are cleared if one of the RX error counters (RX_ERR_COUNTn, FWD_RX_ERR_COUNTn) is written. The access type from the EtherCAT master is R/W.	R

The FWD_RX_ERR_COUNTn register counts forwarded RX frame errors.

30.12.3 ECAT_PROC_ERR_COUNT : ECAT Processing Unit Error Counter Register

Base address: ESC = 0x8013_0000

Offset address: 0x030C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	EPUERRCNT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	EPUERRCNT[7:0]	Processing Unit Error Counter Value Indication ECAT processing unit error counter value counting is stopped when 0xFF is reached. This register counts errors of frames passing the processing unit. Writing to this register clears it. The access type from the EtherCAT master is R/W.	R

The ECAT_PROC_ERR_COUNT register counts frame errors passing the ECAT processing unit.

30.12.4 PDI_ERR_COUNT : PDI Error Counter Register

Base address: ESC = 0x8013_0000

Offset address: 0x030D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	PDIERRCNT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PDIERRCNT[7:0]	PDI Error Counter Value Indication Counting is stopped when 0xFF is reached. Counting starts when an interface error occurs due to access to the PDI. Writing to this register clears it. The access type from the EtherCAT master is R/W.	R

The PDI_ERR_COUNT register counts PDI access errors.

30.12.5 LOST_LINK_COUNTn : Lost Link Counter n Register (n = 0 to 2)

Base address: ESC = 0x8013_0000

Offset address: 0x0310 + 0x1 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	LOSTLINKCNT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	LOSTLINKCNT[7:0]	Lost Link Counter Value Indication Lost link counter value for port n counting is stopped when 0xFF is reached. Counting starts only when port loop is Auto or Auto-Close. Only lost links at open ports are counted. Writing to one of the lost link counter registers clears it. The access type from the EtherCAT master is R/W.	R

The LOST_LINK_COUNTn register counts lost links at port n.

30.13 Watchdog Registers

30.13.1 WD_DIVIDE : Watchdog Divider Register

Base address: ESC = 0x8013_0000

Offset address: 0x0400

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WDDIV[15:0]															
Value after reset:	0	0	0	0	1	0	0	1	1	1	0	0	0	0	1	0

Bit	Symbol	Function	R/W
15:0	WDDIV[15:0]	Watchdog Clock Frequency Divisor Setting Set the frequency divisor of the clock to drive counting by the watchdog timer in units of ticks at 25 MHz. The clock that drives counting by the watchdog timer is obtained by dividing 25 MHz by the value in this register plus 2. The default value is 2498, which corresponds to a period of 100 µs. The access type from the EtherCAT master is R/W.	R

The WD_DIVIDE register is used to set the ratio for dividing 25 MHz to obtain the basic period for incrementing the watchdog timer.

30.13.2 WDT_PDI : Watchdog Time PDI Register

Base address: ESC = 0x8013_0000

Offset address: 0x0410

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WDTIMPDI[15:0]															
Value after reset:	0	0	0	0	0	0	1	1	1	1	1	0	1	0	0	0

Bit	Symbol	Function	R/W
15:0	WDTIMPDI[15:0]	Watchdog Overflow Time Setting Set the time until the PDI watchdog timer overflows as a number of times the watchdog is incremented. With the default values for these bits and the setting of the watchdog divider, the time for a single incrementation is 100 µs, so the watchdog timer overflows when 100 µs ×1000 = 100 ms elapsed. Setting these bits to 0 disables the watchdog timer. Access to the PDI restarts the watchdog timer. The access type from the EtherCAT master is R/W.	R

The WDT_PDI register is used to set the time until the PDI watchdog timer overflows.

30.13.3 WDT_DATA : Watchdog Time Process Data Register

Base address: ESC = 0x8013_0000

Offset address: 0x0420

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WDTIMPD[15:0]															
Value after reset:	0	0	0	0	0	0	1	1	1	1	1	0	1	0	0	0

Bit	Symbol	Function	R/W
15:0	WDTIMPD[15:0]	Watchdog Overflow Time Setting Set the time until the process data watchdog timer overflows as a number of times the watchdog is incremented. With the default values for these bits and the setting of the watchdog divider, the time for a single incrementation is 100 µs, so the watchdog timer overflows when 100 µs × 1000 = 100 ms elapsed. There is one watchdog for all SyncManagers. Setting these bits to 0 disables the watchdog timer. Access to the Watchdog Trigger Enable bit of SyncManager restarts the watchdog timer. The access type from the EtherCAT master is R/W.	R

The WDT_DATA register is used to set the time until the process data watchdog timer overflows.

30.13.4 WDS_DATA : Watchdog Status Process Data Register

Base address: ESC = 0x8013_0000

Offset address: 0x0440

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WDSTAPD
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	WDSTAPD	Watchdog State Indication Indicates the state of the process data watchdog timer triggered by SyncManagers. Reading this register clears bit 6 of the AL Event Request register (AL_EVENT_REQ at 0x0220). 0: The timeout period of the process data watchdog timer elapses 1: The process data watchdog timer is active or disabled	R
15:1	—	The read values are undefined.	R

The WDS_DATA register indicates the state of the process data watchdog timer.

30.13.5 WDC_DATA : Watchdog Counter Process Data Register

Base address: ESC = 0x8013_0000

Offset address: 0x0442

Bit position:	7	6	5	4	3	2	1	0
Bit field:	WDCNTPD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	WDCNTPD[7:0]	Watchdog Counter Value Indication Counter value of the process data watchdog timer counting stops when 0xFF is reached. Counting starts on a timeout of the process data watchdog timer. Writing to one of the watchdog counter registers (WDC_DATA, WDC_PDI at 0x0442 and 0x0443) clears the counter. The access type from the EtherCAT master is R/W.	R

The WDC_DATA register indicates the timeout counter value of the process data watchdog timer.

30.13.6 WDC_PDI : Watchdog Counter PDI Register

Base address: ESC = 0x8013_0000

Offset address: 0x0443

Bit position:	7	6	5	4	3	2	1	0
Bit field:	WDCNTPDI[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	WDCNTPDI[7:0]	Watchdog Counter Value Indication Counter value of the PDI watchdog timer counting stops when 0xFF is reached. Counting starts on a timeout of the PDI watchdog timer. Writing to one of the watchdog counter registers (WDC_DATA, WDC_PDI at 0x0442 and 0x0443) clears the counter. The access type from the EtherCAT master is R/W.	R

The WDC_PDI register indicates the timeout counter value of the PDI watchdog timer.

30.14 SII EEPROM Interface Registers

The EtherCAT controls the SII EEPROM interface if bit 0 is 0 in the EEPROM Configuration register (EEP_CONF at 0x0500) and in the EEPROM PDI Access State register (EEP_STATE at 0x0501). Otherwise, the PDI controls the EEPROM interface.

30.14.1 EEP_CONF : EEPROM Configuration Register

Base address: ESC = 0x8013_0000

Offset address: 0x0500

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	FORCEECAT	CTRLPDI
Value after reset:	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
0	CTRLPDI	PDI EEPROM Control Specifies whether EEPROM control is offered to the PDI. The access type from the EtherCAT master is R/W. 0: The PDI has no EEPROM control 1: The PDI has EEPROM control	R
1	FORCEECAT	EEPROM Access Right Change Forcibly changes the right of access to the EEPROM by the ECAT. The access type from the EtherCAT master is R/W. 0: No change 1: Reset bit 0 of the EEPROM PDI Access State register (EEP_STATE at 0x0501) to 0. That is, prohibit access to the EEPROM by the PDI.	R

Bit	Symbol	Function	R/W
7:2	—	The read values are undefined.	R

The EEP_CONF register is used to configure EEPROM access.

30.14.2 EEP_STATE : EEPROM PDI Access State Register

Base address: ESC = 0x8013_0000

Offset address: 0x0501

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	PDIACCESS
Value after reset:	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	PDIACCESS	EEPROM Access Right Setting Write access from the PDI is only possible when bit 0 is 1 and bit 1 is 0 in the EEPROM Configuration register (EEP_CONF at 0x0500). The access type from the EtherCAT master is R. 0: Prohibits the PDI from access to the EEPROM 1: The PDI has access to the EEPROM	R/W
7:1	—	The read values are undefined. The write value should be 0. The access type from the EtherCAT master is R.	R/W

The EEP_STATE register is used to set the right of access to the EEPROM by the PDI.

30.14.3 EEP_CONT_STAT : EEPROM Control/Status Register

Base address: ESC = 0x8013_0000

Offset address: 0x0502

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BUSY	WRENERR	ACKCMDERR	LOADSTA	CKSUMERR	COMMAND[2:0]			PROMSIZE	READBYTE	—	—	—	—	—	ECATWREN
Value after reset:	0	0	0	0	0	0	0	0	0/1*1	0	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	ECATWREN	ECAT Write Enable*3 This bit is always 1 if the PDI has EEPROM control. The access type from the EtherCAT master is R/W. 0: Write requests are disabled 1: Write requests are enabled	R
5:1	—	The read values are undefined. The write value should be 0.	R/W
6	READBYTE	EEPROM Read Byte Indication Indicates supported EEPROM read bytes. 0: 4 bytes 1: 8 bytes	R
7	PROMSIZE	EEPROM Algorithm Indication Indicates the selected EEPROM algorithm. 0: 1 address byte (1-Kbit to 16-Kbit EEPROMs) 1: 2 address bytes (32-Kbit to 4-Mbit EEPROMs)	R

Bit	Symbol	Function	R/W
10:8	COMMAND[2:0]	Command*3 Write: Initiates the commands below. Read: Indicates the currently executed command. Commands: 0 0 0: No command/EEPROM idle (clear error bits) 0 0 1: Read 0 1 0: Write 1 0 0: Reload Others: Reserved/invalid commands (must not be issued)	R/W
11	CKSUMERR	Checksum Error Indication Indicates checksum error in the ESC configuration area. 0: No error in the checksum 1: Error in the checksum	R
12	LOADSTA	EEPROM Loading Status Indication Indicates EEPROM loading status. 0: EEPROM has been loaded and device information has no problem 1: EEPROM has not been loaded and device information is not available (EEPROM loading in progress or finished with a failure)	R
13	ACKCMDERR	Acknowledge/Command Error Indication Indicates acknowledge/command error.*2 0: No error 1: Missing EEPROM acknowledge or invalid command	R
14	WRENERR	Write Enable Error Indication Indicates write enable error.*2 0: No error 1: Write command without write enable	R
15	BUSY	EEPROM Interface State Indication Indicates a busy state of the EEPROM interface. 0: The EEPROM interface is idle 1: The EEPROM interface is busy	R

Note: Write access depends on the assignment of the EEPROM interface (ECAT/PDI). Write access is generally blocked if the EEPROM interface is busy (bit 15 = 1).
Note 1. This initial value will be changed by setting of EEPROMSIZE bit in EtherCAT Operation Mode Register (ECATOPMOD).
Note 2. Error bits are cleared by writing 000b (or any valid command) to command bits [10:8].
Note 3. ECAT write enable bit 0 is self-cleared at the SOF of the next frame. Command bits [10:8] are also self-cleared after the command is executed (EEPROM busy ends).
Writing 000b to command bits [10:8] also clears the error bits 14 and 13. Command bits [10:8] are ignored if the acknowledge/command error bit 13 is 1.

The EEP_CONT_STAT register is used to control access to the EEPROM and indicate the status.

30.14.4 EEP_ADR : EEPROM Address Register

Base address: ESC = 0x8013_0000

Offset address: 0x0504

Bit position:	31																												0
Bit field:	ADDRESS[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ADDRESS[31:0]	EEPROM Address Setting Actually used EEPROM address bits: [9:0]: EEPROM size of up to 16 Kbits [17:0]: EEPROM size of 32 Kbits to 4 Mbits 0: First word (= 16 bits) 1: Second word ⋮	R/W

Note: Write access depends on the assignment of the EEPROM interface (ECAT/PDI). Write access is generally blocked if the EEPROM interface is busy (bit 15 is 1 in the EEPROM Control/Status register, EEP_CONT_STAT, at 0x0502).

The EEP_ADR register is used to set the EEPROM address to be accessed.

30.14.5 EEP_DATA : EEPROM Data Register

Base address: ESC = 0x8013_0000

Offset address: 0x0508

Bit position:	31																16	15														0
Bit field:	HIDATA[15:0]																LODATA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	LODATA[15:0]	Data to be written to the EEPROM or data read from the EEPROM (lower 2 bytes)	R/W
31:16	HIDATA[15:0]	Data read from the EEPROM (upper 2 bytes)	R

Note: Write access depends on the assignment of the EEPROM interface (ECAT/PDI). Write access is generally blocked if the EEPROM interface is busy (bit 15 is 1 in the EEPROM Control/Status register, EEP_CONT_STAT, at 0x0502).

The EEP_DATA register is used to set write data to the EEPROM or indicates read data from the EEPROM. It can be written in 1-word units and read in 2-word units.

30.15 MII Management Interface Registers

30.15.1 MII_CONT_STAT : MII Management Control/Status Register

Base address: ESC = 0x8013_0000

Offset address: 0x0510

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BUSY	CMDERR	READERR	—	—	—	COMMAND[1:0]		PHYOFFSET[4:0]					MILINK	PDICTRL	WREN
Value after reset:	0	0	0	x	x	x	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
0	WREN	Write Enable This bit is always 1 if the PDI controls the MII management interface. The access type from the EtherCAT master is R/W. 0: Disabled 1: Enabled	R
1	PDICTRL	PDI Control Indication Indicates whether the MII management interface can be controlled by the PDI. The interface is controlled by the MII management ECAT Access State register (MII_ECAT_ACS_STAT at 0x0516) and the MII management PDI Access State register (MII_PDI_ACS_STAT at 0x0517). 0: Only ECAT control 1: PDI control possible	R
2	MILINK	MI Link Detection 0: Not available 1: Available	R
7:3	PHYOFFSET[4:0]	PHY Address Offset Indication Indicate the PHY address offset.	R

Bit	Symbol	Function	R/W
9:8	COMMAND[1:0]	Command Write: Initiates the commands below. Read: Indicates the currently executed command. Commands: 0 0: No command/MI idle (clear error bits) 0 1: Read 1 0: Write Others: Setting prohibited	R/W
12:10	—	The read values are undefined. The write value should be 0.	R/W
13	READERR	Read Error Indication Indicates whether a read error occurred. This bit is cleared by writing to this register. 0: No read error 1: Read error occurred (PHY or register not available)	R/W
14	CMDERR	Command Error Indication Indicates whether a command error occurred. This bit is cleared by executing a valid command or writing 00b to COMMAND[1:0]. 0: Last command was successful 1: Invalid command or write command without write enable	R
15	BUSY	MII Management State Indication Indicates that the MII management interface is busy. 0: MII management interface is idle 1: MII management interface is busy	R

The MII_CONT_STAT register is used to control the MII management interface and to indicate the status.

Write enable bit 0 is self-cleared at the SOF of the next frame. Command bits [9:8] are also self-cleared after the command is executed (busy ends). Writing 00b to command bits also clears the error bits 14 and 13. Command bits are cleared after the command is executed.

Write access depends on the assignment of the management interface (ECAT/PDI). Write access is generally blocked if the management interface is busy (bit 15 = 1 in this register).

30.15.2 PHY_ADR : PHY Address Register

Base address: ESC = 0x8013_0000

Offset address: 0x0512

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PHYADDR[4:0]				
Value after reset:	x	x	x	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	PHYADDR[4:0]	PHY Address Setting	R/W
7:5	—	The read values are undefined.	R

The PHY_ADR register is used to set the PHY address.

Write access depends on the assignment of the management interface (ECAT/PDI). Write access is generally blocked if the management interface is busy (bit 15 is 1 in the MII management control/status register, MII_CONT_STAT, at 0x0510).

30.15.3 PHY_REG_ADR : PHY Register Address Register

Base address: ESC = 0x8013_0000

Offset address: 0x0513

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PHYREGADDR[4:0]				
Value after reset:	x	x	x	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	PHYREGADDR[4:0]	Address of PHY register	R/W
7:5	—	The read values are undefined.	R/W

The PHY_REG_ADR register is used to set the PHY register address.

Write access depends on the assignment of the management interface (ECAT/PDI). Write access is generally blocked if the management interface is busy (bit 15 is 1 in the MII management Control/Status register, MII_CONT_STAT, at 0x0510).

30.15.4 PHY_DATA : PHY Data Register

Base address: ESC = 0x8013_0000

Offset address: 0x0514

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PHYREGDATA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PHYREGDATA[15:0]	PHY Register Data Indication/Setting	R/W

The PHY_DATA register is used to set data to write to PHY registers or to indicate data read from PHY registers.

Write access depends on the assignment of the management interface (ECAT/PDI). Write access is generally blocked if the management interface is busy (bit 15 is 1 in the MII management Control/Status register, MII_CONT_STAT, at 0x0510).

30.15.5 MII_ECAT_ACS_STAT : MII Management ECAT Access State Register

Base address: ESC = 0x8013_0000

Offset address: 0x0516

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ACSMII
Value after reset:	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	ACSMII	MII Management Interface Access Right Setting Right of access to the MII management interface The access type from the EtherCAT master is R/W. 0: Enables access to the MII management interface by the PDI. 1: Exclusive access to the MII management interface by the ECAT	R
7:1	—	The read values are undefined.	R

Note: Write access is only possible when bit 0 is 1 in the MII management PDI Access State register (MII_PDI_ACS_STAT at 0x0517).

The MII_ECAT_ACS_STAT register is used to set the right of access to the MII management interface.

30.15.6 MII_PDI_ACS_STAT : MII Management PDI Access State Register

Base address: ESC = 0x8013_0000

Offset address: 0x0517

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	FORPDI	ACSMII
Value after reset:	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
0	ACSMII	Right of access to the MII management interface The access type from the EtherCAT master is R. 0: Access to the MII management interface by the ECAT 1: Access to the MII management interface by the PDI	R/W
1	FORPDI	Forced change of access by the PDI (forced change of bit 0) The access type from the EtherCAT master is R/W. 0: The value of bit 0 of this register is not changed 1: The value of bit 0 of this register is reset to 0 (the right of access is changed to the ECAT)	R
7:2	—	The read values are undefined. The access type from the EtherCAT master is R.	R/W

Note: Write access to bit 0 from the PDI is only possible if the following two conditions are satisfied.
- Bit 0 is 0 in the MII management ECAT Access State register (MII_ECAT_ACS_STAT at 0x0516).
- Bit 1 is 0 in the MII management PDI Access State register (MII_PDI_ACS_STAT at 0x0517).

The MII_PDI_ACS_STAT register is used to set the right of access to the MII management interface.

30.16 FMMU Registers

30.16.1 FMMUn_L_START_ADR : FMMU Logical Start Address n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x0600 + 0x10 × n

Bit position:	31	0
Bit field:	LSTAADR[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	LSTAADR[31:0]	Logical Start Address Setting Set the start of the logical address within the EtherCAT address space. The access type from the EtherCAT master is R/W.	R

The FMMUn_L_START_ADR register is used to set the logical start address within the EtherCAT address space for FMMU.

30.16.2 FMMUn_LEN : FMMU Length n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x0604 + 0x10 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FMMULEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	FMMULEN[15:0]	Area Size Specification Set the area size in byte units. Address at the end of the logical address range set by the FMMU minus the address at the start of the logical address range set by the FMMU plus 1. The access type from the EtherCAT master is R/W.	R

The FMMUn_LEN register is used to set the length for FMMU area in byte units.

30.16.3 FMMUn_L_START_BIT : FMMU Logical Start Bit n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x0606 + 0x10 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	LSTABIT[2:0]		
Value after reset:	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	LSTABIT[2:0]	Start Bit Setting Set the start bits of the logical start address for FMMU. The access type from the EtherCAT master is R/W.	R
7:3	—	The read values are undefined.	R

The FMMUn_L_START_BIT register is used to set the start bits of the logical start address for FMMU.

30.16.4 FMMUn_L_STOP_BIT : FMMU Logical Stop Bit n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x0607 + 0x10 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	LSTPBIT[2:0]		
Value after reset:	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	LSTPBIT[2:0]	Last Bit Setting Set the last bits of the logical end address for FMMU. The access type from the EtherCAT master is R/W.	R
7:3	—	The read values are undefined.	R

The FMMUn_L_STOP_BIT register is used to set the last bits of the logical end address for FMMU.

30.16.5 FMMUn_P_START_ADR : FMMU Physical Start Address n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x0608 + 0x10 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PHYSTAADR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PHYSTAADR[15:0]	Physical Start Address Setting Set the physical start address to which the logical start address will be mapped. The address is set as an offset from the base address (0x8013_0000). The access type from the EtherCAT master is R/W.	R

The FMMUn_P_START_ADR register is used to set the physical start address of the ESC to which the logical start address will be mapped by the FMMU.

30.16.6 FMMUn_P_START_BIT : FMMU Physical Start Bit n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x060A + 0x10 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	PHYSTABIT[2:0]		
Value after reset:	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	PHYSTABIT[2:0]	Physical Start Bit Setting Set the start bits of the physical start address to which the start bits of the logical start address will be mapped. The access type from the EtherCAT master is R/W.	R
7:3	—	The read values are undefined.	R

The FMMUn_P_START_BIT register is used to set the start bits of the physical start address of the ESC to which the start bits of the logical start address will be mapped by the FMMU.

30.16.7 FMMUn_TYPE : FMMU Type n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x060B + 0x10 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	WRITE	READ
Value after reset:	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
0	READ	Read Access Mapping Setting The access type from the EtherCAT master is R/W. 0: Disabled 1: Enabled	R
1	WRITE	Write Access Mapping Setting The access type from the EtherCAT master is R/W. 0: Disabled 1: Enabled	R
7:2	—	The read values are undefined.	R

The FMMUn_TYPE register is used to set the type of FMMU access.

30.16.8 FMMUn_ACT : FMMU Activate n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x060C + 0x10 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ACTIVATE
Value after reset:	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	ACTIVATE	FMMU Enable/Disable The access type from the EtherCAT master is R/W. 0: Disabled 1: Enabled	R
7:1	—	The read values are undefined.	R

The FMMUn_ACT register is used to enable or disable FMMU.

30.17 SyncManager Registers

30.17.1 SMn_P_START_ADR : SyncManager Physical Start Address n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x0800 + 0x8 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SMSTAADDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SMSTAADDR[15:0]	Physical Start Address Setting Specify the physical start address for the area assigned to SyncManager. The access type from the EtherCAT master is R/W.	R

Note: The SMn_P_START_ADR register can only be written when SyncManager is disabled (bit 0 is 0 in the SyncManager Activate n register (SMn.ACT at 0x0806 + 0x8 × n).

This register is used to set the physical start address for the area assigned to SyncManager.

30.17.2 SMn_LEN : SyncManager Length n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x0802 + 0x8 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SMLEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SMLEN[15:0]	Area Size Setting Set the number of bytes assigned to SyncManager. Set a value greater than 1. Otherwise, SyncManager is not activated. The access type from the EtherCAT master is R/W.	R

Note: This register can only be written when SyncManager is disabled (bit 0 is 0 in the SyncManager Activate n register (SMn.ACT at 0x0806 + 0x8 × n)).

The SMn_LEN register is used to set the size of the area assigned to SyncManager.

30.17.3 SMn_CONTROL : SyncManager Control n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x0804 + 0x8 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	WDTRGEN	IRQPDI	IRQECAT	DIR[1:0]		OPEMODE[1:0]	
Value after reset:	x	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	OPEMODE[1:0]	Operating Mode Setting The access type from the EtherCAT master is R/W. 0 0: Buffer mode (3-buffer mode) 1 0: Mailbox mode (single buffer mode) Others: Reserved	R
3:2	DIR[1:0]	Transfer Direction Setting The access type from the EtherCAT master is R/W. 0 0: Read (ECAT: read access; PDI: write access) 0 1: Write (ECAT: write access; PDI: read access) Others: Reserved	R
4	IRQECAT	ECAT Event Interrupt Setting Enables or disables interrupts (ECAT interrupts) by the ECAT Event Request register (ECAT_EVENT_REQ at 0x0210). The access type from the EtherCAT master is R/W. 0: Disabled 1: Enabled	R
5	IRQPDI	AL Event Interrupt Setting Enables or disables interrupts (PDI interrupts) by the AL Event Request register (AL_EVENT_REQ at 0x0220). The access type from the EtherCAT master is R/W. 0: Disabled 1: Enabled	R
6	WDTRGEN	Watchdog Trigger Setting The access type from the EtherCAT master is R/W. 0: Disabled 1: Enabled	R
7	—	The read value is undefined.	R

Note: This register can only be written when SyncManager is disabled (bit 0 is 0 in the SyncManager Activate n register (SMn.ACT at 0x0806 + 0x8 × n)).

The SMn_CONTROL register is used to set operation of SyncManager.

30.17.4 SMn_STATUS : SyncManager Status n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x0805 + 0x8 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	WRBUF	RDBUF	BUFFERED[1:0]		MAILBOX	—	INTRD	INTWR
Value after reset:	0	0	1	1	0	x	0	0

Bit	Symbol	Function	R/W
0	INTWR	Write Complete Interrupt State Indication 0: Indicates that the buffer was successfully written 1: Indicates that the first byte of the buffer was read (interrupt cleared)	R
1	INTRD	Read Complete Interrupt State Indication 0: Indicates that the buffer was successfully read 1: Indicates that the first byte of the buffer was written (interrupt cleared)	R
2	—	The read value is undefined.	R
3	MAILBOX	Mailbox Status Indication This bit is not used in buffer mode. 0: Mailbox empty 1: Mailbox full	R
5:4	BUFFERED[1:0]	Buffer Status Indication Indicates the buffer status in buffer mode (last written buffer). This bit is not used in mailbox mode. 0 0: 1st buffer 0 1: 2nd buffer 1 0: 3rd buffer 1 1: No buffer written	R
6	RDBUF	Read State Indication Indicates that the buffer is being read.	R
7	WRBUF	Write State Indication Indicates that the buffer is being written.	R

The SMn_STATUS register indicates the state of SyncManager.

30.17.5 SMn_ACT : SyncManager Activate n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x0806 + 0x8 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	LATCHPDI	LATCHECAT	—	—	—	—	REPEATREQ	SMEN
Value after reset:	0	0	x	x	x	x	0	0

Bit	Symbol	Function	R/W
0	SMEN	SyncManager Enable/Disable The access type from the EtherCAT master is R/W. 0: Disabled. Memory is accessed without SyncManager control. 1: Enabled. SyncManager is active and controls memory area set in configuration.	R (ack)
1	REPEATREQ	Repeat Request Toggling of the repeat request signal means that retrying the mailbox is required (primarily used in conjunction with reading of the ECAT mailbox). The access type from the EtherCAT master is R/W.	R (ack)
5:2	—	The read values are undefined.	R
6	LATCHECAT	ECAT Latch Event Specification The access type from the EtherCAT master is R/W. 0: No latch events 1: Generates latch events if the EtherCAT master switches the buffers	R (ack)
7	LATCHPDI	PDI Latch Event Specification The access type from the EtherCAT master is R/W. 0: No latch events 1: Generates latch events if the PDI switches the buffers or accesses the buffer start address	R (ack)

Note: Reading this register from the PDI in all SyncManagers which have changed activation clears bit 4 of the AL Event Request register (AL_EVENT_REQ at 0x0220).

The SMn_ACT register is used to set operation of SyncManager.

30.17.6 SMn_PDI_CONT : SyncManager PDI Control n Register (n = 0 to 7)

Base address: ESC = 0x8013_0000

Offset address: 0x0807 + 0x8 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	REPEATACK	DEACTIVE
Value after reset:	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
0	DEACTIVE	SyncManager Operation Indication/Setting Deactivates SyncManager. Writing 1 is delayed until the end of a frame which is currently processed. The access type from the EtherCAT master is R. 0: Read: Normal operation. SyncManager is activated. Write: Activates SyncManager. 1: Read: SyncManager is deactivated and reset. SyncManager locks access to memory area. Write: Deactivates SyncManager.	R/W
1	REPEATACK	Repeat Acknowledge If this bit is set to the same value as set by bit 0 (repeat request) of the SyncManager activate register (SMn.ACT at 0x0806 + 0x8 × n), the PDI acknowledges the execution of a previous set repeat request. The access type from the EtherCAT master is R.	R/W
7:2	—	The read values are undefined. The write value should be 0.	R/W

The SMn_PDI_CONT register is used to set operation of SyncManager from the PDI.

30.18 Distributed Clock Registers

30.18.1 DC Receive Time Registers

30.18.1.1 DC_RCV_TIME_PORT0 : Receive Time Port 0 Register

Base address: ESC = 0x8013_0000

Offset address: 0x0900

Bit position:	31	0
Bit field:	RCVTIME0[31:0]	
Value after reset:	x x x x x x x x x x x x x x x x x x x x x x x x x x x x x x x x	

Bit	Symbol	Function	R/W
31:0	RCVTIME0[31:0]	Receive Time Indication/Latch The time stamps cannot be read in the same frame in which this register was written. The access type from the EtherCAT master is R/W. Write: A write access to this register with the BWR or FPWR command latches the local time when each port starts to receive a frame (first start bit of preamble). Read: Indicate the local time at the beginning of reception of the last frame containing write access to this register.	R

Writing to the DC_RCV_TIME_PORT0 register latches the received time of frames at all ports and reading this register indicates the received time of a frame latched at port 0.

30.18.1.2 DC_RCV_TIME_PORT1 : Receive Time Port 1 Register

Base address: ESC = 0x8013_0000

Offset address: 0x0904

Bit position:	31																												0
Bit field:	RCVTIME1[31:0]																												
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
31:0	RCVTIME1[31:0]	Receive Time Indication Indicate the local time when port 1 starts to receive a frame (first start bit of preamble) containing the BWR or FPWR command to the receive time port 0 register (DC_RCV_TIME_PORT0 at 0x0900).	R

The DC_RCV_TIME_PORT1 register indicates the received time of the frame latched at port 1.

30.18.1.3 DC_RCV_TIME_PORT2 : Receive Time Port 2 Register

Base address: ESC = 0x8013_0000

Offset address: 0x0908

Bit position:	31																												0
Bit field:	RCVTIME2[31:0]																												
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
31:0	RCVTIME2[31:0]	Receive Time Indication Indicate the local time when port 2 starts to receive a frame (first start bit of preamble) containing the BWR or FPWR command to the receive time port 0 register (DC_RCV_TIME_PORT0 at 0x0900).	R

The DC_RCV_TIME_PORT2 register indicates the received time of the frame latched at port 2.

30.18.2 DC Time Loop Control Unit Registers

30.18.2.1 DC_SYS_TIME : System Time Register

Base address: ESC = 0x8013_0000

Offset address: 0x0910

Bit position:	63																												32
Bit field:	SYSTIME[63:32]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	31																												0
Bit field:	SYSTIME[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
63:0	SYSTIME[63:0]	System Time Indication Access from the ECAT (read-write) Read: Indicate the local copy of the system time when the frame passed the reference clock (such as including a system time delay). The time latched at the start of frame (SOF) is indicated. Write: A written value is compared with the local copy of the system time. The result is input to the time control loop unit. Access from the PDI (read-only) Indicate the local copy of the system time. The time latched when the first byte of this register was read is indicated.	R

The DC_SYS_TIME register indicates the local copy of the system time.

30.18.2.2 DC_RCV_TIME_UNIT : Receive Time ECAT Processing Unit Register

Base address: ESC = 0x8013_0000

Offset address: 0x0918

Bit position:	63																												32
Bit field:	RCVTIMEEPU[63:32]																												
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	31																												0
Bit field:	RCVTIMEEPU[31:0]																												
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
63:0	RCVTIMEEPU[63:0]	Receive Time Indication This register indicates the local time at the beginning of reception by the EtherCAT processing unit of a frame (such as the first start bit of the preamble), including write access to the Receive Time Port 0 register (DC_RCV_TIME_PORT0 at 0x0900).	R

Note: If port 0 is open, the value in this register reflects the same time as the value in the Receive Time Port 0 register (DC_RCV_TIME_PORT0 at 0x0900), but as 64 bits.

The DC_RCV_TIME_UNIT register indicates the received time of a frame latched at EtherCAT processing unit.

30.18.2.3 DC_SYS_TIME_OFFSET : System Time Offset Register

Base address: ESC = 0x8013_0000

Offset address: 0x0920

Bit position:	63																												32
Bit field:	SYSTIMOFST[63:32]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	31																												0
Bit field:	SYSTIMOFST[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

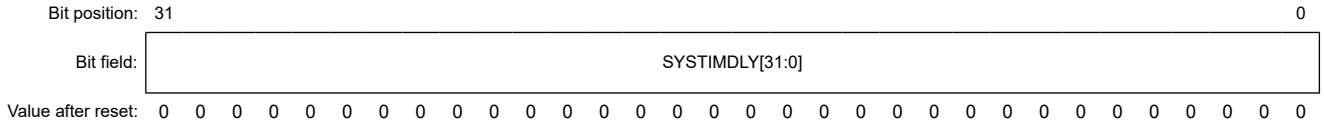
Bit	Symbol	Function	R/W
63:0	SYSTIMOFST[63:0]	System Time and Local Time Difference Indication Indicate a difference between the local time and system time. This offset is added to the local time to obtain the local system time. The access type from the EtherCAT master is R/W.	R

The DC_SYS_TIME_OFFSET register is used to indicate a difference (offset) between the local time and system time.

30.18.2.4 DC_SYS_TIME_DELAY : System Time Delay Register

Base address: ESC = 0x8013_0000

Offset address: 0x0928



Bit	Symbol	Function	R/W
31:0	SYSTIMDLY[31:0]	Propagation Delay Indication Indicate a delay between the reference clock and the ESC. The access type from the EtherCAT master is R/W.	R

The DC_SYS_TIME_DELAY register indicates a propagation delay between the reference clock and slave (ESC).

30.18.2.5 DC_SYS_TIME_DIFF : System Time Difference Register

Base address: ESC = 0x8013_0000

Offset address: 0x092C

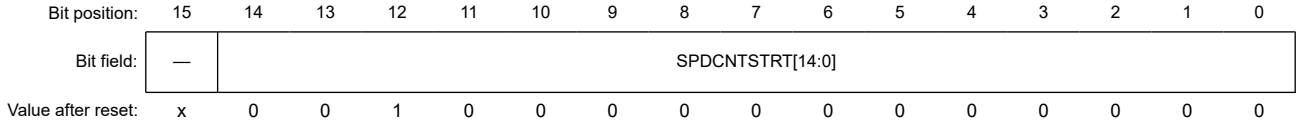
Bit	Symbol	Function	R/W
30:0	DIFF[30:0]	System Time Mean Difference Indication Indicates a mean difference between the local copy of the system time and received system time.	R
31	LCP	System Time Greater/Less Indication Indicates whether the local copy of the system time is greater than or equal to, or is less than, the latest received copy of the system time. 0: Local copy of the system time greater than or equal to the received system time 1: Local copy of the system time less than the received system time	R

The DC_SYS_TIME_DIFF register indicates a mean difference between the local copy of the system time and received system time.

30.18.2.6 DC_SPEED_COUNT_START : Speed Counter Start Register

Base address: ESC = 0x8013_0000

Offset address: 0x0930



Bit	Symbol	Function	R/W
14:0	SPDCNTSTRT[14:0]	Drift Correction Bandwidth Setting Indicate the bandwidth for adjustment of the local copy of the system time (larger values → smaller bandwidth and smoother adjustment). A write access resets the System Time Difference register (DC_SYS_TIME_DIFF at 0x092C) and the Speed Counter Difference register (DC_SPEED_COUNT_DIFF at 0x0932). Valid range: 0x0080 to 0x3FFF The access type from the EtherCAT master is R/W.	R
15	—	The read value is undefined. The access type from the EtherCAT master is R/W. In this case, the write value should be 0.	R

The DC_SPEED_COUNT_START register is used to set the bandwidth for drift correction of the local copy of the system time.

30.18.2.7 DC_SPEED_COUNT_DIFF : Speed Counter Difference Register

Base address: ESC = 0x8013_0000

Offset address: 0x0932

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SPDCNTDIFF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SPDCNTDIFF[15:0]	Clock Period Deviation Indication Indicate the deviation between the local clock period and the clock period of the reference clock (represented by two's complements). Range: ± (speed counter start value - 0x7F)	R

The DC_SPEED_COUNT_DIFF register indicates the deviation between the local clock period and the clock period of the reference clock.

30.18.2.8 DC_SYS_TIME_DIFF_FIL_DEPTH : System Time Difference Filter Depth Register

Base address: ESC = 0x8013_0000

Offset address: 0x0934

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	SYSTIMDEP[3:0]			
Value after reset:	x	x	x	x	0	1	0	0

Bit	Symbol	Function	R/W
3:0	SYSTIMDEP[3:0]	Filter Depth Setting Set the filter depth for averaging the received system time deviation. A write access resets the System Time Difference register (DC_SYS_TIME_DIFF at 0x092C). The access type from the EtherCAT master is R/W.	R
7:4	—	The read values are undefined. The access type from the EtherCAT master is R/W. In this case, the write value should be 0.	R

The DC_SYS_TIME_DIFF_FIL_DEPTH register is used to set the filter depth for averaging the received system time deviation.

30.18.2.9 DC_SPEED_COUNT_FIL_DEPTH : Speed Counter Filter Depth Register

Base address: ESC = 0x8013_0000

Offset address: 0x0935

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	CLKPERDEP[3:0]			
Value after reset:	x	x	x	x	1	1	0	0

Bit	Symbol	Function	R/W
3:0	CLKPERDEP[3:0]	Filter Depth Setting Set the filter depth for averaging the clock period deviation. A write access resets the internal speed counter filter. The access type from the EtherCAT master is R/W.	R
7:4	—	The read values are undefined. The access type from the EtherCAT master is R/W. In this case, the write value should be 0.	R

The DC_SPEED_COUNT_FIL_DEPTH register is used to set the filter depth for averaging the clock period deviation.

30.18.3 Cyclic Unit Control Registers

30.18.3.1 DC_CYC_CONT : Cyclic Unit Control Register

Base address: ESC = 0x8013_0000

Offset address: 0x0980

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	LATCH1	LATCH0	—	—	—	SYNCOUT
Value after reset:	x	x	0	0	x	x	x	0

Bit	Symbol	Function	R/W
0	SYNCOUT	SYNC Output Unit Control Setting The access type from the EtherCAT master is R/W. 0: ECAT control 1: PDI control	R
3:1	—	The read values are undefined.	R
4	LATCH0	Latch Input Unit 0 Control Setting Latch interrupt is routed to the ECAT or PDI in accordance with this setting. The access type from the EtherCAT master is R/W. 0: ECAT control 1: PDI control	R
5	LATCH1	Latch Input Unit 1 Control Setting Latch interrupt is routed to the ECAT or PDI in accordance with this setting. The access type from the EtherCAT master is R/W. 0: ECAT control 1: PDI control	R
7:6	—	The read values are undefined.	R

The DC_CYC_CONT register sets whether to control SYNC and latch units by the ECAT or PDI.

30.18.4 SYNC Output Unit Registers

30.18.4.1 DC_ACT : Activation Register

Base address: ESC = 0x8013_0000

Offset address: 0x0981

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DBGPULSE	NEARFUTURE	STARTTIME	EXTSTARTTIME	AUTOACT	SYNC1	SYNC0	SYNCACT
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SYNCACT	Sync Output Unit Activation Activates the Sync output unit. Write 1 after the start time is written. 0: Deactivated 1: Activated	R/W
1	SYNC0	SYNC0 Output Setting Sets SYNC0 output. 0: Deactivated 1: SYNC0 pulse output is generated	R/W
2	SYNC1	SYNC1 Output Setting Sets SYNC1 output. 0: Deactivated 1: SYNC1 pulse output is generated	R/W
3	AUTOACT	SYNC Output Unit Activation Sets whether to activate the Sync output unit automatically by writing to the Start Time Cyclic Operation register (DC_CYC_START_TIME at 0x0990): 0: Deactivated 1: Activated. Bit 0 is automatically set to 1 in this register after the start time is written.	R/W
4	EXTSTARTTIME	Start Time Cyclic Operation Extension Extends start time cyclic operation. 0: No extension 1: Extends the start time written with 32 bits to 64 bits	R/W
5	STARTTIME	Start Time Plausibility Selects whether checking the plausibility of the start time and response to implausible start times is to proceed. 0: Disabled. Sync signal is generated if the start time is reached. 1: Sync signal is generated immediately if the start time is outside the range of the near future.	R/W
6	NEARFUTURE	Near Future Range Setting Sets the range to be considered the near future. 0: Up to 2^{63} ns from now (1/2 of the DC width) 1: Up to 2^{31} ns from now (about 2.1 sec.)	R/W
7	DBGPULSE	Debug Pulse Setting Sets Sync signal debug pulse. This bit is self-cleared and always read as 0. 0: Deactivated 1: Immediately generates a single debug ping on the SYNC0 and SYNC1 pins in accord with the setting of bits 2 and 1 of this register.	R/W

Note: Writing to this register depends on the setting of bit 0 of the Cyclic Unit Control register (DC_CYC_CONT at 0x0980).

The DC_ACT register is used to activate the Sync output unit.

30.18.4.2 DC_PULSE_LEN : SYNC Signal Pulse Length Register

Base address: ESC = 0x8013_0000

Offset address: 0x0982

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PULSELEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PULSELEN[15:0]	SYNC Signal Pulse Length Indication Indicate the pulse length of SYNC signals (in units of 10 ns) 0: Acknowledge mode. In this mode, SYNC signal is cleared by reading the SYNC0 or SYNC1 status register (DC_SYNC0/1_STAT at 0x098E, 0x098F).	R

The DC_PULSE_LEN register indicates the pulse length of SYNC signals.

30.18.4.3 DC_ACT_STAT : Activation Status Register

Base address: ESC = 0x8013_0000

Offset address: 0x0984

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	START TIME	SYNC 1ACT	SYNC 0ACT
Value after reset:	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
0	SYNC0ACT	SYNC0 Status Indication Indicates the activation state of SYNC0. 0: First SYNC0 pulse is not pending 1: First SYNC0 pulse is pending	R
1	SYNC1ACT	SYNC1 Status Indication Indicates the activation state of SYNC1. 0: First SYNC1 pulse is not pending 1: First SYNC1 pulse is pending	R
2	STARTTIME	Plausibility Result Indication Indicates the plausibility check result of the Start Time Cyclic Operation register (DC_CYC_START_TIME at 0x0990) while the Sync output unit is activated. 0: The start time is within the near future 1: The start time is out of the near future	R
7:3	—	The read values are undefined.	R

The DC_ACT_STAT register indicates the activation status of SYNC output signals.

30.18.4.4 DC_SYNC0_STAT : SYNC0 Status Register

Base address: ESC = 0x8013_0000

Offset address: 0x098E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SYNC 0STA
Value after reset:	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	SYNC0STA	SYNC0 State Indication Indicates the SYNC0 state for acknowledge mode. SYNC0 in acknowledge mode is cleared by reading this register from the PDI. This bit is only used in acknowledge mode.	R
7:1	—	The read values are undefined.	R

The DC_SYNC0_STAT register indicates the state of SYNC0 output. It is only used in acknowledge mode.

30.18.4.5 DC_SYNC1_STAT : SYNC1 Status Register

Base address: ESC = 0x8013_0000

Offset address: 0x098F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SYNC 1STA
Value after reset:	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	SYNC1STA	SYNC1 State Indication Indicates the SYNC1 state for acknowledge mode. SYNC1 in acknowledge mode is cleared by reading this register from the PDI. This bit is only used in acknowledge mode.	R
7:1	—	The read values are undefined.	R

The DC_SYNC1_STAT register indicates the state of SYNC1 output. It is only used in acknowledge mode.

30.18.4.6 DC_CYC_START_TIME : Start Time Cyclic Operation/Next SYNC0 Pulse Register

Base address: ESC = 0x8013_0000

Offset address: 0x0990

Bit position:	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bit field:	STATIM[63:32]																															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	STATIM[31:0]																															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
63:0	STATIM[63:0]	Start Time Setting/System Time Indication Write: Set the start time (in the system time) of cyclic operation in ns units. Read: Indicate the system time of the next SYNC0 pulse in ns units.	R/W

Note:
- Writing to this register depends on the setting of bit 0 of the Cyclic Unit Control register (DC_CYC_CONT at 0x0980). Only writable when bit 0 is 0 in the SYNC Activation register (DC_ACT at 0x0981).
- When auto-activation is enabled, the upper 32 bits are automatically extended if only the lower 32 bits are written within one frame.

Writing to this register sets the start time of cyclic operation. Reading this register indicates the system time of the next SYNC0 pulse.

30.18.4.7 DC_NEXT_SYNC1_PULSE : Next SYNC1 Pulse Register

Base address: ESC = 0x8013_0000

Offset address: 0x0998

Bit position:	63																												32
Bit field:	SYNC1PULSE[63:32]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	31																												0
Bit field:	SYNC1PULSE[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
63:0	SYNC1PULSE[63:0]	SYNC1 Pulse System Time Indication Indicate the system time of the next SYNC1 pulse in ns units.	R

The DC_NEXT_SYNC1_PULSE register indicates the system time of the next SYNC1 pulse.

30.18.4.8 DC_SYNC0_CYC_TIME : SYNC0 Cycle Time Register

Base address: ESC = 0x8013_0000

Offset address: 0x09A0

Bit position:	31																												0
Bit field:	SYNC0CYC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SYNC0CYC[31:0]	Time Between Consecutive SYNC0 Pulses Set the time between two consecutive SYNC0 pulses in ns units. 0: Single-shot mode. Only one SYNC0 pulse is generated in single-shot mode.	R/W

Note: Writing to this register depends on the setting of bit 0 of the Cyclic Unit Control register (DC_CYC_CONT at 0x0980).

The DC_SYNC0_CYC_TIME register is used to set the time between consecutive SYNC0 pulses.

30.18.4.9 DC_SYNC1_CYC_TIME : SYNC1 Cycle Time Register

Base address: ESC = 0x8013_0000

Offset address: 0x09A4

Bit position:	31																												0
Bit field:	SYNC1CYC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SYNC1CYC[31:0]	Time between SYNC1 and SYNC0 Pulses Set the time between SYNC1 and SYNC0 pulses in ns units.	R/W

Note: Writing to this register depends on the setting of bit 0 of the Cyclic Unit Control register (DC_CYC_CONT at 0x0980).

The DC_SYNC1_CYC_TIME register is used to set the time between SYNC1 and SYNC0 pulses.

30.18.5 Latch Input Unit Registers

30.18.5.1 DC_LATCH0_CONT : Latch 0 Control Register

Base address: ESC = 0x8013_0000

Offset address: 0x09A8

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	NEGEDGE	POSEDGE
Value after reset:	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
0	POSEDGE	Latch 0 Positive Edge Function Setting Sets the function of the rising edge of the latch 0 input signal. 0: Continuous latch active 1: Single event (only first event active)	R/W
1	NEGEDGE	Latch 0 Negative Edge Function Setting Sets the function of the falling edge of the latch 0 input signal. 0: Continuous latch active 1: Single event (only first event active)	R/W
7:2	—	The read values are undefined. The write value should be 0. The access type from the EtherCAT master is R.	R/W

Note: Writing to this register depends on the setting of bit 4 of the Cyclic Unit Control register (DC_CYC_CONT at 0x0980).

The DC_LATCH0_CONT register is used to control the edge function of the latch 0 input signal.

30.18.5.2 DC_LATCH1_CONT : Latch 1 Control Register

Base address: ESC = 0x8013_0000

Offset address: 0x09A9

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	NEGEDGE	POSEDGE
Value after reset:	x	x	x	x	x	x	0	0

Bit	Symbol	Function	R/W
0	POSEDGE	Latch 1 Positive Edge Function Setting Sets the function of the rising edge of the latch 1 input signal. 0: Continuous latch active 1: Single event (only first event active)	R/W
1	NEGEDGE	Latch 1 Negative Edge Function Setting Sets the function of the falling edge of the latch 1 input signal. 0: Continuous Latch active 1: Single event (only first event active)	R/W
7:2	—	The read values are undefined. The write value should be 0. The access type from the EtherCAT master is R.	R/W

Note: Writing to this register depends on the setting of bit 5 of the Cyclic Unit Control register (DC_CYC_CONT at 0x0980).

The DC_LATCH1_CONT register is used to control the edge function of the latch 1 input signal.

30.18.5.3 DC_LATCH0_STAT : Latch 0 Status Register

Base address: ESC = 0x8013_0000

Offset address: 0x09AE

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	PINSTATE	EVENTNEG	EVENTPOS
Value after reset:	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
0	EVENTPOS	Latch 0 Positive Edge Event Indication Indicates detection of rising edges of the event latch 0 signal. This flag is cleared by reading the Latch 0 Time Positive Edge register (DC_LATCH0_TIME_POS at 0x09B0). 0: Rising edge not detected or continuous mode 1: Rising edge detected and mode is single-event	R
1	EVENTNEG	Latch 0 Negative Edge Event Indication Indicates detection of falling edges of the event latch 0 signal. This flag is cleared by reading the Latch 0 Time Negative Edge register (DC_LATCH0_TIME_NEG at 0x09B8). 0: Falling edge not detected or continuous mode 1: Falling edge detected and mode is single-event	R
2	PINSTATE	Latch 0 Input Pin State Indication Indicates the state of the latch 0 input pin.	R
7:3	—	The read values are undefined.	R

The DC_LATCH0_STAT register indicates the state of the latch 0 input signal.

30.18.5.4 DC_LATCH1_STAT : Latch 1 Status Register

Base address: ESC = 0x8013_0000

Offset address: 0x09AF

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	PINSTATE	EVENTNEG	EVENTPOS
Value after reset:	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
0	EVENTPOS	Latch 1 Positive Edge Event Indication Indicates detection of rising edges of the event latch 1 signal. This flag is cleared by reading the Latch 1 Time Positive Edge register (DC_LATCH1_TIME_POS at 0x09C0). 0: Rising edge not detected or continuous mode 1: Rising edge detected and mode is single-event	R
1	EVENTNEG	Latch 1 Negative Edge Event Indication Indicates detection of falling edges of the event latch 1 signal. This flag is cleared by reading the Latch 1 Time Negative Edge register (DC_LATCH1_TIME_NEG at 0x09C8). 0: Falling edge not detected or continuous mode 1: Falling edge detected and mode is single-event	R
2	PINSTATE	Latch 1 Input Pin State Indication Indicates the state of the latch 1 input pin.	R
7:3	—	The read values are undefined.	R

The DC_LATCH1_STAT register indicates the state of the latch 1 input signal.

30.18.5.5 DC_LATCH0_TIME_POS : Latch 0 Time Positive Edge Register

Base address: ESC = 0x8013_0000

Offset address: 0x09B0

Bit position:	63																												32
Bit field:	SYSTIME[63:32]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	31																												0
Bit field:	SYSTIME[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
63:0	SYSTIME[63:0]	System Time Indication Indicate the system time captured at the rising edge of the latch 0 input signal. Reading this register clears bit 0 of the Latch 0 Status register (DC_LATCH0_STAT at 0x09AE).	R

Note:
- Bits [63:8] are internally latched (ECAT/PDI independently) when bits [7:0] are read, which guarantees reading a consistent value
- Clearing the latch 0 status flag function depends on the setting of bit 4 of the Cyclic Unit Control register (DC_CYC_CONT at 0x0980).

The DC_LATCH0_TIME_POS register indicates the system time at the rising edge of the latch 0 input signal.

30.18.5.6 DC_LATCH0_TIME_NEG : Latch 0 Time Negative Edge Register

Base address: ESC = 0x8013_0000

Offset address: 0x09B8

Bit position:	63																												32
Bit field:	SYSTIME[63:32]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	31																												0
Bit field:	SYSTIME[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
63:0	SYSTIME[63:0]	System Time Indication Indicate the system time captured at the falling edge of the latch 0 input signal. Reading this register clears bit 1 of the Latch 0 Status register (DC_LATCH0_STAT at 0x09AE).	R

Note:
- Bits [63:8] are internally latched (ECAT/PDI independently) when bits [7:0] are read, which guarantees reading a consistent value
- Clearing the latch 0 status flag function depends on the setting of bit 4 of the Cyclic Unit Control register (DC_CYC_CONT at 0x0980).

The DC_LATCH0_TIME_NEG register indicates the system time at the falling edge of the latch 0 input signal.

30.18.5.7 DC_LATCH1_TIME_POS : Latch 1 Time Positive Edge Register

Base address: ESC = 0x8013_0000

Offset address: 0x09C0

Bit position:	63																												32
Bit field:	SYSTIME[63:32]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	31																												0
Bit field:	SYSTIME[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
63:0	SYSTIME[63:0]	System Time Indication Indicate the system time captured at the rising edge of the latch 1 input signal. Reading this register clears bit 0 of the Latch 1 Status register (DC_LATCH1_STAT at 0x09AF).	R

Note:
- Bits [63:8] are internally latched (ECAT/PDI independently) when bits [7:0] are read, which guarantees reading a consistent value
- Clearing the latch 1 status flag function depends on the setting of bit 5 of the Cyclic Unit Control register (DC_CYC_CONT at 0x0980).

The DC_LATCH1_TIME_POS register indicates the system time at the rising edge of the latch 1 input signal.

30.18.5.8 DC_LATCH1_TIME_NEG : Latch 1 Time Negative Edge Register

Base address: ESC = 0x8013_0000

Offset address: 0x09C8

Bit position:	63																												32
Bit field:	SYSTIME[63:32]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	31																												0
Bit field:	SYSTIME[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
63:0	SYSTIME[63:0]	System Time Indication Indicate the system time captured at the falling edge of the latch 1 input signal. Reading this register clears bit 1 of the Latch 1 Status register (DC_LATCH1_STAT at 0x09AF).	R

Note:
- Bits [63:8] are internally latched (ECAT/PDI independently) when bits [7:0] are read, which guarantees reading a consistent value
- Clearing the latch 1 status flag function depends on the setting of bit 5 of the Cyclic Unit Control register (DC_CYC_CONT at 0x0980).

The DC_LATCH1_TIME_NEG register indicates the system time at the falling edge of the latch 1 input signal.

30.18.6 SyncManager Event Time Registers

30.18.6.1 DC_ECAT_CNG_EV_TIME : Buffer Change Event Time Register

Base address: ESC = 0x8013_0000

Offset address: 0x09F0

Bit position:	31																												0
Bit field:	ECATCHANGE[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ECATCHANGE[31:0]	Local Time Indication Indicate the local time at the beginning of a frame which causes at least one SyncManager to generate an ECAT event (switching the buffers).	R

Note: Bits [31:8] are internally latched (ECAT/PDI independently) when bits [7:0] are read, which guarantees reading a consistent value.

The DC_ECAT_CNG_EV_TIME register indicates the local time at the beginning of a frame which causes SyncManager to generate an ECAT event (switching the buffers).

30.18.6.2 DC_PDI_START_EV_TIME : PDI Buffer Start Event Time Register

Base address: ESC = 0x8013_0000

Offset address: 0x09F8

Bit position:	31																												0
Bit field:	PDISTART[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PDISTART[31:0]	Local Time Indication Indicate the local time when at least one SyncManager has generated a PDI event (access to the address where a buffer starts).	R

Note: Bits [31:8] are internally latched (ECAT/PDI independently) when bits [7:0] are read, which guarantees reading a consistent value.

The DC_PDI_START_EV_TIME register indicates the local time when SyncManager has generated a PDI event (access to the address where a buffer starts).

30.18.6.3 DC_PDI_CNG_EV_TIME : PDI Buffer Change Event Time Register

Base address: ESC = 0x8013_0000

Offset address: 0x09FC

Bit position:	31																												0
Bit field:	PDICHANGE[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PDICHANGE[31:0]	Local Time Indication Indicate the local time when at least one SyncManager has generated a PDI event (switching the buffers).	R

Note: Bits [31:8] are internally latched (ECAT/PDI independently) when bits [7:0] are read, which guarantees reading a consistent value.

The DC_PDI_CNG_EV_TIME register indicates the local time when SyncManager has generated a PDI event (switching the buffers).

30.19 Other Registers

30.19.1 PRODUCT_ID : Product ID Register

Base address: ESC = 0x8013_0000

Offset address: 0x0E00

Bit position:	63																													32
Bit field:	PROID[63:32]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	31																													0
Bit field:	PROID[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
63:0	PROID[63:0]	Product ID Indication	R

The PRODUCT_ID register indicates the product ID.

30.19.2 VENDOR_ID : Vendor ID Register

Base address: ESC = 0x8013_0000

Offset address: 0x0E08

Bit position:	63																													32
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	31																													0
Bit field:	VENDORID[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	VENDORID[31:0]	Vendor ID Indication	R
63:32	—	The read values are undefined.	R

The VENDOR_ID register indicates the vendor ID.

30.19.3 USER_RAM : User RAM

This area of RAM indicates the supported features dependent on the IP core configuration and takes up the 128 bits from 0x8013_0F80 to 0x8013_0FFF. An initial value of 1 means that the implementation of this module supports the corresponding feature, except in the case of bits [7:0], which indicate the number of bits defined in the user RAM and the initial value is 0x33 for this module.

Bit position	Description	Initial value
7:0	Number of bits for defining extended functionality. The value is 51 (0x33) for this module.	0x33
8	Extended DL Control register (0x0102, 0x0103)	1

Bit position	Description	Initial value
9	AL Status Code register (0x0134, 0x0135)	1
10	ECAT event mask (0x0200, 0x0201)	1
11	Configured station alias (0x0012, 0x0013)	1
12	General input (0x0F18, 0x0F1F)	0
13	General output (0x0F10, 0x0F17)	0
14	AL event mask (0x0204, 0x0207)	1
15	Physical read/write offset (0x0108, 0x0109)	1
16	Watchdog divider writable (0x0400, 0x0401) and watchdog PDI (0x0410, 0x0F11)	1
17	Watchdog counter (0x0442, 0x0443)	1
18	Write protection (0x0020, 0x0031)	1
19	Reset (0x0040, 0x0041)	1
20	Reserved	0
21	DC SyncManager event time (0x09F0, 0x09FF)	1
22	ECAT processing unit/PDI error counter (0x030C, 0x030D)	1
23	EEPROM size configurable (bit 7 at 0x0502) 0: EEPROM size fixed up to 16 Kbits 1: EEPROM size configurable	1
26:24	Reserved	0
27	Lost link counter (0x0310, 0x0313)	1
28	MII management interface (0x0510, 0x0515)	1
29	Enhanced link detection MII	1
30	Enhanced link detection EBUS	0
31	RUN LED	1
32	Link/activity LED	1
33	Reserved	0
35:34	Reserved	1
36	Reserved	0
37	Reserved	1
38	DC Time loop control assigned to PDI	0
39	Link detection and configuration by MI	0
40	MI control by PDI	1
41	Automatic TX shift	1
42	EEPROM emulation	0
49:43	Reserved	0
50	ERR LED, RUN/ERR LED override	1
Others	Reserved	Reserved

30.19.4 DATA_RAM : Process Data RAM

The process data RAM is used for process data and mailbox and takes up 8 KB from 0x8013_1000 to 0x8013_2FFF.

This RAM is only accessible when the EEPROM is correctly loaded (for example, when bit 0 is 1 in the ESC DL Status register, ESC_DL_STATUS, at 0x0110).

30.20 Setting the Module-Stop Function

EtherCAT modules are stopped in the initial state. If the modules are to be used, set the MSTPCRE.MSTPCRE02 bit for release from the module-stop state. Resetting the module-stop state is prohibited following release from the module-stop state. Operation of the modules if they are stopped following release and then released again is not guaranteed. Release from the module-stop state can proceed again after the modules have been returned to their initial states (stopped) by a reset.

30.21 Initial Settings

To initialize the EtherCAT, follow the procedure below:

- Set the offset address of the PHY module in the ECATOFFADR register.
- Set the size of the EEPROM in the ECATOPMOD register.
- Set the delay time of the TXEN and TXDn in the ECATDBGC register.
  It is recommended to use automatic TX shift function by connecting TXCLK from PHY to this LSI. In that case, manual delay time adjustment of the TXEN and TXDn is not basically needed.
- Release the EtherCAT from the module-stop state by using the MSTPCRE02 bit in the MSTPCRE register.
- Release the ESC and PHY modules from the reset state by using the MRCTLE03 and MRCTLE04 bits in the MRCTLE register.

On release from the reset state, the ESC will automatically load the EEPROM data and be activated.

30.22 Configuration of the Reset Circuit

Figure 30.2 shows the configuration of the reset circuit of the EtherCAT Slave Controller (ESC). When reset request by ESC_RESET_ECAT (0x0040) or ESC_RESET_PDI (0x0041) is received, ESC stops and reset output from ESC becomes high level. At the same time, ESC_RST interrupt is generated and ESC_RESETOUT# pin outputs low level.

To release reset state of ESC, MRCTLE04 bit of MRCTLE register must be changed from 0 → 1 → 0 after ESC_RST interrupt is detected. When reset input to ESC is deasserted, reset output from ESC becomes 0 and simultaneously ESC is rebooted with loading EEPROM. It takes around 1ms to finish EEPROM loading. Adjust clear timing of MRCTLE04 bit of MRCTLE register so that Ethernet PHY have enough reset duration. Figure 30.3 shows the timing diagram.

ECATRESOUT register can also control ESC_RESETOUT# pin independent of reset of ESC. When setting RESOUT_EN bit in ECATRESOUT register to 0, reset output from ESC is not output to ESC_RESETOUT# pin. When setting FORCE_RESET bit in ECATRESOUT register to 1, ESC_RESETOUT# pin goes low regardless the status of reset output from ESC.

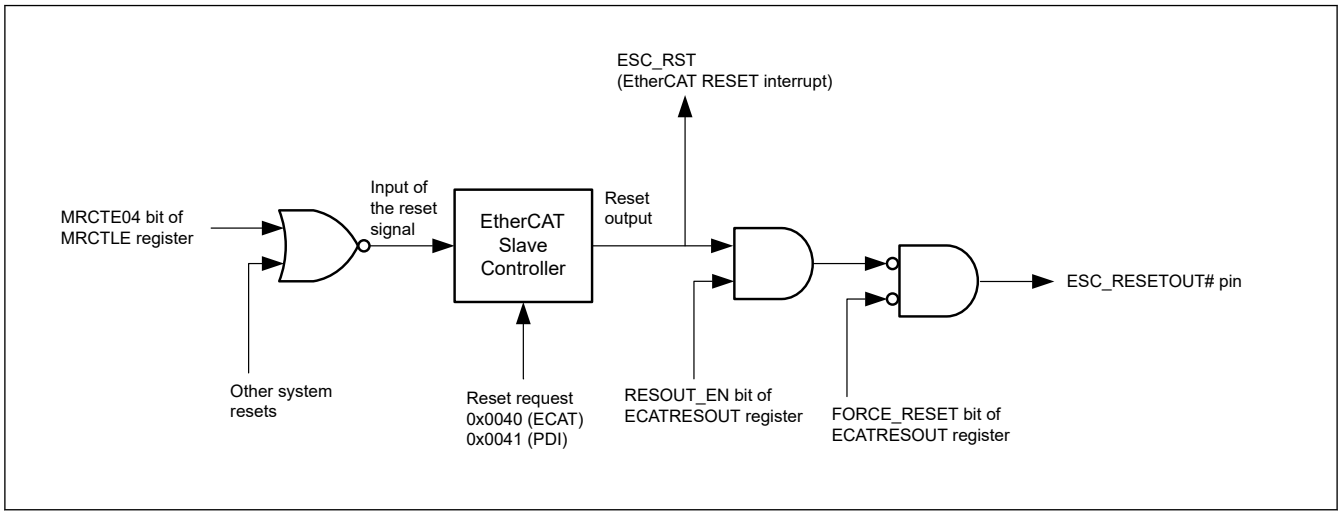


Figure 30.2 Configuration of the reset circuit of the EtherCAT slave controller

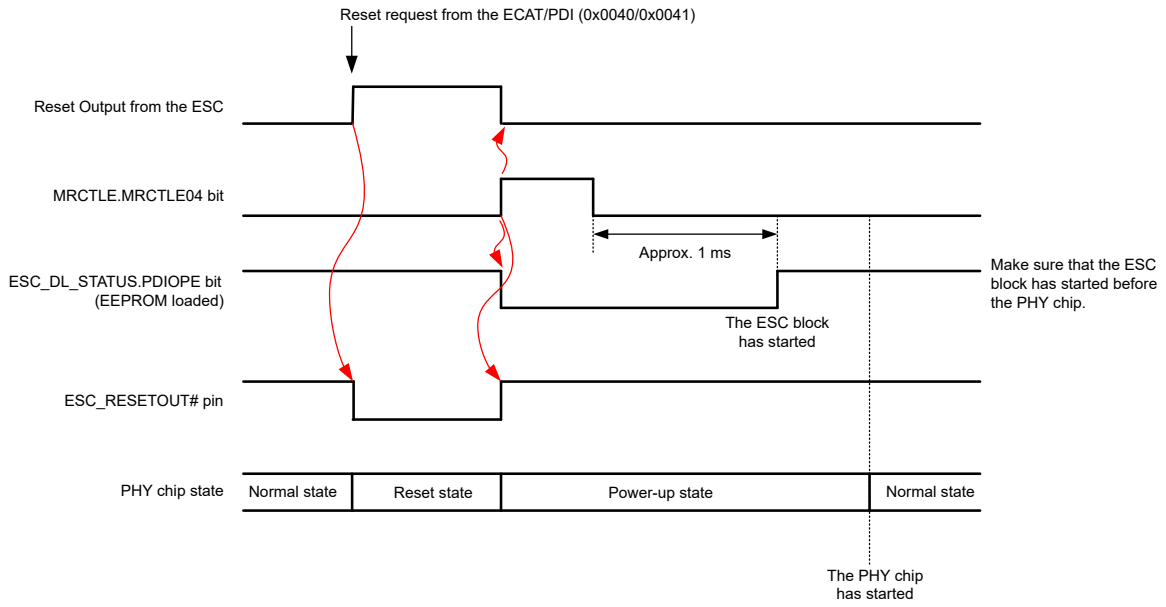

Note: ECASTRESOUT register is the initial value (0x0000_0002).

Figure 30.3 Reset Timing of EtherCAT Slave Controller

30.23 Usage Notes

1. Even if write protection is enabled, 0x0138 can be written.
2. When consecutive commands were issued from PDI to EEPROM, the latter command may not be accepted. Issue the commands with enough interval (e.g. 2 µs).
3. When VLAN tagged frame is used, ECAT reset register 0x0040 cannot be written.
4. ESC DL Control (0x0101) loop setting Auto-Close (01): if port waits for write access to be opened, the temporary loop bit (0x0100[1]) is not taken into account when a write command to ESC DL Control occurs.
5. Changing SyncSignal cycle times during activation may lead to extremely long cycle times. Additionally, changing cycle time from PDI may result in unwanted cycle times or extremely long delays. When cycle times are changed, disable SyncSignal.
6. DC Sync1 is missed once, when single shot is used, then DC SyncSignal generation deactivated, then cyclic generation activated.
7. Incorrect station alias address may be used when 0x0012 is changed and frame is received while change of 0x0013 is not completed yet.

31. USB 2.0 Host Module (USBHC)

31.1 Overview

The USB module of this LSI is a dual-role device that has USB 2.0 host and function modules.

The LSI handles a single USB port for either host controller or function controller operation. The Common Control register (COMMCTRL) is used to switch between host controller and function controller operation.

Since operation as a host controller or a function controller is exclusive of each other, dynamic switching between the types of operation is not possible. This section describes host controller operation.

The USB 2.0 host controller:

- Conforms to Universal Serial Bus Specification Revision 2.0
- Conforms to Open Host Controller Interface (OHCI) Specification for USB Rev. 1.0a
- Conforms to Enhanced Host Controller Interface (EHCI) Specification for USB Rev.1.1*1
- Supports USB 2.0 high-speed (480 Mbps), full-speed (12 Mbps), and low-speed (1.5 Mbps) transfer
- Supports the USB 2.0 compliance test function.

Note 1. Hardware prefetching is not supported.

Figure 31.1 shows a block diagram of the USB module.

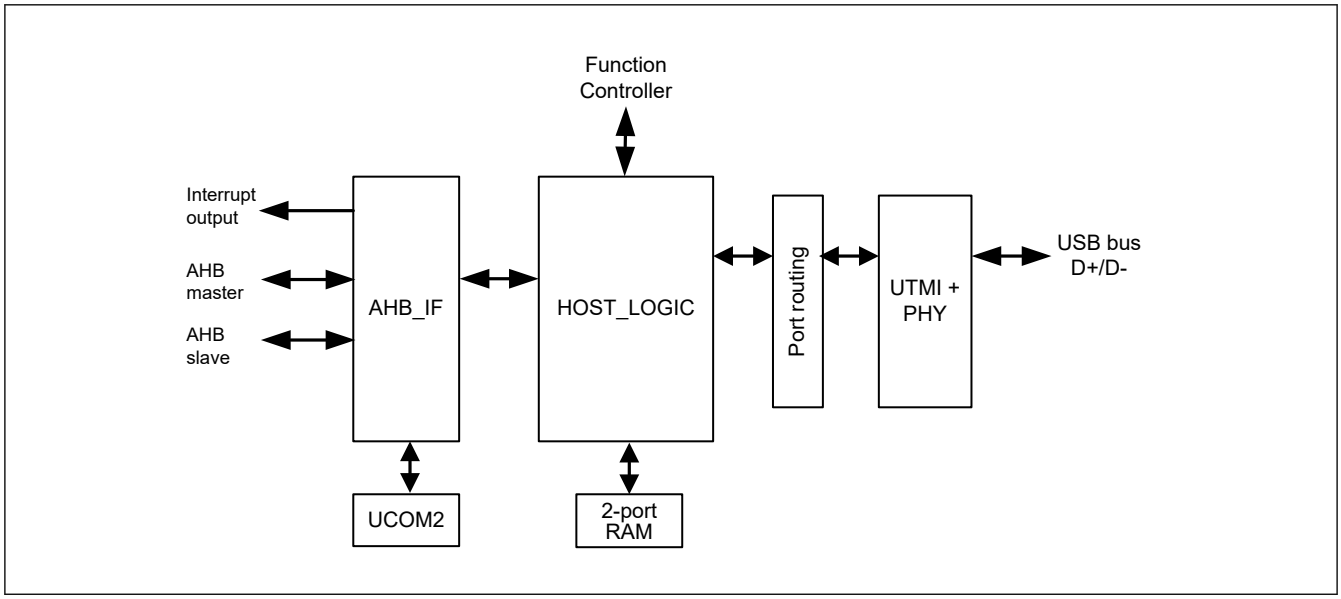

Figure 31.1 Block diagram of the USB module

(1) Host Logic

A USB 2.0 logic conforms to the EHCI and OHCI standards. It has control circuits such as a list processing circuit, a serial-parallel circuit, and a USB buffer. It executes high-speed, low-speed, and full-speed USB transfer.

(2) UTMI+ Transceiver

A USB 2.0 UTMI transceiver with an interface conforms to the UTMI+ standard.

31.1.1 Precautions on the Use of USB Host Controller

31.1.1.1 General Precautions

This section describes precautions on the use of the USB host controller.

1. Dynamic changes in PCLKAM and USB_CLK are not supported except for the clock stop state.

2. When using isochronous transfer, evaluate performance at the application level to confirm that the expected performance is obtained.
3. The USB host controller outputs the logical OR of multiple internal interrupt signals. See section 31.5. Interrupts.
4. It may take a long time to actually clear an interrupt after a register is accessed to clear the interrupt. For the action necessary during this wait time, see section 31.5.3. Time Required to Clear Interrupt Signals.

31.1.1.2 AHB Interface

The read or written data is not guaranteed for register access while the clock is stopped.

31.1.1.3 Operating Procedure

See the operating procedure described in section 31.7.1. Sample of Initial Settings.

31.3 Register Descriptions

This section describes details of the register functions.

31.3.1 OHCI Operational Registers

Access the OHCI operational registers after starting up the PHY internal PLL. For details, see Figure 31.7.

31.3.1.1 HCREVISION : HcRevision Register

Base address: USBHC = 0x9204_0000

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	REV[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
7:0	REV[7:0]	HCI revision These bits indicate the version of the HCI specifications implemented in the host logic. As the host logic conforms to OHCI standard 1.0a, this value is set to 0x10.	R
31:8	—	These bits are read as 0.	R

31.3.1.2 HCCONTROL : HcControl Register

Base address: USBHC = 0x9204_0000

Offset address: 0x004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	RWE	RWC	IR	HCFS[1:0]		BLE	CLE	IE	PLE	CBSR[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CBSR[1:0]	Control/bulk transfer service ratio (ControlBulkServiceRatio) **CBSR** / **Service ratio of bulk ED : Control ED** 00b / 1:1 01b / 2:1 10b / 3:1 11b / 4:1	R/W
2	PLE	Periodic list setting (PeriodicListEnable) This bit specifies whether to perform periodic list processing. The setting of this bit takes effect from the next frame. 0: Periodic list processing is not done 1: Period list processing is done	R/W
3	IE	Isochronous ED processing setting (IsochronousEnable) This bit specifies whether to perform isochronous ED processing. The setting of this bit takes effect from the next frame. When an isochronous ED is found during list processing, the host logic checks this bit to determine whether to perform isochronous ED processing. 0: Isochronous ED processing is enabled 1: Isochronous ED processing is disabled	R/W
4	CLE	Control list processing setting (ControlListEnable) This bit specifies whether to perform control list processing. The setting of this bit takes effect from the next frame. The control list can be modified only when this value is 0. 0: Control list processing is not done 1: Control list processing is done	R/W
5	BLE	Bulk list processing setting (BulkListEnable) This bit specifies whether to perform bulk list processing. The setting of this bit takes effect from the next frame. The bulk list can be modified only when this value is 0. 0: Bulk list processing is not done 1: Bulk list processing is done	R/W
7:6	HCFS[1:0]	Host logic operation status (Host Controller FunctionalState) These bits indicate the operating state of the host logic. On entering the USB operational state, the host logic starts management of frames delimited at 1-ms intervals. The operating state is always controlled by software except for transition to the USB resume state due to remote wakeup in the USB suspend state. These bits indicate the USB reset state after a hardware reset. After a software reset, the state shifts to the USB suspend state. 0 0: USB Reset 0 1: USB Resume 1 0: USB Operational 1 1: USB Suspend	R/W

Bit	Symbol	Function	R/W
8	IR	HcInterruptStatus interrupt path setting (InterruptRouting) This bit sets the output path for the interrupts indicated in the HcInterruptStatus register. The value set for this bit has no meaning because there is only one OHCI interrupt path for this host logic.	R/W
9	RWC	Remote Wakeup support setting (RemoteWakeUpConnect) This bit indicates whether the host logic supports remote wakeup. To support remote wakeup by the system, set this bit during initialization. 0: Remote Wakeup is not supported 1: Remote Wakeup is supported	R/W
10	RWE	PME assertion control (RemoteWakeUpEnable) This host logic does not use the PME assertion control bit. The value set for this bit has no meaning in this host logic.	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

The HCCONTROL register sets the operation mode for the OHCI host logic.

31.3.1.3 HCCOMMANDSTATUS : HcCommandStatus Register

Base address: USBHC = 0x9204_0000

Offset address: 0x008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	OCR	BLF	CLF	HCR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	HCR	Host logic software reset start (HostController Reset) This bit starts software reset of the host logic. When this bit is set, the USB suspend state is entered regardless of the functional state of the host logic.	W
1	CLF	Control list TD (ControlList Filled) This bit indicates whether TD exists in the control list. The host logic checks this bit when starting the processing of the start ED in the control list. When this bit is 0, the host logic does not begin list processing. When this bit is 1, the host logic starts control list processing and clears this bit to 0. On detecting TD, the host logic restores this bit to 1 and continues control list processing. When the host logic completes list processing, it clears this bit to 0. If TD is not found in the list or software does not set this bit to 1, this bit remains at 0 and list processing stops. When creating a list again and executing processing of the list, set this bit before starting list processing by setting bit 4 (CLE) in the HcControl register. 0: TD exists in the control list 1: TD does not exist in the control list	R/W
2	BLF	Bulk list TD (BulkListFilled) This bit indicates whether TD exists in the bulk list. The host logic checks this bit when starting the processing of the start ED in the bulk list. When this bit is 0, the host logic does not begin list processing. When this bit is 1, the host logic starts bulk list processing and clears this bit to 0. Upon detecting TD, the host logic restores this bit to 1 and continues bulk list processing. When the host logic completes list processing, it clears this bit to 0. If TD is not found in the list or software does not set this bit to 1, this bit remains at 0 and list processing stops. When creating a list again and executing processing of the list, set this bit before starting list processing by setting bit 5 (BLE) in the HcControl register. 0: TD exists in the bulk list 1: TD does not exist in the bulk list	R/W

Bit	Symbol	Function	R/W
3	OCR	Host logic control right change (OwnershipChangeRequest) This host logic does not use this bit, which changes the control right of the host logic. The value set for this bit has no meaning in this host logic.	W
15:4	—	These bits are read as 0. The write value should be 0.	R/W
17:16	SOC[1:0]	Schedule overrun count (Scheduling OverrunCount) These bits count the number of times a schedule overrun occurs. This value is incremented every time a schedule overrun occurs. When the value reaches 11b, it returns to 00b. Counting continues even while bit 0 (SO) in the HcInterruptStatus register is set.	R
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The HCCOMMANDSTATUS register is used when the host logic receives commands from software or checks the current host logic status.

31.3.1.4 HCINTERRUPTSTATUS : HcInterruptStatus Register

Base address: USBHC = 0x9204_0000

Offset address: 0x00C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	OC	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	RHSC	FNO	UE	RD	SF	WDH	SO
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SO	USB schedule overrun (Scheduling Overrun) This is an interrupt bit to indicate that the USB schedule has overrun in a frame. When the USB schedule overruns, this bit is set after HccaFrameNumber for the next frame is updated. When this bit is set, bits [17:16] (SOC) in the HcCommandStatus register are also incremented. Writing 1 to this bit clears the interrupt. 0: No SO interrupt has occurred 1: SO interrupt has occurred	R/W
1	WDH	Host logic HccaDoneHead update (Writeback Done Head) This is an interrupt bit to indicate that the host logic has updated the contents of HccaDoneHead. The host logic sets this bit immediately after updating HccaDoneHead, and does not update HccaDoneHead until this bit is cleared. Writing 1 to this bit clears the interrupt. 0: No WDH interrupt has occurred 1: WDH interrupt has occurred	R/W
2	SF	HccaFrameNumber update (StartOfFrame) This is an interrupt bit to indicate that HccaFrameNumber has been updated at the beginning of a frame. The host logic updates HccaFrameNumber and sets this bit when transmitting an SOF packet. Writing 1 to this bit clears the interrupt. 0: No SF interrupt has occurred 1: SF interrupt has occurred	R/W

Bit	Symbol	Function	R/W
3	RD	Resume detection (Resume Detected) This is an interrupt bit to indicate that Resume has been detected. This bit is set when assertion of the Resume signal by a device on the USB is detected. This bit is not set when software issues USB Resume. Writing 1 to this bit clears the interrupt. 0: No RD interrupt has occurred 1: RD interrupt has occurred	R/W
4	UE	USB non-related system error detection (Unrecoverable Error) This is an interrupt bit to indicate that a system error on the PCI bus that is not related to the USB has been detected. Writing 1 to this bit clears the interrupt. 0: No UE interrupt has occurred 1: UE interrupt has occurred	R/W
5	FNO	FrameNumber bit MSB change (Frame Number Overflow) This is an interrupt bit to indicate that the MSB of bits [15:0] (FrameNumber) in the HcFmNumber register has changed. This bit is set after HccaFrameNumber is updated in the frame where the MSB of the FrameNumber bits changes from 0 to 1 or from 1 to 0. Writing 1 to this bit clears the interrupt. 0: No FNO interrupt has occurred 1: FNO interrupt has occurred	R/W
6	RHSC	HcRhStatus/HcRhPortStatus register status (RootHubStatus Change) This is an interrupt bit to indicate that the state of the HcRhStatus register or the HcRhPortStatus register has changed. This bit is set when the HcRhStatus or HcRhPortStatus register state is changed by a hardware source. Writing 1 to this bit clears the interrupt. 0: No RHSC interrupt has occurred 1: RHSC interrupt has occurred	R/W
29:7	—	These bits are read as 0. The write value should be 0.	R/W
30	OC	Host logic control right change (OwnershipChange) This is an interrupt bit to indicate that bit 3 (OCR) in the HcCommandStatus register is set (the OCR bit is not used in this host logic). The value set for this bit has no meaning in this host logic.	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The HCINTERRUPTSTATUS register indicates the states of events that trigger interrupts.

If an event occurs, the host logic sets 1 to the corresponding bit. When 1 is set to a bit in this register while 1 is set to the corresponding interrupt enable bit and the MasterInterruptEnable bit in the HcInterruptEnable register, an interrupt is generated.

31.3.1.5 HCINTERRUPTENABLE : HcInterruptEnable Register

Base address: USBHC = 0x9204_0000

Offset address: 0x010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MIE	OCE	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	RHSCE	FNOE	UEE	RDE	SFE	WDHE	SOE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SOE	SO interrupt source enable (Scheduling OverrunEnable) This bit enables SO as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done 1: SO interrupt is enabled	R/W
1	WDHE	WDH interrupt source enable (WritebackDone HeadEnable) This bit enables WDH as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done. 1: WDH interrupt is enabled	R/W
2	SFE	SF interrupt source enable (StartOfFrame) This bit enables SF as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done 1: SF interrupt is enabled	R/W
3	RDE	RD interrupt source enable (Resume DetectedEnable) This bit enables RD as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done 1: RD interrupt is enabled	R/W
4	UEE	UE interrupt source enable (Unrecoverable ErrorEnable) This bit enables UE as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done 1: UE interrupt is enabled	R/W
5	FNOE	FNO interrupt source enable (FrameNumber OverflowEnable) This bit specifies FNO as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done 1: FNO interrupt is enabled	R/W
6	RHSCE	RHSC interrupt source enable (RootHubStatus ChangeEnable) This bit enables RHSC as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done 1: RHSC interrupt is enabled	R/W
29:7	—	These bits are read as 0. The write value should be 0.	R/W
30	OCE	OC interrupt source enable (OwnershipChangeEnable) This bit enables OC as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done 1: OC interrupt is enabled	R/W
31	MIE	Interrupt 8 source enable (MasterInterrupt Enable) This bit enables interrupt source settings in bits [30:0] in this register. When this bit is 0, all interrupts are masked. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done 1: The specified interrupt is enabled	R/W

The HCINTERRUPTENABLE register controls whether to generate an interrupt for each event. The position of each enable bit in this register is the same as the corresponding interrupt bit in the HcInterruptStatus register.

An interrupt is generated when all the following conditions are satisfied:

1. The corresponding bit in the HcInterruptStatus register is set to 1.

2. The corresponding bit in the HcInterruptEnable register is set to 1.
3. The MasterInterruptEnable (MIE) bit in the HcInterruptEnable register is set to 1.

Note: Writing 0 to any of the bits in this register does not change the read value.

31.3.1.6 HCINTERRUPTDISABLE : HcInterruptDisable Register

Base address: USBHC = 0x9204_0000

Offset address: 0x014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MID	OCD	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	RHSCD	FNOD	UED	RDD	SFD	WDHD	SOD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SOD	SO interrupt source disable (Scheduling Overrun Disable) This bit disables the interrupt source SO. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done 1: The interrupt source SO is disabled	R/W
1	WDHD	WDH interrupt source disable (Writeback DoneHead Disable) This bit disables the interrupt source WDH. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done 1: The interrupt source WDH is disabled	R/W
2	SFD	SF interrupt source disable (StartOfFrame Disable) This bit disables the interrupt source SF. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done 1: The interrupt source SF is disabled	R/W
3	RDD	RD interrupt source disable (Resume Detected Disable) This bit disables the interrupt source RD. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done 1: The interrupt source RD is disabled.	R/W
4	UED	UE interrupt source disable (Unrecoverable ErrorDisable) This bit disables the interrupt source UE. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done 1: The interrupt source UE is disabled	R/W
5	FNOD	FNO interrupt source disable (FrameNumberOverflow Disable) This bit disables the interrupt source FNO. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done 1: The interrupt source FNO is disabled	R/W

Bit	Symbol	Function	R/W
6	RHSCD	RHSC interrupt source disable (RootHub StatusChange Disable) This bit disables the interrupt source RHSC. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done 1: The interrupt source RHSC is disabled	R/W
29:7	—	These bits are read as 0. The write value should be 0.	R/W
30	OCD	OC interrupt source disable (OwnershipChangeDisable) 0: Nothing is to be done 1: OC is deleted from the interrupt sources	R/W
31	MID	Interrupt 8 source disable (Master Interrupt Disable) This bit disables interrupt source settings in bits [30:0] in HcInterruptEnable. When this bit is 0, all interrupts are masked. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done 1: The interrupt set is disabled	R/W

The position of each disable bit in this register is the same as the corresponding interrupt bit in the HcInterruptStatus register.

The HCINTERRUPTDISABLE register is connected to the HcInterruptEnable register. When 1 is set to a bit in this register, the corresponding bit in the HcInterruptEnable register is cleared.

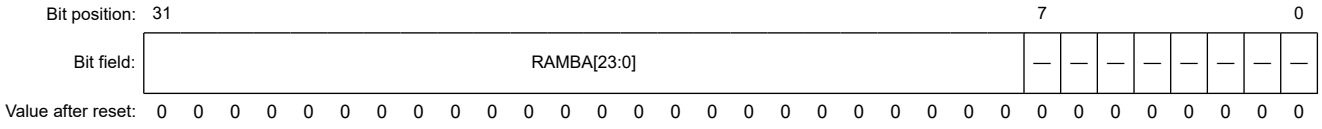
The read values in this register are the current values in the HcInterruptEnable register.

Note: Writing 0 to any of the bits in this register does not change the value of the corresponding bit in the HcInterruptEnable register.

31.3.1.7 HCHCCA : HcHCCA Register

Base address: USBHC = 0x9204_0000

Offset address: 0x018



Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
31:8	RAMBA[23:0]	RAM base address setting These bits specify the base address of the RAM allocated to the host controller communication area. Specify a value in these bits during initialization. The host logic requests a 256-byte area starting from the base address specified in these bits as HCCA.	R/W

The HCHCCA register indicates the physical address of the Host Controller Communication Area (referred to as HCCA hereafter).

Bits [7:0] of this register are fixed to 0x00 because the HCCA is allocated in units of 256 bytes.

31.3.1.8 HCPERIODCCURRENTIED : HcPeriodicCurrentED Register

Base address: USBHC = 0x9204_0000

Offset address: 0x01C

Bit position:	31																								4			0
Bit field:	PCED[27:0]																								—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0.	R
31:4	PCED[27:0]	ED physical address (PeriodicCurrentED) These bits indicate the physical address of the current ED being processed in the periodic list. The host logic updates these bits when completing the ED list processing.	R

The HCPERIODCCURRENTIED register indicates the physical address of the current isochronous or interrupt endpoint descriptor being processed.

31.3.1.9 HCCONTROLHEADED : HcControlHeadED Register

Base address: USBHC = 0x9204_0000

Offset address: 0x020

Bit position:	31																								4			0
Bit field:	CHED[27:0]																								—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
31:4	CHED[27:0]	Start ED physical address (ControlHeadED) These bits specify the physical address of the start ED in the control list. To execute control transfer, specify these bits before setting the CLE bit in the HcControl register.	R/W

The HCCONTROLHEADED register indicates the physical address of the start endpoint descriptor in the control list.

31.3.1.10 HCCONTROLCURRENTED : HcControlCurrentED Register

Base address: USBHC = 0x9204_0000

Offset address: 0x024

Bit position:	31																								4			0
Bit field:	CCED[27:0]																								—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
31:4	CCED[27:0]	ED physical address (ControlCurrentED) These bits indicate the physical address of the current ED being processed in the control list. When processing of the current ED is completed, the host logic moves on to the next ED. The host logic continues list processing until the end of the frame. When the host logic reaches the end of the list, it checks bit 1 (CLF) in the HcCommandStatus register. When the CLF bit is 1, the host logic copies the content of the CHED bits in the HcControlHeadED register to the CCED bits and clears the CLF bit. When the CLF bit is 0, the host logic does nothing. Software is permitted to update the HcControlCurrentED register only when bit 4 (CLE) in the HcControl register is cleared. When the CLE bit is 1, software is only allowed to read the value of the HcControlCurrentED register. To indicate the end of the list, 0x0 is initially set to this register.	R/W

The HCCONTROLCURRENTED register indicates the physical address of the current endpoint descriptor being processed in the control list.

31.3.1.11 HCBULKHEADED : HcBulkHeadED Register

Base address: USBHC = 0x9204_0000

Offset address: 0x028

Bit position:	31																									4			0
Bit field:	BHED[27:0]																									—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
31:4	BHED[27:0]	Start ED physical address (BulkHeadED) These bits specify the physical address of the start ED in the bulk list. To execute bulk transfer, specify these bits before setting bit 5 (BLE) in the HcControl register.	R/W

The HCBULKHEADED register indicates the physical address of the start endpoint descriptor in the bulk list.

31.3.1.12 HCBULKCURRENTED : HcBulkCurrentED Register

Base address: USBHC = 0x9204_0000

Offset address: 0x02C

Bit position:	31																									4			0
Bit field:	BCED[27:0]																									—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
31:4	BCED[27:0]	ED physical address (BulkCurrentED) These bits indicate the physical address of the current ED being processed in the bulk list. When processing of the current ED is completed, the host logic moves on to the next ED. The host logic continues list processing until the end of the frame. When the host logic reaches the end of the list, it checks bit 1 (CLF) in the HcCommandStatus register. When the CLF bit is 1, the host logic copies the content of the BHED bits in the HcBulkHeadED register to the BCED bits and clears the CLF bit. When the CLF bit is 0, the host logic does nothing. Software is permitted to update the HcBulkCurrentED register only when bit 4 (CLE) in the HcControl register is cleared. When the CLE bit is 1, software is only allowed to read the value of the HcBulkCurrentED register. To indicate the end of the list, 0 is initially set to this register.	R/W

The HCBULKCURRENTED register indicates the physical address of the current endpoint descriptor being processed in the bulk list.

31.3.1.13 HCDONEHEAD : HcDoneHead Register

Base address: USBHC = 0x9204_0000

Offset address: 0x030

Bit position:	31																									4			0
Bit field:	DH[27:0]																									—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0.	R
31:4	DH[27:0]	HcDoneHead physical address (DoneHead) These bits indicate the physical address of HcDoneHead in the host logic. This is the physical address of the last completed TD to be added to the Done queue. When processing of the TD is completed, the host logic writes the content of the HcDoneHead register to the NextTD bit of the TD. At that time, the host logic overwrites the content of the HcDoneHead register with the address of the TD. After the host logic writes the content of this register to the HCCA, it sets 0 to this register. In addition, the host logic sets bit 1 (WDH) in the HcInterruptStatus register to 1.	R

The HCDONEHEAD register indicates the physical address of the last completed transfer descriptor (referred to as TD hereafter) to be added to the Done queue.

In normal operation, software is not required to read this register because the content of this register is periodically written to the HCCA.

31.3.1.14 HCFMINTERVAL : HcFmInterval Register

Base address: USBHC = 0x9204_0000

Offset address: 0x034

Bit position:	31	30														16		13												0
Bit field:	FIT	FSMPS[14:0]															—	—	FI[13:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	1	1	0	1	1	0	1	1	1	1	1

Bit	Symbol	Function	R/W
13:0	FI[13:0]	Frame interval setting (FrameInterval) These bits specify the length (bit time) of a frame used for FS transfer. To conform to the USB standard (one frame = 1 ms), set these bits to 0x2EDF.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
30:16	FSMPS[14:0]	FS transfer packet maximum size setting (FSLagest DataPacket) These bits specify the maximum amount of data that can be transferred without generating a schedule overrun. This setting is compared with the current location in the frame to determine up to which data in the frame can be transferred. The maximum amount depends on the system bus performance, and it should be specified by the driver. The maximum value allowed for these bits is 0x2778. Do not set a value greater than 0x2778.	R/W
31	FIT	Frame synchronization (FrameInterval Toggle) This bit is used to match the frame settings between software and the host logic. When updating the FI bits, software should toggle this bit. When loading the FI bit value, the host logic copies the FIT value to bit 31 (FRT) in the HcFmRemaining register. Software can check if the new FI bit setting has been reflected by comparing the value specified in this bit when the FI bits are written to, and the value read from the FRT bit.	R/W

The HCFMINTERVAL register contains a 14-bit value that indicates the length of a frame (bit time) and a 15-bit value that indicates the maximum size of a packet that the host logic can send and receive at full speed without generating a schedule overrun.

By using the FI bit, adjustments are possible in units of frames.

31.3.1.15 HCFNREMAINING : HcFmRemaining Register

Base address: USBHC = 0x9204_0000

Offset address: 0x038

Bit position:	31														13														0
Bit field:	FRT	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FR[13:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	1	1	0	1	1	0	1	1	1	1	1

Bit	Symbol	Function	R/W
13:0	FR[13:0]	Down counter frame (FrameRemaining) These are the register bits of a 14-bit down counter which counts down the current remaining time value during transmission of a frame. The value of these bits is decremented over time. When the value reaches 0x0000, these bits are reloaded with the frame interval value by copying this value from bits [13:0] (FI) in the HcFmInterval register, after which counting down is restarted.	R
30:14	—	These bits are read as 0.	R
31	FRT	Frame synchronization (FrameRemainingToggle) This bit is used to match the frame settings between software and the host logic. When the FR bits reach 0x0000, the host logic copies the value of bits [13:0] (FI) in the HcFmInterval register to the FR bits and also copies the value of bit 31 (FIT) in the HcFmInterval register to this bit. Software can check if the FI bit setting has been copied to the FR bits by comparing the values of the FIT bit and this bit.	R

The HCFNREMAINING register is a 14-bit down counter which counts down the current remaining time during transfer of a frame.

31.3.1.16 HCFMNUMBER : HcFmNumber Register

Base address: USBHC = 0x9204_0000

Offset address: 0x03C

Bit position:	31																15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	FN[15:0]	Elapsed frame number (FrameNumber) These bits indicate the elapsed frame count. The count in these bits is incremented when the HcFmRemaining register is reloaded. When the value reaches 0xFFFF, it is rolled over to 0x0000. When the host logic enters the USB operational state, the value in these bits is automatically incremented. After the host logic increments the value in these bits at the frame boundary and sends an SOF packet, the value in these bits is written to the HCCA. However, that happens before the host logic reads the first ED of that frame. After writing to the HCCA, the host logic sets bit 2 (SF) in the HcInterruptStatus register.	R
31:16	—	These bits are read as 0.	R

The HCFMNUMBER register indicates a 16-bit counter value.

31.3.1.17 HCPERIODSTART : HcPeriodicStart Register

Base address: USBHC = 0x9204_0000

Offset address: 0x040

Bit position:	31																		13												0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PS[13:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	PS[13:0]	Periodic list processing start time (PeriodicStart) These bits indicate the time when the host logic starts periodic list processing in a frame. Specify a value in these bits by software during initialization of the host logic. When the value of bits [13:0] (FR) in the HcFmRemaining register is greater than the value specified in these bits, non-periodic lists take priority over periodic lists. The OHCI standard recommends that this value be set to about 90% of the value of bits [13:0] (FI) in the HcFmInterval register. Therefore, the recommended value is 0x2A2F.	R/W
31:14	—	These bits are read as 0. The write value should be 0.	R/W

The HCPERIODSTART register indicates the time (using 14 bits) when the host logic starts periodic list processing in a frame.

31.3.1.18 HCLSTHRESHOLD : HcLSThreshold Register

Base address: USBHC = 0x9204_0000

Offset address: 0x044

Bit position:	31																				11										0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LS[11:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	1	0	1	0	0	0

Bit	Symbol	Function	R/W
11:0	LS[11:0]	Transferrable threshold (LSThreshold) These bits specify the threshold value to determine whether LS transfer can be done in the remaining frame time. When the FmRemaining value is greater than this threshold value, LS transfer can be started.	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The HCLSTHRESHOLD register contains the value of 12 bits that are used to determine whether the host logic can perform LS transfer in the remaining frame time.

31.3.1.19 HCRHDESCRIPTORA : HcRhDescriptorA Register

Base address: USBHC = 0x9204_0000

Offset address: 0x048

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	POTPGT[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	NOCP	OCPM	DT	NPS	PSM	NDP[7:0]							
Value after reset:	0	0	0	0	1	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
7:0	NDP[7:0]	Downstream port number (NumberDownstreamPorts) These bits specify the number of downstream ports supported by the root hub in the host logic.	R
8	PSM	Power switch control (PowerSwitchingMode) This bit specifies how to control the power switch to each port of the root hub. While bits [31:16] (PPCM) in the HcRhDescriptorB register are set, each port responds only to Set/ClearPortPower. While the bits are cleared, each port is controlled by Set/ClearGlobalPower. This bit setting is valid only when the NPS bit is cleared. 0: Power to all ports is controlled together 1: Power to each port is separately controlled	R/W
9	NPS	Power control (NoPower Switching) This bit specifies how to control the port power. 0: Port power can be switched on and off 1: Port power is always turned on while the host logic is operating	R/W
10	DT	Device type (DeviceType) This bit indicates that the root hub is not a compound device. As the root hub is not allowed to be a compound device, this bit is always read as 0.	R
11	OCPM	Overcurrent state reporting (OverCurrentProtection Mode) This bit specifies how to report the overcurrent state of the root hub. This bit should be set to the same mode as that specified in the PSM bit. This setting is valid only when the NOCP bit is cleared. 0: Overcurrent state of all ports is collectively reported 1: Overcurrent state of each port is separately reported	R/W
12	NOCP	Overcurrent function support (NoOver Current Protection) This bit specifies whether to support the overcurrent protection function for the root hub. 0: Overcurrent protection function is supported 1: Overcurrent protection function is not supported	R/W
23:13	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
31:24	POTPGT[7:0]	Wait time (PowerOnToPowerGood Time) These bits indicate the time that software should wait before accessing a root hub port after power supply to the port is started. The unit of time is 2 ms. Therefore, the wait time is obtained by POTPGT × 2 ms.	R/W

The HCRHDESCRIPTORA register is one of the registers that indicates the characteristics of the root hub.

31.3.1.20 HCRHDESCRIPTORB : HcRhDescriptorB Register

Base address: USBHC = 0x9204_0000

Offset address: 0x04C

Bit position:	31															16	15													0
Bit field:	PPCM[15:0]																DR[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DR[15:0]	Device Removable These bits indicate whether the device connected to each port in the root hub is removable. Each bit is dedicated to a single port. The USB host controller has port 1 only.	R/W
31:16	PPCM[15:0]	Port Power Control Mask These bits specify power control commands for each port. This setting is valid when bit 8 (PSM) in the HcRhDescriptorA register is set. Each bit is dedicated to a single port. The USB host controller has port 1 only.	R/W

Bit	Value	Description
DR[0]	—	Reserved
DR[1]	0	Device connected to port 1 is not removable.
	1	Device connected to port 1 is removable.
DR[15:2]	—	Reserved

Bit	Value	Description
PPCM[0]	—	Reserved
PPCM[1]	0	All ports are collectively controlled (Set/ClearGlobalPower).
	1	Port 1 is separately controlled (Set/ClearPortPower).
PPCM[15:2]	—	Reserved

The HCRHDESCRIPTORB register is one of the registers that indicate the characteristics of the root hub.

31.3.1.21 HCRHSTATUS : HcRhStatus Register

Base address: USBHC = 0x9204_0000

Offset address: 0x050

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CRWE	—	—	—	—	—	—	—	—	—	—	—	—	—	OCIC	LPSC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DRWE	—	—	—	—	—	—	—	—	—	—	—	—	—	OCI	LPS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

<table>
<tr><th>Bit</th><th>Symbol</th><th>Function</th><th>R/W</th></tr>
<tr><td>0</td><td>LPS</td><td>Local power status (LocalPowerStatus)
The meaning of this bit differs when it is read and written.
When read: LocalPowerStatus
This product does not support the local power status function. This bit is always read as 0.
When written: ClearGlobalPower
Setting this bit to 1 turns off the power to a port.
The port to be turned off is determined according to the settings of bit 8 (PSM) in the HcRhDescriptorA register and bits [31:16] (PPCM) in the HcRhDescriptorB register.
<table>
<tr><th>Value</th><th>PSM</th><th>PPCM[1]</th><th>Description</th></tr>

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	LSDA	PPS	—	—	—	PRS	POCI	PSS	PES	CCS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CCS	Connection status indication (CurrentConnectStatus) The meaning of this bit differs when it is read and written. When written: ClearPortEnable This bit is used to clear the PES bit. Writing 1 causes the port to enter the disabled state. Writing 0 has no effect. When read: CurrentConnectStatus This bit indicates the current connection state of the downstream port. 0: No device is connected 1: Device is connected	R/W
1	PES	Port enable status (PortEnableStatus) The meaning of this bit differs when it is read and written. When written: SetPortEnable This bit is used to set the PES bit. Writing 1 causes the port to enter the enabled state. Writing 0 has no effect. If this bit is written to while the CCS bit is cleared, this bit is not set but the CSC bit is set to notify the driver of an attempt to enable a disconnected port. When read: PortEnableStatus This bit indicates whether the port is enabled or disabled. The host logic automatically clears this bit on detecting the overcurrent state, disconnection, power-off, or a babble error. At this time, the PESC bit is set. This bit cannot be set while the CCS bit is cleared (no device is connected). The host logic sets this bit when a port reset is completed and the PRSC bit is set, or when a port enters the suspend state and the PRSC bit is set. 0: Port is disabled 1: Port is enabled	R/W
2	PSS	Suspend/Resume status (PortSuspendStatus) The meaning of this bit differs when it is read and written. When written: SetPortSuspend This bit is used to clear the PES bit. Writing 1 makes the port enter the disabled state. Writing 0 has no effect. If this bit is written to while the CCS bit is cleared, this bit is not set but the CSC bit is set to notify the driver of an attempt to suspend a disconnected port. When read: PortSuspendStatus This bit indicates that the port is in the suspend state or the resume sequence. This bit is not set while the CCS bit is cleared (no device is connected). This bit is cleared with the following timing: ● When the resume sequence is completed and the PSSC bit is set ● When a port reset is completed and the PRSC bit is set ● In the USB RESUME state 0: Port is in normal transfer state 1: Port is in suspend state	R/W

Bit	Symbol	Function	R/W
3	POCI	Downstream port overcurrent detection (PortOverCurrentIndicator) The meaning of this bit differs when it is read and written. When written: ClearSuspendStatus This bit terminates the suspend state and starts the resume sequence. Writing 1 starts the resume sequence. Writing 0 has no effect. The resume sequence starts only while the PSS bit is set. When read: PortOverCurrentIndicator This bit indicates that a downstream port has entered the overcurrent state. It is valid only while the overcurrent state is reported separately for each port (OCPM = 1 in the HcRhDescriptorA register). While the overcurrent state in all ports is collectively reported, this bit is 0b. 0: Port is in normal state 1: Port is in overcurrent state	R
4	PRS	Port reset status (PortResetStatus) The meaning of this bit differs when it is read and written. When written: SetPortReset This bit applies a port reset to a downstream port. Writing 1 to this bit starts a 10-ms port reset. Writing 0 has no effect. If this bit is written to while the CCS bit is cleared, this bit is not set but the CSC bit is set to notify software of an attempt to reset a port where no device is connected. When read: PortResetStatus This bit indicates the reset state of the port. It is cleared at the same time as when the PRSC bit is set after a 10-ms port reset is completed. This bit cannot be set while the CCS bit is cleared (no device is connected). 0: Port reset is not in progress 1: Port reset is in progress	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	PPS	Power status (PortPowerStatus) The meaning of this bit differs when it is read and written. When written: SetPortPower This bit turns the port power on when power is separately controlled for each port. Writing 1 turns the port on. Writing 0 has no effect. When read: PortPowerStatus This bit indicates the power state of the port. It is cleared when an overcurrent is detected. 0: Port power is off 1: Port power is on	R/W
9	LSDA	Device speed (LowSpeedDeviceAttached) The meaning of this bit differs when it is read and written. When written: ClearPortPower This bit turns off the port power when power is separately controlled for each port. Writing 1 turns the port off. Writing 0 has no effect. When read: LowSpeedDeviceAttached This bit indicates the speed of the device connected to the port. This status bit is valid only while the CCS bit is set. 0: FS device is connected 1: LS device is connected	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	CSC	CCS bit status (ConnectStatus Change) This bit indicates that the CCS bit value has changed. The host logic sets this bit when the CCS bit changes due to device connection or disconnection. In addition, when a request for port reset, port suspension, or port enable is issued in the disconnection state, this bit is set to make software re-evaluate the device connection state. It is cleared when 1 is written by software. 0: Nothing is to be done regarding CCS 1: CCS has changed	R/W
17	PESC	PES bit status (PortEnable StatusChange) This bit indicates that the PES bit value has changed. It is set when the port state has changed due to a hardware event, such as the overcurrent state, disconnection, power-off, or a babble error. It is cleared when 1 is written by software. 0: Nothing is to be done regarding PES 1: PES state has changed	R/W

Bit	Symbol	Function	R/W
18	PSSC	RESUME sequence complete (PortSuspend StatusChange) This bit indicates that the RESUME sequence has been completed. It is set when all RESUME processing by hardware has been completed. It is cleared when 1 is written by software. In addition, it is cleared when the PRSC bit is set. 0: RESUME has not been completed 1: RESUME has been completed	R/W
19	OCIC	Overcurrent state detection (OverCurrent IndicateChange) This bit is set when the overcurrent state of the port has been detected. It is cleared when 1 is written by software. It is valid only while the overcurrent state is reported separately for each port (OCPM = 1 in the HcRhDescriptorA register). 0: Nothing is to be done regarding overcurrent state 1: Overcurrent state has changed	R/W
20	PRSC	Port reset complete (PortReset StatusChange) This bit indicates that a port reset has been completed. It is set when the host logic has completed a 10-ms hardware reset. It is cleared when 1 is written by software. 0: Port reset has not been completed, or nothing is to be done regarding the PRS bit 1: Port reset has been completed	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

The HCRHPORTSTATUS1 register is used to control and report port events.

31.3.2 EHCI Operational Registers

Access the EHCI operational registers after starting up the PHY internal PLL. For details, see Figure 31.7.

31.3.2.1 CAPL_VERSION : Capability Registers Length and EHCI Version Number Register

Base address: USBHC = 0x9204_0000

Offset address: 0x100

Bit position:	31																16								7								0
Bit field:	HCIVN[15:0]																—	—	—	—	—	—	—	—	CRL[7:0]								
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	

Bit	Symbol	Function	R/W
7:0	CRL[7:0]	Capability Registers Length These bits indicate the start address of the host logic operational registers. As the host logic operational registers are allocated from address 0x20, this value is set to 0x20.	R
15:8	—	These bits are read as 0.	R
31:16	HCIVN[15:0]	EHCI Version Number These bits indicate the version of the EHCI specifications supported by the host logic. As the host logic conforms to the EHCI Rev. 1.1, this value is set to 0x0110.	R

31.3.2.2 HCSPARAMS : Structural Parameters Register

Base address: USBHC = 0x9204_0000

Offset address: 0x104

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	DBGPTNUM[3:0]				—	—	—	P_INDICATOR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	N_CC[3:0]				N_PCC[3:0]				PTRR	—	—	PPC	N_PORTS[3:0]			
Value after reset:	0	0	0	1	0	0	0	1	1	0	0	1	0	0	0	1

Bit	Symbol	Function	R/W
3:0	N_PORTS[3:0]	Number of downstream ports (Number of Ports) These bits indicate the number of physical downstream ports used by the host logic. These bits reflect the setting of bits [1:0] (Port_no) in the PCI Configuration EXT1 register. As the USB host controller has only one port, this value is set to 1. 0x1: 1 port Others: Reserved	R
4	PPC	Port power control (Port Power Control) This bit indicates how to control the port power in the host logic. 0: Port power is always on 1: Port power is controlled using bit 12 (PP) in the PORTSC1 register	R
6:5	—	These bits are read as 0.	R
7	PTRR	Port routing rules This bit indicates how ports are mapped in the OHCI host logic. As the value of the HCSP_PORTROUTE register shows the mapping in the host logic, this value is set to 1.	R
11:8	N_PCC[3:0]	Number of ports (Number of Ports per Companion Controller) These bits indicate the number of the ports supported by one OHCI host logic unit. These bits reflect the setting of bits [1:0] (Port_no) in the PCI Configuration EXT1 register.	R
15:12	N_CC[3:0]	Number of OHCI host logic (Number of Companion Controller) These bits indicate the number of OHCI host logic units related to the EHCI host logic. As the host logic has one OHCI host logic unit, this value is set to 1.	R
16	P_INDICATOR	Port indicator control support This bit indicates whether the host logic supports the port indicator control function. As the host logic does not support the port indicator control function, this value is set to 0.	R
19:17	—	These bits are read as 0.	R
23:20	DBGPTNUM[3:0]	Debug port number These bits indicate that the host logic ports are debug ports. As the host logic has no debug ports, this value is set to 0.	R
31:24	—	These bits are read as 0.	R

31.3.2.3 HCCPARAMS : Capability Parameters Register

Base address: USBHC = 0x9204_0000

Offset address: 0x108

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	PL32	PCEC	LPMC	HP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EECP[7:0]								IST[3:0]				—	ASPC	PFLF	AC64
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Bit	Symbol	Function	R/W
0	AC64	Memory pointer selection This bit indicates whether data structures use 32-bit address memory pointers or 64-bit address memory pointers. As the host logic supports data structures using 32-bit address memory pointers, this value is set to 0. Address memory pointers of 64-bits are not supported.	R
1	PFLF	Programming frame list flag This bit indicates the setting regarding the frame list size that software can use. This value is set to 1 in the host logic. When this bit is set to 1, the available frame list size can be specified through bits [3:2] (Frame List Size) in the USBCMD register. A frame list of size smaller than 4 KB can be specified.	R
2	ASPC	Asynchronous schedule park support capability This bit indicates whether to support the park mode for the high-speed QH (queue head) in the asynchronous schedule. As the host logic supports this function, this value is set to 1.	R
3	—	This bit is read as 0.	R
7:4	IST[3:0]	Isochronous data structure threshold As the host logic in this product does not support caching of the isochronous data structure in the entire frame, these bits are set to 0.	R
15:8	EECP[7:0]	Offset address (EHCI Extend Capabilities Pointer) These bits indicate the offset address for the EHCI extend capabilities registers. As the host logic does not support the EHCI extend capabilities registers, these bits are set to 0.	R
16	HP	Hardware prefetch capability As the host logic does not support the hardware prefetch capability defined in EHCI V1.1, this bit is set to 0.	R
17	LPMC	Link power management capability As the host logic supports Link Power Management (LPM) defined in EHCI V1.1, this bit is set to 1. When LPMC = 1, it means that the host logic supports the LPM L1 state and controls LPM by using bit 9 (LPMCTL), bits [24:23] (SUSPSTS[1:0]), and bits [31:25] (DVADDR[6:0]) in the PORTSC1 register. When LPMC = 0, the applicable bits in the PORTSC1 register mentioned above are treated as reserved bits.	R
18	PCEC	Per-port change event capability As the host logic supports the per-port change event capability defined in EHCI V1.1, this bit is set to 1. When this bit is 1, it means that the host logic supports the per-port change event capability. It also means that this bit is associated with bit 15 (per-port change event enable) in the USBCMD register, bit 2 (Port Change Detect) in the USBSTS register, and bit 2 (Port Change Interrupt Enable) in the USBINTR register. When PCEC = 0, the applicable bits in the registers mentioned above are treated as reserved bits.	R

Bit	Symbol	Function	R/W
19	PL32	32-frame periodic list capability As the host logic supports 32-Frame Periodic List defined in EHCI V1.1, this bit is set to 1. When this bit is 1, it means that the host logic supports 32-Frame Periodic List when 11b is set in bits [3:2] (frame list size) in the USBCMD register.	R
31:20	—	These bits are read as 0.	R

31.3.2.4 HCSP_PORTROUTE : Companion Port Route Description Register

Base address: USBHC = 0x9204_0000

Offset address: 0x10C

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	OHCI Host Port Indication These bits indicate the ports that the OHCI host logic controls. As the host logic has one OHCI host logic unit, these bits are set to 0x00000000.	R

The HCSP_PORTROUTE register indicates how ports are mapped in the OHCI controller. The register is enabled only when bit 7 (port routing rules) in the HCSPARAMS register is 1.

31.3.2.5 USBCMD : USB Command Register

Base address: USBHC = 0x9204_0000

Offset address: 0x120

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	HIRD[3:0]				ITC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PPCE E	—	—	—	ASPM E	—	ASPMC[1:0]		LHCR	IAAD	ASYN SE	PSE	FLS[1:0]		HCRE SET	RS
Value after reset:	0	0	0	0	1	0	1	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RS	EHCI host logic run/stop (Run/Stop) This bit activates or stops the EHCI host logic. When this bit is set to 1, the host logic starts operation. As long as this value is 1, the host logic continues operation. Note that this bit should be set to 1 only while the host logic is in the halt state. Bit 12 (HCHalted) in the USBSTS register indicates that the host logic has completed transactions and entered the halt state. 0: Stopped (the host logic has completed transactions and halted) 1: Activated (the host logic executes the schedule)	R/W

Bit	Symbol	Function	R/W
1	HCRESET	Host logic initialization (Host Controller Reset) This bit initializes the host logic. When this bit is set to 1, the host logic initializes the internal pipelines and state machine. Communication through the USB stops immediately. A USB reset is not issued to downstream ports at this time. This reset does not initialize the PCI configuration registers, but it initializes the EHCI operational registers and the port ownership is returned to OHCI. This bit is automatically cleared to 0 by the host logic when the reset is completed. The reset cannot be aborted by software by writing 0 to this bit. This bit should be set only while bit 12 (HCHalted) in the USBSTS register is 1.	R/W
3:2	FLS[1:0]	Frame list size These bits specify the frame list size. The setting in these bits determines the size of the Frame List Current index in the FRINDEX register. 0 0: 1024 elements (4096 bytes) 0 1: 512 elements (2048 bytes) 1 0: 256 elements (1024 bytes) 1 1: 32 elements (128 bytes)	R/W
4	PSE	Periodic schedule enable This bit specifies whether to advance or skip periodic list processing. 0: Periodic list processing is not executed (skipped) 1: Periodic list processing is executed using the PERIODICLISTBASE register	R/W
5	ASYNSE	Asynchronous schedule enable This bit specifies whether to advance or skip asynchronous list processing. 0: Asynchronous list processing is not executed (skipped) 1: Asynchronous list processing is executed using the ASYNCLISTADDR register	R/W
6	IAAD	Interrupt on Async Advance Doorbell This bit is used as a doorbell by software. Software sets this bit to 1 to generate an interrupt when processing proceeds with the next QH (queue head). While bit 5 (Interrupt on Async Advance Enable) in the USBINTR register is set to 1, an interrupt is generated with the next interrupt timing after 1 is written to this bit. If this bit is set while bit 5 (Interrupt on Async Advance Enable) in the USBINTR register is 0, correct operation is not guaranteed. This bit is cleared by the host logic. On completing the processing of a QH normally, the host logic clears this bit to 0 and sets bit 5 (Interrupt on Async Advance) in the USBSTS register to 1.	R/W
7	LHCR	Light host controller reset execution status This bit indicates the state of Light Host Controller Reset execution. As the host logic does not support Light Host Controller Reset, this value is fixed to 0.	R
9:8	ASPMC[1:0]	Asynchronous schedule park mode count These bits specify the number of transactions that can be executed in succession from one QH (queue head). A value from 0x1 to 0x3 can be specified. This setting is valid when bit 11 (Asynchronous Schedule Park Mode Enable) is 1.	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	ASPME	Asynchronous schedule park mode enable This bit enables or disables the park mode. 0: Disabled 1: Enabled	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	PPCEE	Per-port change event enable This bit is used by software to enable the per-port change event capability defined by bit 2 (Port Change Detect) in the USBSTS register and bit 2 (Port Change Interrupt Enable) bit in the USBINTR register.	R/W

Bit	Symbol	Function	R/W
23:16	ITC[7:0]	Host logic interrupt generation maximum rate (Interrupt Threshold Control) These bits indicate the maximum rate at which the host logic generates an interrupt. Correct operation is not guaranteed if a value not shown below is written to these bits. 0x00: Reserved 0x01: 1 micro-frame 0x02: 2 micro-frames 0x04: 4 micro-frames 0x08: 8 micro-frames (1 ms) 0x10: 16 micro-frames (2 ms) 0x20: 32 micro-frames (4 ms) 0x40: 64 micro-frames (8 ms)	R/W
27:24	HIRD[3:0]	Host-Initiated Resume Duration (Minimum K-state drive time) These bits are used by software. The bits indicate the minimum amount of time the host controller drives the K-state during a resume from an LPM state (L1). The value of these bits is sent to the connected devices with the LPM capability by the HIRD field contained in the bmAttributes field in an LPM token. Encoding for these bits is defined in the bits named HIRD in an LPM token. Specifically, 0x0 equals 50 µs and each additional increment adds 75 µs. For example, 0x1 equals 125 µs and 0x4 equals 1175 µs.	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

The USBCMD register indicates the commands that are executed by the host logic.

31.3.2.6 USBSTS : USB Status Register

Base address: USBHC = 0x9204_0000

Offset address: 0x124

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PTCGDETC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ASS	PSCHSTS	RECLAM	EHCSTS	—	—	—	—	—	—	IAAIS	HSYSE	FLROV	PTCGDET	USBERRINT	USBINT
Value after reset:	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	USBINT	USB transfer complete (USB Interrupt) This bit indicates that USB transfer has been completed. The host logic sets this bit to 1 when either of the following conditions is satisfied: ● USB transfer is completed ● A short packet is received Even if USB transfer has ended with an error, this bit is set to 1 when the IOC (Interrupt On Complete) bit in the TD is 1. Writing 1 can clear this bit. Writing 0 has no effect. 0: USB transfer has not been completed 1: USB transfer has been completed	R/W
1	USBERRINT	USB transaction status (USB Error Interrupt) This bit indicates that a USB transaction has ended with an error. The host logic sets this bit to 1 when a USB transaction has ended with an error. If 1 is set to the IOC bit in the TD that caused an error interrupt, 1 is set to both the USBERRINT bit and the USBINT bit. Writing 1 can clear this bit. Writing 0 has no effect. 0: USB transaction has been completed normally 1: USB transaction has ended with an error	R/W

Bit	Symbol	Function	R/W
2	PTCGDET	Port state change detection This bit indicates that the port state has changed. The host logic sets this bit to 1 when any of the following conditions is satisfied in a port for which bit 13 (Port Owner) in the PORTSC[n] register is set to 0. [1 setting condition] ● Bit 1 (Connect Status Change) in the PORTSC[n] register has changed from 0 to 1 (device connection or disconnection has been detected) ● Bit 3 (Port Enable/Disable Change) in the PORTSC[n] register has changed from 0 to 1 (the port enabled state has changed) ● Bit 5 (Over-current Change) in the PORTSC[n] register has changed from 0 to 1 (the overcurrent state has been detected) ● Bit 6 (Force Port Resume) in the PORTSC[n] register has changed from 0 to 1 (indicating detection of a J-to-K transition on a port while suspended) Writing 1 by software can clear this bit. Writing 0 has no effect.	R/W
3	FLROV	Frame list rollover The host logic sets this bit to 1 when the value of the Frame Index bits in the FRINDEX register returns from the maximum value to 0x000 (rollover). The maximum value at which rollover occurs depends on bits [3:2] (Frame List Size) in the USBCMD register. Writing 1 can clear this bit. Writing 0 has no effect. 0: Frame list has not returned to 0x000 1: Frame list has returned to 0x000	R/W
4	HSYSE	Host system error This bit is set to 1 when a serious error occurs in the host logic. Such an error includes a parity error in the PCI system. If this error occurs, the host logic clears bit 0 (RS) in the USBCMD register to 0 to stop execution of the remaining TDs. Writing 1 can clear this bit. Writing 0 has no effect. 0: No system error has occurred 1: System error has occurred	R/W
5	IAAIS	Async advance interrupt status This bit indicates the Async Advance interrupt state. On fetching QH, the host logic checks bit 6 (Interrupt on Async Advance Doorbell (IAAD)) in the USBCMD register. When IAAD = 1, the host logic clears the IAAD bit and sets this bit after completing QH processing normally. When bit 5 (Interrupt on Async Advance Enable) in the USBINTR register is 1, an interrupt is generated from this source with the next interrupt timing after this bit is set to 1. Writing 1 can clear this bit. Writing 0 has no effect. 0: No Async Advance interrupt has occurred 1: Async Advance interrupt state has been detected	R/W
11:6	—	These bits are read as 0. The write value should be 0.	R/W
12	EHCSTS	EHCI host logic status (HCHalted) This bit is set to 0 when bit 0 (RS) in the USBCMD register is 1. When the RS bit is cleared to 0 by the host logic or software, the EHCI host logic stops execution and this bit is set to 1 by the host logic. 0: EHCI host logic is in execution 1: EHCI host logic is stopped	R
13	RECLAM	Empty asynchronous schedule detection (Reclamation) This bit is used to detect an empty asynchronous schedule. The host logic clears this bit to 0 after a reset or when it fetches QH with H = 1. When the host logic executes an asynchronous transaction or has detected a start event, it sets this bit to 1. When the host logic fetches QH with H = 1 while this bit is 0, the Async Sched Sleeping mode is entered.	R
14	PSCHSTS	Periodic schedule status This bit indicates the current state of the periodic schedule. The periodic schedule is enabled (1) or disabled (0) when the values of this bit and bit 4 (Periodic Schedule Enable) in the USBCMD register are the same. 0: Periodic schedule is disabled 1: Periodic schedule is enabled	R

Bit	Symbol	Function	R/W
15	ASS	Asynchronous schedule status This bit indicates the current state of the asynchronous schedule. The asynchronous schedule is enabled (1) or disabled (0) when the values of this bit and bit 5 (Asynchronous schedule enable) in the USBCMD register are the same. 0: Asynchronous schedule is disabled 1: Asynchronous schedule is enabled	R
31:16	PTCGDETC[15:0]	Port-n Change Detect Each of these bits is the Port Change Detect bit for a specific port. Bit 16 is the port change detect bit for port 1, bit 17 is the port change detect bit for port 2, and so on. For example, when bit 16 is set to 1, it means the status change of port 1 was detected. These bits are used by software only when bit 15 (Per-Port Change Events Enable) in the USBCMD register is set to 1.	R/W

The USBSTS register indicates interrupt sources and various states of the host logic.

The result of a transaction on the USB bus is not indicated in this register.

31.3.2.7 USBINTR : USB Interrupt Enable Register

Base address: USBHC = 0x9204_0000

Offset address: 0x128

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PCGIE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	INTAADVE	HSEE	FMLSTROE	PTCGIE	USBEIE	USBIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	USBIE	USB interrupt enable This bit enables or disables the setting in bit 0 (USBINT) in the USBSTS register. When USBSTS.USBINT = 1 while this bit is set to 1, the host logic generates an interrupt at the next interrupt threshold. The interrupt is acknowledged by software when the USBINT bit is cleared. 0: Disabled 1: Enabled (interrupt indicated by the USBINT bit)	R/W
1	USBEIE	USB error interrupt enable This bit enables or disables the setting in bit 1 (USBERRINT) in the USBSTS register. When USBSTS.USBERRINT = 1 while this bit is set to 1, the host logic generates an interrupt at the next interrupt threshold. The interrupt is acknowledged by software when the USBERRINT bit is cleared. 0: Disabled 1: Enabled (interrupt indicated by the USBERRINT bit)	R/W
2	PTCGIE	Port change interrupt enable This bit enables or disables the setting in bit 2 (Port Change Detect) in the USBSTS register. When the Port Change Detect bit is set to 1 while this bit is set to 1, the host logic generates an interrupt at the next interrupt threshold. The interrupt is acknowledged by software when the Port Change Detect bit is cleared. 0: Disabled 1: Enabled (interrupt indicated by the Port Change Detect bit)	R/W

Bit	Symbol	Function	R/W
3	FMLSTROE	Frame list rollover enable This bit enables or disables the setting in bit 3 (Frame List Rollover) in the USBSTS register. When the Frame List Rollover bit is set to 1 while this bit is set to 1, the host logic generates an interrupt at the next interrupt threshold. The interrupt is acknowledged by software when the Frame List Rollover bit is cleared. 0: Disabled 1: Enabled (interrupt indicated by the Frame List Rollover bit)	R/W
4	HSEE	Host system error enable This bit enables or disables the setting in bit 4 (Host System Error) in the USBSTS register. When the Host System Error bit is set to 1 while this bit is set to 1, the host logic generates an interrupt at the next interrupt threshold. The interrupt is acknowledged by software when the Host System Error bit is cleared. 0: Disabled 1: Enabled (interrupt indicated by the Host System Error bit)	R/W
5	INTAADVE	Interrupt on async advance enable This bit enables or disables the setting in bit 5 (Interrupt on Async Advance) in the USBSTS register. When the Interrupt on Async Advance bit is set to 1 while this bit is set to 1, the host logic generates an interrupt at the next interrupt threshold. The interrupt is acknowledged by software when the Interrupt on Async Advance bit is cleared. 0: Disabled 1: Enabled (interrupt indicated by the Interrupt on Async Advance bit)	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W
31:16	PCGIE[15:0]	Port-n Change Interrupt Enable Each of these bits is the Port Change Interrupt Enable bit for a specific port. Bit 16 is the Port Change Interrupt Enable bit for port 1, bit 17 is the Port Change Interrupt Enable bit for port 2, and so on. When one of these bits is set to 1 and the corresponding bit (one of PTCGDETC[15:0], Port-n Change Detect) in the USBSTS register is set to 1, the host logic generates an interrupt. Only bit 16 is enabled because the USB host controller only supports port 1. The interrupt is acknowledged by software when the Port-n Change Detect bit is cleared.	R/W

The USBINTR register enables or disables reporting of interrupts.

When a bit in this register is set to 1 and the corresponding interrupt bit is set to 1, an interrupt is generated.

The interrupt sources that are disabled in this register can be detected by allowing software to poll for events stored in the USBSTS register.

31.3.2.8 FRINDEX : USB Frame Index Register

Base address: USBHC = 0x9204_0000

Offset address: 0x12C

Bit position:	31														13																0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FRAMEINDEX[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	FRAMEINDEX[13:0]	Frame index These bits are used by the host logic to add an index to the periodic frame list. This value is incremented at the end of each micro-frame. Bits [N:3] are used as the Frame List Current index. This means that the current frame list is accessed 8 times before proceeding with the next index number. The value of N is determined as follows according to the setting of bits [3:2] (Frame List Size) in the USBCMD register. **Frame List Size / Number Elements / N** 00b (1024) 12 01b (512) 11 10b (256) 10 11b (32) 12 This register should be accessed only while the host logic is stopped (bit 12 (HCHalted) = 1 in the USBSTS register). This setting is reflected in the SOF frame number for the SOF token.	R/W
31:14	—	These bits are read as 0. The write value should be 0.	R/W

The FRINDEX register is used by the host logic to add an index to the periodic frame list.

31.3.2.9 CTRLDSSEGMENT : Control Data Structure Segment Register

Base address: USBHC = 0x9204_0000

Offset address: 0x130

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	The host logic does not support 64-bit addressing and does not use this register. Therefore, do not access this register.	R

31.3.2.10 PERIODICLISTBASE : Periodic Frame List Base Address Register

Base address: USBHC = 0x9204_0000

Offset address: 0x134

Bit position:	31																				12												0
Bit field:	PFLSA[19:0]																				—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	—	These bits are read as 0. The write value should be 0.	R/W
31:12	PFLSA[19:0]	Periodic frame list start address These bits indicate the start address of the periodic frame list stored in the system memory. Software should specify the start address in this register before the host logic starts list processing. The host logic uses the values in these bits and bits [13:0] (Frame Index) in the FRINDEX register to determine the frame list to be processed. The address of the periodic frame list should be aligned with a 4-KB boundary. Correct operation cannot be guaranteed if the value in these bits is modified during operation.	R/W

31.3.2.11 ASYNCLISTADDR : Next Asynchronous List Address Register

Base address: USBHC = 0x9204_0000

Offset address: 0x138

Bit position:	31																								5					0
Bit field:	LPL[26:0]																								—	—	—	—	—	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	—	These bits are read as 0. The write value should be 0.	R/W
31:5	LPL[26:0]	Asynchronous Queue Head link pointer address (Link Pointer Low) These bits indicate the address of the next asynchronous queue head in the system memory to be processed. The address of the asynchronous queue head should be aligned with a 32-byte boundary.	R/W

31.3.2.12 CONFIGFLAG : Configure Flag Register

Base address: USBHC = 0x9204_0000

Offset address: 0x160

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CF	Port routing control circuit configuration flag (Configure Flag) This bit controls the default setting of the port routing control circuit regarding whether the ports are routed to OHCI or EHCI. Software should set this bit to 1 at the end of host logic configuration process. 0: Port routing control circuit routes each port to the OHCI host logic by default 1: Port routing control circuit routes each port to the EHCI host logic by default	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

31.3.2.13 PORTSC1 : Port 1 Status and Control Register

Base address: USBHC = 0x9204_0000

Offset address: 0x164

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DVADDR[6:0]							SUSPSTS[1:0]		WKOC_E	WKDSCNNT_E	WKCNNT_E	PTTST[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PTINDCTL[1:0]		PTOWNR	PP	LINESTS[1:0]		LPMCTL	PTRST	SUSPEND	FRCPTRSM	OVCC	OVCACT	PTESC	PTE	CSC	CCSTS
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CCSTS	Port connection status This bit indicates the connection state of the port. On detecting device connection, the host logic sets this bit to 1. The host logic also sets this bit to 1 when PTTST[3:0] = 0101b (Test FORCE_ENABLE) even if no device is connected. On detecting device disconnection, the host logic clears this bit to 0. When PP = 0 or PTOWNR = 0, this bit becomes 0. 0: No device is connected to the port 1: Device is connected to the port	R
1	CSC	Connect status change This bit indicates that the value of bit 0 (Current Connect Status) has changed. Writing 1 can clear this bit. Writing 0 has no effect. When PP = 0, this bit becomes 0. 0: Value of bit 0 (Current Connect Status) has not changed 1: Value of bit 0 (Current Connect Status) has changed	R/W
2	PTE	Port enable/disable status This bit indicates the enabled/disabled state of the port. After resetting a port and detecting that the connected device is an HS device, the host logic enables the port and sets this bit to 1. Software cannot set this bit to 1. On detecting device disconnection or an error, the host logic disables the port and clears this bit to 0. Software can write 0 to disable the port. In this case, however, the bit value changes only after the port state actually changes. While the port is disabled, data transfer to downstream ports is blocked except for a port reset. When PP = 0, this bit becomes 0. Note that when PTTST[3:0] = 0101b (Test FORCE_ENABLE), the port is enabled regardless of the port state and this bit is set to 1. 0: Port is disabled 1: Port is enabled	R/W
3	PTESC	Port enable/disable status change This bit indicates that the enabled/disabled state of the port has changed. On detecting a frame babble error, the host logic disables the port and sets this bit to 1. Writing 1 can clear this bit. Writing 0 has no effect. When PP = 0, this bit becomes 0. 0: Frame babble error has not occurred 1: Frame babble error has been detected	R/W
4	OVCACT	Port overcurrent status This bit indicates the overcurrent state of the port. On detecting an overcurrent, the host logic clears bit 12 (PP) and its related bits and sets this bit to 1. This bit is automatically cleared from 1 to 0 when the overcurrent state is resolved. 0: Port is not in overcurrent state 1: Port is in overcurrent state	R
5	OVCC	Over-current Change This bit indicates that the value of bit 4 (OVCACT) has changed. Writing 1 can clear this bit. Writing 0 has no effect. 0: Value of bit 4 (OVCACT) has not changed 1: Value of bit 4 (OVCACT) has changed	R/W

<table>
<tr><th>Bit</th><th>Symbol</th><th>Function</th><th>R/W</th></tr>
<tr><td>6</td><td>FRCPTRSM</td><td>Force Port Resume (Port resume detection flag)
This bit indicates detection of the resume state at the port.
When a transition from the J to the K state (RemoteWakeup) is detected while the port is suspended, the host logic sets this bit and bit 2 (Port Change Detect) or bits [31:16] (Port-n Change Detect [15:0]) in the USBSTS register to 1. If software writes 1 to the Force Port Resume bit, the host logic does not set the Port Change Detect bit or the Port-n Change Detect bits to 1.
The resume signal (FS K State) is driven on the USB port while this bit is 1. Clear this bit to 0 after an appropriate period has passed.
Writing 0 to this bit while it is 1 returns the port to the HS Idle state. Until then, this bit remains at 1.
After software writes 0 to this bit, the host logic must complete the transition to the HS Idle state within 2 ms. If the port is in the L1 state, software does not need to write 0 to this bit because the host logic sends a resume signal when necessary and clears this bit after the port resumes. However, the length of the resume signal driven by the host logic must be set in bits [27:24] (Host-Initiated Resume Duration) in the USBCMD register.
When PP = 0, this bit becomes 0.
0: Resume (K-state) has not been detected or output
1: Resume (K-state) has been detected or output</td><td>R/W</td></tr>
<tr><td>7</td><td>SUSPEND</td><td>Port suspend
The combination of the settings of this bit and bit 2 (Port Enabled/Disabled) indicate the port state as follows.
<table>
<tr><th>PTE</th><th>SUSPEND</th><th>Port State</th></tr>
<tr><td>0</td><td>x</td><td>Disabled</td></tr>
<tr><td>1</td><td>0</td><td>Enabled</td></tr>
<tr><td>1</td><td>1</td><td>Suspend</td></tr>
</table>
Set this bit to 1 to transition the port to the L1 or L2 suspend state. The type of suspend state (L1 or L2) the host logic supports depends on the value of the Suspend using L1 bit.
In the suspend state, data transfer from this port to the downstream port is blocked unless the port is reset. When this bit is set to 1 during data transfer, reflection in the status bit and blocking of transfer follow completion of the current transfer.
Software should write 1 to this bit. It can write 1 only while PP = 1, PTOWNR = 0, and CCSTS = 1 in the register in the host logic.
This bit is always cleared to 0 under either of the following conditions:
● Software clears the Force Port Resume bit to 0
● Completion of resume is detected
● Software sets the Port Reset (PTRST) bit to 1
● Port Owner (PTOWNR) bit is set to 1 (OHCI)
● Port Power (PP) bit is set to 0
● Port Enabled/Disabled (PTE) bit is set to 0
This bit indicates the suspend state of the port.
0: Port is not in suspend state
1: Port is in suspend state</td><td>R/W</td></tr>
<tr><td>8</td><td>PTRST</td><td>Port reset status
When software writes 1 to this bit while it is 0, the bus reset sequence defined in the USB2.0 standard begins. Write 0 to this bit to terminate the bus reset sequence. Note that this bit must be retained at 1 for long enough time for the bus reset sequence to be completed according to the USB2.0 standard.
When bit 12 (HCHalted) in the USBSTS register is 1, the port should not be reset.
This bit becomes 0 when the PP, PTOWNR, or CCSTS bit satisfies the following conditions.
Writing 1 does not start the bus reset sequence.
● PP = 0
● PTOWNR = 1
● CCSTS = 0
This bit indicates the reset state of the port.
0: Port is not in reset state
1: Port is in reset state</td><td>R/W</td></tr>
</table>

<table>
<tr><th>Bit</th><th>Symbol</th><th>Function</th><th>R/W</th></tr>
<tr><td>9</td><td>LPMCTL</td><td>LPM control
This bit is used to select Suspend using L1 (LPM) or Suspend using L2.
When 1 is written to bit 7 (SUSPEND) while this bit is 1, the host logic transitions the attached device to the LPM state.
When this bit is 1 and the Device Address bits are other than 0x0000, setting the Suspend bit to 1 makes the host logic create an LPM token for transitioning the attached device to the L1 state. When this bit is 0, the host logic uses the L2 suspend mechanism.
Writing to this bit is permitted only when bit 7 (SUSPEND) is 0. When SUSPEND = 1, both 0 and 1 cannot be written to this bit.
0: Suspend using L2
1: Suspend using L1 (LPM)</td><td>R/W</td></tr>
<tr><td>11:10</td><td>LINESTS[1:0]</td><td>D+/D− logic level
These bits indicate the current logical levels on the D+ and D− lines of the USB port (bit 11: D+, bit 10: D−).
They are used to detect an LS device before a port reset or a sequence for enabling the port. Therefore, the values in these bits are valid only while bit 3 (Port Enable/Disable) = 0 and bit 0 (Current Connect Status) = 1.
<table>
<tr><th>Bit 11 (D+)</th><th>Bit 10 (D−)</th><th>USB State</th><th>Interpretation</th></tr>
<tr><td>0</td><td>0</td><td>SE0</td><td>Not an LS device.
Moves to the EHCI port reset execution process.</td></tr>
<tr><td>0</td><td>1</td><td>K State</td><td>An LS device has been connected.
Passes the port ownership from EHCI to OHCI.</td></tr>
<tr><td>1</td><td>0</td><td>J State</td><td>Not an LS device.
Moves to the EHCI port reset execution process.</td></tr>
<tr><td>1</td><td>1</td><td>Undefined</td><td>Not an LS device.
Moves to the EHCI port reset execution process.</td></tr>
</table></td><td>R</td></tr>
<tr><td>12</td><td>PP</td><td>Port Power Supply Control (Port Power)
This bit controls power supply to the port.
When this bit is 0, power is not supplied to the port. The port does not operate and connection or disconnection cannot be detected.
If an overcurrent is detected while this bit is 1, the host logic clears this bit to 0 and stops power supply to the port. However, as explained later, when the PPC bit is 0, this bit is fixed to 1 and power supply to the port does not stop.
The function of this bit depends on the setting of bit 4 (PPC) in the HCSPARAMS register.
<table>
<tr><th>PPC</th><th>PP</th><th>Description</th></tr>
<tr><td>0</td><td>1</td><td>This bit is fixed to 1, and power is always supplied to the port</td></tr>
<tr><td>1</td><td>0/1</td><td>Power supply to the port is determined by this bit</td></tr>
</table>
0: No power is supplied to the port
1: Power is supplied to the port</td><td>R/W</td></tr>
<tr><td>13</td><td>PTOWNR</td><td>Port ownership
This bit indicates whether OHCI or EHCI has the port ownership.
This bit is cleared to 0 when bit 0 (CF) in the CONFIGFLAG register changes from 0 to 1.
This bit is set to 1 when the CF bit is 0.
Software should set this bit to 1 to pass the port ownership to OHCI when the connected device is not a high-speed device.
0: EHCI has the port ownership
1: OHCI has the port ownership</td><td>R/W</td></tr>
<tr><td>15:14</td><td>PTINDCTL[1:0]</td><td>As the host logic does not support the port indicator control function, these bits are set to 00b.
Writing to these bits does not affect the operation.</td><td>R</td></tr>
</table>

Bit	Symbol	Function	R/W
19:16	PTTST[3:0]	Pin test control These bits control the test mode. For details of the test mode, see Chapter 7 in the USB Specification Revision 2.0. When the value is other than 0000b, the host logic is operating in test mode. **Port Test Control[3:0] / Mode** 0000b: Normal 0001b: Test J_STATE 0010b: Test K_STATE 0011b: Test SE0_NAK 0100b: Test Packet 0101b: Test FORCE_ENABLE Other than the above: Reserved	R/W
20	WKCNNT_E	Device connection detection enable (Wake on Connect Enable) Writing 1 to this bit enables detection of device connection as a wakeup event. When PP = 0, this bit becomes 0.	R/W
21	WKDSCNNT_E	Device disconnection detection enable (Wake on Disconnect Enable) Writing 1 to this bit enables detection of device disconnection as a wakeup event. When PP = 0, this bit becomes 0.	R/W
22	WKOC_E	Overcurrent state detection enable (Wake on Over-current Enable) Writing 1 to this bit enables detection of the overcurrent state as a wakeup event. When PP = 0, this bit becomes 0.	R/W
24:23	SUSPSTS[1:0]	Suspend status These bits indicate a response from a connected device to an LPM token (L1 transition request). The host logic updates these bits immediately when the L1 transition request processing is completed. To avoid race conditions with hardware, a value must be set to these bits when SUSPEND = 0. 0 0: Device successfully entered the L1 state (ACK is received from the device) 0 1: Device was unable to enter the L1 state at this time (NYET is received from the device) 1 0: Device does not support L1 state transitions (STALL is received from the device) 1 1: Other than above (such as a timeout error)	R/W
31:25	DVADDR[6:0]	USB device address These bits indicate the USB device address (7 bits) of the device attached to the downstream port and are used when an LPM token is sent. When the value of these bits is 0x00, no device that requires these bits is connected.	R/W

31.3.3 AHB Bridge Registers

31.3.3.1 INTENABLE : INT_ENABLE Register

Base address: USBHC = 0x9204_0000

Offset address: 0x200

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	WAKEON_INTEN	UCOM_INTEN	USBH_INTBEN	USBH_INTAEN	AHB_INTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AHB_INTEN	AHB_INT bit control This bit enables or disables the interrupt source indicated in bit 0 (AHB_INT) in the INT_STATUS register. 0: Disabled 1: Enabled	R/W
1	USBH_INTAEN	USBH_INTA bit control This bit enables or disables the interrupt source indicated in bit 1 (USBH_INTA) in the INT_STATUS register. 0: Disabled 1: Enabled	R/W
2	USBH_INTBEN	USBH_INTB bit control This bit enables or disables the interrupt source indicated in bit 2 (USBH_INTB) in the INT_STATUS register. 0: Disabled 1: Enabled	R/W
3	UCOM_INTEN	UCOM_INT bit control This bit enables or disables the interrupt source indicated in bit 3 (UCOM_INT) in the INT_STATUS register. 0: Disabled 1: Enabled	R/W
4	WAKEON_INTEN	WAKEON_INT bit control This bit enables or disables the interrupt source indicated in bit 4 (WAKEON_INT) in the INT_STATUS register. 0: Disabled 1: Enabled	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

The INTENABLE register enables or disables each interrupt source indicated in the INT_STATUS register. When an interrupt source is disabled, the interrupt signal is not asserted even when the interrupt source is generated and the corresponding bit in the INT_STATUS register is set to 1.

31.3.3.2 INTSTATUS : INT_STATUS Register

Base address: USBHC = 0x9204_0000

Offset address: 0x204

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	WAKEON_INT	UCOM_INT	USBH_INTB	USBH_INTA	AHB_INT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AHB_INT	AHB bus error indication This bit indicates that an AHB bus error has occurred. Writing 1 clears this bit. 0: AHB bus error has not occurred. 1: AHB bus error has occurred	R/W
1	USBH_INTA	OHCI interrupt status This bit indicates the state of the OHCI interrupt. The interrupt can be cleared using the HcInterruptStatus register (one of OHCI operational registers). 0: INTA interrupt has not occurred 1: INTA interrupt has occurred	R

Bit	Symbol	Function	R/W
2	USBH_INTB	USBH_INTB EHCI interrupt status This bit indicates the state of the USBH_INTB EHCI interrupt. The interrupt can be cleared using the USBSTS register (one of EHCI operational registers). 0: INTB interrupt has not occurred 1: INTB interrupt has occurred	R
3	UCOM_INT	UCOM register interrupt status This bit indicates the state of the interrupt from the UCOM register. The interrupt can be cleared using the UCOM2 register. 0: UCOM register interrupt has not occurred 1: UCOM register interrupt has occurred	R
4	WAKEON_INT	WAKEON interrupt status This bit indicates the state of the WAKEON interrupt from the host logic. Writing 1 clears this bit. 0: WAKEON interrupt has not occurred 1: WAKEON interrupt has occurred	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

The INTSTATUS register indicates the state of interrupt sources in the AHB bridge and the state of interrupt signals from the OHCI, EHCI, and UCOM modules.

31.3.3.3 AHBBUSCTR : AHB_BUS_CTR Register

Base address: USBHC = 0x9204_0000

Offset address: 0x208

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PROT_TYPE[3:0]				—	—	—	PROT_MODE	—	—	ALIGN_ADDRESS[1:0]		—	—	MAX_BURST_LEN[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	MAX_BURST_LEN[1:0]	Maximum burst length These bits select the maximum burst length when the AHB master interface initiates a transfer. 0 0: INCR16 0 1: INCR8 1 0: INCR4 1 1: SINGLE	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
5:4	ALIGN_ADDRESS[1:0]	Address boundary setting These bits set the address boundary when the AHB master interface initiates a burst transfer. 0 0: 1-KB boundary is not exceeded when initiating a burst transfer 0 1: 64-byte boundary is not exceeded when initiating a burst transfer 1 0: 32-byte boundary is not exceeded when initiating a burst transfer (The maximum burst length is INCR8 in this case. The 32-byte boundary is exceeded when the maximum burst length is INCR16.) 1 1: 16-byte boundary is not exceeded when initiating a burst transfer. (The maximum burst length is INCR4 in this case. The 16-byte boundary is exceeded when the maximum burst length is INCR8 or greater.)	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
8	PROT_MODE	This bit selects the MHPROT[3:0] mode when the AHB master interface initiates a transfer. 0: Value of PROT_TYPE[3:0] is output as MHPROT[3:0] 1: 0000b is set as MHPROT[3:0] for DMA transfer when the last data of a burst is transferred. The value of PROT_TYPE[3:0] is used as MHPROT[3:0] for other data in a burst.	R/W
11:9	—	These bits are read as 0. The write value should be 0.	R/W
15:12	PROT_TYPE[3:0]	These bits set MHPROT[3:0] when the AHB master interface initiates a transfer.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Name	Value	Description
15	PROT_TYPE[3]	0	Cache is disabled
		1	Cache is enabled
14	PROT_TYPE[2]	0	Buffer is disabled
		1	Buffer is enabled
13	PROT_TYPE[1]	0	Access by a user
		1	Privileged access
12	PROT_TYPE[0]	0	Operation code
		1	Data

The AHBBUSCTR register specifies the AHB master and slave functions.

31.3.3.4 USBCTR : USBCTR Register

Base address: USBHC = 0x9204_0000

Offset address: 0x20C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	DIRPD	PLL_RST	USBH_RST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
0	USBH_RST	Software reset for the core When this bit is set to 1, the entire core is reset. Set this bit when the AHB master interface in the core is inactive. Access to the host logic is enabled in 10 PCLKAM clock cycles after this bit is written to. 0: Nothing occurs 1: Host logic is reset	W
1	PLL_RST	Reset of USB PHY PLL Reset to the PHY PLL is asserted. 0: Release PLL reset 1: Assert PLL reset	R/W
2	DIRPD	Direct transition to power-down state If this bit is set to 1, USB subsystem moves to power-down state. 0: Normal operation 1: Direct power-down state	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

31.3.4 Core Defined Registers

31.3.4.1 REVID : Revision and Core ID Register

Base address: USBHC = 0x9204_0000

Offset address: 0x300

Bit position:	31								24								15								8	7							0
Bit field:	COREID[7:0]								—	—	—	—	—	—	—	—	MAJV[7:0]								MINV[7:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
7:0	MINV[7:0]	Minor Version These bits indicate the minor version of the host logic.	R
15:8	MAJV[7:0]	Major Version These bits indicate the major version of the host logic.	R
23:16	—	This bit is read as 0.	R
31:24	COREID[7:0]	Core ID These bits indicate the ID of the host logic.	R

31.3.4.2 OCSLPTIMSET : Overcurrent Detection/Sleep Timer Setting Register

Base address: USBHC = 0x9204_0000

Offset address: 0x310

Bit position:	31			28				20	19																						0
Bit field:	—	—	—	TIMER_SLEEP[8:0]					TIMER_OC[19:0]																							
Value after reset:	0	0	0	0	1	1	0	0	1	0	0	0	0	0	1	1	0	0	0	0	1	1	0	1	0	1	0	0	0	0	0	0

Bit	Symbol	Function	R/W
19:0	TIMER_OC[19:0]	Overcurrent Timer setting When the overcurrent input, USB_OVRCUR, is asserted (driven to low) continuously longer than these bit setting time, the USB module determines the occurring overcurrent. This value should be set to more than 1 to 2 ms for the AHB clock and PCLKAM frequencies. One bit means 1 clock cycle. 1 ms at PCLKAM = 200 MHz: 0x3_0D04 (default setting)	R/W
28:20	TIMER_SLEEP[8:0]	Detection/Sleep Timer Setting These bits are timer setting for RemoteWakeup receive detection time during sleep and measuring Resume-K time. This value should be set to more than 1 µs for the AHB clock and PCLKAM frequencies. One bit means 1 clock cycle. PCLKAM = 200 MHz: 0x0C8 (default setting)	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

The OCSLPTIMSET register specifies the detection time of overcurent.

31.3.5 UCOM Registers

31.3.5.1 COMMCTRL : Common Control Register

Base address: USBHC = 0x9204_0000

Offset address: 0x800

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PERI	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
30:0	—	These bits are read as 0. The write value should be 0.	R/W
31	PERI	USB mode setting This bit specified whether to place the USB module in host mode or function mode. 0: Host mode 1: Function mode	R/W

The COMMCTRL register specifies whether to use USB module in host mode or function mode.

31.3.5.2 OBINTSTA : OTG-BC Interrupt Status Register

Base address: USBHC = 0x9204_0000

Offset address: 0x804

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DPMONCHG_STA	DMMONCHG_STA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	SESSVLDCHG_STA	IDDIGCHG_STA	VVLDCHG_STA	—	—	—	—	—	—	VBSTAINT_STA	VBSTACHG_STA	OCINT_STA	IDCHG_STA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	IDCHG_STA	USB_OTG_ID change status This bit is set when the value that is input from the USB_OTG_ID pin has changed. The initial value is 1. Before using this bit, clear the status. 0: Value input from the USB_OTG_ID pin has not changed 1: Value input from the USB_OTG_ID pin has changed	R/W*1
1	OCINT_STA	USB_OVRCUR assertion status This bit is set when the USB_OVRCUR pin is asserted. 0: USB_OVRCUR pin is not asserted (remains 1) 1: USB_OVRCUR pin is asserted (change to 0)	R/W*1
2	VBSTACHG_STA	VBSTA[3:0] change status This bit is set when the value of bits [31:28] (VBSTA[3:0]) in the VBCTRL register has changed. 0: Value of the VBSTA[3:0] bits has not changed 1: Value of the VBSTA[3:0] bits has changed	R/W*1

Bit	Symbol	Function	R/W
3	VBSTAINT_STA	VBUS voltage status interrupt This bit is set when the value of bits [31:28] (VBSTA[3:0]) in the VBCTRL register equals to the value set for bits [23:20] (VBLVL[3:0]) in the VBCTRL register. This bit is set instantly when the value of the VBSTA[3:0] bits equals to the value of the VBLVL[3:0] bits. After that, if this bit is cleared and the value of the VBSTA[3:0] bits is unchanged, the bit is not set even if the values of the VBSTA[3:0] bits and the VBLVL[3:0] bits are the same. This bit is set again when the value of the VBSTA[3:0] bits changes and the values of the VBSTA[3:0] bits and the VBLVL[3:0] bits become the same again. 0: Value of VBSTA[3:0] bits is not the same as the value of the VBLVL[3:0] bits 1: Value of VBSTA[3:0] bits is the same as the value of the VBLVL[3:0] bits.	R/W*1
9:4	—	These bits are read as 0. The write value should be 0.	R/W
10	VVLDCHG_STA	VBUSVALID change status This bit is set if the VBUSVALID bit of the PHYCTRL register has changed. 0: The VBUSVALID bit of the PHYCTRL register has not changed 1: The VBUSVALID bit of the PHYCTRL register has changed	R/W*1
11	IDDIGCHG_STA	IDDIG0 change status This bit is set if the IDDIG0 bit of the PHYCTRL register has changed. 0: The IDDIG0 bit of the PHYCTRL register has not changed 1: The IDDIG0 bit of the PHYCTRL register has changed	R/W*1
12	SESSVLDCHG_STA	OTGSESSVLD change status This bit is set if the OTGSESSVLD bit of the PHYCTRL register has changed. 0: The OTGSESSVLD bit of the PHYCTRL register has not changed 1: The OTGSESSVLD bit of the PHYCTRL register has changed	R/W*1
15:13	—	These bits are read as 0. The write value should be 0.	R/W
16	DMMONCHG_STA	DMMON change status This bit is set if the DMMON bit of the LINECTRL1 register has changed. 0: The DMMON bit of the LINECTRL1 register has not changed 1: The DMMON bit of the LINECTRL1 register has changed	R/W*1
17	DPMONCHG_STA	DPMON change status This bit is set if the DPMON bit of the LINECTRL1 register has changed. 0: The DPMON bit of the LINECTRL1 register has not changed 1: The DPMON bit of the LINECTRL1 register has changed	R/W*1
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 clears this bit. Writing 0 has no effect.

The OBINTSTA register indicates whether interrupt sources related to USB OTG have occurred.

An OBINT interrupt is generated when a bit is set in this register and the corresponding bit is not masked in the OBINTEN register.

31.3.5.3 OBINTEN : OTG-BC Interrupt Enable Register

Base address: USBHC = 0x9204_0000

Offset address: 0x808

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DPMONCHG_EN	DMMONCHG_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	SESSVLDCHG_EN	IDDIGCHG_EN	VVLDCHG_EN	—	—	—	—	—	—	VBSTAINT_EN	VBSTACHG_EN	OCINT_EN	IDCHG_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IDCHG_EN	IDCHG_STA Interrupt enable This bit enables or disables the interrupt flagged by the IDCHG_STA bit. 0: Interrupt flagged by the IDCHG_STA bit is disabled. 1: Interrupt flagged by the IDCHG_STA bit is enabled	R/W
1	OCINT_EN	OCINT_STA interrupt enable This bit enables or disables the interrupt flagged by the OCINT_STA bit. 0: Interrupt flagged by the OCINT_STA bit is disabled 1: Interrupt flagged by the OCINT_STA bit is enabled	R/W
2	VBSTACHG_EN	VBSTACHG_STA interrupt enable This bit enables or disables the interrupt flagged by the VBSTACHG_STA. 0: Interrupt flagged by the VBSTACHG_STA bit is disabled 1: Interrupt flagged by the VBSTACHG_STA bit is enabled	R/W
3	VBSTAINT_EN	VBSTAINT_STA interrupt enable This bit enables or disables the interrupt flagged by the VBSTAINT_STA. 0: Interrupt flagged by the VBSTAINT_STA bit is disabled 1: Interrupt flagged by the VBSTAINT_STA bit is enabled	R/W
9:4	—	These bits are read as 0. The write value should be 0.	R/W
10	VVLDCHG_EN	VVLDCHG_STA interrupt enable This bit enables or disables the interrupt flagged by the VVLDCHG_STA. 0: Interrupt flagged by the VVLDCHG_STA bit disabled 1: Interrupt flagged by the VVLDCHG_STA bit enabled	R/W
11	IDDIGCHG_EN	IDDIGCHG_STA interrupt enable This bit enables or disables the interrupt flagged by the IDDIGCHG_STA. 0: Interrupt flagged by the IDDIGCHG_STA bit disabled 1: Interrupt flagged by the IDDIGCHG_STA bit enabled	R/W
12	SESSVLDCHG_EN	SESSVLDCHG_STA interrupt enable This bit enables or disables the interrupt flagged by the SESSVLDCHG_STA. 0: Interrupt flagged by the SESSVLDCHG_STA bit disabled 1: Interrupt flagged by the SESSVLDCHG_STA bit enabled	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
16	DMMONCHG_EN	DMMONCHG_STA interrupt enable This bit enables or disables the interrupt flagged by the DMMONCHG_STA. 0: Interrupt flagged by the DMMONCHG_STA bit disabled 1: Interrupt flagged by the DMMONCHG_STA bit enabled	R/W
17	DPMONCHG_EN	DPMONCHG_STA interrupt enable This bit enables or disables the interrupt flagged by the DPMONCHG_STA. 0: Interrupt flagged by the DPMONCHG_STA bit disabled 1: Interrupt flagged by the DPMONCHG_STA bit enabled	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The OBINTEN register enables or disables the interrupts that are flagged by the OBINTSTA register.

An OBINT interrupt is generated when a bit is set the OBINTSTA register and the corresponding bit is set in the OBINTEN register.

31.3.5.4 VBCTRL : VBUS Control Register

Base address: USBHC = 0x9204_0000

Offset address: 0x80C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	VBSTA[3:0]				—	—	—	—	VBLVL[3:0]				—	—	OCISEL	OCCLRIEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	VGPUO	—	SIDDQREL	VBUSENSEL	VBOUT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	VBOUT	VBUS drive control (USB_VBUSEN pin) This bit is used to assert the VBUS power path by controlling external power supply IC. 0: VBUS output is disabled. (USB_VBUSEN is driven to low.) 1: VBUS output is enabled. (USB_VBUSEN is driven to high.)	R/W
1	VBUSENSEL	USB_VBUSEN pin control 0: USB_VBUSEN is controlled by PPON1 1: USB_VBUSEN is controlled by VBOUT bit in this register	R/W
2	SIDDQREL	SIDDQ mode control 0: SIDDQ mode is set 1: SIDDQ mode is released	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	VGPUO	USB_EXICEN pin control This bit is used to control external power supply IC. 0: USB_EXICEN is driven to low 1: USB_EXICEN is driven to high	R/W
15:5	—	These bits are read as 0. The write value should be 0.	R/W
16	OCCLRIEN	USB_VBUSEN pin control at occurrence of overcurrent This bit specifies whether to automatically clear the VBOUT bit if an overcurrent occurs. If an overcurrent occurs, bit 1 (OCINT_STA) in the OBINTSTA register is set. 0: VBOUT bit is not automatically cleared if an overcurrent occurs 1: VBOUT bit is automatically cleared if an overcurrent occurs	R/W
17	OCISEL	Overcurrent detection This bit selects the signal to be used for detecting an overcurrent. 0: OCI signal that is output by the host logic This signal is treated as an indication of an overcurrent if the USB_OVRCUR pin is asserted longer than the overcurrent detection time set in bits [19:0] (TIMER_OC[19:0]) in the OCSLPTIMSET register. 1: Inverted signal from the USB_OVRCUR pin When this signal is selected, the overcurrent detection time set in the TIMER_OC[19:0] bits is not used. The system assumes an overcurrent has occurred if the USB_OVRCUR pin is asserted for 5 clock cycles or more.	R/W
19:18	—	These bits are read as 0. The write value should be 0.	R/W
23:20	VBLVL[3:0]	VBUS level detection These bits are used to detect, using an interrupt, that VBUS has reached a certain level. When the value of the voltage level of VBUS equals to the value set for these bits, the interrupt flagged by the VBSTAINT_STA bit in the OBINTSTA register is generated.	R/W
27:24	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
31:28	VBSTA[3:0]	VBUS indication These bits indicate the voltage level of VBUS. The bits indicate the input from the USB_VUBUSIN pin as is. VBSTA[3:2] and VBSTA[0] bits are fixed to 0. VBSTA[1] bit indicates USB_VUBUSIN input level if DRVVBUS bit in PHYCTRL register is 1 and VBSTA[1] is fixed to 0 if DRVVBUS bit in PHYCTRL register is 0.	R

The VBCTRL register controls VBUS when the USB module is used in OTG mode.

31.3.5.5 LINECTRL1 : Line Control Port 1 Register

Base address: USBHC = 0x9204_0000

Offset address: 0x810

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	DPRPD_EN	DP_RPD	DMRPD_EN	DM_RPD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	DPMON	DMMON	—	IDMON
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*1

Bit	Symbol	Function	R/W
0	IDMON	Indicates a value of USB_OTG_ID input pin.	R
1	—	This bit is read as 0.	R
2	DMMON	Indicates a value of USB bus DM.	R
3	DPMON	Indicates a value of USB bus DP.	R
15:4	—	These bits are read as 0. The write value should be 0.	R/W
16	DM_RPD	Controls USB bus (DM) 15 kΩ pulldown resistor when DMPPD_EN = 1. 0: DM-side 15 kΩ pulldown resistor is OFF 1: DM-side 15 kΩ pulldown resistor is ON	R/W
17	DMRPD_EN	Enables DM_RPD to control USB bus (DM) 15 kΩ pulldown resistor. 0: Control of DM-side 15 kΩ pulldown resistor by DM_RPD disabled 1: Control of DM-side 15 kΩ pulldown resistor by DM_RPD enabled	R/W
18	DP_RPD	Controls USB bus (DP) 15 kΩ pulldown resistor when DRPPD_EN = 1. 0: DP-side 15 kΩ pulldown resistor is OFF 1: DP-side 15 kΩ pulldown resistor is ON	R/W
19	DPRPD_EN	Enables DP_RPD to control USB bus (DP) 15 kΩ pulldown resistor. 0: Control of DP-side 15 kΩ pulldown resistor by DP_RPD disabled 1: Control of DP-side 15 kΩ pulldown resistor by DP_RPD enabled	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. This value depends on the USB_OTG_ID input pin.

31.3.5.6 PHYCTRL : PHY Control Register

Base address: USBHC = 0x9204_0000

Offset address: 0x830

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	OTGSESSVLD	IDDIG0	VBUSVALID	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	IDPULLUP0	DRVVBUS	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	DRVVBUS	Drive VBUS 0: The VBUS Valid comparator is disabled. 1: The VBUS Valid comparator is enabled.	R/W
5	IDPULLUP0	ID Input Sample Enable 0: ID pin sampling is disabled, and the IDDIG0 bit is not valid. 1: ID pin sampling is enabled, and the IDDIG0 bit is valid.	R/W
17:6	—	These bits are read as 0. The write value should be 0.	R/W
18	VBUSVALID	VBUS Valid Indicator 0: USB_VUBUSIN level is not valid. 1: USB_VUBUSIN level is valid.	R
19	IDDIG0	Mini A/B Plug Indicator 0: The connected plug is a mini-A plug. 1: The connected plug is a mini-B plug.	R
20	OTGSESSVLD	OTG Device Session Valid Indicator 0: OTG Device Session is no valid. 1: OTG Device Session is valid.	R
31:21	—	These bits are read as 0. The write value should be 0.	R/W

The PHYCTRL register controls VBUS and OTG_ID.

31.4 Clock Lines

31.4.1 Externally Supplied Clocks

Table 31.3 describes the two clock signals that are supplied from within the LSI to the USB host controller.

Table 31.3 List of externally supplied clocks

Clock signal	Function	Frequency
PCLKAM	AHB clock	200 MHz
USB_CLK	Reference clock	50 MHz

31.5 Interrupts

31.5.1 Interrupt Control Registers

31.5.1.1 U2H_INT Control Registers

U2H_INT is an interrupt signal generated by the AHB bridge. Registers in the AHB bridge are used to check and clear the interrupt state and to enable interrupts.

Table 31.4 U2H_INT Control Registers

Operation	Control Register
Check and clear interrupt state	INT_STATUS register
Enable interrupts	INT_ENABLE register

31.5.1.2 U2H_OHCI_INT Control Registers

U2H_OHCI_INT is the INTA interrupt signal from the host logic. Each interrupt is basically controlled through registers in the host logic, but to assert the interrupt signal, the interrupt enable bit in the AHB bridge must be set.

Table 31.5 U2H_OHCI_INT Control Registers

Operation	Control Register
Check and clear interrupt state	HcInterruptStatus register
Enable interrupts	HcInterruptEnable register HcInterruptDisable register INT_ENABLE register (bit 1 (USBH_INTAEN))

31.5.1.3 U2H_EHCI_INT Control Registers

U2H_EHCI_INT is the INTB interrupt signal from the host logic. Each interrupt is basically controlled through registers in the host logic, but to assert the interrupt signal, the interrupt enable bit in the AHB bridge must be set.

Table 31.6 U2H_EHCI_INT Control Registers

Operation	Control Register
Check and clear interrupt state	USBSTS register
Enable interrupts	USBINTR register INT_ENABLE register (bit 2 (USBH_INTBEN))

31.5.1.4 U2H_OBINT Control Registers

U2H_OBINT is the UCOM interrupt signal from the host logic. Each interrupt is basically controlled through registers in the host logic, but to assert the interrupt signal, the interrupt enable bit in the AHB bridge must be set.

Table 31.7 U2H_OBINT Control Registers

Operation	Control Register
Check and clear interrupt state	OBINTSTA register
Enable interrupts	OBINTEN register INT_ENABLE register (bit 3 (UCOM_INTEN))

31.5.1.5 U2H_WAKEON_INT Control Registers

U2H_WAKEON_INT is the WAKEON interrupt signal from the host logic. Each interrupt is basically controlled through registers in the host logic, but to assert the interrupt signal, the interrupt enable bit in the AHB bridge must be set.

Table 31.8 U2H_WAKEON_INT Control Registers

Operation	Control Register
Check and clear interrupt state	INT_STATUS register (bit 4 (WAKEON_INT))
Enable interrupts	PORTSC1 register (bits 22 to 20) INT_ENABLE register (bit 4 (WAKEON_INTEN))

31.5.2 U2H_BIND_INT

The U2H_BIND_INT interrupt signal is generated as the logical OR of the following five interrupt source signals:

- U2H_INT
- U2H_OHCI_INT

- U2H_EHCI_INT
- U2H_OBINT
- U2H_WAKEON_INT.

The states of the U2H_OBINT, U2H_WAKEON_INT, U2H_OHCI_INT, and U2H_EHCI_INT signals are reflected in the INT_STATUS register in the AHB bridge. Read the register to check which source was responsible for a generated interrupt.

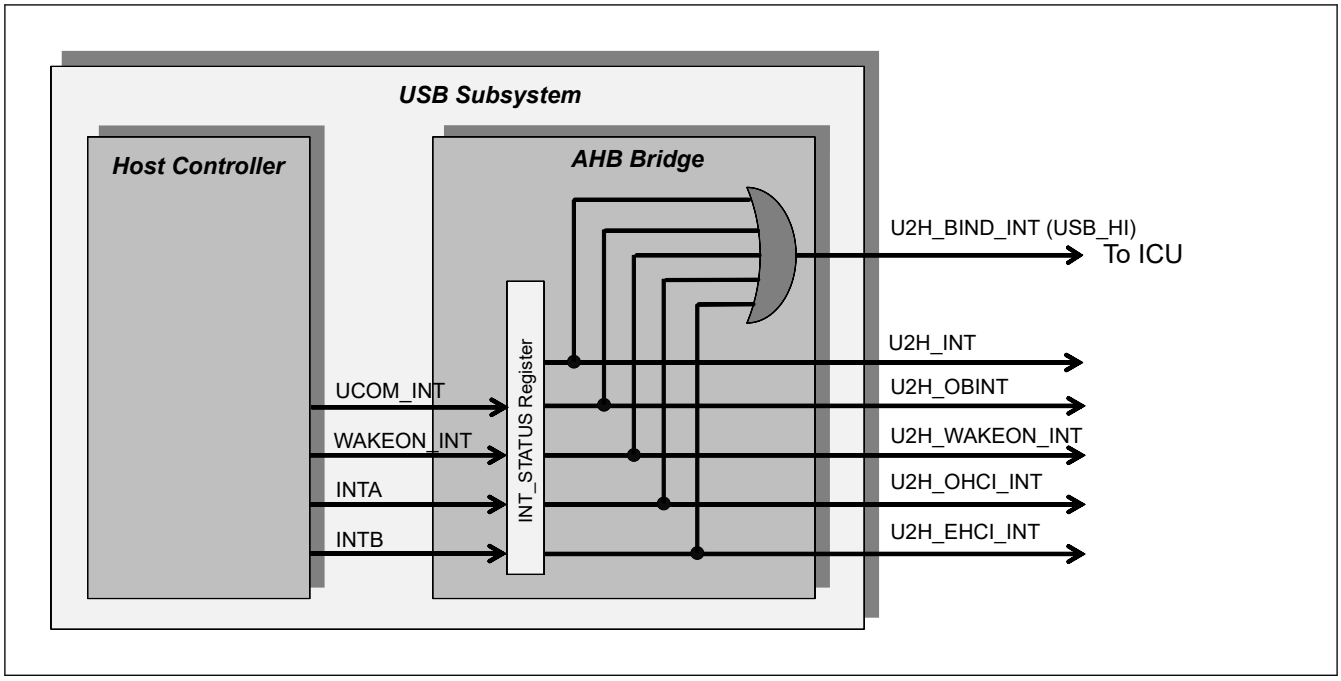

Figure 31.2 Image of interrupt signal integration

31.5.3 Time Required to Clear Interrupt Signals

It may take a long time to actually clear the interrupt after the register for clearing the interrupt source is written to due to the posted write operation of the AHB bridge.

Measure should be taken to prevent false detection before the next interrupt is detected after the register access for clearing the interrupt is completed.

31.6 Overcurrent Control and VBUS Control

31.6.1 Overcurrent Control

This section describes the operation of the USB_OVRCUR and USB_VBUSEN signals used for overcurrent detection at the USB port and VBUS control.

31.6.1.1 USB_OVRCUR and USB_VBUSEN Signal Functions

Table 31.9 shows the meaning of the USB_OVRCUR and USB_VBUSEN signals.

Table 31.9 USB_OVRCUR and USB_VBUSEN

Pin	I/O	Level	Meaning
USB_OVRCUR	Input	1	No overcurrent has been detected
		0	Overcurrent has been detected
USB_VBUSEN	Output	1	Power supply to VBUS is on
		0	Power supply to VBUS is off

31.6.1.2 Conditions for Asserting and Deasserting USB_VBUSEN Output Signal

Figure 31.3 shows a timing diagram for the assertion and deassertion of USB_OVRCUR and USB_VBUSEN.

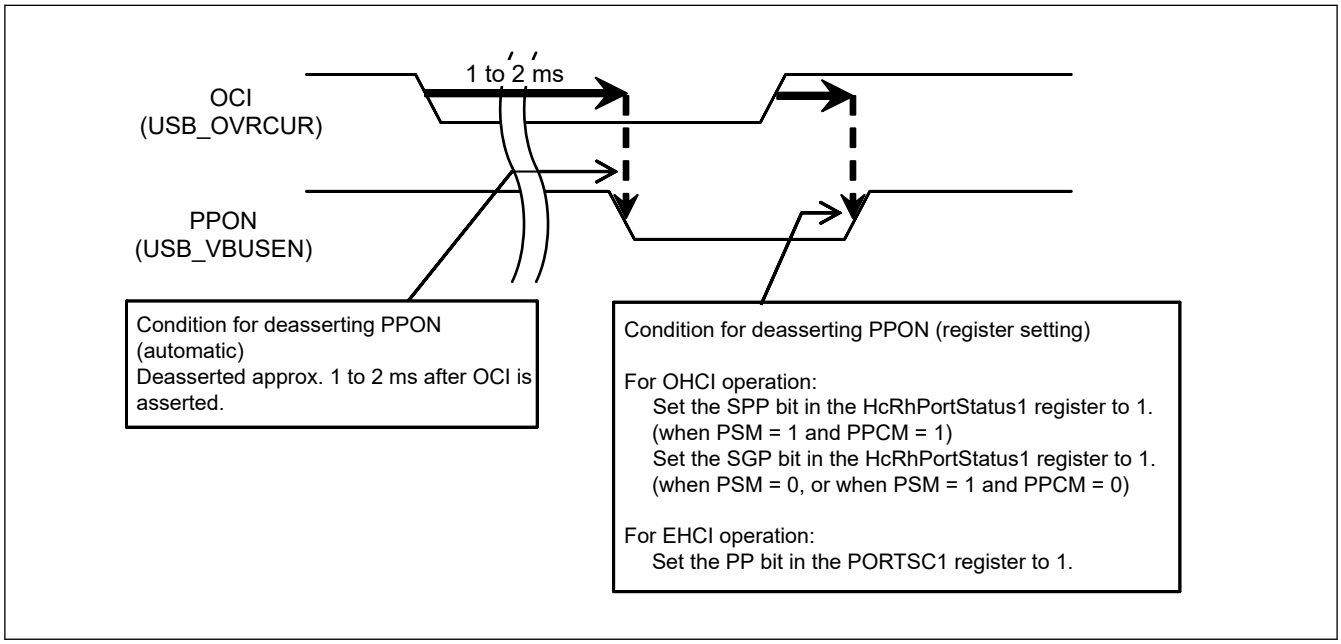

Figure 31.3 Timing diagram for the assertion and deassertion of USB_OVRCUR and USB_VBUSEN

USB_VBUSEN is not asserted automatically after USB_OVRCUR is deasserted. USB_VBUSEN is asserted when software sets the port power bit after USB_OVRCUR is deasserted.

31.6.2 VBUS Control

When the USB port is not used, VBUS can be stopped to reduce power consumption by connecting the USB_OVRCUR and USB_VBUSEN pins to the high-side switch (although this may not be possible depending on the connections with peripheral circuits).

Table 31.10 shows the relationship between USB_VBUSEN and VBUS.

Table 31.10 Relationship between USB_VBUSEN and VBUS

USB_VBUSEN	VBUS
0	Stopped
1	Operated

The USB_VBUSEN operation when USB_OVRCUR is asserted depends on the settings in the OHCI operational register as shown in Table 31.11.

Table 31.11 Register settings and USB_VBUSEN operation

OHCI operational registers				
HcRhDescriptorA Register			HcRhDescriptorB	
NOCP bit	NPS bit	PSM bit	PPCM[1] bit	USB_VBUSEN output pin operation
1	—	—	—	Fixed to 1
—	1	—	—	Fixed to 1
0	0	0	—	Deasserted (0) when USB_OVRCUR is asserted (0)
		1	0	
			1	

Note: When NPS = 1, the host logic detects an overcurrent but does not deassert USB_VBUSEN.

31.6.3 Initial Settings of PPON1

ON and OFF of PPON1 (PortPower) is controlled by the Port Control register of OHCI/EHCI operational registers listed in Table 31.12 for general usage after reset without setting the NOCP and NPS bits in the HcRhDescriptorA register. PPON1 is turned on when at least one of the following bits is ON:

- SPP
- SGP
- PP

In general, bits SPP, SGP, and PP are cleared to 0 when an overcurrent is detected.

Table 31.12 OHCI and EHCI operational registers

Register		Bit	Symbol
OHCI operation	HcRhPortStatus1 register	8	SPP
	HcRhPortStatus register	16	SGP*1
EHCI operation	PORTSC1 register	12	PP

Note 1. This is not generally used with the single-port version. For PPON control by this bit, the bit must be in the state of PSM = 0, or PSM = 1 and PPCM = 0.

PPON1 is turned on by setting the NOCP or NPS bit to 1 regardless of the Port Power bit of the specified ports.

The initial settings of the PPON1 control bits (SPP, SGP, PP, NOCP, and NPS) are all 0 (OFF). Setting these bits to 1 (ON) during initial setting required a procedure in the following flow.

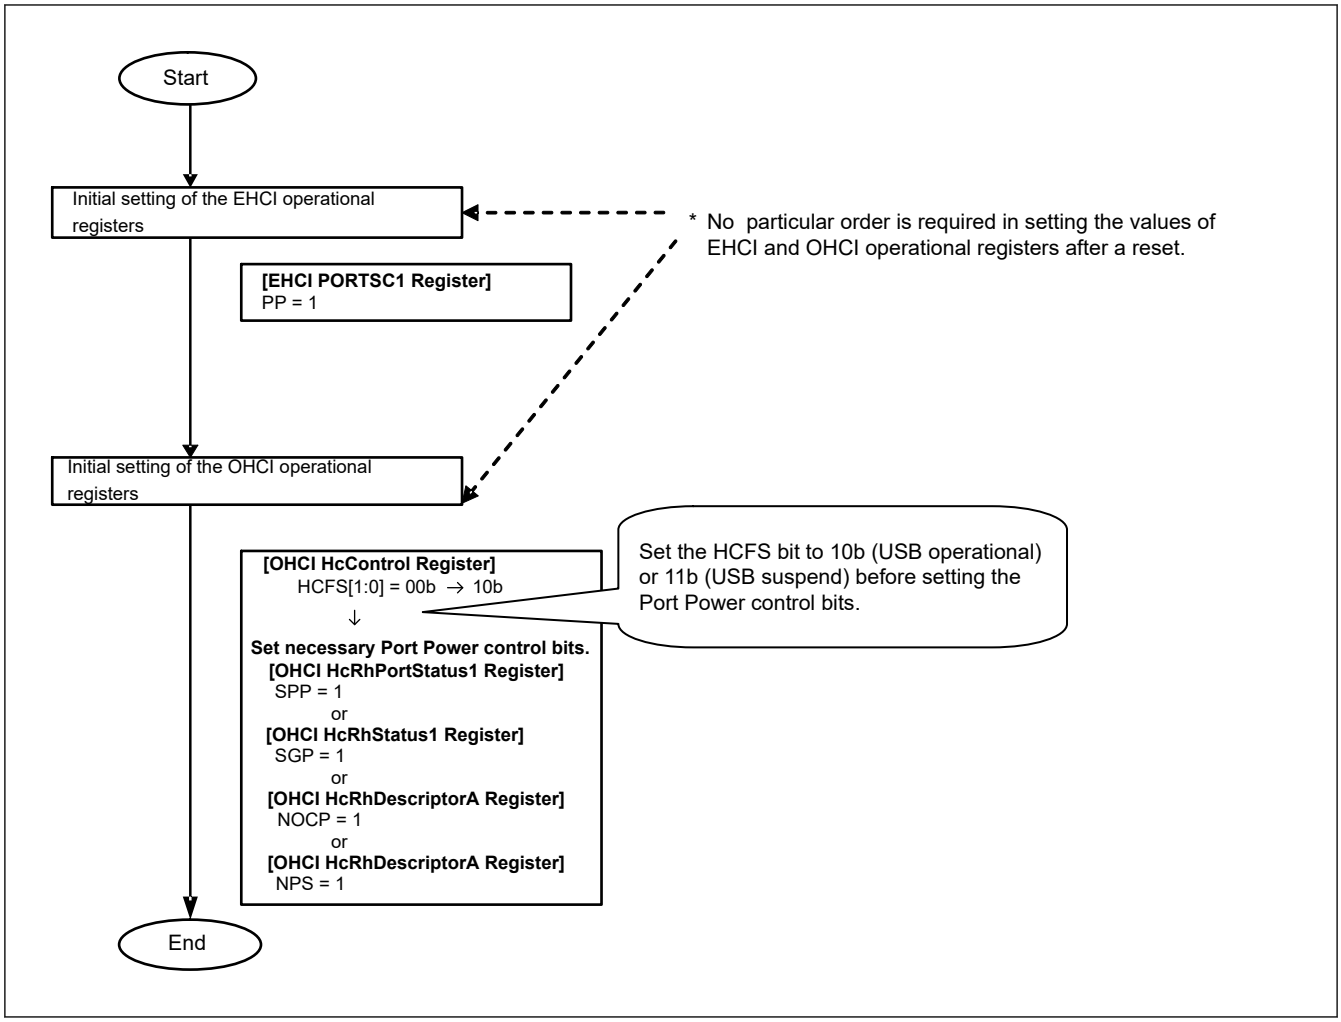

Figure 31.4 Initial settings flow of PPON1

31.6.4 Procedure for USB_VBUSEN Control for Overcurrent Detection

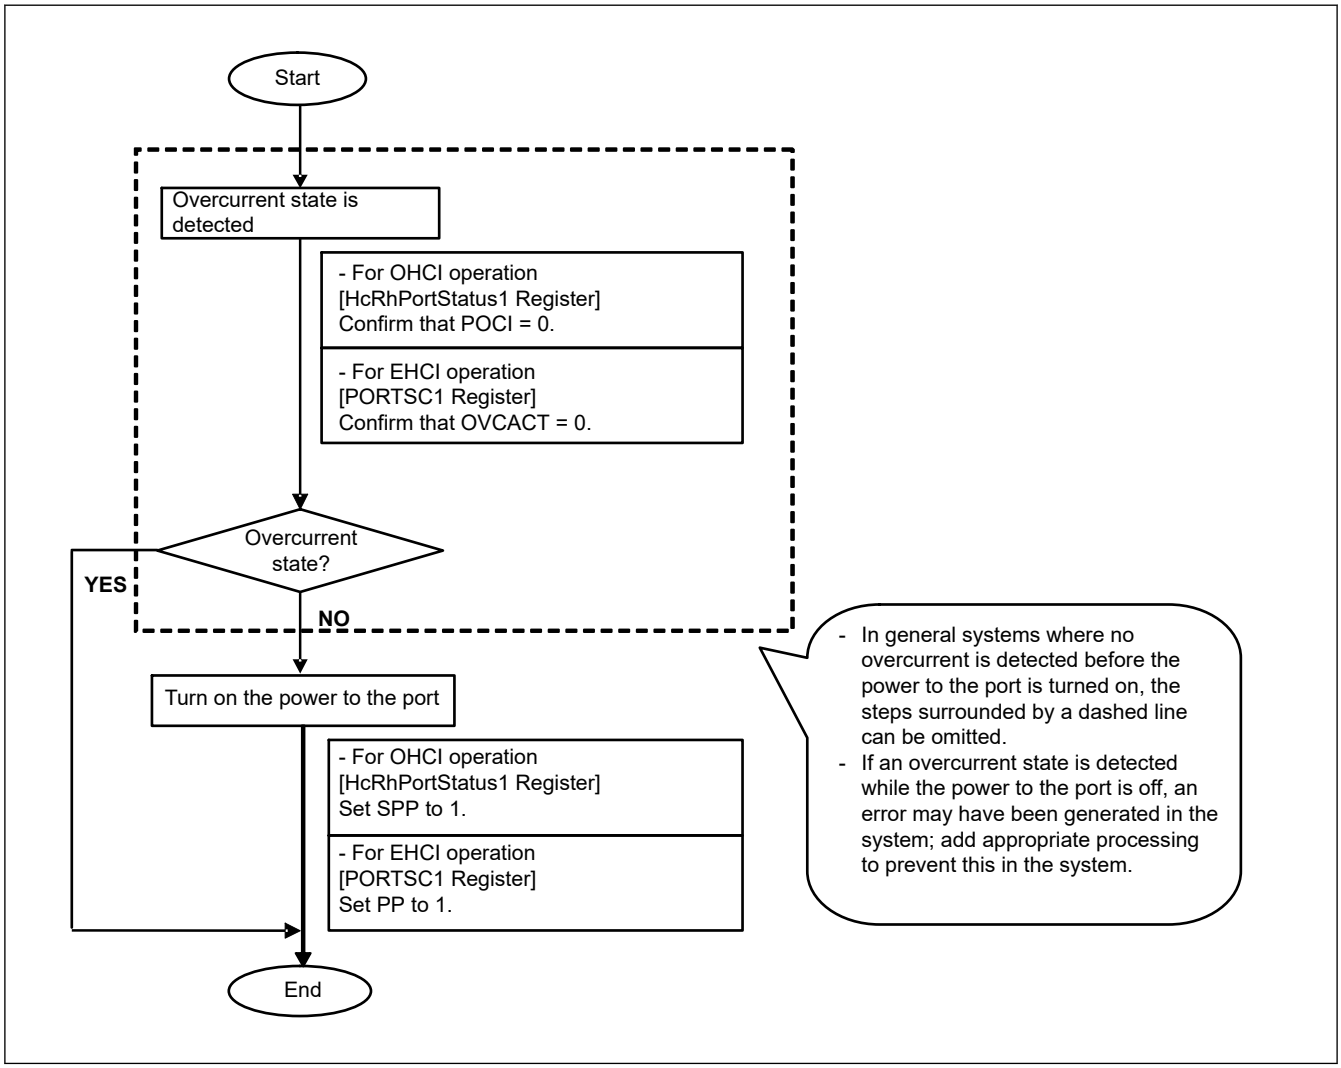

Figure 31.5 Flow of USB_VBUSEN control for overcurrent detection

31.6.5 Procedure for USB_VBUSEN Setting

Figure 31.6 shows the procedure for USB_VBUSEN setting in a system where USB_OVRCUR may be active (0) at system startup.

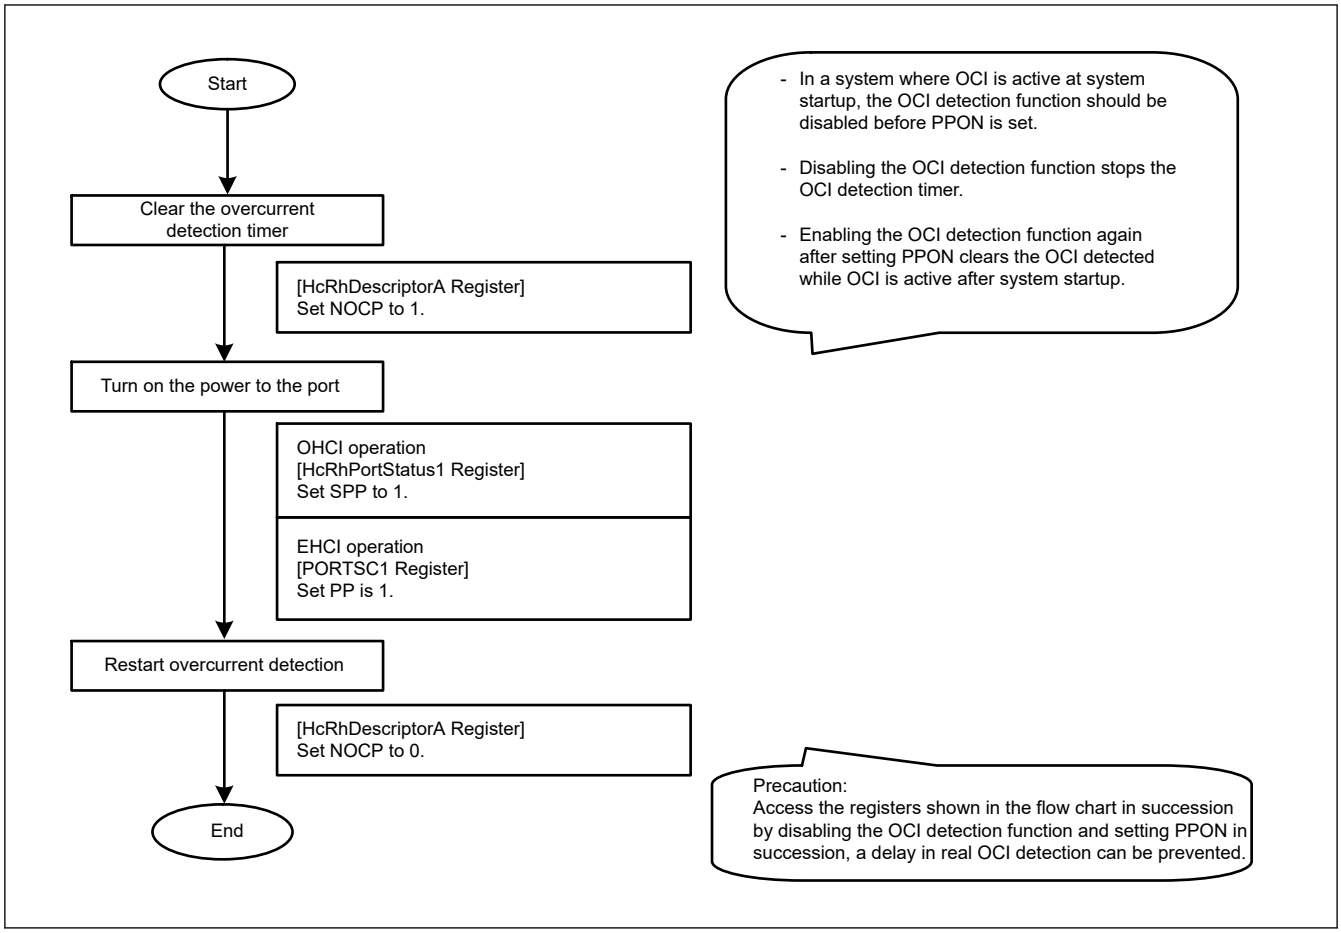

Figure 31.6 Flow for USB_VBUSEN setting

31.7 Initial Setting Sequence

31.7.1 Sample of Initial Settings

This section shows sample initial settings to implement the following functions:

- Access to OHCI/EHCI operational registers
- Data transfer from the host logic to the AHB bus.

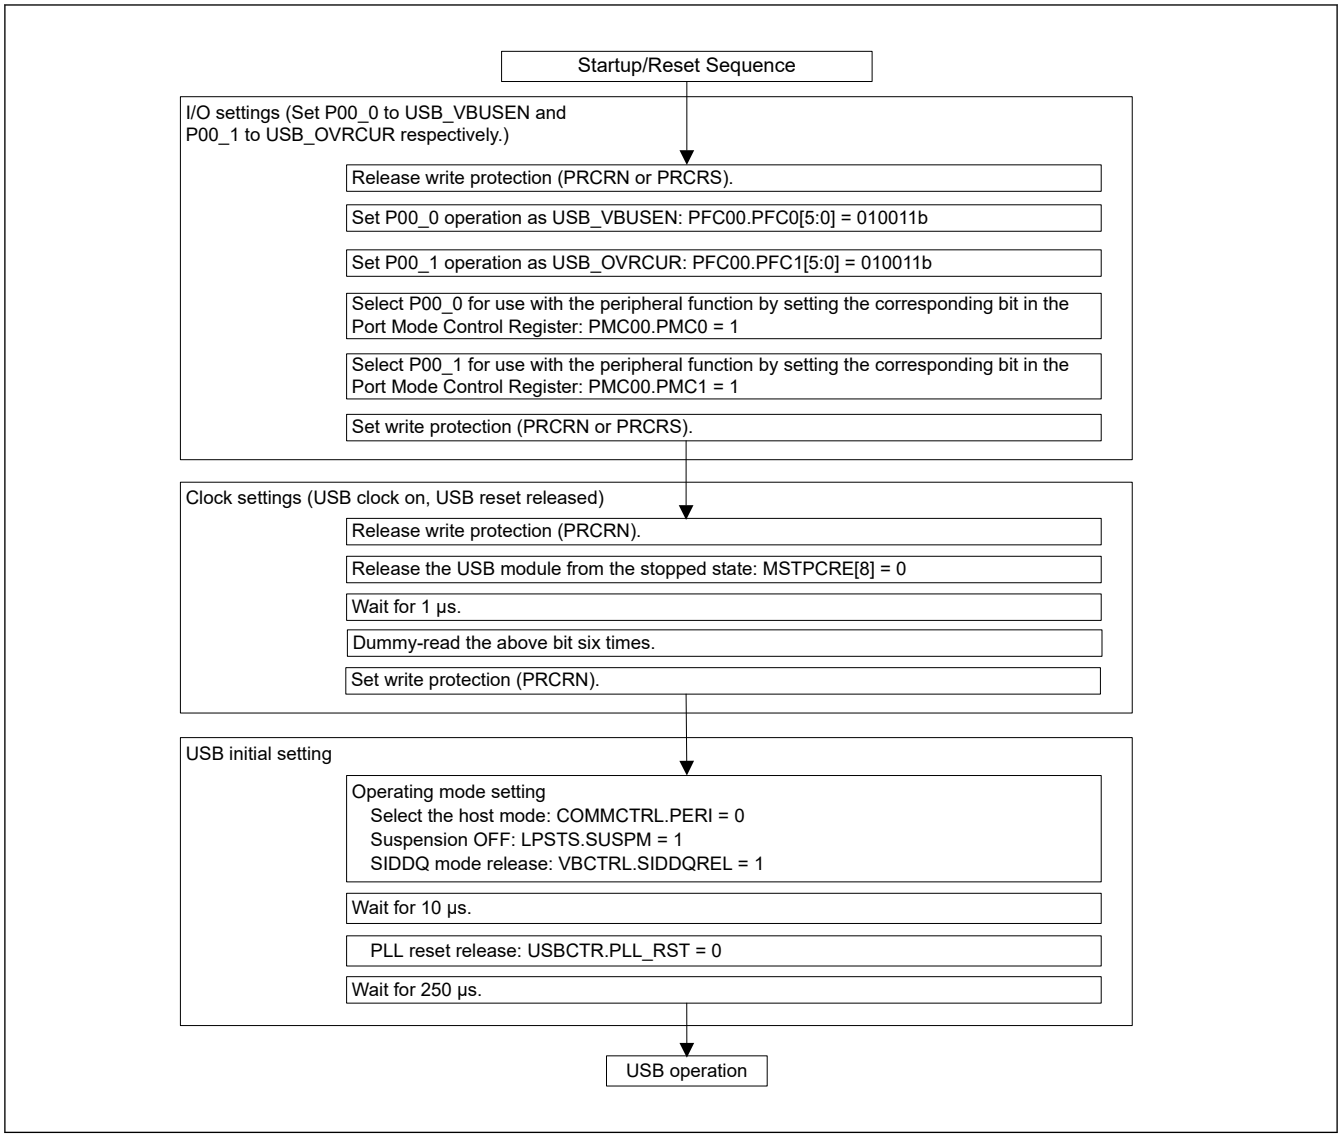

Figure 31.7 Initial setting sequence

31.8 OTG Control

31.8.1 Port Power (VBUS) Control and Connection with External Power-Supply IC

The following procedure describes how to control the port power (VBUS) when using this module for OTG:

1. Control the port power through the associated UCOM registers.
2. Connect the external power-supply IC and the corresponding pins of this module according to the following table.

LSI pin name	I/O	Connection
USB_OTG_ID	I	Connect this pin as input from the IC power supply
USB_VUBUSIN	I	Connect this pin as input from the IC power supply
USB_VBUSEN	O	Connect this pin as output to the IC power supply
USB_EXICEN	O	Connect this pin as output to the IC power supply
USB_OVRCUR	I	Connect this pin as input from the IC power supply If the power-supply IC does not support overcurrent detection capability, this input signal should be tied to high level.

31.8.2 OTG System Configuration Example

Figure 31.8 shows an example of connections to support the OTG function. The configuration includes an external power-supply IC.

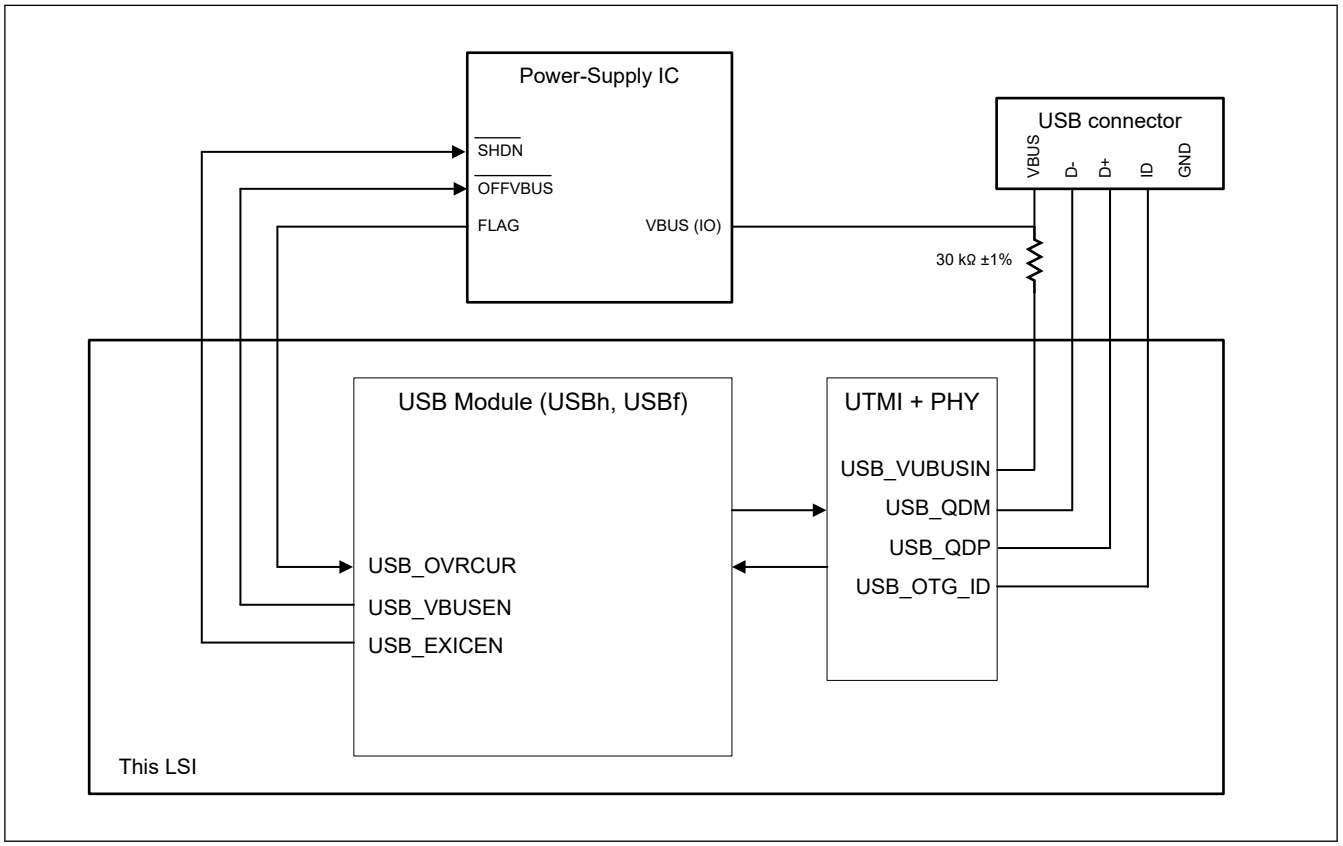

Figure 31.8 OTG system configuration example

31.8.3 OTG Initial Setting Procedure

Figure 31.9 shows the initial setting procedure when this module is used for OTG. The figure shows the steps before detection of A-plug or B-plug connection through the ID and VBUS pins.

Assuming the control of ID and VBUS:

VBUS control: VBCTRL.VBOUT

ID detection: UTMI+PHY

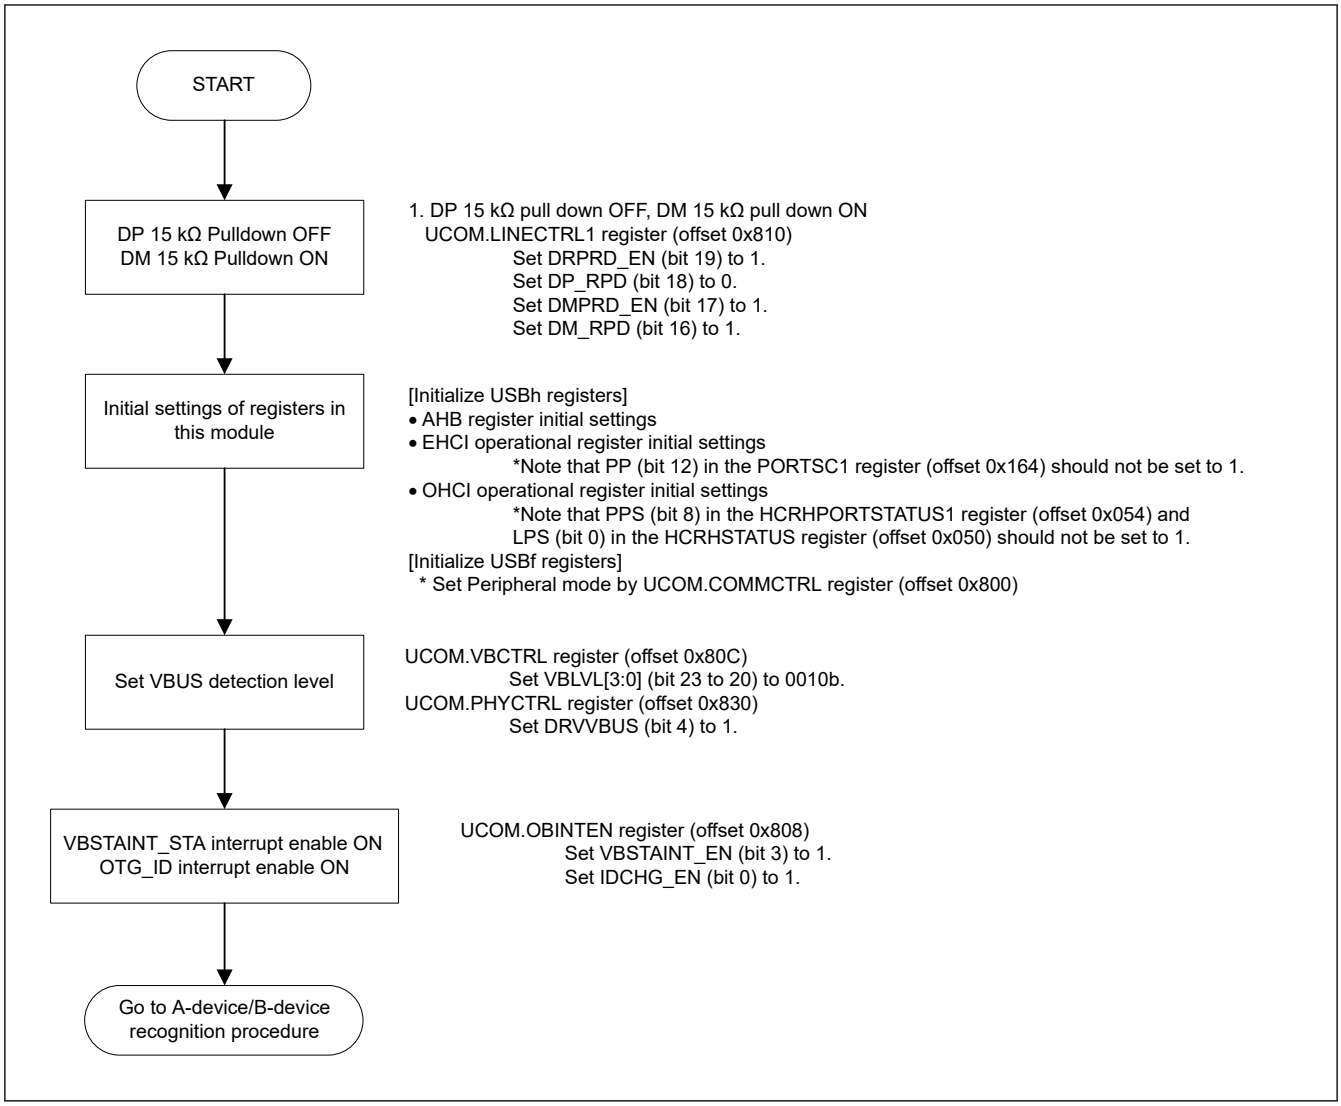

Figure 31.9 OTG initial setting procedure

31.8.4 A-Device/B-Device Recognition Procedure

Figure 31.10 shows the control procedure for operating this module as an A-device or a B-device through A-plug or B-plug connection following the steps described in section 31.8.3. OTG Initial Setting Procedure or section 31.8.5. Disconnect Detection Procedure.

Assuming the control of ID and VBUS:

VBUS control: VBCTRL.VBOUT

ID detection: UTMI+PHY

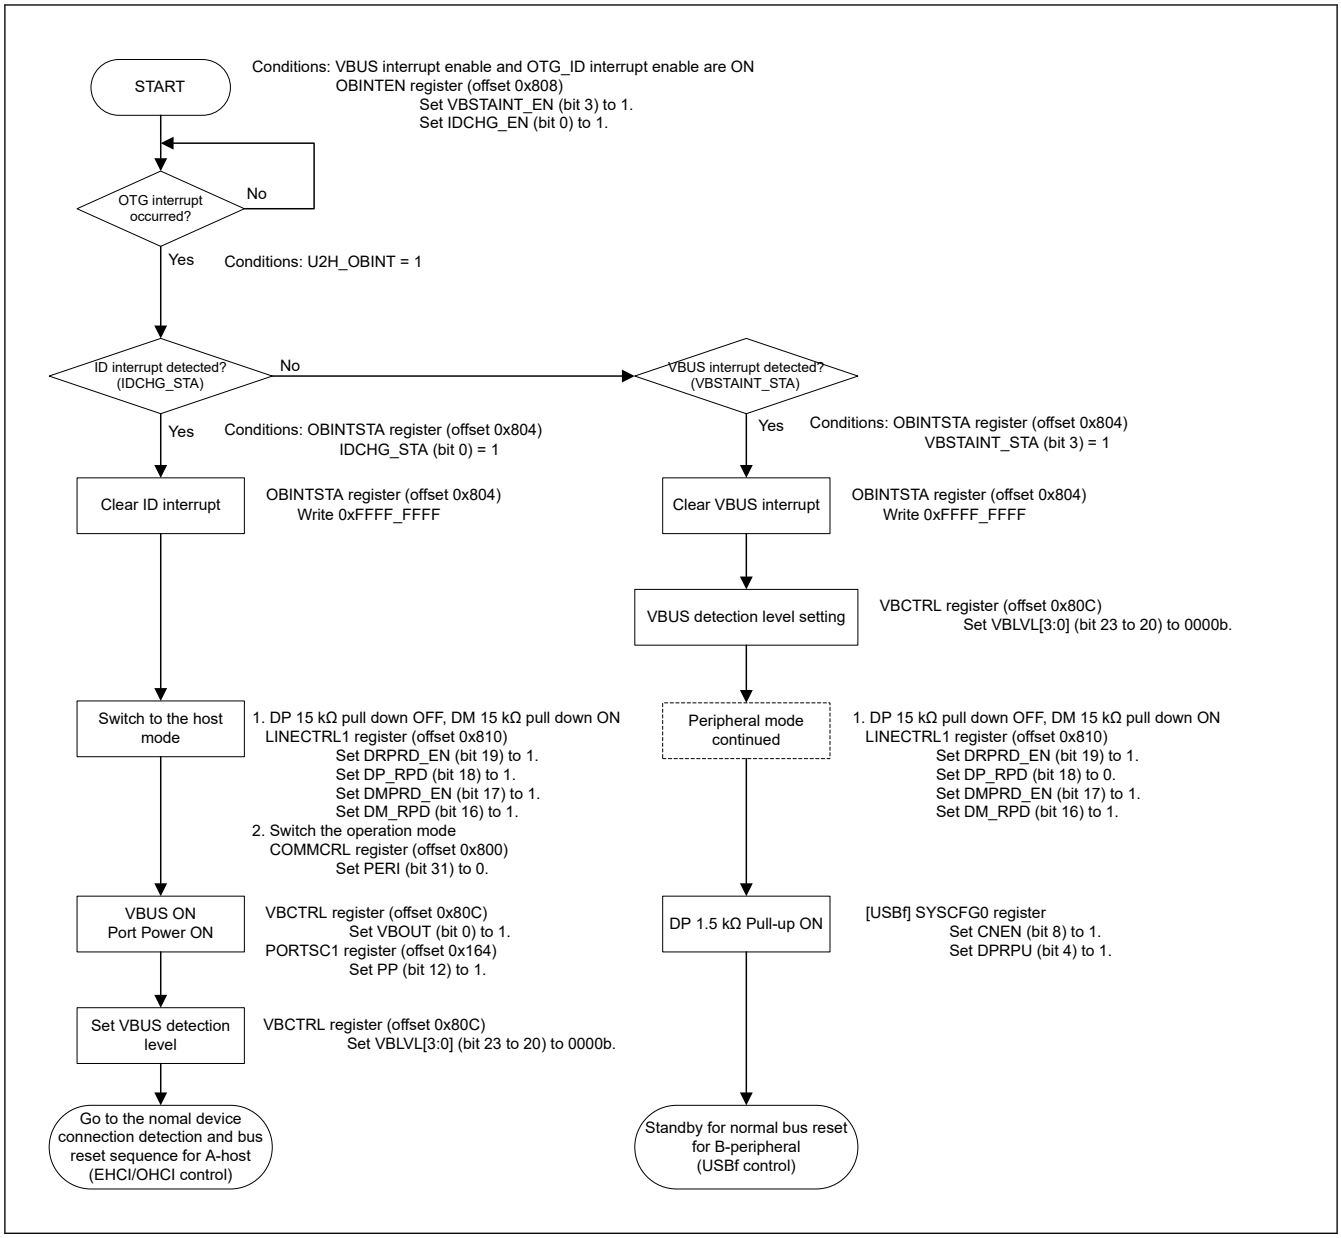

Figure 31.10 A-Device/B-Device recognition procedure

31.8.5 Disconnect Detection Procedure

Figure 31.11 shows the disconnect detection procedure. Disconnect detection means detection of a physical disconnection of an A-plug or B-plug from a USB port.

Assuming the control of ID and VBUS:

VBUS control: VBCTRL.VBOUT

ID detection: UTMI+PHY

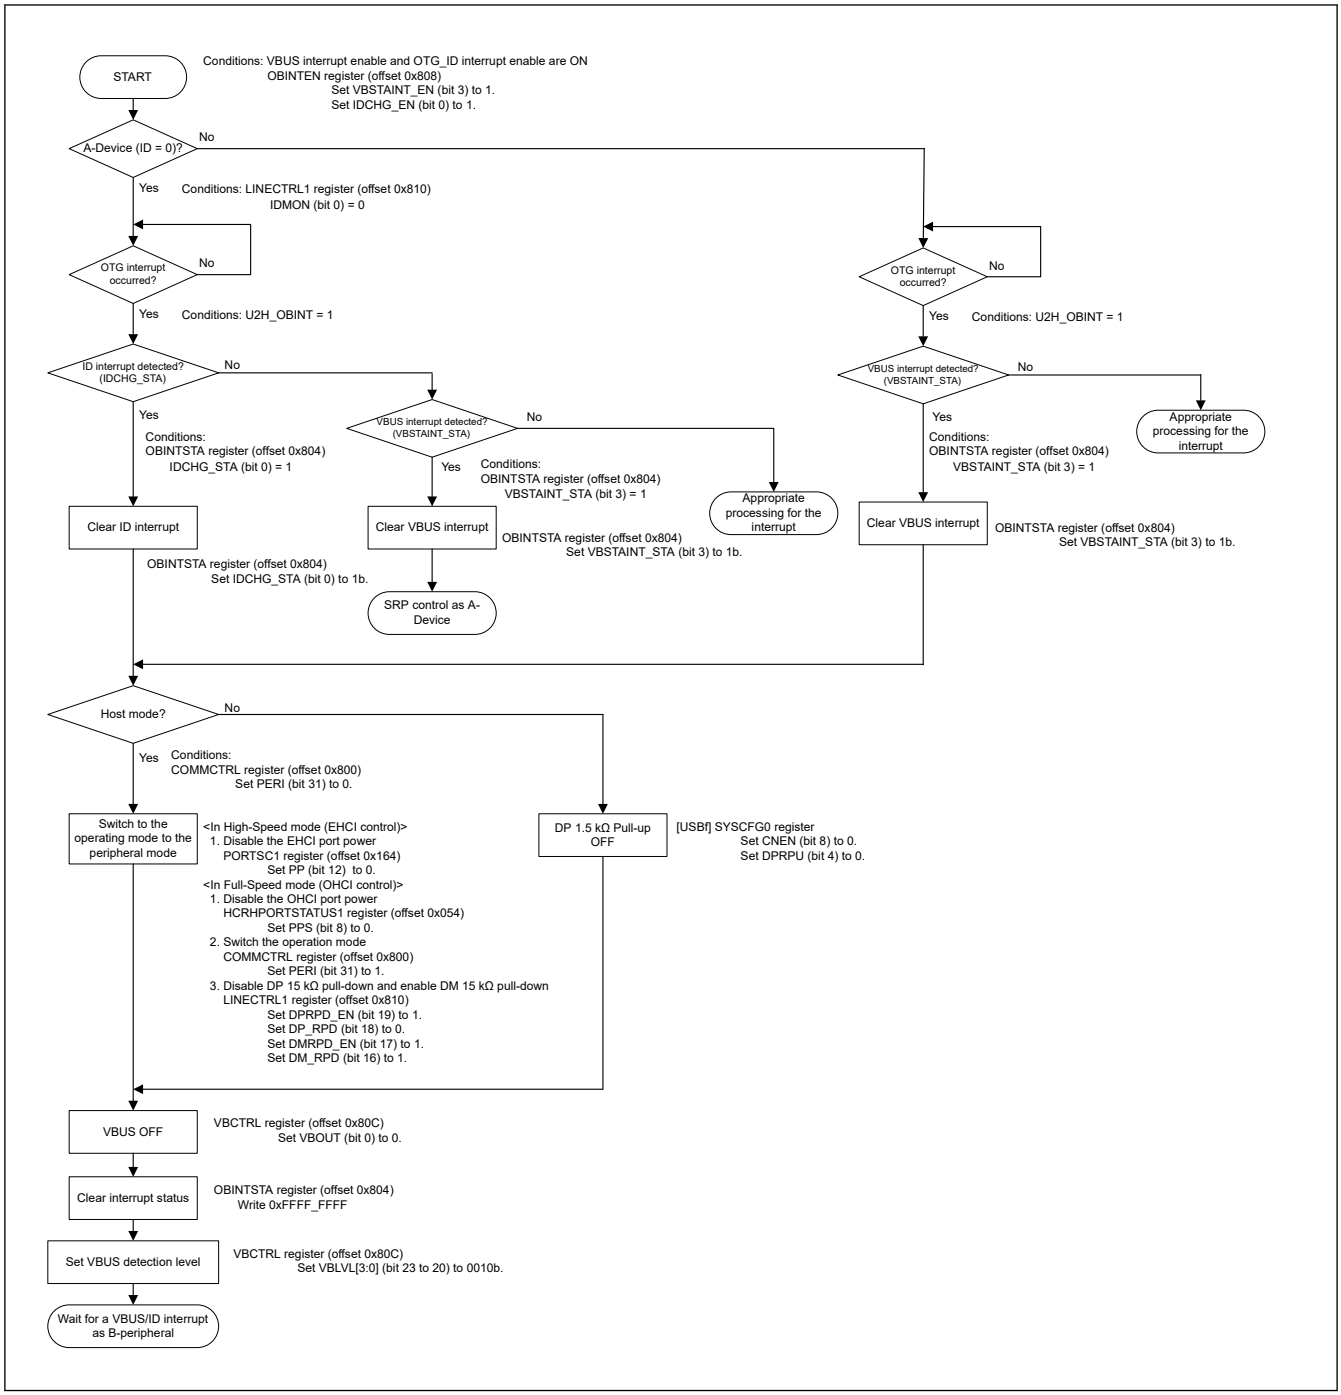

Figure 31.11 Disconnect detection procedure

31.8.6 HNP Control Procedure (Conforming to OTG Revision 2.0)

31.8.6.1 HNP Control Procedure for A-Device (Switching from A-Host to A-Peripheral)

Figure 31.12 shows the control procedure after a request from B-device for the host role is detected from the result of HNP polling for the B-device.

For HNP Control in High-Speed Mode (controlled by EHCI):

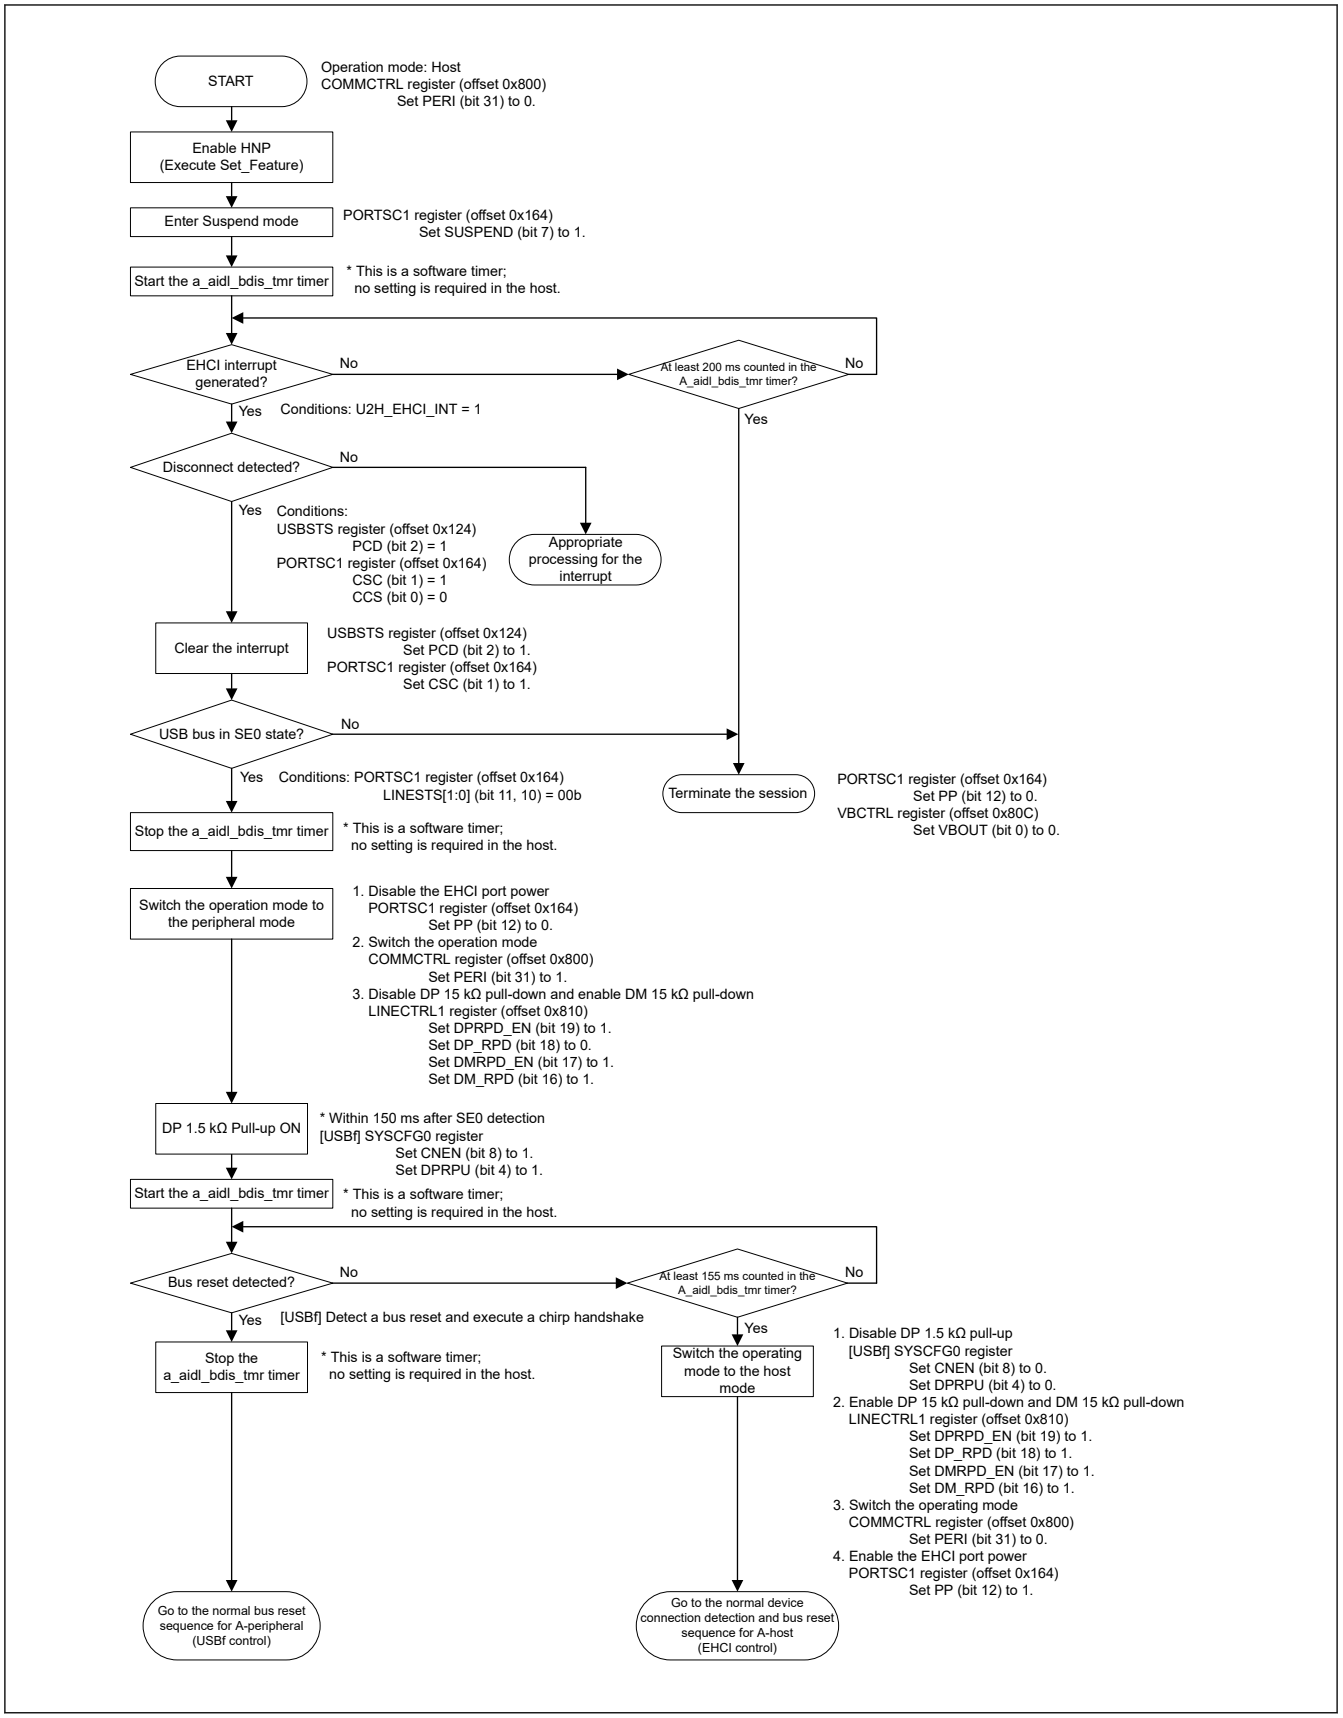

Figure 31.12 HNP control procedure for A-device (switching from A-host to A-peripheral in High-Speed mode)

For HNP control in Full-Speed mode (controlled by OHCI):

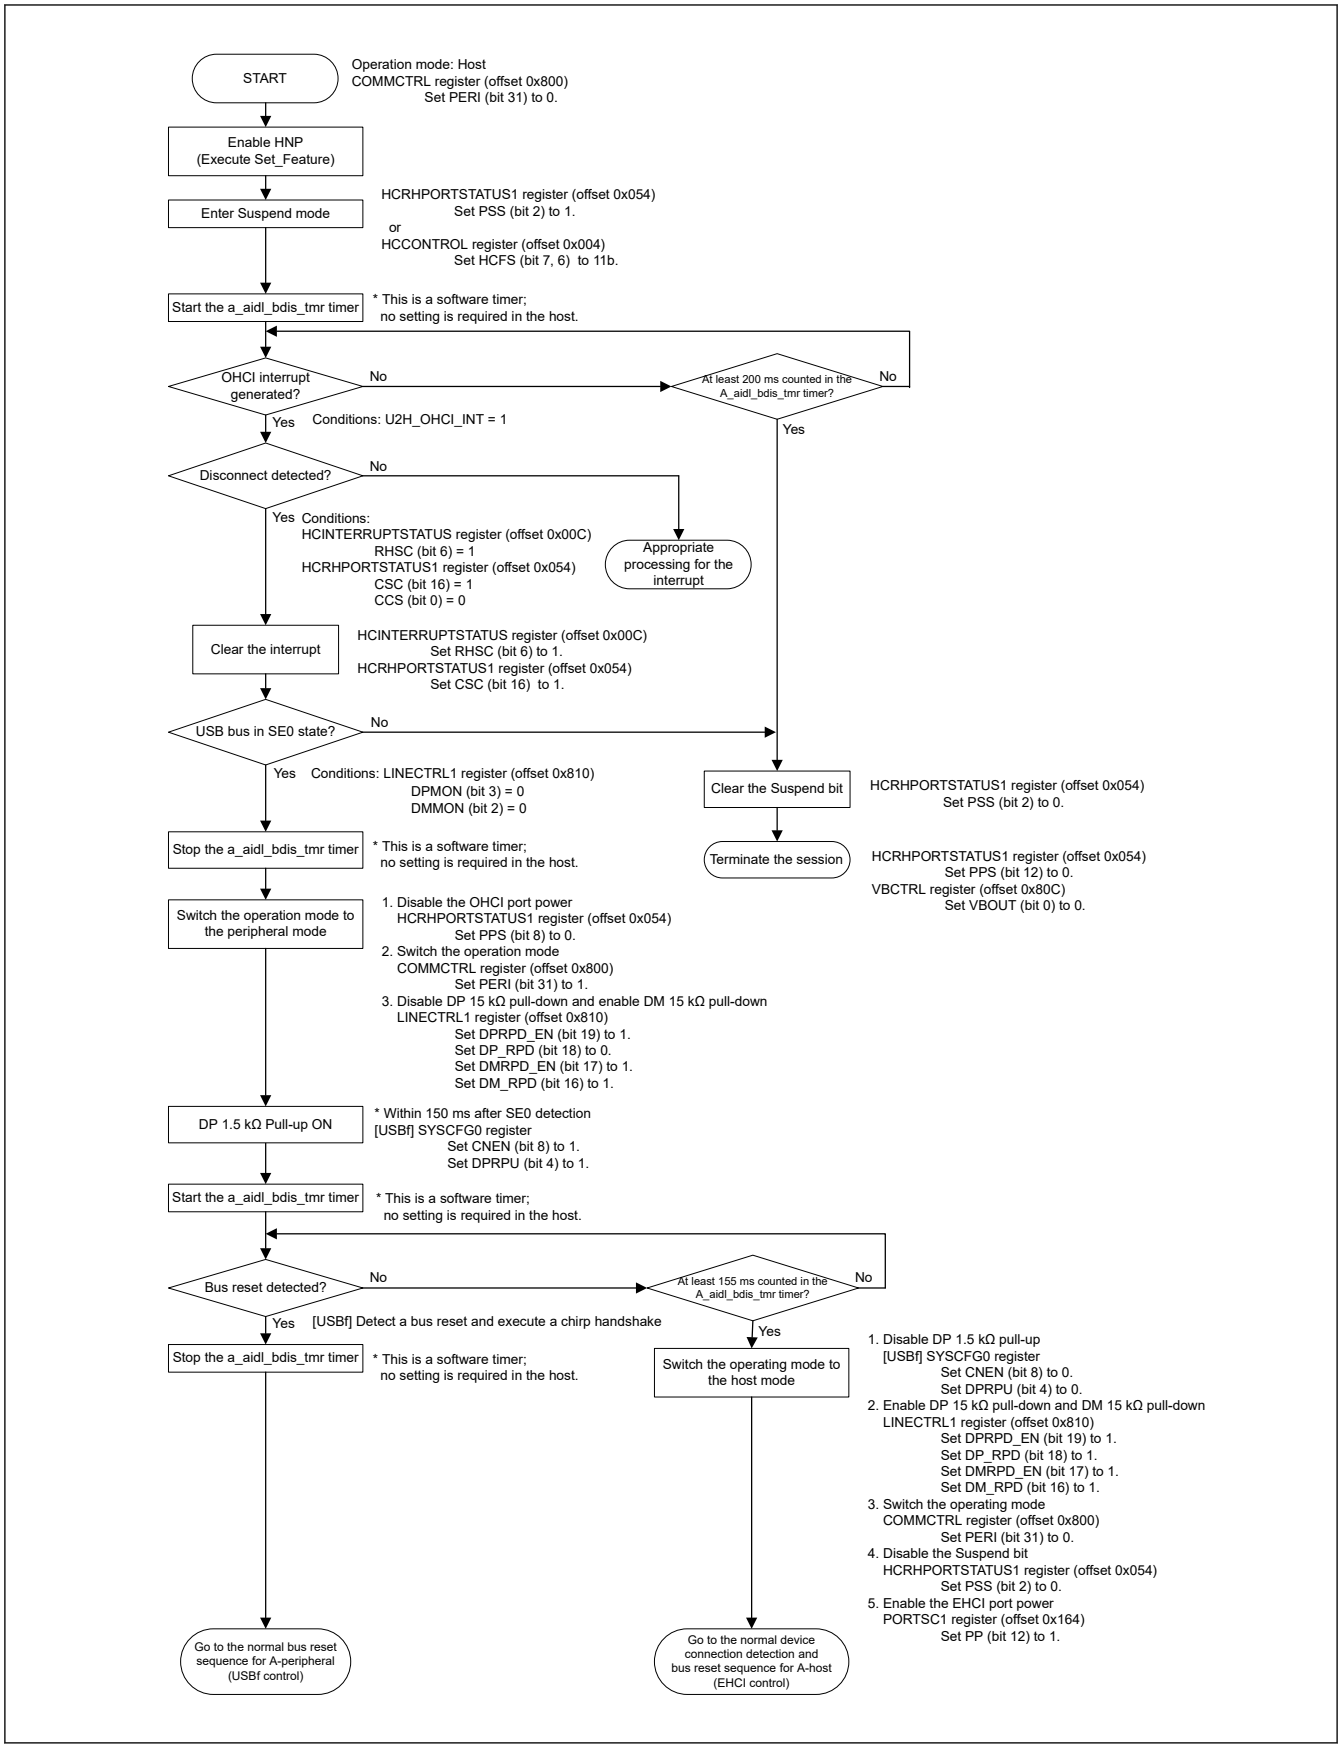

Figure 31.13 HNP control procedure for A-device (switching from A-host to A-peripheral in Full-Speed mode)

31.8.6.2 HNP Control Procedure for A-Device (Switching from A-Peripheral to A-Host)

Assumed conditions:

Even for FS OTG, EHCI is assumed to be the port owner after switching of the role from peripheral to host. Therefore, the procedure for switching from A-peripheral to A-host is not separately provided for each of OHCI and EHCI.

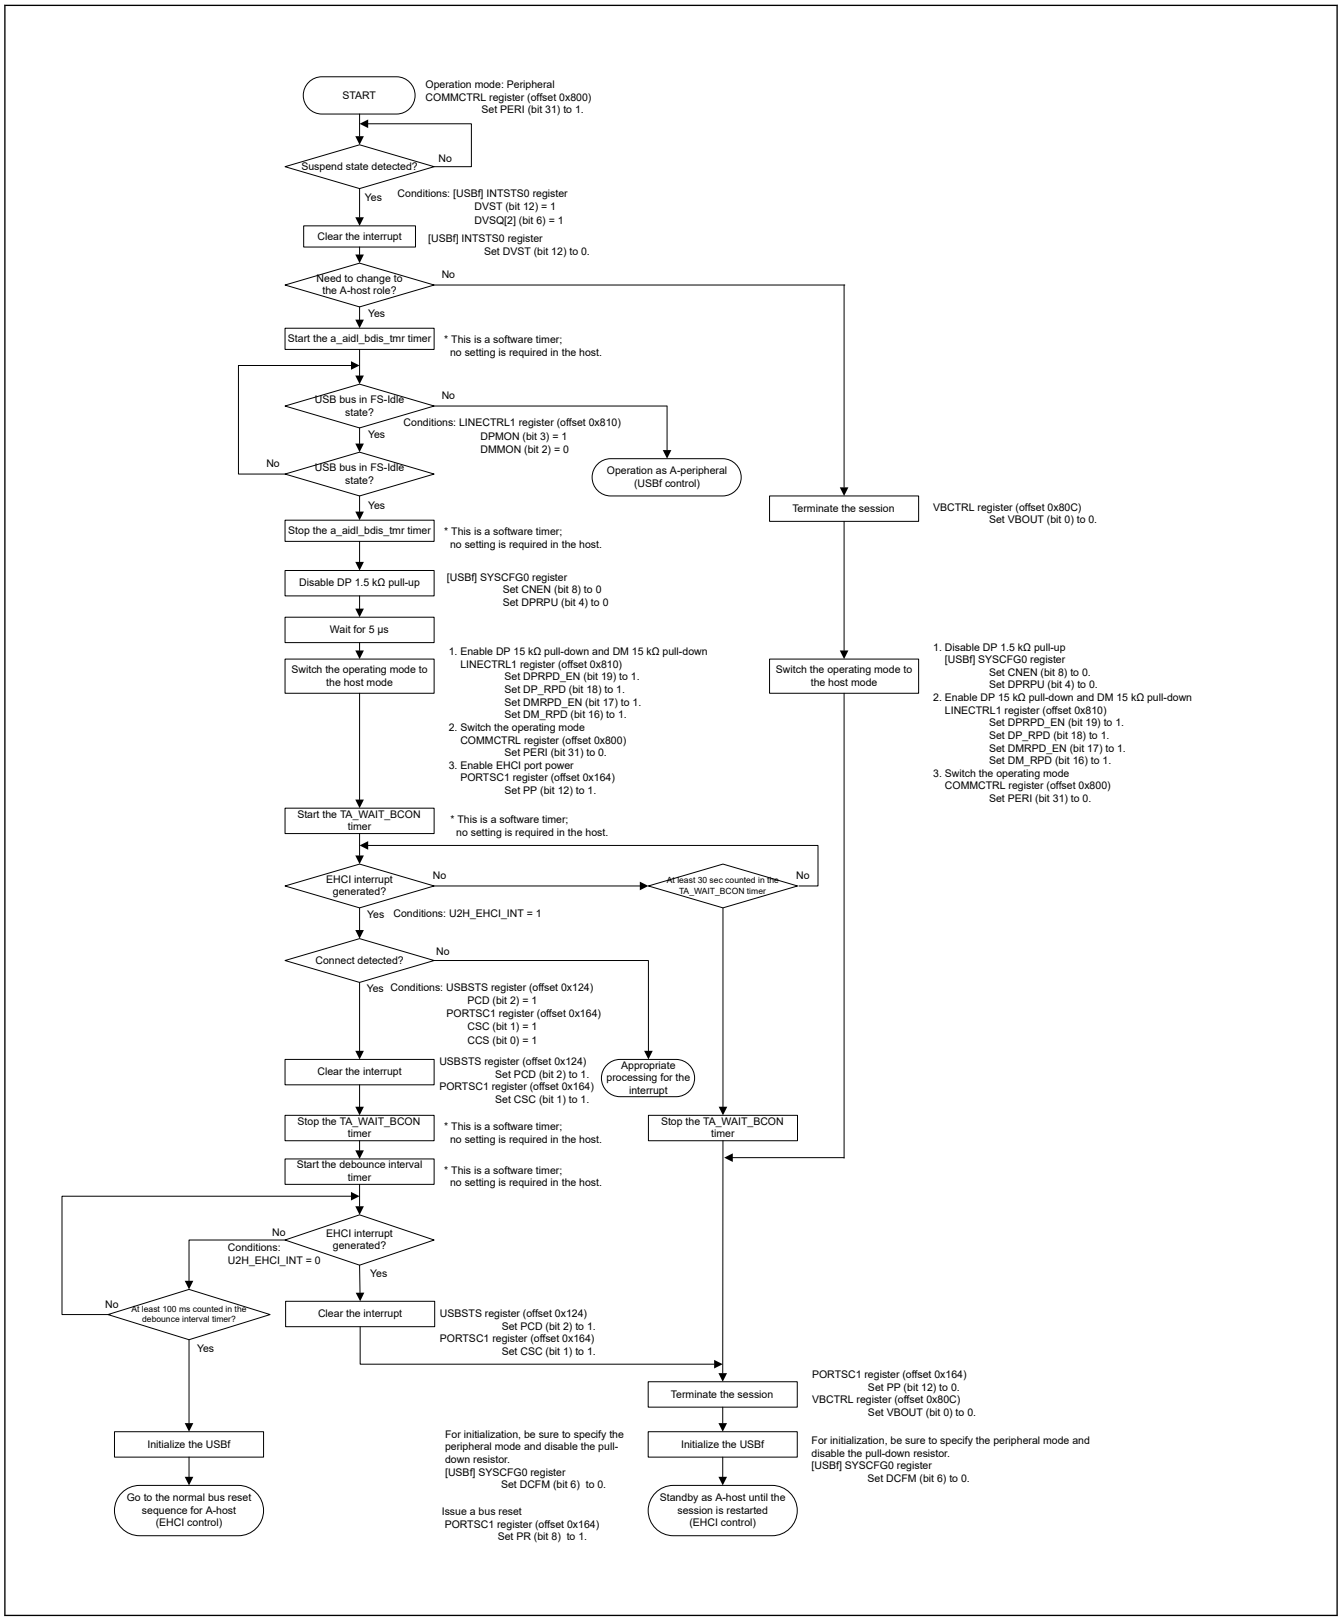

Figure 31.14 HNP control procedure for A-device (switching from A-periperal to A-host)

31.8.6.3 HNP Polling Procedure for A-Device

Figure 31.15 shows the procedure to check whether B-peripheral is requesting the host role when this LSI is an A-host.

For HNP polling in High-Speed mode (controlled by EHCI):

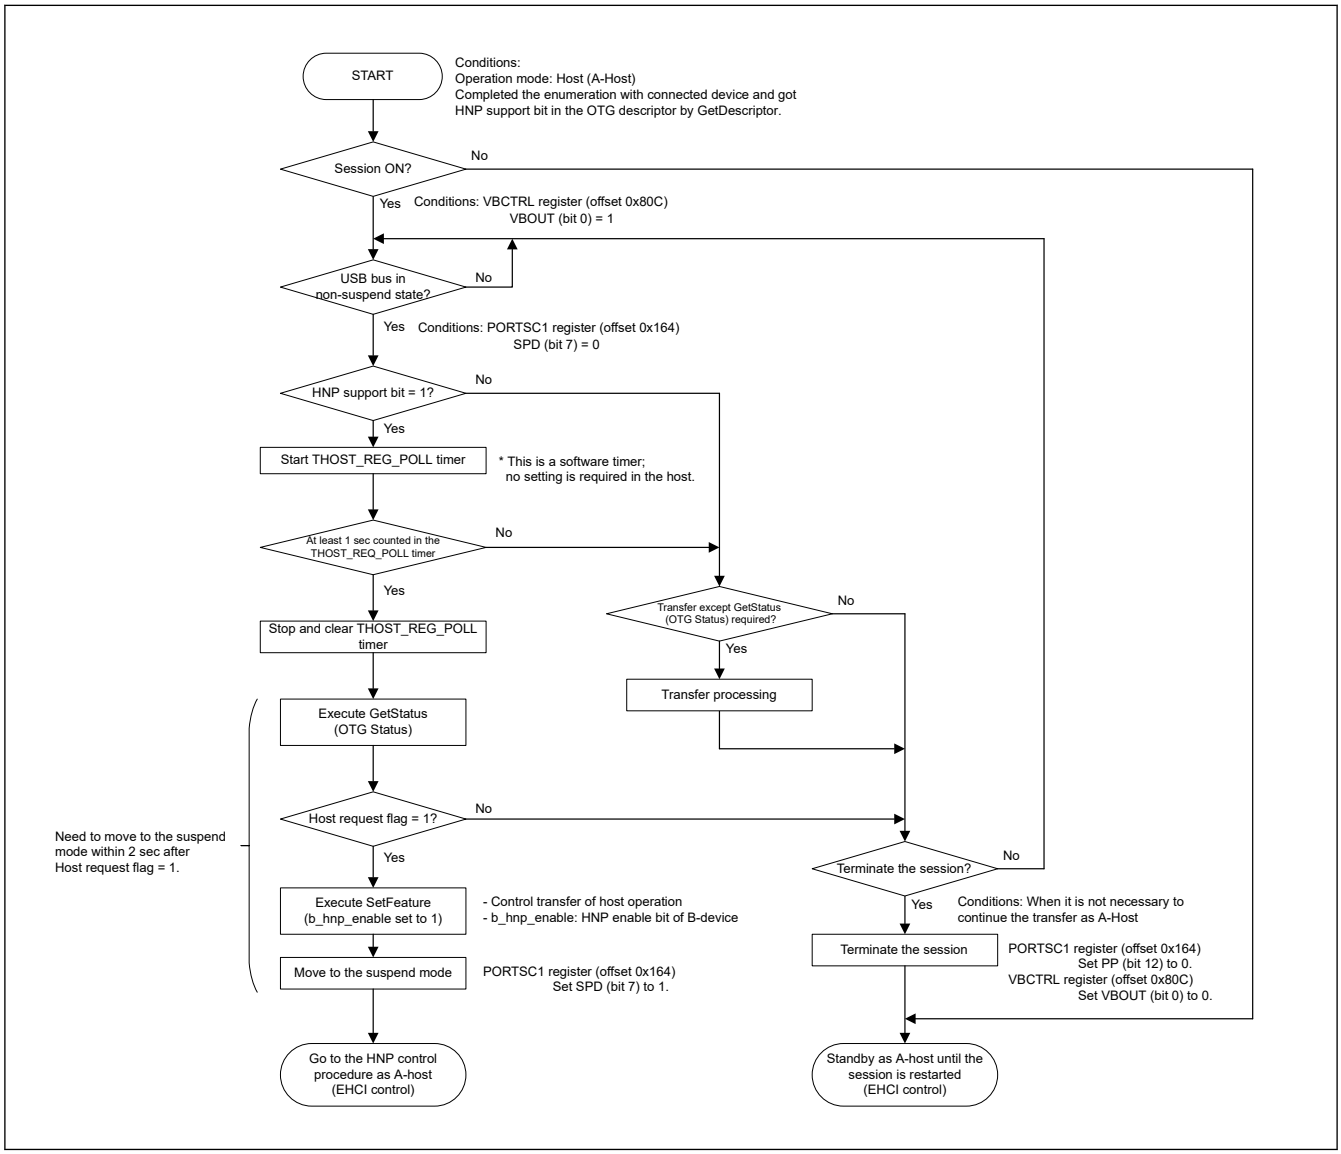

Figure 31.15 HNP polling procedure for A-device

For HNP polling in Full-Speed mode (controlled by OHCI):

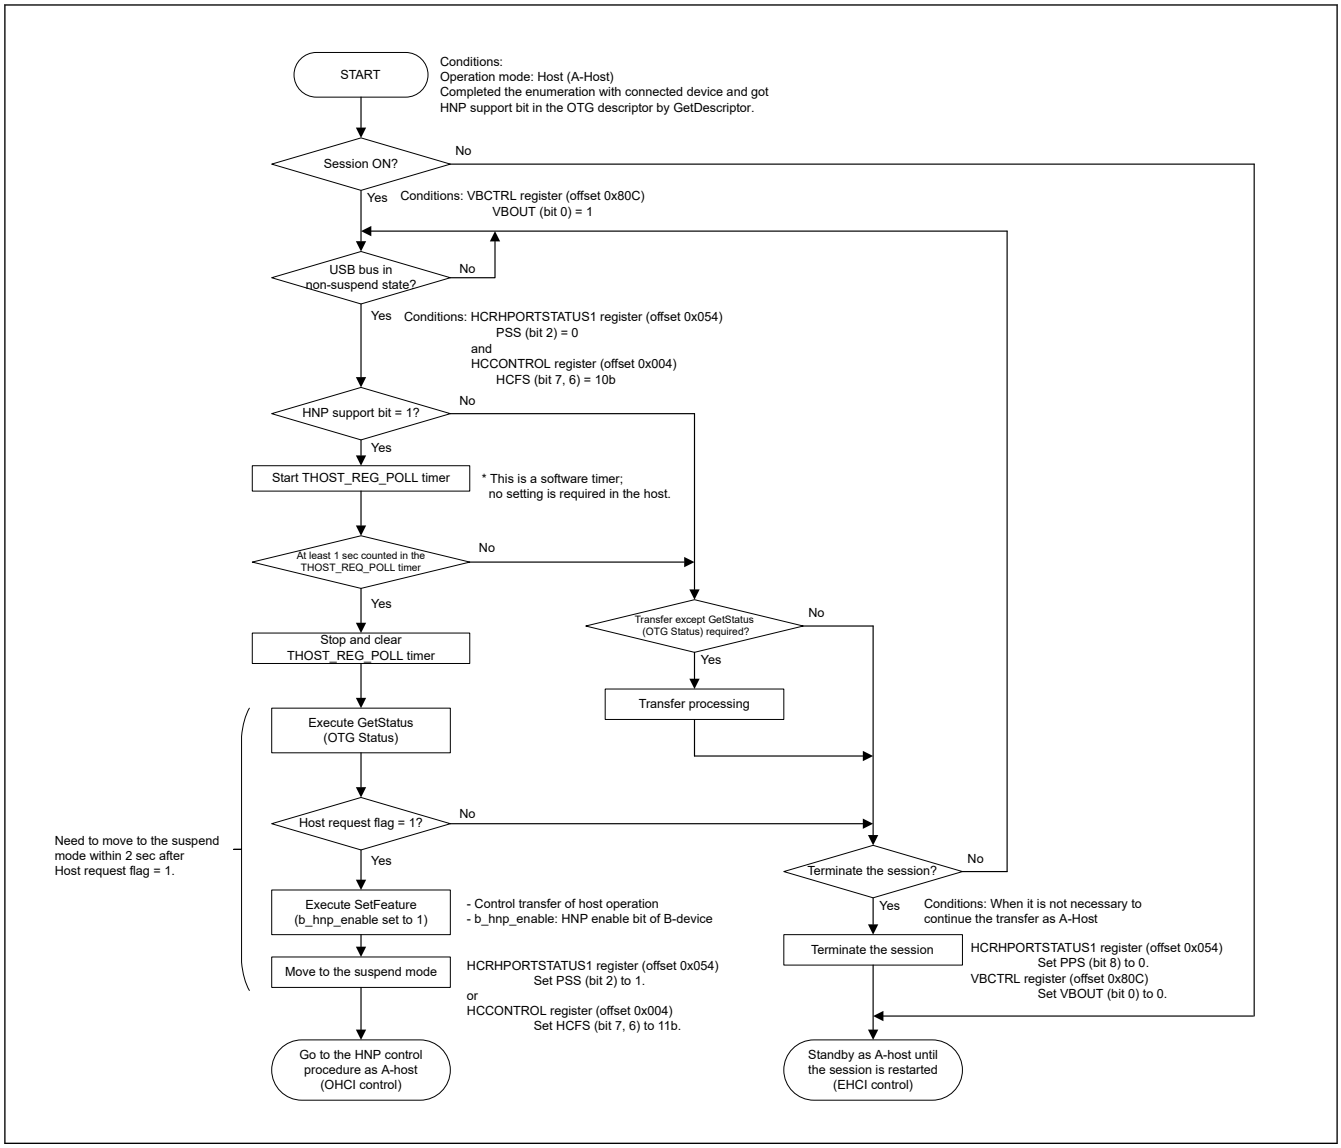

Figure 31.16 HNP polling procedure for A-device

31.8.6.4 HNP Control Procedure for B-Device (Switching from B-Peripheral to B-Host)

Figure 31.17 shows the procedure after the A-device issues set feature.

Assumed conditions:

Even for FS OTG, EHCI is assumed to be the port owner after switching the role from peripheral to host. Therefore, the procedure for switching from the B-peripheral to the B-host is not separately provided for each of OHCI and EHCI.

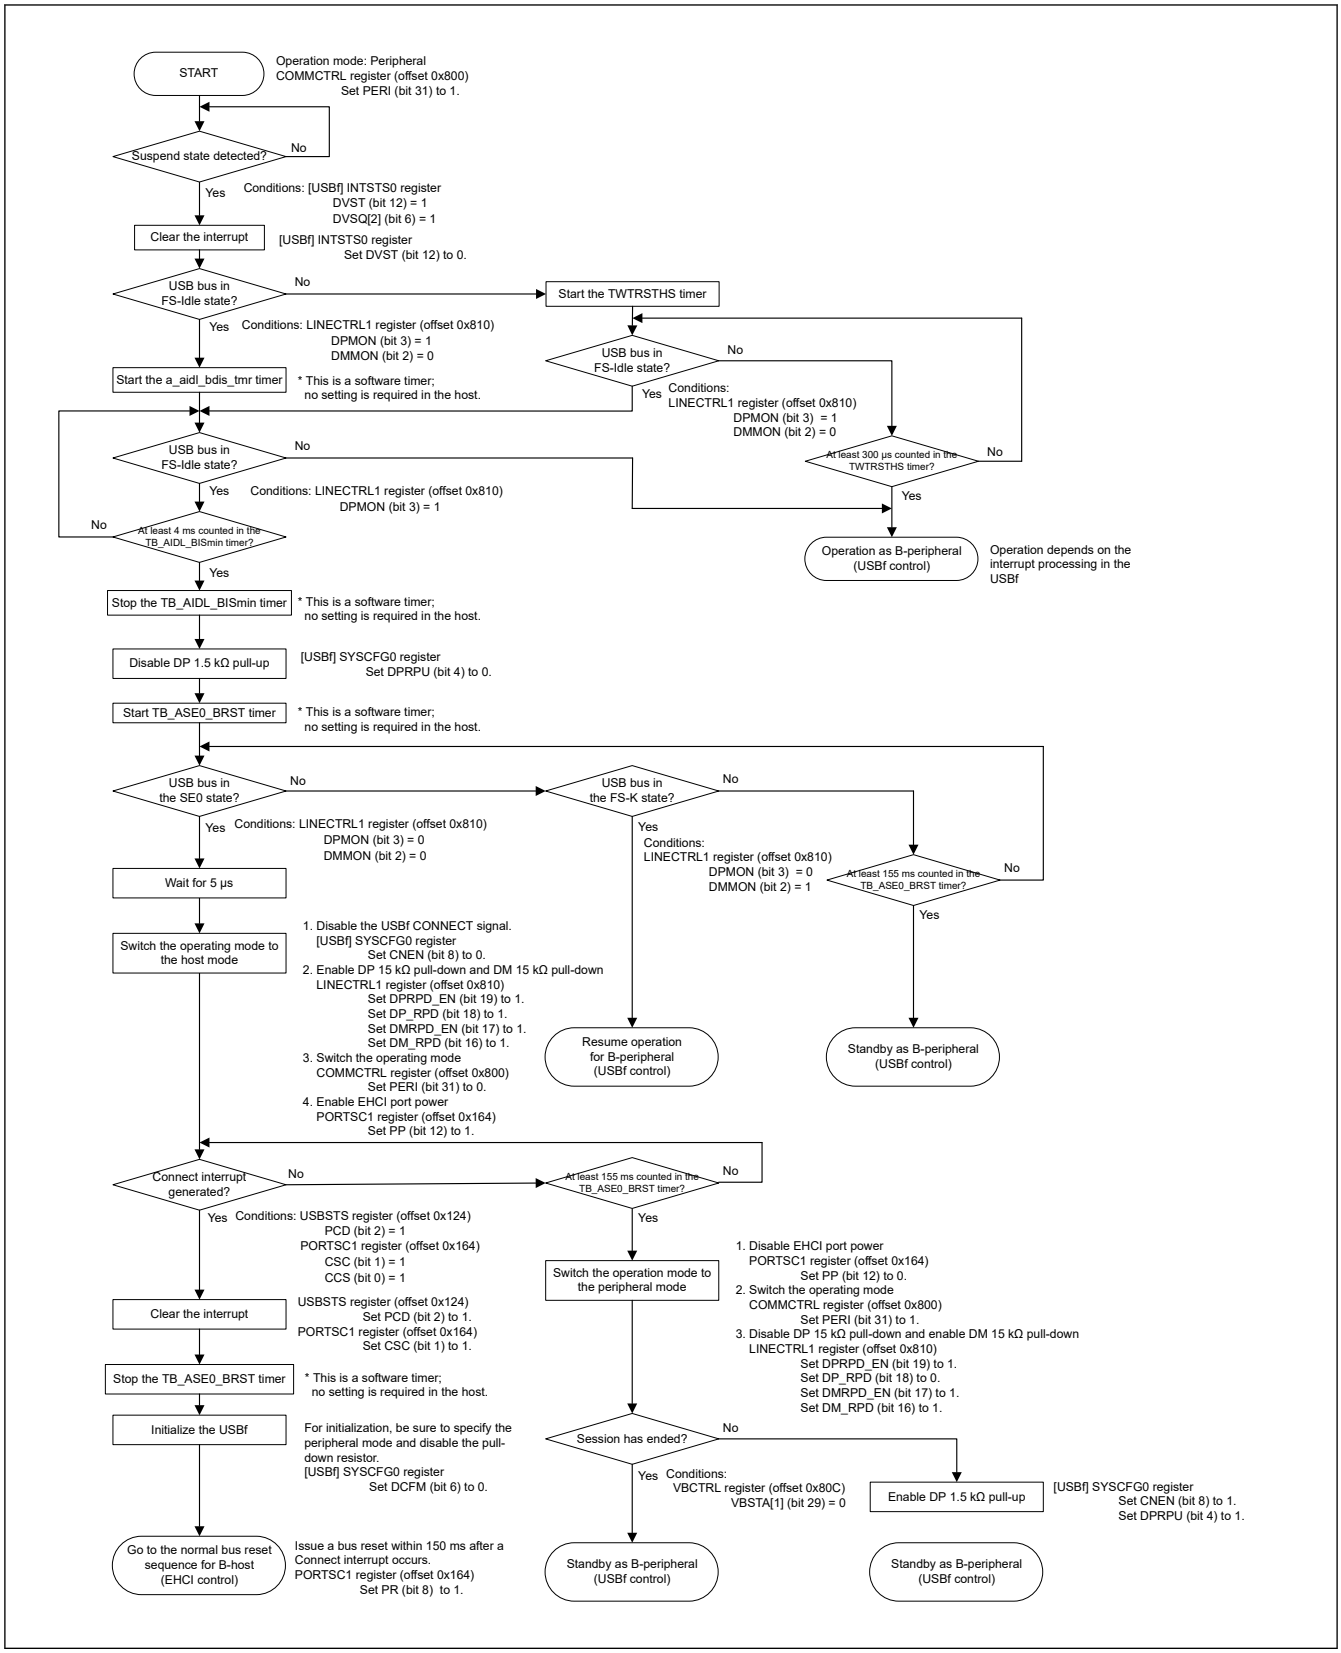

Figure 31.17 HNP control procedure for B-device (switching from B-periperal to B-host)

31.8.6.5 HNP Control Procedure for B-Device (Switching from B-Host to B-Peripheral)

Figure 31.18 shows the procedure after no transfer is performed by the B-host.

Assuming the control of ID and VBUS

VBUS control: VBCTRL.VBOUT

ID detection: Power-supply IC

For HNP control in High-Speed mode (controlled by EHCI):

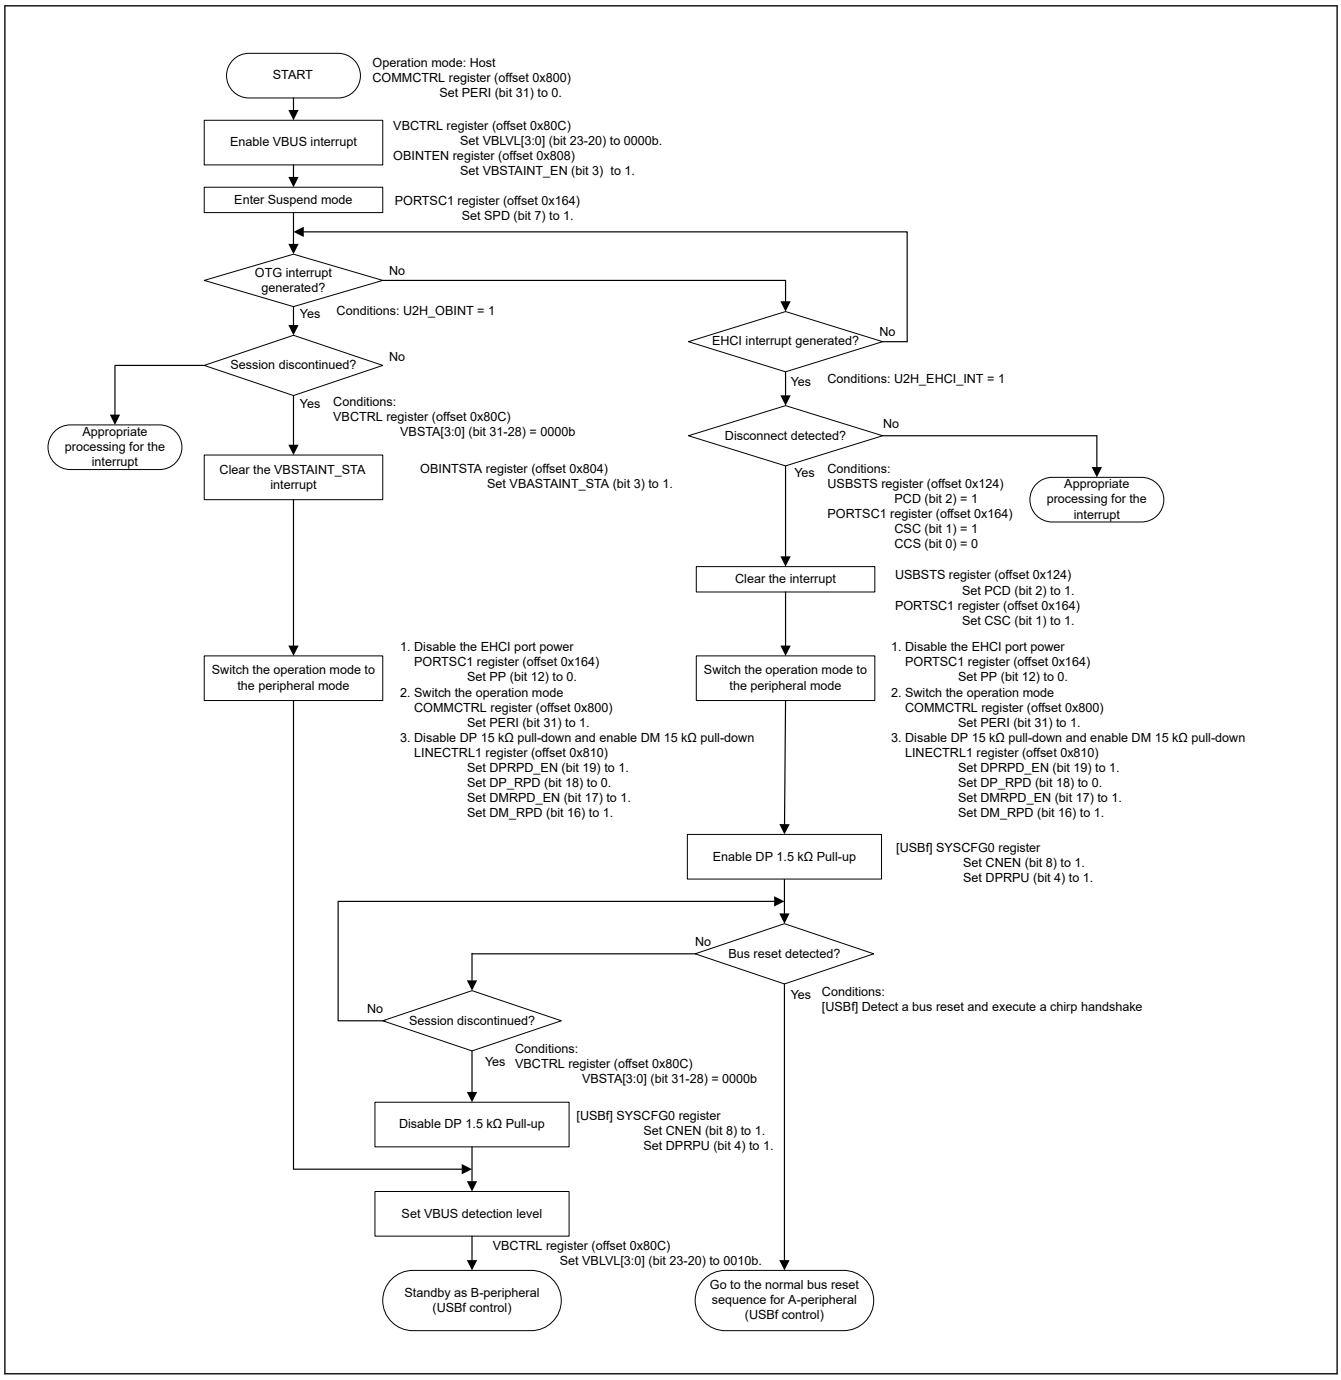

Figure 31.18 HNP control procedure for B-device (switching from B-host to B-peripheral in High-Speed mode)

For HNP control in Full-Speed mode (controlled by OHCI):

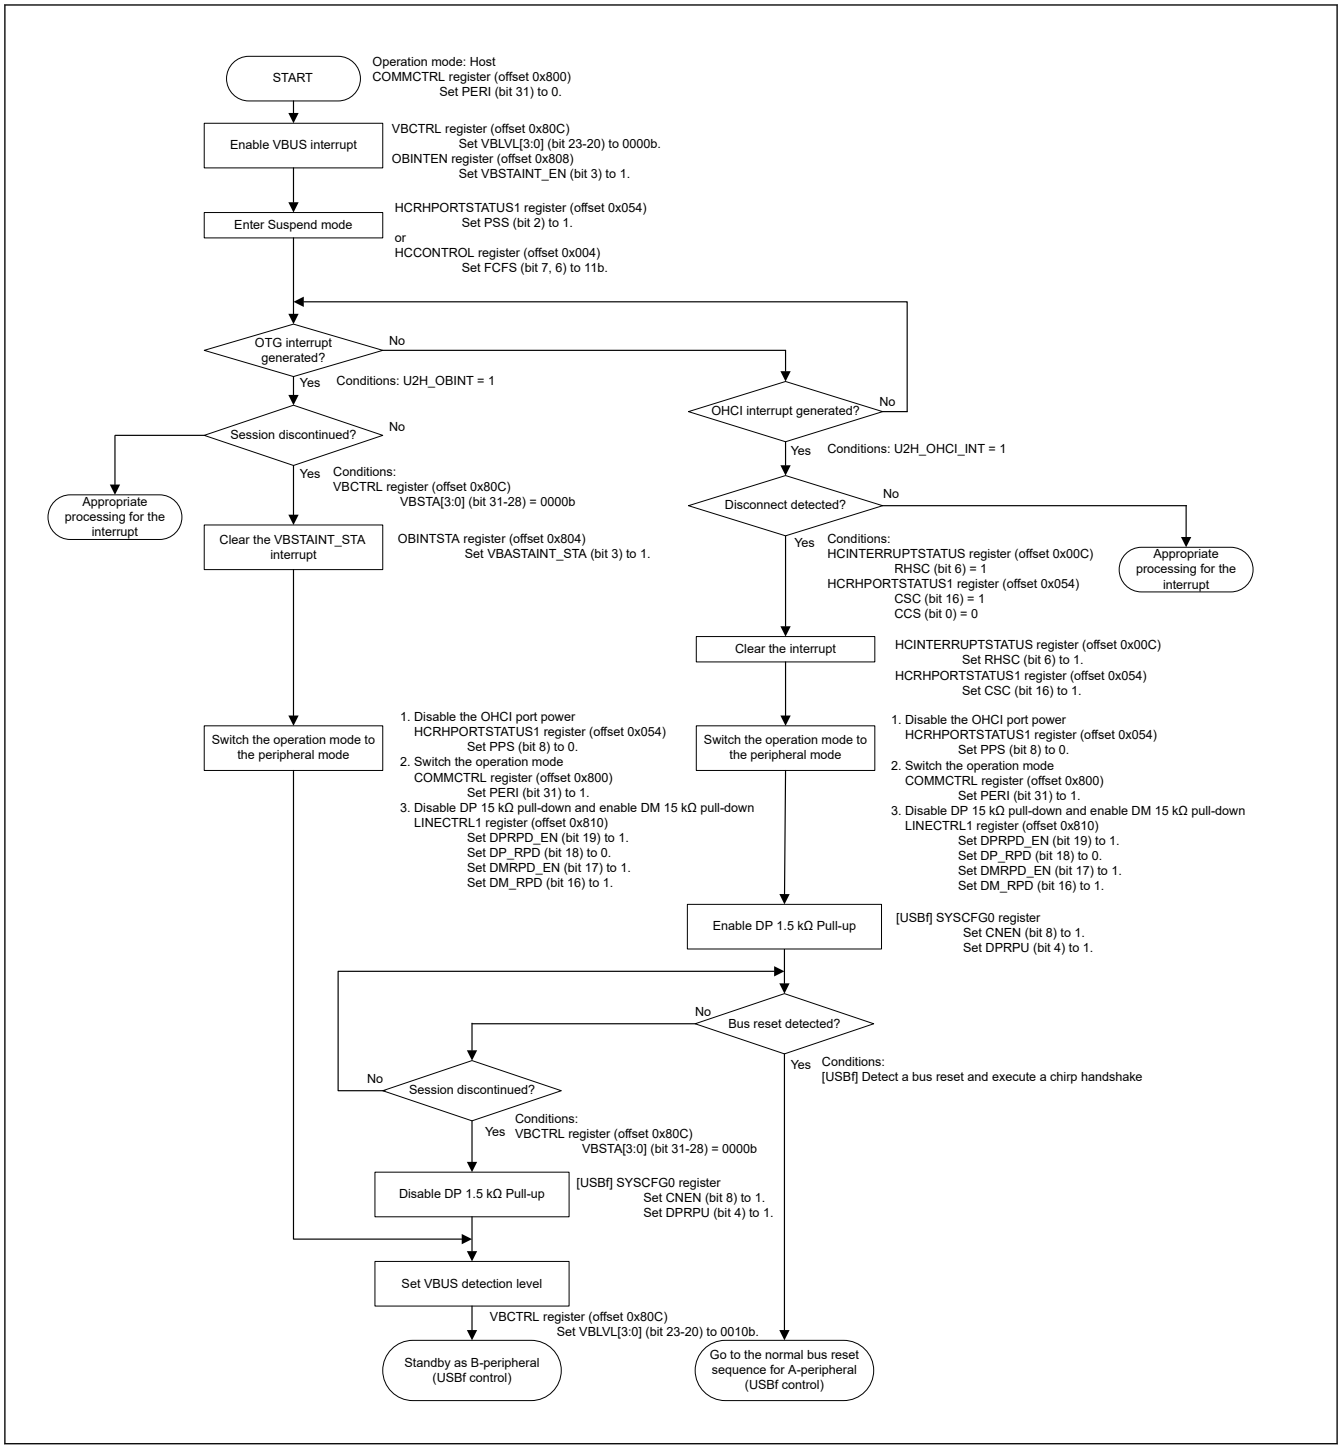

Figure 31.19 HNP control procedure for B-device (switching from B-host to B-peripheral in Full-Speed mode)

31.8.7 SRP Control Procedure (Conforming to OTG Revision 2.0)

31.8.7.1 SRP Control Procedure for A-Device

Figure 31.20 shows the procedure starting with the step for terminating a session because the B-device issues no request for the host role and the A-device does not need to transfer data.

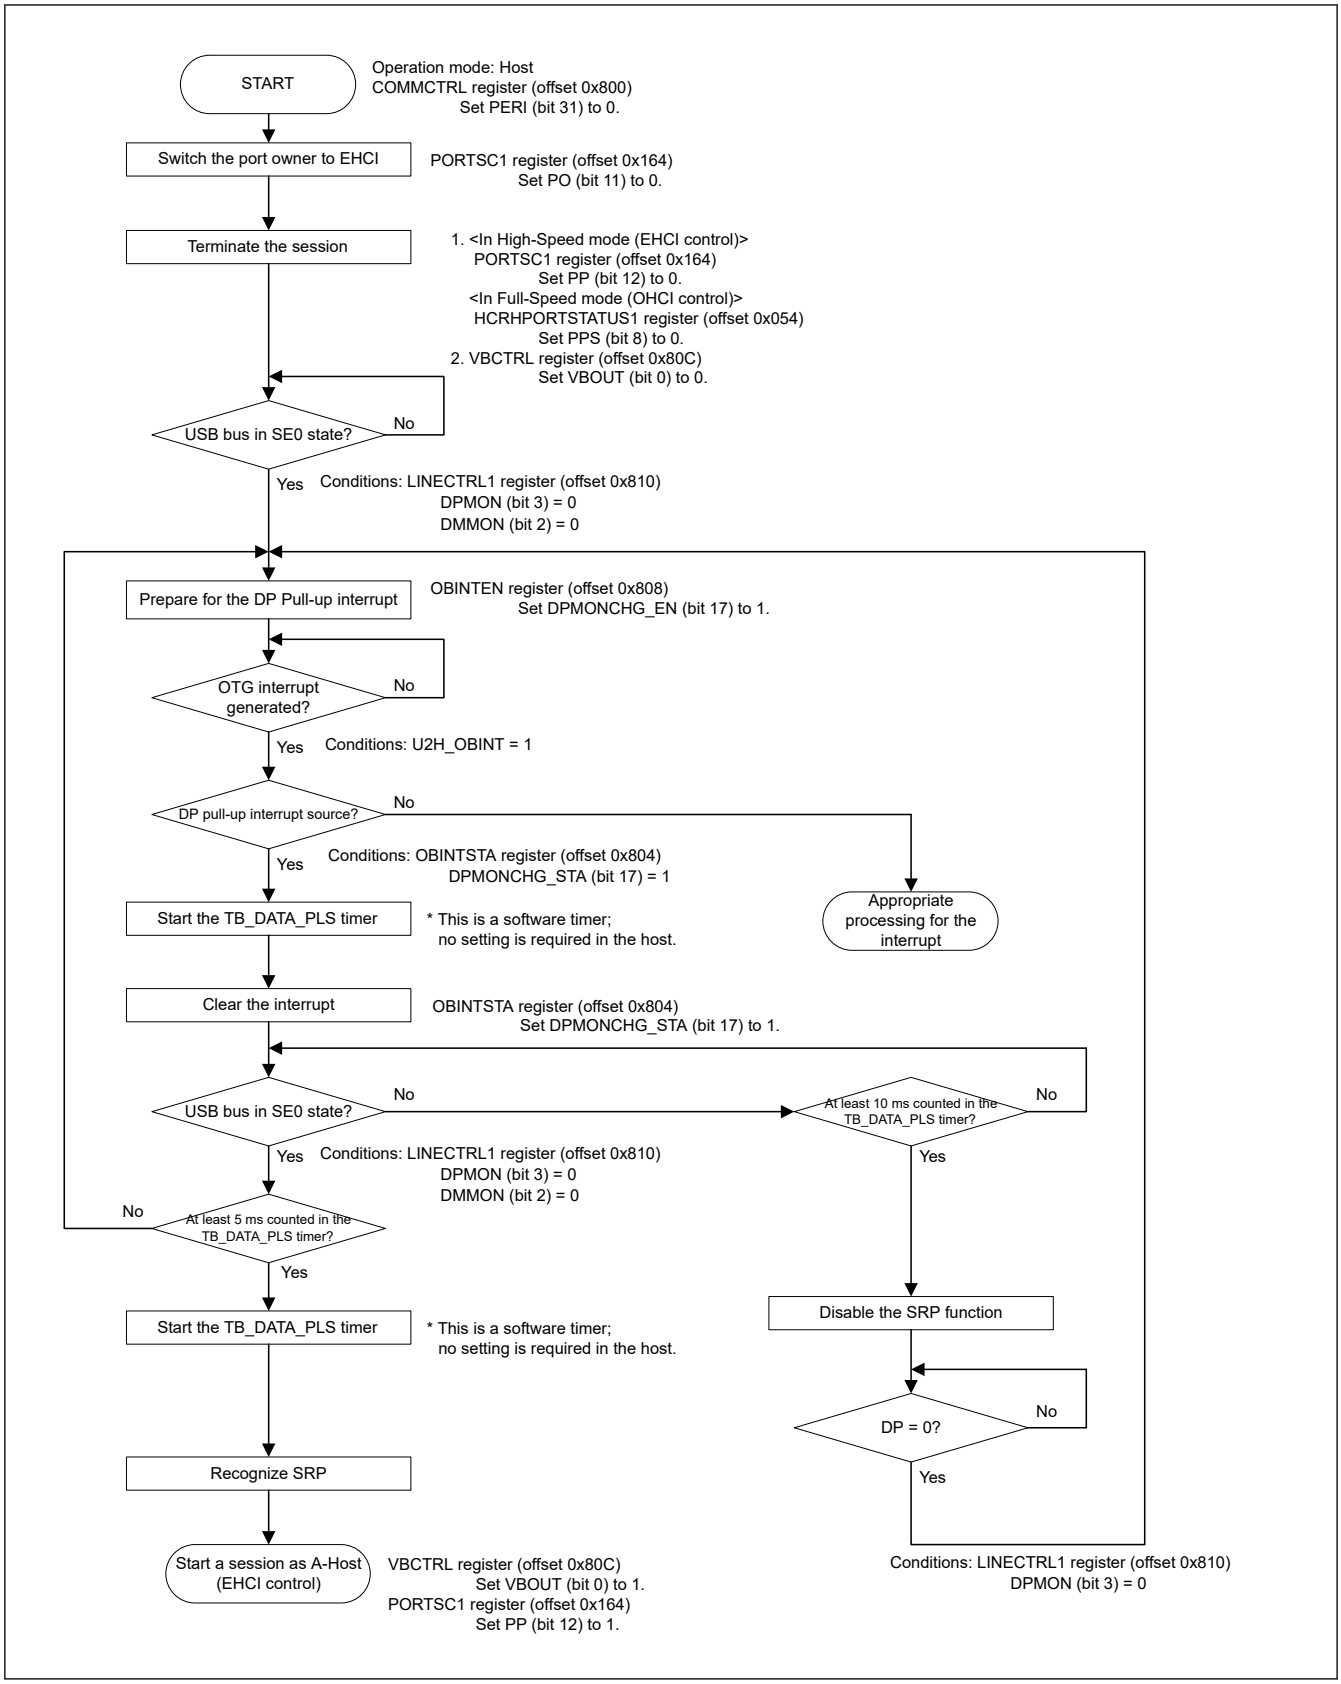

Figure 31.20 SRP control procedure for A-device

31.8.7.2 SRP Control Procedure for B-Device

Figure 31.21 shows the procedure from the standby state for a termination request of a session from the A-device.

Assuming the control of ID and VBUS

VBUS control: VBCTRL.VBOUT

ID detection: Power-supply IC

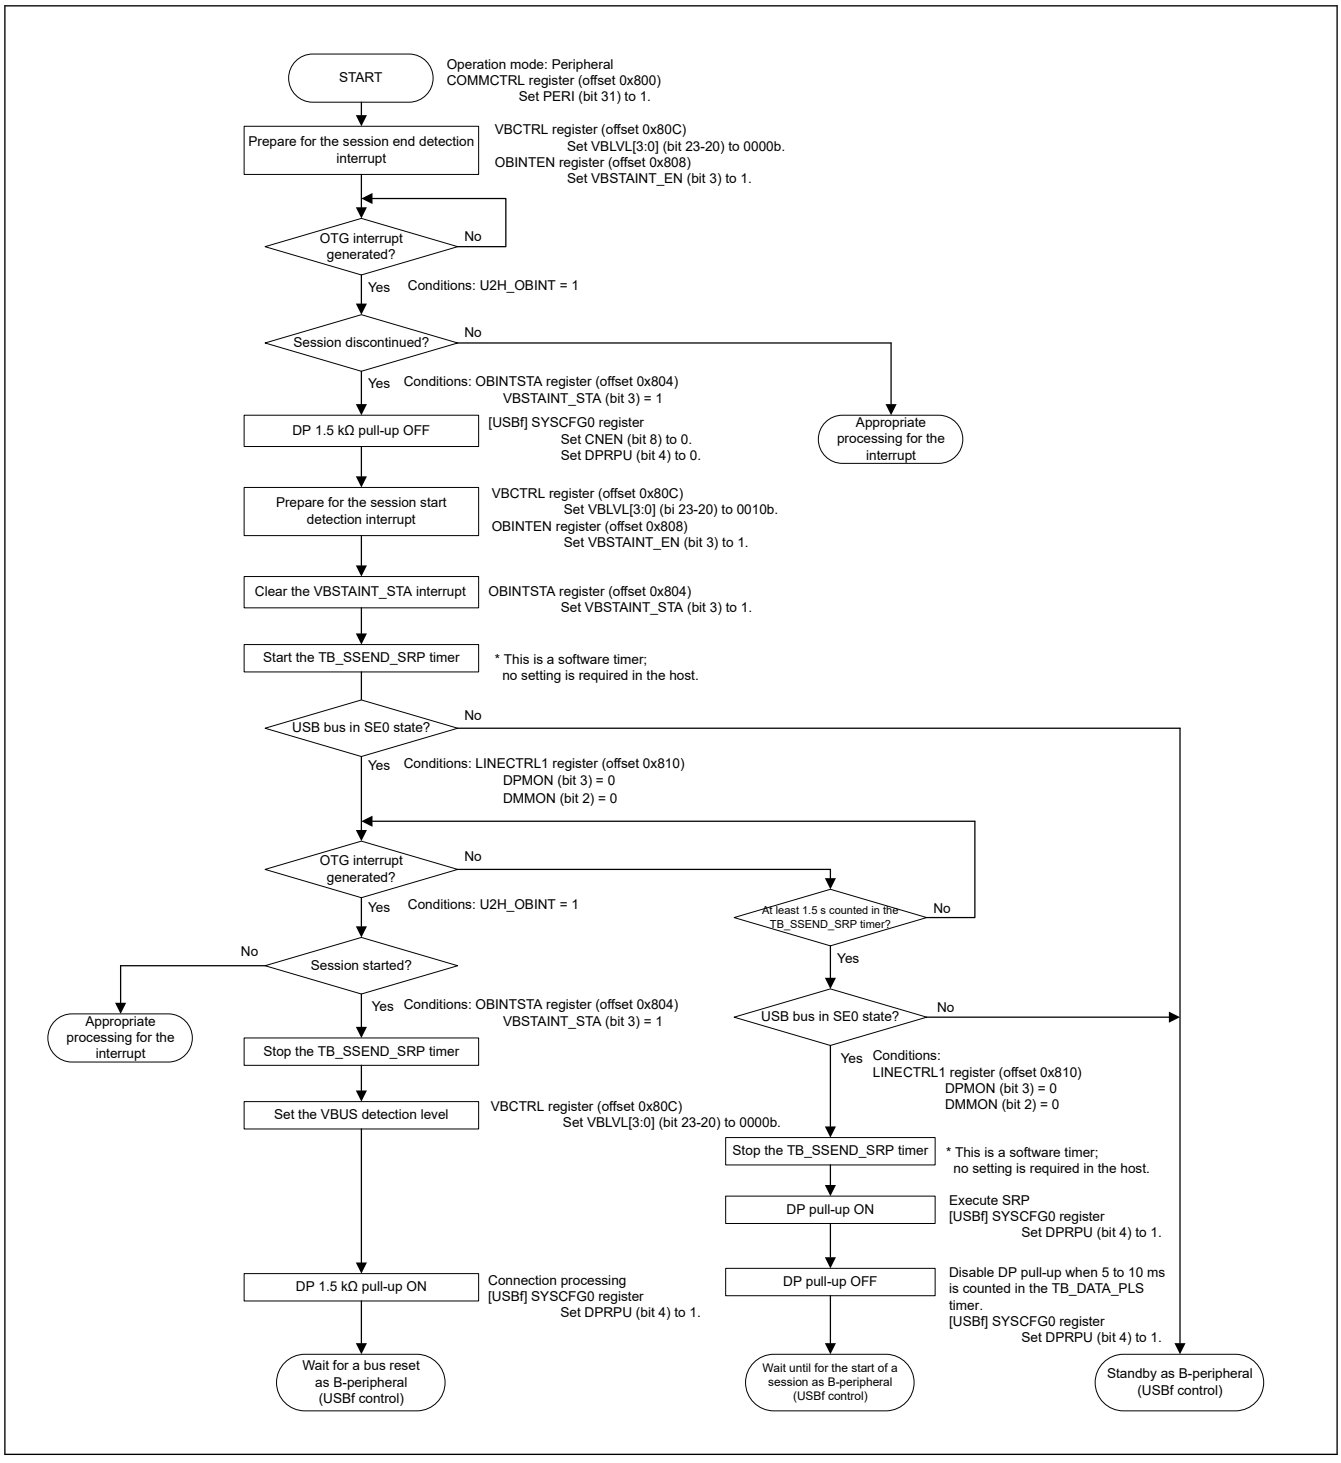

Figure 31.21 SRP control procedure for B-device

32. USB 2.0 HS Function Module (USBf)

32.1 Overview

The USB module of this LSI is a dual-role device that has USB 2.0 host and function modules.

This LSI has a single USB port for two functions for host and function. These functions can be switched by the common control register (COMMCTRL).

Since operation as a host controller or a function controller are exclusive of each other, dynamic switching between the types of operation is not possible.

This section describes function controller operation.

The USBf module supports high-speed transfer and full-speed transfer defined by the USB 2.0 specification.

This LSI supports all transfer types that are defined in the USB specification. It incorporates an 8 KB buffer memory for data transfer and can use up to 10 pipes. Pipes 1 to 9 can be assigned an arbitrary endpoint number according to the user system.

Table 32.1 Specifications of the USB Module

Item	Description
For High-Speed USB	• Built-in USB function controller
For all types of USB transfer	• Support for all types of USB transfer: – Control transfer – Bulk transfer – Interrupt transfer (high-bandwidth transfers not supported) – Isochronous transfer (high-bandwidth transfers not supported)
Bus interface	• Two DMA interfaces available – The dedicated AHB master interface for each DMA channel • High-speed data transfer for access to the internal FIFOs at 60 MB/second (when the bus width is 32 bits)
Pipe configuration	• 8 KB of buffer memory for USB communications • Up to 10 pipes can be selected (including the default control pipe) • Programmable pipe configuration • Any endpoint number can be assigned to pipes 1 to 9 • Transfer conditions that can be set for each pipe are listed below. Pipe 0: Control transfer, single buffer fixed at 64 bytes Pipes 1 and 2: Bulk transfer or isochronous transfer can be selected, continuous transfer mode, programmable buffer size (specifiable as up to 2 KB, double buffer is also specifiable) Pipes 3 to 5: Bulk transfer, continuous transfer mode, programmable buffer size (specifiable as up to 2 KB, double buffer is also specifiable) Pipes 6 to 9: Interrupt transfer, single buffer fixed at 64 bytes
Features of function controller operation	• High-speed (480 Mbps) and full-speed transfer (12 Mbps) are supported • Automatic recognition of high-speed operation or full-speed operation based on automatic response to the reset handshake • Control transfer stage monitoring • Monitoring of device state • Automatic response to SET_ADDRESS requests • NAK response interrupt function (NRDY) • SOF interpolation
Other functions	• Judging the end of transfer on the basis of a transaction count • Adjustable timing for BRDY interrupt event notification (BFRE) • Automatic clearing of the buffer memory after the data for the pipe specified in the DxFIFO port has been read (DCLRM) • NAK setting for response PID generated by end of transfer (SHTNAK)

Figure 32.1 is a block diagram of the USB module.

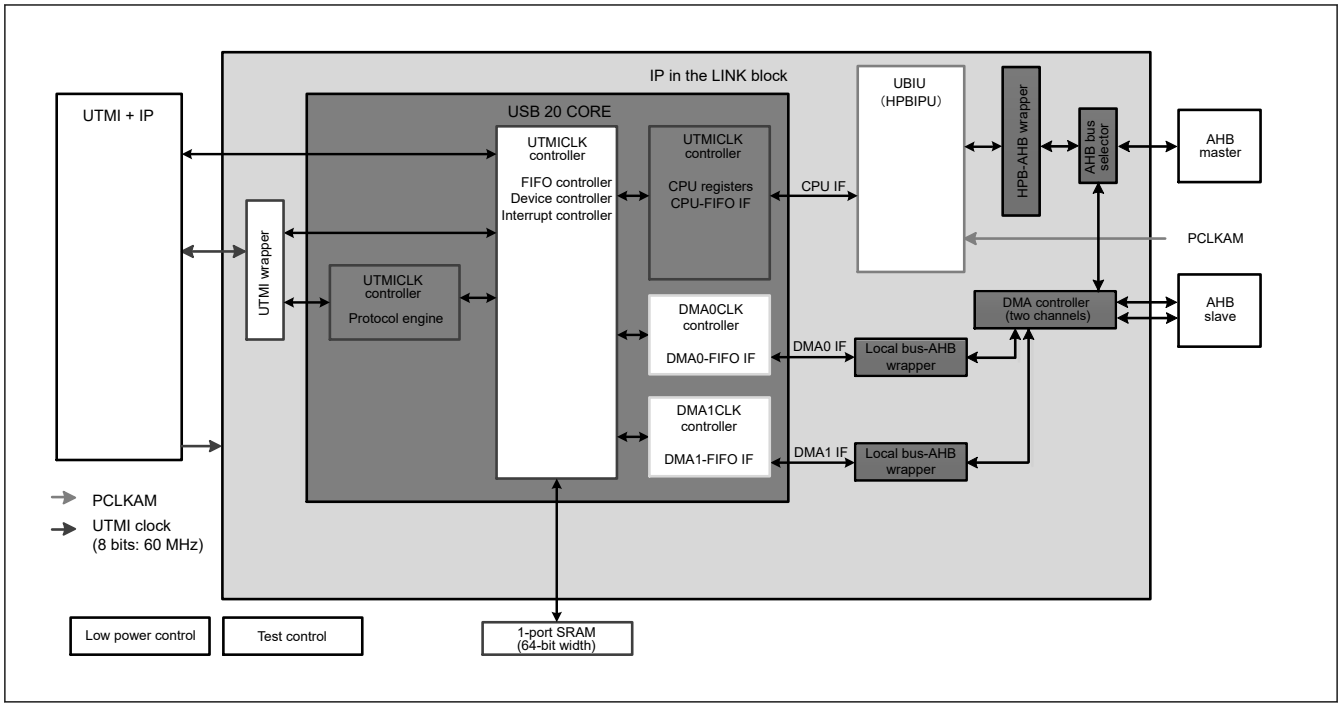

Figure 32.1 Block diagram of the USB module

Data transfer between this controller and the host controller connected to the USB bus uses buffer memory assigned to each pipe. For communication between this controller and the host controller, this controller converts the data stored in buffer memory into USB data packets and outputs them to the USB bus serially, and also inputs data packets from the USB bus and stores them in buffer memory.

32.1.1 Identification of the USB Transfer Speed

The hardware can automatically identify the USB transfer speed.

32.1.2 Bus Interface

(1) How to access the FIFO buffer memory

The following two types of access are available for the FIFO buffer memory for USB data transfers. To read from or write to the FIFO buffer memory, access (read or write) the FIFO ports from the CPU (DMAC).

Two channels of DMAC are provided.

1. CPU access
   Specify a FIFO port address and write data to the FIFO buffer memory or read data from the FIFO buffer memory.
2. DMA access
   Specify the dedicated DMAC and write data to the FIFO buffer memory or read data from the FIFO buffer memory.

USB data transfer is done in little endian. The byte endian swap function is available for FIFO port access; for 16 bit or 32 bit access, the endian can be switched through register settings.

32.1.3 USB Event

This controller sends an interrupt to the ICU to notify an event in USB operation.

Sending interrupts for notification can be enabled or disabled separately for each interrupt type and source through software settings.

32.1.4 USB Data Transfer

This controller performs all types of USB data transfer: control transfer, bulk transfer, interrupt transfer, and isochronous transfer. The following numbers of pipes are available for each transfer type.

- One pipe dedicated to control transfer
- Four pipes dedicated to interrupt transfer
- Three pipes dedicated to bulk transfer
- Two pipes selectively used for bulk transfer or isochronous transfer

Each pipe should be set up as necessary for the desired USB transfer in accordance with the user system; for example, transfer type, endpoint number, or maximum packet size.

This controller has an 8 KB buffer memory. For pipes dedicated for bulk transfer or selective pipes for bulk transfer or isochronous transfer, buffer memory assignment, buffer operating mode setting, or other necessary settings should be made in accordance with the user system. By setting the buffer operating mode, such as double buffer structure or continuous data packet transfer mode, fast data transfer is achieved with fewer interrupts.

CPU and DMA controller access to the buffer memory is made through three FIFO port registers.

32.1.5 DMA Transfer

This controller provides two channels of the DMA interface having the following functions.

- DMA transaction mode: Fetching in both register and link modes are supported
- Transfer size: A transfer size from 1 to 128 bytes can be selected separately for the transfer source and transfer destination
- Skip (scatter/gather) function: The access size and skip size can be specified separately for the transfer source and destination
- Suspend function: A running DMA transaction can be suspended temporarily
- Interval function: The interval of DMA transfers can be specified to control the bus occupancy

32.3 Register Descriptions

32.3.1 System Configuration Control

32.3.1.1 SYSCFG0 : System Configuration Control Register 0

Base address: USBF = 0x9204_1000

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CNEN	HSE	—	DRPD	DPRPU	—	—	—	USBE
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

Bit	Symbol	Function	R/W
0	USBE	USB Block Operation Enable Enables or disables operation of the USB block. 0: USB block operation is disabled. 1: USB block operation is enabled.	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	DPRPU	D+ Line Resistor Control Enables or disables pulling up the D+ line in function controller operation. 0: Pulling up the line is disabled. 1: Pulling up the line is enabled.	R/W
5	DRPD	D+/D− Line Resistor Control Always set 0 at initialization.	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	HSE	High-Speed Operation Enable Enables or disables high-speed operation. 0: High-speed operation is disabled (full-speed). 1: High-speed operation is enabled (the controller detects the communication speed)	R/W
8	CNEN	Single-End Receiver Operation Enable Enables or disables the single-end receiver to operate. 0: Single-end receiver operation is disabled. 1: Single-end receiver operation is enabled.	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

Writing to this register is possible even while the UTMI clock (output of the clock signal from the PLL in the USB) is stopped. Note however that any values that are set while the UTMI clock is stopped are reflected after oscillation of the UTMI clock is restarted.

USBE bit (USB Block Operation Enable)

The setting of the USBE bit enables or disables operation of the USB block.

When the USBE bit is modified from 1 to 0, this controller initializes the bits listed in Table 32.4.

Table 32.4 Registers initialized by writing USBE = 0

Register Name	Bit Name
SYSSTS0	LNST
DVSTCTR0	RHST
INTSTS0	DVSQ
USBADDR	USBADDR
USBREQ	bRequest bmRequestType
USBVAL	wValue
USBINDX	wIndex
USBLENG	wLength

The value of this bit must be changed when SUSPM = 1 and after the UTMI clock oscillation is started.

DRPD and DPRPU bit (D+/D− Line Resistor Control)

Settings related to USB data bus resistance are given in Table 32.5, USB Data Bus Resistance Control. Use the DRPD and DPRPU bits to select USB data bus resistance.

Table 32.5 USB data bus resistance control

Settings		USB data bus resistance control		
DRPD	DPRPU	D− Line	D+ Line	Remarks
0	0	Open	Open	
0	1	Open	Pull-up	Make these settings when the module is used as a function controller.
1	0	Pull-down	Pull-down	Setting prohibited
1	1	Pull-down	Pull-up	Setting prohibited

D+ pull-up resistance control for function controller operation (DPRPU)

When this bit set to 1, this controller pulls up the D+ line to 3.3V and can notify the USB host that the function module is attached.

The controller cancels pulling-up of the D+ line by modifying this bit from 1 to 0, and the state for the USB host can be shown as detached.

HSE bit (High-Speed Operation Enable)

Setting this bit to 1 enables high-speed operation. Setting the HSE bit to 1 lets this controller perform high-speed or fullspeed operation based on the results of reset handshake.

Setting the HSE bit to 0 lets this controller perform full-speed operation.

On the other hand, setting the HSE bit to 1 lets this controller perform the reset handshake protocol and then perform high-speed or full-speed operation automatically according to the results.

This bit can be modified when DPRPU = 0.

CNEN bit (Single-End Receiver Operation Enable)

Setting this bit to 1 enables the single-end receiver to operate. This bit is used to prevent inrush current damage due to the floating state of the single-end receiver when it is detached. Furthermore, this bit makes it possible to see the LNST bits.

Set this bit to 1 when VBUS is detected by a VBUS interrupt, and clear this bit to 0 when VBUS is removed.

32.3.1.2 SYSCFG1 : System Configuration Control Register 1

Base address: USBF = 0x9204_1000

Offset address: 0x02

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	AWAIT[5:0]						—	—	BWAIT[5:0]					
Value after reset:	0	0	0	0	1	1	1	1	0	0	0	0	1	1	1	1

Bit	Symbol	Function	R/W
5:0	BWAIT[5:0]	CPU Bus Access Wait Specification Specify the number of wait cycles for access to this controller. 0x00: 0 wait cycles (2 access cycles) ⋮ 0x02: 2 wait cycles (4 access cycles) ⋮ 0x04: 4 wait cycles (6 access cycles) ⋮ 0x0F: 15 wait cycles (17 access cycles) (value after reset) ⋮ 0x3F: 63 wait cycles (65 access cycles)	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
13:8	AWAIT[5:0]	AHB-DMA Bridge Bus Access Wait Specification Specify the number of wait cycles for access to this controller. 0x00: 0 wait cycles (2 access cycles) ⋮ 0x02: 2 wait cycles (4 access cycles) ⋮ 0x04: 4 wait cycles (6 access cycles) ⋮ 0x0F: 15 wait cycles (17 access cycles) (value after reset) ⋮ 0x3F: 63 wait cycles (65 access cycles)	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

BWAIT[5:0] bits (CPU Bus Access Wait Specification)

For continuous access to the registers at addresses of this controller beginning at 0x80201004, at least 67 ns must be secured.

To satisfy this restriction, control wait cycles using the frequency of CPU clock (PCLKAM). The value after a reset is the maximum value (17 clock cycles), so select an appropriate value no greater than this. For this LSI, more than 9 wait cycles (11 access cycles) is needed.

This setting is the same as that for waiting in access to a FIFO port register. The maximum speeds of access to the FIFO ports are as follows:

MBW = 10b (32 bit width): Max 60 MB/sec

MBW = 01b (16 bit width): Max 30 MB/sec

MBW = 00b (8 bit width): Max 15 MB/sec

AWAIT[5:0] bits (AHB-DMA Bridge Bus Access Wait Specification)

These bits specify the number of wait cycles for access to the AHB-DFIFO0/AHB-DFIFO1 bus.

Restrictions for access cycles are the same as those for the CPU bus access wait specification bits (BWAIT).

32.3.1.3 SYSSTS0 : System Configuration Status Register

Base address: USBF = 0x9204_1000

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LNST[1:0]	
Value after reset:	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	LNST[1:0]	USB Data Line Status Monitor Indicate the state of the USB line.	R
15:2	—	These bits are read as 0.	R

Note: When a USB bus reset is detected, this register value is undefined.

LNST[1:0] bits (USB Data Line Status Monitor)

The states of USB data bus line of this controller is shown in Table 32.6. The controller monitors the states of USB data bus lines (D+ and D− lines) in the LNST bits of the SYSSTS0 register.

Reference to the LNST bits must be made following attach processing (DPRPU = 1) after USBE has been set to 1.

Table 32.6 States of USB data bus line

LNST[1]	LNST[0]	Full-speed operations	High-speed operations	Chirp operations*1
0	0	SE0	Squelch*2	Squelch*2
0	1	J state	Unsquelch*3	Chirp J*4
1	0	K state	Invalid	Chirp K*5
1	1	SE1	Invalid	Invalid

Note 1. Chirp: Reset handshake protocol being executed in high-speed operations enabled state (HSE = 1)
Note 2. Squelch: SE0 or idle state
Note 3. Unsquelch: High-speed J state or high-speed K state
Note 4. Chirp J: Chirp J-state
Note 5. Chirp K: Chirp K-state

32.3.2 USB Signal Control

32.3.2.1 DVSTCTR0 : Device State Control Register 0

Base address: USBF = 0x9204_1000

Offset address: 0x08

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	WKUP	—	—	—	—	—	RHST[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	RHST[2:0]	Reset Handshake Indicate the state of reset handshake.	R
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	WKUP	Wakeup Output Enables or disables the remote wakeup (resume signal output). Only 1 can be written to this bit. 0: Remote wakeup signal is not output. 1: Remote wakeup signal is output.	R/W

Bit	Symbol	Function	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, The WKUP is set to 0 and other bits are undefined.

RHST[2:0] bits (Reset Handshake)

These bits indicate the result of reset handshake. Table 32.7 lists the results of reset handshake.

Table 32.7 State of Reset Handshake

Bus state	RHST bit value
Powered or no connection	000b
Reset handshake in progress	100b
Full-speed connection	010b
High-speed connection	011b

When the HSE bit is set to 1, the RHST bits indicate 100b when this controller detects a USB bus reset. Then, these bits indicate 011b when this controller outputs Chirp-K and detects Chirp-JK from the USB host three times. If the connection speed is not fixed to high speed within 2.5 ms after Chirp-K output, these bits indicate 010b.

When the HSE bit is set to 0, these bits indicate 010b when the controller detects a USB bus reset.

A DVST interrupt is generated when the value of the RHST bits is 010b or 011b after the USB bus reset is detected by the controller.

WKUP bit (Wakeup Output)

With the WKUP bit set to 1, this controller outputs the remote wakeup signal to the USB bus.

This controller controls the output time of a remote wakeup signal. When this bit is set to 1 by software, the controller clears this bit to 0 after outputting the 10 ms K-state.

According to the USB Specifications, the USB bus idle state must be kept for 5 ms or longer before a remote wakeup signal is sent. If this controller writes 1 to this bit right after detection of the suspended state, the K-state will be output after 2 ms.

Do not write 1 to this bit unless the device is in the suspended state (bits DVSQ = 1xxb) and the USB host enables the remote wakeup signal.

When this bit is set to 1, the internal clock must not be stopped even in the suspended state (write 1 to this bit while the SUSPM bit = 1).

32.3.3 Test Mode

32.3.3.1 TESTMODE : USB Test Mode Register

Base address: USBF = 0x9204_1000

Offset address: 0x0C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	UTST[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	UTST[3:0]	Test Mode *See the detailed description below.	R/W
15:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

UTST[3:0] bits (Test Mode)

Writing values to these bits allows this controller to output a USB test signal during high-speed operations. Table 32.8 shows the test mode operations of the controller.

Table 32.8 Test mode operations

Test mode	UTST settings
Normal operation	0000b
Test_J	0001b
Test_K	0010b
Test_SE0_NAK	0011b
Test_Packet	0100b
Test_Force_Enable	—
Reserved	0101b to 0111b

Write to these bits according to the SetFeature request from the USB host during high-speed communication.

This controller does not enter the suspended state while these bits are 0001b to 0100b.

To perform normal USB communications after the test mode is set, apply a hardware reset.

32.3.4 FIFO Ports

32.3.4.1 CFIFO, DnFIFO : FIFO Port Register (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x014 (CFIFO/CFIFOL/CFIFOLL)
0x016 (CFIFOH)
0x017 (CFIFOHH)
0x018 + 0x4 × n (DnFIFO/DnFIFOL/DnFIFOLL)
0x01A + 0x4 × n (DnFIFOH)
0x01B + 0x4 × n (DnFIFOHH)

Bit position:	31																												0
Bit field:	FIFOPORT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FIFOPORT[31:0]	FIFO Port Accessing these bits allows reading the received data from the FIFO buffer or writing the transmit data to the FIFO buffer.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

The transmission/reception buffer of this controller is made up of a FIFO structure (FIFO buffer). Use the FIFO port register for access to the FIFO buffer. There are three FIFO ports: CFIFO, D0FIFO, and D1FIFO ports. Also, there is a DxFIFO continuous transfer port for continuous transfer. Each FIFO port consists of a port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer memory and writing of data to the FIFO buffer memory, a port select register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that is used to select the pipe assigned to the FIFO port, and a port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR).

The FIFO ports have the following restrictions.

1. Access to an FIFO buffer for DCP should be through the CFIFO port.
2. Access to an FIFO buffer by DMA transfer when DFACC = 00b (cycle stealing mode) should be through the DxFIFO port.
3. Access to an FIFO buffer by DMA transfer when DFACC = 01b or 10b (16 byte or 32 byte continuous access mode) should be through the DxFIFO continuous transfer port.
4. The DxFIFO ports can also be accessed by the CPU.

5. When using functions specific to the FIFO port, the pipe number (selected pipe) specified by the CURPIPE bits cannot be changed (when the DMA transfer function is used, etc.).
6. Registers containing the FIFO port do not affect the other FIFO ports.
7. Do not assign the same pipe to separate FIFO ports.
8. In the FIFO buffer state, there are two types of access rights: one assigned to the CPU, and the other to SIE. Access from the CPU is not possible when SIE has the rights to access the FIFO buffer.

FIFOPORT[31:0] bits (FIFO Port)

This controller accesses the FIFO buffer assigned to the pipe number written to the CURPIPE bits of the corresponding select registers (CFIFOSEL, D0FIFOSEL, and D1FIFOSEL) through access to any of these registers by software.

This register can only be accessed when the FRDY bit of each control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) indicates 1 (or while DnFIFOSEL.DREQE = 1).

The valid bits of this register depend on the settings of the corresponding MBW and BIGEND bits.

Table 32.9 to Table 32.11 list the valid bits.

Table 32.9 Endian operation in 32 bit access (MBW = 10)

BIGEND	b31 to b24	b23 to b16	b15 to b8	b7 to b0
0	N + 3 address	N + 2 address	N + 1 address	N + 0 address
1	N + 0 address	N + 1 address	N + 2 address	N + 3 address

Table 32.10 Endian operation in 16 bit access (MBW = 01)

BIGEND	b31 to b24	b23 to b16	b15 to b8	b7 to b0
0	Writing: Invalid Reading: Prohibited*1		N + 1 address	N + 0 address
1	N + 0 address	N + 1 address	Writing: Invalid Reading: Prohibited*1	

Note 1. Reading data from the invalid bits in word or byte units is prohibited.

Table 32.11 Endian operation in 8 bit Access (MBW = 00)

BIGEND	b31 to b24	b23 to b16	b15 to b8	b7 to b0
0	Writing: Invalid Reading: Invalid*1			N + 0 address
1	N + 0 address	Writing: Invalid Reading: Prohibited*1		

Note 1. Reading data from the invalid bits in word or byte units is prohibited.

32.3.4.2 CFIFOSEL : CFIFO Port Select Register

Base address: USBF = 0x9204_1000

Offset address: 0x20

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RCNT	REW	—	—	MBW[1:0]		—	BIGEND	—	—	ISEL	—	CURPIPE[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CURPIPE[3:0]	FIFO Port Access Pipe Specification Specify the pipe number to access the CFIFO port. 0x0: DCP 0x1: Pipe 1 0x2: Pipe 2 ⋮ 0x8: Pipe 8 0x9: Pipe 9 Others: Setting prohibited	R/W
4	—	This bit is read as 0. The write value should be 0.	R/W
5	ISEL	FIFO Port Access Direction when DCP is Selected Specifies access direction of the FIFO port when DCP is selected in CURPIPE bits. 0: Reading from the buffer memory 1: Writing to the buffer memory	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	BIGEND	FIFO Port Endian Control Specifies the CFIFO port byte endian. 0: Little endian 1: Big endian	R/W
9	—	This bit is read as 0. The write value should be 0.	R/W
11:10	MBW[1:0]	CFIFO Port Access Bit Width Specify the bit width for accessing the CFIFO port. 0 0: 8 bit width 0 1: 16 bit width 1 0: 32 bit width 1 1: Setting prohibited	R/W
13:12	—	These bits are read as 0. The write value should be 0.	R/W
14	REW	Buffer Pointer Rewind Specifies 1 when rewinding the buffer pointer. This bit is read as 0. 0: The buffer pointer is not rewound. 1: The buffer pointer is rewound.	R/W
15	RCNT	Read Count Mode Specifies the read mode for the value in the DTLN bits in CFIFOCTR. 0: The DTLN bits are cleared when all of the received data has been read from the CFIFO. 1: The DTLN bits are decremented each time the received data is read from the CFIFO.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

Write the pipe number for the data to be read or written through the CFIFO port.

When modifying this bit field, write this bit first and then read this bit. Only when the written value matches the read one, proceed to the next process.

Do not specify the same pipe in the CURPIPE bits of the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.

Even if the setting of these bits is modified during access to the FIFO buffer, the state of the FIFO buffer is retained, with continued access proceeding after these bits are re-set to the value before the modification.

ISEL bit (FIFO Port Access Direction when DCP is Selected)

To change this bit when the specified pipe is DCP, first write the data to this bit and then read it. Proceed to the next process after checking if the written value matches with the read value.

When the settings of this bit are modified during access to the FIFO buffer, access up to then is saved. Access to the buffer can be continued after rewriting the settings.

Settings in this bit should be made at the same as that of the CURPIPE bits.

BIGEND bit (FIFO Port Endian Control)

In this bit, set the byte endian for the CFIFO port.

For details, see the description of FIFO Port Bits (CFIFO, D0FIFO, and D1FIFO).

MBW[1:0] bits (CFIFO Port Access Bit Width)

In this bit field, set the bit width for accessing the CFIFO port.

When the pipe specified in the CURPIPE bits is in the receiving direction, if reading is started after setting this bit field, do not modify the value of the MBW bits until all data is read.

When the specified pipe is in the receiving direction, modify the value of the CURPIPE bit once and then set the CURPIPE and MBW bits at the same time.

For the procedure for changing the CURPIPE bit, see the description for the same.

When the specified pipe is in the transmitting direction, to switch the bit width from 8 bits to 16 or 32 bits or from 16 bits to 32 bits is not allowed while writing to the buffer memory is in progress.

With the 16 bit or 32 bit width setting, writing to odd bytes is possible by exercising byte access control.

REW bit (Buffer Pointer Rewind)

When the selected pipe is in the receiving direction, setting the REW bit to 1 while the FIFO buffer is being read allows re-reading the FIFO buffer from the first data (in double-buffer operation, re-reading the currently-read FIFO buffer plane from the first data is allowed).

Do not set REW to 1 simultaneously with modifying the CURPIPE bits. Before setting REW to 1, be sure to check that FRDY is 1.

To re-write to the FIFO buffer again from the first data for the pipe in the transmitting direction, use the BCLR bit.

RCNT bit (Read Count Mode)

When 0 is written to this bit, if all received data of the FIFO buffer assigned to the pipe specified in the CURPIPE bits (selected pipe) is read (when the data is read on one side of a double buffer), this controller clears the DTLN bits in the CFIFOCTR register to 0.

When 1 is written to this bit, the controller decrements the value of the DTLN bits in the CFIFOCTR register whenever the received data is read from the FIFO buffer assigned to the specified pipe.

32.3.4.3 DnFIFOSEL : DnFIFO Port Select Register (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x028 + 0x4 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RCNT	REW	DCLRM	DREQE	MBW[1:0]		—	BIGEND	—	—	—	—	CURPIPE[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CURPIPE[3:0]	FIFO Port Access Pipe Specification 0x0: Not specified 0x1: Pipe 1 0x2: Pipe 2 ⋮ 0x8: Pipe 8 0x9: Pipe 9 Others: Setting prohibited	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	BIGEND	FIFO Port Endian Control Specifies the DnFIFO port byte endian. 0: Little endian 1: Big endian	R/W

Bit	Symbol	Function	R/W
9	—	This bit is read as 0. The write value should be 0.	R/W
11:10	MBW[1:0]	FIFO Port Access Bit Width Specify the bit width for accessing the FIFO port. 0 0: 8 bit width 0 1: 16 bit width 1 0: 32 bit width 1 1: Setting prohibited	R/W
12	DREQE	DMA Request Enable This bit is used to notify for DMAC. 0: DMA request is disabled 1: DMA request is enabled	R/W
13	DCLRM	Auto Buffer Memory Clear Mode after Specified Pipe Data is Read Enables or disables automatic clearing of the buffer memory after data has been read out using the selected pipe. 0: Auto buffer clear mode is disabled 1: Auto buffer clear mode is enabled	R/W
14	REW	Buffer Pointer Rewind Specifies 1 when rewinding the buffer pointer. This bit is read as 0. 0: The buffer pointer is not rewound 1: The buffer pointer is rewound	R/W
15	RCNT	Read Count Mode Specifies the read mode for the value in the DTLN bits in Dx_FIFOCTR. 0: The DTLN bits are cleared when all of the received data has been read. 1: The DTLN bits are decremented each time the received data is read.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

Write the pipe number for the data to be read or written through the DxFIFO port.

When modifying this bit field, first write a value to this bit field and then read it. Check if the write value matches the read value and then proceed to the next process.

Do not specify the same pipe in the CURPIPE bits of the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.

Even if the setting of these bits is modified during access to the FIFO buffer, the state of the FIFO buffer is retained, with continued access proceeding after these bits are re-set to the value before the modification.

BIGEND bit (FIFO Port Endian Control)

Write the byte endian for the DxFIFO port in this bit.

For details, see the description of FIFO Port Bits (CFIFO, D0FIFO, and D1FIFO).

MBW[1:0] bits (FIFO Port Access Bit Width)

Write the bit width for accessing the DxFIFO port in this bit.

When the pipe specified in the CURPIPE bits is in the receiving direction, if reading is started after setting this bit field, do not modify the value of the MBW bits until all data is read.

When the specified pipe is in the receiving direction, set the CURPIPE and MBW bits at the same time.

For the procedure for changing the CURPIPE bit, see the description for the same.

For details, see the description of CURPIPE[3:0] Bits (FIFO Port Access Pipe Specification Bits).

DREQE bit (DMA Request Enable)

Use this bit to enable or disable DMA request.

When enabling DMA request, set this bit to 1 after setting the CURPIPE bits.

When modifying the setting of the CURPIPE bits, do so after setting this bit to 0.

DCLRM bit (Auto Buffer Memory Clear Mode after Specified Pipe Data is Read)

After reading data in the specified pipe, disable or enable automatic clearing of the FIFO buffer. When 1 is written to this bit, this controller sets the BCLR bit to 1 for a FIFO buffer if a zero-length packet is received when the FIFO buffer assigned to the specified pipe is empty, or when a short packet is received and the data is completely read while BFRE = 1.

When using this controller with the BRDYM bit set to 1, be sure to set this bit to 0.

REW bit (Buffer Pointer Rewind)

When the selected pipe is in the receiving direction, setting the REW bit to 1 while the FIFO buffer is being read allows re-reading the FIFO buffer from the first data (in double-buffer operation, re-reading the currently-read FIFO buffer plane from the first data is allowed).

Do not set the REW bit to 1 simultaneously with modifying the CURPIPE bits. Before setting the REW bit to 1, be sure to check that the FRDY bit is 1.

To re-write to the FIFO buffer again from the first data for the pipe in the transmitting direction, use the BCLR bit.

RCNT bit (Read Count Mode)

When 0 is written to this bit, if all received data of the FIFO buffer assigned to the pipe specified in the CURPIPE bits (selected pipe) is read (when the data is read on one side of a double buffer), this controller clears the DTLN bits in the DxFIFOCTR register to 0.

When 1 is written to this bit, the controller decrements the value of the DTLN bits in the DxFIFOCTR register whenever the received data is read from the FIFO buffer assigned to the specified pipe.

32.3.4.4 CFIFOCTR, DnFIFOCTR : FIFO Port Control Register (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x022 (CFIFOCTR)
0x02A + 0x4 × n (DnFIFOCTR)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BVAL	BCLR	FRDY	—	DTLN[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	DTLN[11:0]	Receive Data Length Indicate the length of the receive data.	R
12	—	This bit is read as 0. The write value should be 0.	R/W
13	FRDY	FIFO Port Ready Indicates whether the FIFO port can be accessed. 0: FIFO port is not accessible. 1: FIFO port is accessible.	R
14	BCLR	CPU Buffer Clear Specifies 1 to clear the FIFO buffer on the CPU side for the selected pipe. Only 1 can be written to this bit. This bit is read as 0. 0: Invalid 1: Clears the CPU buffer memory on the CPU side.	R/W
15	BVAL	Buffer Memory Valid Flag Specifies 1 when writing has ended in the CPU-side FIFO buffer for the pipe specified in CURPIPE (selected pipe). Only 1 can be written to this bit. 0: Invalid 1: Writing ended	R/W

Note: When a USB bus reset is detected, this register value is undefined.

DTLN[11:0] bits (Receive Data Length)

The DTLN bits indicate the length of the receive data. While the FIFO buffer is being read, the DTLN bits indicate different values depending on the RCNT bit value as described below.

1. When RCNT = 0:
   The length of received data is set in these bits, and the value is retained until all received data has been read from a single FIFO buffer plane.
   While BFRE is 1, these bits retain the length of the receive data until BCLR is set to 1 even after all data has been read.
2. When RCNT = 1:
   This controller decrements the value indicated by these bits each time data is read from the FIFO buffer.
   (The value is decremented by 1 when MBW is 00b, by 2 when MBW is 01b, and by 4 when MBW is 10b.)
   This controller sets these bits to 0 when all data has been read from one FIFO buffer plane. However, in double-buffer operation, if data has been received in one FIFO buffer plane before all data has been read from the other plane, this controller sets these bits to indicate the length of the receive data in the latter plane when all data has been read from the former plane.
   When reading these bits during FIFO buffer reading while RCNT = 1, note that these bits are updated within 150 ns after a read cycle for the FIFO port.

FRDY bit (FIFO Port Ready)

This bit indicates whether the FIFO port can be accessed from the CPU (DMAC).

In the following cases, the controller sets FRDY to 1, but data cannot be read via the FIFO port because there is no data to be read. In these cases, set BCLR to 1, clear the FIFO buffer, and then enable transmission and reception of the next data.

1. A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty.
2. A short packet is received and the data is completely read while BFRE is 1.

BCLR bit (CPU Buffer Clear)

When this bit is set to 1, this controller clears the FIFO buffer on the CPU for the selected pipe.

When double-buffer operation is set for the FIFO buffer assigned to the selected pipe, this controller clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the selected pipe is the DCP, setting BCLR to 1 allows this controller to clear the FIFO buffer regardless of whether the FIFO buffer is on the CPU side or SIE side. When clearing the buffer on the SIE side, set the PID bits for the DCP to NAK before setting BCLR to 1.

When the selected pipe is not the DCP, writing 1 to this bit should be done while FRDY indicates 1. When checking the FRDY bit after executing BCLR, allow an interval of at least 80 ns after executing BCLR before referencing FRDY.

BVAL bit (Buffer Memory Valid Flag)

When the pipe specified in the CURPIPE bits (selected pipe) is for transmission, write 1 to this bit in the following cases. This controller sets the FIFO buffer from the CPU side to the SIE side, enabling transmission.

1. To transmit the short packet, set this bit to 1 after data has been written.
2. To transmit a zero-length packet, set this bit to 1 before writing data to FIFO.
3. Set this bit to 1 after the number of data bytes has been written for the pipe in continuous transfer mode, where the number is a natural integral multiple of the maximum packet size and less than the buffer size.

When the data of the maximum packet size has been written for the pipe in non-continuous transfer mode, this controller sets this bit to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When 1 is written to the BVAL and BCLR bits at the same time when the specified pipe is in the transmitting direction, the controller clears the old data and enables the transmission of a zero-length packet.

Writing 1 to this bit should be done while FRDY indicates 1. When checking the FRDY bit after executing BVAL, allow an interval of at least 80 ns after executing BVAL before referencing FRDY.

When the specified pipe is in the receiving direction, do not write 1 to this bit.

32.3.5 Enabling Interrupts

32.3.5.1 INTENB0 : Interrupt Enable Register 0

Base address: USBF = 0x9204_1000

Offset address: 0x30

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	VBSE	RSME	SOFE	DVSE	CTRE	BEMPE	NRDYE	BRDYE	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	BRDYE	Buffer Ready Interrupt Enable Enables or disables the USB interrupt output when the BRDY interrupt is detected. 0: Interrupt output disabled 1: Interrupt output enabled	R/W
9	NRDYE	Buffer Not Ready Response Interrupt Enable Enables or disables the USB interrupt output when the NRDY interrupt is detected. 0: Interrupt output disabled 1: Interrupt output enabled	R/W
10	BEMPE	Buffer Empty Interrupt Enable Enables or disables the USB interrupt output when the BEMP interrupt is detected. 0: Interrupt output disabled 1: Interrupt output enabled	R/W
11	CTRE	Control Transfer Stage Transition Interrupt Enable Enables or disables the USB interrupt output when the CTRT interrupt is detected. 0: Interrupt output disabled 1: Interrupt output enabled	R/W
12	DVSE	Device State Transition Interrupt Enable Enables or disables the USB interrupt output when the DVST interrupt is detected. 0: Interrupt output disabled 1: Interrupt output enabled	R/W
13	SOFE	Frame Number Update Interrupt Enable Enables or disables the USB interrupt output when the SOF interrupt is detected. 0: Interrupt output disabled 1: Interrupt output enabled	R/W
14	RSME	Resume Interrupt Enable Enables or disables the USB interrupt output when the RESM interrupt is detected. 0: Interrupt output disabled 1: Interrupt output enabled	R/W
15	VBSE	VBUS Interrupt Enable Enables or disables the USB interrupt output when the VBINT interrupt is detected. 0: Interrupt output disabled 1: Interrupt output enabled	R/W

Note: When a USB bus reset is detected, this register value is undefined.

32.3.5.2 INTENB1 : Interrupt Enable Register 1

Base address: USBF = 0x9204_1000

Offset address: 0x32

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PDDETINTE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PDDETINTE	PDDETINT Detection Interrupt Enable Enables or disables the USB interrupt output when a PDDETINT detection interrupt is detected. 0: Interrupt output disabled 1: Interrupt output enabled	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

32.3.5.3 BRDYENB : BRDY Interrupt Enable Register

Base address: USBF = 0x9204_1000

Offset address: 0x36

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPEBRDYE[9:0]									
Value after reset:	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PIPEBRDYE[9:0]	BRDY Interrupt Enable for Each Pipe Enable or disable the BRDY interrupt for each pipe. 0: Interrupt output disabled 1: Interrupt output enabled	R/W
15:10	—	The read values are undefined. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.
Note: The bit number corresponds to the pipe number.

PIPEBRDYE[9:0] bits (BRDY Interrupt Enable for Each Pipe)

On detecting the BRDY interrupt for the pipe corresponding to the bit in this register which has been set to 1 by software, this controller sets 1 to the corresponding PIPEBRDY bit in BRDYSTS and the BRDY bit in INTSTS0, and asserts the interrupt signal through USB_FI.

While at least one PIPEBRDY bit in BRDYSTS indicates 1, this controller asserts the interrupt signal through USB_FI when the corresponding interrupt enable bit of this register is changed from 0 to 1 by software.

32.3.5.4 NRDYENB : NRDY Interrupt Enable Register

Base address: USBF = 0x9204_1000

Offset address: 0x38

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPENRDYE[9:0]									
Value after reset:	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PIPENRDYE[9:0]	NRDY Interrupt Enable for Each Pipe Enable or disable the NRDY interrupt for each pipe. 0: Interrupt output disabled 1: Interrupt output enabled	R/W
15:10	—	The read values are undefined. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.
Note: The bit number corresponds to the pipe number.

PIPENRDYE[9:0] bits (NRDY Interrupt Enable for Each Pipe)

On detecting the NRDY interrupt for the pipe corresponding to the bit in this register which has been set to 1 by software, this controller sets 1 to the corresponding PIPENRDY bit in NRDYSTS and the NRDY bit in INTSTS0, and asserts the interrupt signal through the USB Function Interrupt (USB_FI).

While at least one PIPENRDY bit in NRDYSTS indicates 1, this controller asserts the interrupt signal through USB_FI when the corresponding interrupt enable bit of this register is changed from 0 to 1 by software.

32.3.5.5 BEMPENB : BEMP Interrupt Enable Register

Base address: USBF = 0x9204_1000

Offset address: 0x3A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPEBEMPE[9:0]									
Value after reset:	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PIPEBEMPE[9:0]	BEMP Interrupt Enable for Each Pipe Enable or disable the BEMP interrupt for each pipe. 0: Interrupt output disabled 1: Interrupt output enabled	R/W
15:10	—	The read values are undefined. The write value should be 0.	R/W

Note:
- When a USB bus reset is detected, this register value is undefined.
- The bit number corresponds to the pipe number.

PIPEBEMPE[9:0] bits (BEMP Interrupt Enable for Each Pipe)

On detecting the BEMP interrupt for the pipe corresponding to the bit in this register which has been set to 1 by software, this controller sets 1 to the corresponding PIPEBEMP bit in BEMPSTS and the BEMP bit in INTSTS0, and asserts the interrupt signal through USB_FI.

While at least one PIPEBEMP bit in BEMPSTS indicates 1, this controller asserts the interrupt signal through USB_FI when the corresponding interrupt enable bit of this register is changed from 0 to 1 by software.

32.3.6 SOF Control Register

32.3.6.1 SOFCFG : SOF Pin Configuration Register

Base address: USBF = 0x9204_1000

Offset address: 0x3C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	BRDYM	INTL	EDGESTS	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	EDGESTS	Interrupt Edge Processing Status Indicates the state of processing in response to interrupts when edge-sensing has been selected. 0: Processing in response to an edge-sensed interrupt is not in progress. 1: Processing in response to an edge-sensed interrupt is in progress	R

Bit	Symbol	Function	R/W
5	INTL	Interrupt Output Sense Select*2 Selects sense mode for USB interrupt output. 0: Edge sense 1: Level sense	R/W
6	BRDYM	PIPEBRDY Interrupt Status Clear Timing*1 Specifies the timing for clearing the PIPEBRDY interrupt state. This bit can be set only in the initial setting (before communications). The setting cannot be changed once communication starts. 0: Software clears the state. 1: Hardware clears the state by reading from the FIFO buffer or by writing to the FIFO buffer.	R/W
15:7	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.
Note 1. When setting the BRDYM bit to 1, set the INTL bit to 1 (level sense).
Note 2. With the INTL bit set to 0, to stop the system clock (SUSPM = 0) after clearing the interrupt state, write 0 to the SUSPM bit after checking that the EDGESTS bit is set to 0.

32.3.7 Interrupt Status

32.3.7.1 INTSTS0 : Interrupt Status Register 0

Base address: USBF = 0x9204_1000

Offset address: 0x40

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	VBINT	RESM	SOFR	DVST	CTRT	BEMP	NRDY	BRDY	VBSTS	DVSQ[2:0]			VALID	CTSQ[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	x	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CTSQ[2:0]	Control Transfer Stage Indicate the control transfer stage. 0 0 0: Idle or setup stage 0 0 1: Control read data stage 0 1 0: Control read status stage 0 1 1: Control write data stage 1 0 0: Control write status stage 1 0 1: Control write (no data) status stage 1 1 0: Control transfer sequence error 1 1 1: Reserved	R
3	VALID	USB Request Reception Indicates whether reception of the USB request has been detected. When writing to this bit, only 0 can be written. 0: Not detected 1: Setup packet reception	R/W
6:4	DVSQ[2:0]	Device State Indicate the device state. 0 0 0: Powered state 0 0 1: Default state 0 1 0: Address state 0 1 1: Configured state 1 x x: Suspended state	R
7	VBSTS	VBUS Input Status Indicates the input state of the USB_VUBUSIN pin. 0: USB_VUBUSIN pin is at the low level 1: USB_VUBUSIN pin is at the high level	R

Bit	Symbol	Function	R/W
8	BRDY	BRDY Interrupt Status Indicates the BRDY interrupt state. 0: BRDY interrupts not generated 1: BRDY interrupts generated	R
9	NRDY	NRDY Interrupt Status Indicates the NRDY interrupt state. 0: NRDY interrupts not generated 1: NRDY interrupts generated	R
10	BEMP	BEMP Interrupt Status Indicates the BEMP interrupt state. 0: BEMP interrupts not generated 1: BEMP interrupts generated	R
11	CTRT	Control Transfer Stage Transition Interrupt Status Indicates the control transfer stage transition interrupt state. When writing to this bit, only 0 can be written. 0: Control transfer stage transition interrupts not generated 1: Control transfer stage transition interrupts generated	R/W*1
12	DVST	Device State Transition Interrupt Status Indicates the device state transition interrupt state. When writing to this bit, only 0 can be written. 0: Device state transition interrupts not generated 1: Device state transition interrupts generated	R/W*1
13	SOFR	Frame Number Update Interrupt Status Indicates the frame number update interrupt state. When writing to this bit, only 0 can be written. 0: SOF interrupts not generated 1: SOF interrupts generated	R/W*1
14	RESM	Resume Interrupt Status*2 Indicates the resume detection interrupt state. When writing to this bit, only 0 can be written. 0: Resume interrupts not generated 1: Resume interrupts generated	R/W*1
15	VBINT	VBUS Change Detect Interrupt Status*2 Indicates the VBUS change detection interrupt state. When writing to this bit, only 0 can be written. 0: VBUS interrupts not generated 1: VBUS interrupts generated	R/W*1

Note: When a USB bus reset is detected, The DVST is set to 1 and DVSQ[2:0] are set to 001b and other bits are undefined.
Note 1. To clear the state indicated by the VBINT, RESM, SOFR, DVST or CTRT bits, write 0 only to the bit to be cleared, and write 1 to the other bits. Do not write 0 to the status bit set to 0.
Note 2. The controller detects the change in state indicated by the VBINT and RESM bits of this register, even while the clock is being stopped (SUSPM = 0), and conveys the interrupt if the corresponding interrupt is enabled. When the clock is enabled, clear the state using software.

BRDY bit (BRDY Interrupt Status)

This controller sets a BRDY bit to 1 when, among the PIPEBRDY bits for which the corresponding PIPEBRDYE bits in BRDYENB have been set to 1, at least one PIPEBRDY bit in BRDYSTS is set to 1 (that is, when this controller detects the BRDY interrupt state in at least one pipe among the pipes for which software has enabled the output of BRDY interrupts).

For the conditions for the setting of PIPEBRDY bits, see the description of the BRDYSTS register.

When a BRDY bit has been set to 1, the controller clears the bit in response to software writing 0 to all PIPEBRDY bits corresponding to PIPEBRDYE bits which have been set to 1.

A BRDY bit will not be cleared to 0 in response to software only writing 0 to individual bits that have been set to 1.

NRDY bit (NRDY Interrupt Status)

This controller sets an NRDY bit to 1 when, among the PIPEBRDY bits for which the corresponding PIPENRDYE bits in NRDYENB have been set to 1, at least one PIPENRDY bit in BNRDYSTS is set to 1 (that is, when this controller detects the NRDY interrupt state in at least one pipe among the pipes for which software has enabled the output of NRDY interrupts).

For the conditions for the setting of PIPENRDY bits, see the description of the NRDYSTS register.

When an NRDY bit has been set to 1, the controller clears the bit in response to software writing 0 to all PIPENRDY bits corresponding to PIPENRDYE bits which have been set to 1.

An NRDY bit will not be cleared to 0 in response to software only writing 0 to individual bits that have been set to 1.

BEMP bit (BEMP Interrupt Status)

This controller sets a BEMP bit to 1 when, among the PIPEBRDY bits for which the corresponding PIPEBEMPE bits in BEMPENB have been set to 1, at least one PIPEBEMP bit in BEMPSTS is set to 1 (that is, when this controller detects the BEMP interrupt state in at least one pipe among the pipes for which software has enabled the output of BEMP interrupts).

For the conditions for the setting of PIPEBEMP bits, see the description of the BEMPSTS register.

When a BEMP bit has been set to 1, the controller clears the bit in response to software writing 0 to all PIPEBEMP bits corresponding to PIPEBEMPE bits which have been set to 1.

A BEMP bit will not be cleared to 0 in response to software only writing 0 to individual bits that have been set to 1.

CTRT bit (Control Transfer Stage Transition Interrupt Status)

If this controller detects the stage transition of control transfer, it updates the CTSQ value and sets 1 to this bit.

When this interrupt occurs, clear the state before the controller detects the next control transfer stage transition.

DVST bit (Device State Transition Interrupt Status)

If this controller detects a change in the device state, it updates the DVSQ value and sets 1 to this bit.

When this interrupt occurs, clear the state before the controller detects the next device state transition.

SOFR bit (Frame Number Update Interrupt Status)

The conditions when the controller sets 1 in this bit are below.

When updating the frame number, this controller sets 1 to this bit (this interrupt is detected every 1 ms).

The controller detects the SOFR interrupt by internal interpolation even if the SOF packet from the USB host is corrupted.

RESM bit (Resume Interrupt Status)

If this controller is in the suspended state (DVSQ = 1xxb) and the DP pin falling edge is detected, 1 is set to this bit.

VBINT bit (VBUS Change Detect Interrupt Status)

When this controller detects a change in the USB_VUBUSIN pin input value (from high to low and from low to high), 1 is written to this bit. The controller writes the input value of the USB_VUBUSIN pin to the VBSTS bit. When the VBINT interrupt occurs, use the software to execute a consistency check several times during reading the VBSTS bit, and remove the chattering effect.

32.3.7.2 INTSTS1 : Interrupt Status Register 1

Base address: USBF = 0x9204_1000

Offset address: 0x42

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PDDETINT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PDDETINT	PDDET Detection Interrupt Status*1 Indicates the PDDETINT interrupt status. 0: PDDET interrupts not generated 1: PDDET interrupts generated	R/W*2
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, The bit 12 is set to 1 and other bits are undefined.

Note 1. To clear the status indicated by the PDDETINT bit, write 0 to bit0 only and 1 to other bits. Do not write 0 to status bits that indicate 0.

Note 2. This controller detects changes in the status indicated by the PDDETINT bit in this register even while the clock is stopped (SUSPM = 0), and reports corresponding interrupts if they are enabled. Perform a software status clear after the clock is enabled.

PDDETINT bit (PDDET Detection Interrupt Status)

This bit is set to 1 when a change (high to low or low to high) in EXH_PDDETSTS (BC1/2-PD detection status signal) is detected. When a PDDETINT interrupt is generated, read the PDDETSTS bit several times by software to perform debounce processing.

32.3.7.3 BRDYSTS : BRDY Interrupt Status Register

Base address: USBF = 0x9204_1000

Offset address: 0x46

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPEBRDY[9:0]									
Value after reset:	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PIPEBRDY[9:0]	BRDY Interrupt Status for Each Pipe*1 Indicate the BRDY interrupt state for each pipe. When writing to these bits, only 0 can be written. 0: Interrupts not generated 1: Interrupts generated	R/W*2*3
15:10	—	The read values are undefined. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.
Note 1. The bit number corresponds to the pipe number.
Note 2. When BRDYM = 0, to clear the state of each bit of this register, write 0 only to the bit to be cleared and 1 to other bits.
Note 3. When BRDYM = 0, clearing these interrupt status bits should be done before accessing the FIFO.

PIPEBRDY[9:0] bits (BRDY Interrupt Status for Each Pipe)

When the BRDY interrupt is detected for a pipe by this controller, the controller sets 1 in the corresponding PIPEBRDY[9:0] bit of the BRDYSTS register. Here, when 1 is written to the corresponding bit of BRDYENB register by using the software, the controller sets 1 to the BRDY bit of the INTSTS0 register.

The conditions for generating and clearing the BRDY interrupt depend on the settings of the SOFCFG.BRDYM bit and PIPECFG.BFRE bit for each pipe as described below.

- When BRDYM = 0 and BFRE = 0
  With these settings, the BRDY interrupt indicates that the FIFO port is accessible.
  On any of the following conditions, this controller generates the internal BRDY interrupt request trigger and sets 1 to the PIPEBRDY bit corresponding to the selected pipe.

  1. For the pipe in the transmitting direction

     (a) When the software has modified the DIR bit from 0 to 1

     (b) When the controller ends the packet transmission of the selected pipe in the condition where writing is not possible from the CPU to the FIFO buffer that has been assigned to the selected pipe (when the BSTS bit is read as 0).
     In continuous transmission/reception mode, the request trigger is generated when data of one plane of the FIFO buffer is complete.

     (c) In double-buffer operation, one FIFO buffer being empty on completion of the writing of data to the other FIFO buffer.
     The request trigger is not generated until completion of writing data to the currently-written FIFO buffer plane even if transmission to the other FIFO buffer is completed.

     (d) When the hardware flushes the buffer of the pipe for isochronous transfers.

     (e) The FIFO buffer making the transition from the write-disabled to the write-enabled state in response to writing of 1 to the ACLRM bit.
     The request trigger is not generated for the DCP (that is, during data transmission for control transfers).

2. For the pipe in the receiving direction

   (a) When packet reception is completed successfully thus enabling the FIFO buffer to be read when read-access from the CPU to the FIFO buffer for the selected pipe is disabled (when the BSTS bit is read as 0).
   The request trigger is not generated for the transaction in which DATA-PID disagreement occurs.
   When a short packet is received, the request trigger is generated even if the FIFO buffer has available space.
   When the transaction counter is used, the request trigger is generated on receiving the specified number of packets.
   In this case, the request trigger is generated even if the FIFO buffer has available space.

   (b) In double-buffer operation, one FIFO buffer being ready for reading on completion of the reading of data from the other FIFO buffer.
   The request trigger is not generated until completion of reading data from the currently-read FIFO buffer plane even if reception by the other FIFO buffer is completed.
   The BRDY interrupt is not generated in the status stage of control transfers.
   The PIPEBRDY interrupt state of the selected pipe can be cleared to 0 by writing 0 to the corresponding PIPEBRDY interrupt status bit in the BRDYSTS register. In this case, 1s should be written to the PIPEBRDY interrupt status bits for the other pipes.
   Be sure to clear the BRDY state before accessing the FIFO buffer.

- When BRDYM = 0 and BFRE = 1
With these settings, this controller generates the BRDY interrupt on completion of the reading of all data for a single transfer using the pipe in the receiving direction, and sets 1 to the PIPEBRDY bit corresponding to the selected pipe.
On any of the following conditions, this controller determines that the last data for a single transfer has been received.

  1. When a short packet including a zero-length packet is received.
  2. When the transaction counter register (TRNCNT bits) is used and the number of packets specified by the TRNCNT bits is completely received.

  When the pertinent data is completely read out after any of the above determination conditions has been satisfied, this controller determines that all data for a single transfer has been completely read out.
  When a zero-length packet is received when the FIFO buffer is empty, the controller determines that all data for a single transfer has been completely read out upon the FRDY and the DTLN bits of the FIFO port control register are set to 1 and 0, respectively.
  In this case, write 1 to the BCLR bit of the corresponding FIFOCTR register by software to start the next transfer.
  With these settings, this controller does not detect the BRDY interrupt for the pipe in the transmitting direction.
  The PIPEBRDY interrupt state of the selected pipe can be cleared to 0 by writing 0 to the corresponding PIPEBRDY interrupt status bit. In this case, 1s should be written to the PIPEBRDY interrupt status bits for the other pipes.
  In this mode, the BFRE bit setting should not be modified until all data for a single transfer has been processed.
  When it is necessary to modify the BFRE bit before completion of processing, all the FIFO buffers for the selected pipe should be cleared using the ACLRM bit.

- When BRDYM = 1 and BFRE = 0
With these settings, the PIPEBRDY values are linked to the BSTS bit settings for each pipe. In other words, the BRDY interrupt status bits (PIPEBRDY) are set to 1 or 0 by this controller depending on the FIFO buffer state.

  1. For the pipe in the transmitting direction
     The setting of a BRDY interrupt status bit is 1 while the port register of the corresponding FIFO buffer is ready for written data and 0 when it is not able to accept written data.
     However, the BRDY interrupt is not generated in response to setting of the bit to 1 if writing to the DCP in the transmitting direction can proceed.
  2. For the pipe in the receiving direction
     The setting of a BRDY interrupt status bit is 1 while the port register of the FIFO buffer is ready for reading and 0 when all data have been read.

  When a zero-length packet is received when the FIFO buffer is empty, the corresponding bit is set to 1 and the BRDY interrupt continues to be effective until 1 is written to BCLR.
  With this setting, the PIPEBRDY bit cannot be cleared to 0.
  When BRDYM is set to 1, all of the BFRE bits (for all pipes) should be cleared to 0.
  When BRDYM is set to 1, the INTL bit should be set to 1 (level control).

32.3.7.4 NRDYSTS : NRDY Interrupt Status Register

Base address: USBF = 0x9204_1000

Offset address: 0x48

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPENRDY[9:0]									
Value after reset:	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PIPENRDY[9:0]	NRDY Interrupt Status for Each Pipe*1 Indicate the NRDY interrupt state for each pipe. When writing to these bits, only 0 can be written. 0: Interrupts not generated 1: Interrupts generated	R/W*2
15:10	—	The read values are undefined. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.
Note 1. The bit number corresponds to the pipe number.
Note 2. To clear the state indicated by each bit of this register, write 0 only to the bit to be cleared and 1 to the other bits.

PIPENRDY[9:0] bits (NRDY Interrupt Status for Each Pipe)

On generating the internal NRDY interrupt request for the pipe whose PID bits are set to BUF, this controller sets the corresponding PIPENRDY bit in NRDYSTS in the register to 1. If the corresponding bit in the NRDYENB register is set to 1, this controller sets the NRDY bit in INTSTS0 in the register to 1.

The conditions on which this controller generates the internal NRDY interrupt request for a given pipe are described below.

However, the internal NRDY interrupt request is not generated during status stage execution of the control transfer.

1. When the pipe is in the transmitting direction
   (a) When an IN Token is received while there is no transmission data in the FIFO buffer and the corresponding PIPE PID bit is set to BUF (01):
   In this case, this controller generates an NRDY interrupt request at the reception of the IN token, setting the PIPENRDY bit to 1.
   For the pipe for the isochronous transfers in which an interrupt is generated, this controller transmits a zerolength packet, setting the OVRN bit to 1.
2. For the pipe in the receiving direction
   (a) When the PID bits for the corresponding pipe are set to BUF (01) and an OUT token is received while there is no open space in the FIFO buffer:
   For the pipe for the isochronous transfers in which an interrupt is generated, this controller generates an NRDY interrupt request at the reception of the OUT token, setting the PIPENRDY bit to 1 and OVRN bit to 1.
   For the pipe for the transfers other than isochronous transfers in which an interrupt is generated, this controller generates an NRDY interrupt request when an NAK handshake is transferred after the data following the OUT token was received, setting the PIPENRDY bit to 1.
   However, during re-transmission (due to DATA-PID disagreement), the NRDY interrupt request is not generated.
   In addition, if an error occurs in the DATA packet, the NRDY interrupt request is not generated.
   (b) When the PID bits for the corresponding pipe are set to BUF (01) and a PING token is received while there is no open space in the FIFO buffer:
   In this case, this controller generates an NRDY interrupt request at the reception of the PING token, setting the PIPENRDY bit to 1.
   (c) In an isochronous transfer pipe, when the PID bits are set to BUF (01) and data is not received successfully within the interval frame:
   In this case, this controller generates an NRDY interrupt request at the reception of an SOF, and sets the PIPENRDY bit to 1.

32.3.7.5 BEMPSTS : BEMP Interrupt Status Register

Base address: USBF = 0x9204_1000

Offset address: 0x4A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPEBEMP[9:0]									
Value after reset:	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PIPEBEMP[9:0]	BEMP Interrupt Status for Each Pipe*1 Indicate the BEMP interrupt state for each pipe. When writing to these bits, only 0 can be written. 0: Interrupts not generated 1: Interrupts generated	R/W*2
15:10	—	The read values are undefined. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.
Note 1. The bit number corresponds to the pipe number.
Note 2. To clear the state indicated by each bit of this register, write 0 only to the bit to be cleared and 1 to the other bits.

PIPEBEMP[9:0] bits (BEMP Interrupt Status for Each Pipe)

On detecting the BEMP interrupt for the pipe whose PID bits are set to BUF by software, this controller sets the corresponding PIPEBEMP bit in BEMPSTS to 1. If the corresponding bit in BEMPENB is set to 1 by software, this controller sets the BEMP bit in INTSTS0 to 1.

The following describes the conditions on which this controller generates the internal BEMP interrupt request.

1. For the pipe in the transmitting direction, when the FIFO buffer of the corresponding pipe is empty on completion of transmission (including zero-length packet transmission).
   In single-buffer operation, the internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for the pipe other than DCP.
   However, the internal BEMP interrupt request is not generated on any of the following conditions.
   (a) When writing data to the FIFO buffer on the CPU (DMAC) side is started by software on completion of transmitting data of one plane in double-buffer operation.
   (b) When the buffer is cleared (emptied) by setting the ACLRM or BCLR bit to 1.
   (c) When IN transfer (zero-length packet transmission) is performed during the control transfer status stage.
2. For the pipe in the receiving direction
   When the successfully-received data packet size exceeds the specified maximum packet size.
   In this case, this controller generates the BEMP interrupt request, setting the corresponding PIPEBEMP bit to 1, and discards the received data and modifies the setting of the PID bits of the corresponding pipe to STALL (11). However, the internal BEMP interrupt request is not generated on any of the following conditions.
   (a) When a CRC error or bit stuffing error is detected in the received data.
   (b) When a setup transaction is being performed.

Writing 0 to the PIPEBEMP bit clears the state; writing 1 to the PIPEBEMP bit has no effect.

32.3.8 Frame Number Registers

32.3.8.1 FRMNUM : Frame Number Register

Base address: USBF = 0x9204_1000

Offset address: 0x4C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	OVRN	CRCE	—	—	—	FRNM[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	FRNM[10:0]	Frame Number Indicate the latest frame number.	R
13:11	—	These bits are read as 0. The write value should be 0.	R/W
14	CRCE	CRC Error Detection Status Indicates whether a CRC error has been detected in the pipe during isochronous transfer. When writing to this bit, only 0 can be written. 0: No error 1: An error occurred.	R/W
15	OVRN	Overrun/Underrun Detection Status*1 Indicates whether an overrun/underrun error has been detected in the pipe during isochronous transfer. When writing to this bit, only 0 can be written. 0: No error 1: An error occurred.	R/W

Note: When a USB bus reset is detected, this register value is undefined.
Note 1. The OVRN bit is for use in debugging. When designing a system, control the timing so that neither overrun nor underrun occurs.

FRNM[10:0] bits (Frame Number)

This controller sets these bits to indicate the latest frame number, which is updated every time an SOF packet is issued or received (every 1 ms).

When reading these bits by software, repeat reading until the same value is read twice.

CRCE bit (CRC Error Detection Status)

In an isochronous transfer pipe, this controller sets 1 to this bit when a CRC error or bit stuffing error has been detected.

This bit can be cleared by writing 0 to it by software. In this case, write 0x8000 when OVRN is not to be cleared at the same time.

This controller generates an internal NRDY interrupt request when it detects a CRC error. For details, see NRDY Interrupt Enable Bit for Each Pipe (PIPENRDYE).

OVRN bit (Overrun/Underrun Detection Status)

For the isochronous transfer pipe, this controller sets 1 to this bit when an overrun/underrun is detected.

When an overrun/underrun is detected, the controller issues an internal NRDY request. See NRDY Interrupt Enable Bit for Each Pipe (PIPENRDYE) for details.

This bit can be cleared writing 0 to it by software. In this case, write 0x4000 when CRCE is not to be cleared at the same time.

This controller sets this bit to 1 on any of the following conditions.

1. For the isochronous transfer pipe in the transmitting direction, the IN token is received before all the transmit data has been written to the FIFO buffer.
2. For the isochronous transfer pipe in the receiving direction, the OUT token is received when no FIFO buffer planes are empty.

32.3.8.2 UFRMNUM : Frame Number Register

Base address: USBF = 0x9204_1000

Offset address: 0x4E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	UFRNM[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	UFRNM[2:0]	Microframe Number Indicate the µframe number.	R
15:3	—	These bits are read as 0.	R

Note: When a USB bus reset is detected, this register value is undefined.

UFRNM[2:0] bits (Microframe Number)

This controller sets these bits to indicate the µframe number during high-speed operation. During operation other than high-speed operation, this controller sets these bits to 0x00.

When reading these bits, repeat reading until the same value is read twice.

32.3.9 USB Address

32.3.9.1 USBADDR : USB Address Register

Base address: USBF = 0x9204_1000

Offset address: 0x50

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	USBADDR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	USBADDR[6:0]	USB Address Indicate the USB address assigned by the host.	R
15:7	—	These bits are read as 0.	R

Note: When a USB bus reset is detected, The USBADDR[6:0] is set to 0000000b and other bits are undefined.

USBADDR[6:0] bits (USB Address)

These bits indicate the USB address assigned by the host when the SetAddress request is successfully processed.

If a USB bus reset is detected by the controller, 0x00 is set to this bit.

32.3.10 USB Request Registers

The USB request registers are used to store the setup requests for control transfers. The values of the USB request that have been received are stored.

32.3.10.1 USBREQ : USB Request Type Register

Base address: USBF = 0x9204_1000

Offset address: 0x54

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BREQUEST[7:0]								BMREQUESTTYPE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	BMREQUESTTYPE[7:0]	Request Type USB request bmRequestType value	R
15:8	BREQUEST[7:0]	Request USB request bRequest value	R

BMREQUESTTYPE[7:0] bits (Request Type)

These bits indicate the USB request data value received by this controller in the setup transaction. Writing to these bits by software has no effect.

BREQUEST[7:0] bits (Request)

These bits indicate the USB request data value received by this controller in the setup transaction. Writing to these bits by software has no effect.

32.3.10.2 USBVAL : USB Request Value Register

Base address: USBF = 0x9204_1000

Offset address: 0x56

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WVALUE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WVALUE[15:0]	Value USB request wValue value	R

WVALUE[15:0] bits (Value)

These bits are used to read the value of the USB request wValue. Bits 7 to 0 are lower-order byte.

These bits indicate the USB request wValue value received by this controller in the setup transaction. Writing to these bits by software has no effect.

32.3.10.3 USBINDX : USB Request Index Register

Base address: USBF = 0x9204_1000

Offset address: 0x58

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WINDEX[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WINDEX[15:0]	Index USB request wIndex value	R

WINDEX[15:0] bits (Index)

These bits are used to read the value of the USB request wIndex. Bits 7 to 0 are lower-order byte.

These bits indicate the USB request wIndex value received by this controller in the setup transaction. Writing to these bits by software has no effect.

32.3.10.4 USBLENG : USB Request Length Register

Base address: USBF = 0x9204_1000

Offset address: 0x5A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WLENGTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WLENGTH[15:0]	Length USB request wLength value	R

WLENGTH[15:0] bits (Length)

These bits are used to read the value of the USB request wLength. Bits 7 to 0 are lower-order byte.

These bits indicate the USB request wLength value received in setup transaction by the controller. Writing to these bits by software has no effect.

32.3.11 DCP Configuration

32.3.11.1 DCPCFG : DCP Configuration Register

Base address: USBF = 0x9204_1000

Offset address: 0x5C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CNTMD	SHTNAK	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	SHTNAK	Disabling PIPE at the End of Transfer Specifies whether to change PID to NAK at the end of transfer when receiving direction is specified for the default control pipe. 0: The pipe continues at the end of transfer. 1: The pipe is disabled at the end of transfer.	R/W
8	CNTMD	Continuous Transfer Mode Specifies whether to enable the default control pipe communication in continuous transfer mode. 0: Continuous transfer mode disabled 1: Continuous transfer mode enabled	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

32.3.11.2 DCPMAXP : DCP Maximum Packet Size Register

Base address: USBF = 0x9204_1000

Offset address: 0x5E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	MXPS[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	MXPS[6:0]	Maximum Packet Size Specify the maximum data payload (maximum packet size) for the DCP.	R/W
15:7	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

MXPS[6:0] bits (Maximum Packet Size)

Set the maximum data payload (maximum packet size) for the DCP in these bits. 0x40 (64 bytes) is the value after a reset.

The MXPS bits should be set to the value based on the USB specification.

The MXPS bits should be set while PID = NAK and before setting the CURPIPE bits.

Before modifying these bits after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

While MXPS is 0, do not write to the FIFO buffer or do not set PID to BUF.

32.3.11.3 DCPCTR : DCP Control Register

Base address: USBF = 0x9204_1000

Offset address: 0x60

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BSTS	—	—	—	—	—	—	SQCLR	SQSET	SQMON	PBUSY	—	—	CCPL	PID[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PID[1:0]	Response PID These bits control the response type of this controller during control transfer. 0 0: NAK response 0 1: BUF response (depending on the buffer state) 1 0: STALL response 1 1: STALL response	R/W
2	CCPL	Control Transfer End Enable Setting this bit to 1 enables the status stage of the control transfer to be completed. 0: End of the control transfer disabled 1: End of the control transfer enabled	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	PBUSY	PIPE Busy Indicates whether the selected pipe is currently being used by the USB bus. 0: The pipe is not being used by the USB bus. 1: The pipe is being used by the USB bus.	R

Bit	Symbol	Function	R/W
6	SQMON	Sequence Toggle Bit Monitor Indicates the expected value of the sequence toggle bit for the next transaction during the DCP transfer. 0: DATA0 1: DATA1	R
7	SQSET	Toggle Bit Set Specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during the DCP transfer. This bit is read as 0. When writing to this bit, only 1 can be written. 0: Writing has no effect 1: Specifies DATA1	R/W
8	SQCLR	Toggle Bit Clear Specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during the DCP transfer. This bit is read as 0. When writing to this bit, only 1 can be written. 0: Writing has no effect 1: Specifies DATA0	R/W
10:9	—	These bits are read as 0. The write value should be 0.	R/W
11	—	This bit is read as 0. The write value should be 1.	R/W
12	—	The read value is undefined. The write value should be 0.	R/W
14:13	—	These bits are read as 0. The write value should be 1.	R/W
15	BSTS	Buffer Status Indicates whether access to the DCP FIFO buffer is enabled or disabled. 0: Buffer access disabled 1: Buffer access enabled	R

Note: When a USB bus reset is detected, The CCPL is set to 0 and PID[1:0] are set to 0 and other bits are undefined.

PID[1:0] bits (Response PID)

Change the setting of these bits from NAK to BUF by software during data stage or status stage of control transfers.

This controller changes the setting of these bits in the following conditions:

1. This controller changes the setting of the PID bits to select NAK response (00) on receiving the setup packet. Here, this controller sets VALID to 1. The setting of the PID bits cannot be changed until VALID is set to 0.
2. This controller sets the PID bits to select STALL response (11) on receiving the data of the size exceeding the maximum packet size when the PID bits have been set to select BUF response.
3. This controller sets the PID bits to select STALL response (1x) on detecting the control transfer sequence error.
4. This controller sets the PID bits to select NAK response on detecting the USB bus reset.

This controller does not reference to the setting of the PID bits while the SET_ADDRESS request is processed (auto processing).

CCPL bit (Control Transfer End Enable)

Setting this bit to 1 while the corresponding PID bits are set to BUF enables the stage of the control transfer to be completed.

Specifically, during control read transfer, this controller transmits the ACK handshake in response to the OUT transaction from the USB host, and outputs the zero-length packet in response to the IN transaction from the USB host during control writing or no-data control transfer. However, on detecting the SET_ADDRESS request, this controller operates in auto response mode from the setup stage up to the status stage completion irrespective of the setting of this bit.

This controller modifies this bit from 1 to 0 on receiving the new setup packet.

1 cannot be written by software to this bit while VALID is 1.

PBUSY bit (PIPE Busy)

This controller modifies this bit from 0 to 1 upon start of the USB transaction for the selected pipe, and modifies the bit from 1 to 0 upon completion of one transaction.

Reading this bit after the PID bits have been set to NAK allows checking that modification of the pipe settings is possible.

SQMON bit (Sequence Toggle Bit Monitor)

This bit indicates the expected value of the sequence toggle bit of the selected pipe.

This bit is toggled upon normal completion of the transaction. However, this bit is not toggled when a DATA-PID disagreement occurs during the receiving transfer.

This controller sets this bit to 1 (specifies DATA1 as the expected value) upon normal reception of the setup packet.

This controller does not reference to this bit during the IN/OUT transaction of the status stage, and does not allow this bit to toggle upon normal completion.

SQSET bit (Toggle Bit Set)

Setting this bit to 1 by software allows this controller to set DATA1 as the expected value of the sequence toggle bit of the selected pipe. This bit always indicates 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

Set this bit to 1 while PID is NAK and before setting the CURPIPE bits.

Before setting this bit to 1 after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY is 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

SQCLR bit (Toggle Bit Clear)

Setting this bit to 1 by software allows this controller to set DATA0 as the expected value of the sequence toggle bit of the selected pipe. This bit always indicates 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

Set this bit to 1 while PID is NAK and before setting the CURPIPE bits.

Before setting this bit to 1 after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

BSTS bit (Buffer Status)

This bit indicates whether access from the CPU to the FIFO buffer assigned to the DCP is possible.

The meaning of the BSTS bit depends on the ISEL bit setting as follows.

1. When ISEL = 0: indicates whether the received data can be read from the buffer.
2. When ISEL = 1: indicates whether the data for transmission can be written to the buffer.

32.3.12 Pipe Configuration Register

Pipes 1 to 9 should be set using the PIPESEL, PIPECFG, PIPEBUF, PIPEMAXP, PIPEPERI, PIPExCTR, PIPExTRE and PIPExTRN registers.

After selecting the pipe using the PIPESEL register, functions of the pipe should be set using the PIPECFG, PIPEBUF, PIPEMAXP and PIPEPERI registers. The PIPExCTR, PIPExTRE and PIPExTRN registers can be set regardless of the pipe selection in the PIPESEL register.

32.3.12.1 PIPESEL : Pipe Window Select Register

Base address: USBF = 0x9204_1000

Offset address: 0x64

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	PIPESEL[3:0]	Pipe Window Select Specify the pipe corresponding to the PIPECFG, PIPEBUF, PIPEMAXP, PIPEPERI registers. 0x0: No pipe selected 0x1: Pipe 1 0x2: Pipe 2 0x3: Pipe 3 0x4: Pipe 4 0x5: Pipe 5 0x6: Pipe 6 0x7: Pipe 7 0x8: Pipe 8 0x9: Pipe 9 Others: Reserved	R/W
15:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

PIPESEL[3:0] bit (Pipe Window Select)

When a value between 0001b and 1001b is set in these bits, the information and settings for the corresponding pipe can be read from the PIPECFG, PIPEBUF, PIPEMAXP, PIPEPERI registers. After a pipe is specified by setting these bits, the values set by software to the PIPECFG, PIPEBUF, PIPEMAXP, PIPEPERI registers are reflected in the corresponding pipe transfer type by this controller.

When 0000b is set in PIPESEL, 0 is read from all of the bits in the PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI registers. When 0000b is set in PIPESEL, writing to the bits in these registers has no effect.

32.3.12.2 PIPECFG : Pipe Configuration Register

Base address: USBF = 0x9204_1000

Offset address: 0x68

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TYPE[1:0]		—	—	—	BFRE	DBLB	CNTMD	SHTNAK	—	—	DIR	EPNUM[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	EPNUM[3:0]	Endpoint Number Specify endpoint number for the selected pipe.	R/W
4	DIR	Transfer Direction Specifies pipe transfer direction for the selected pipe. 0: Receiving direction 1: Transmitting direction	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	SHTNAK	Pipe Disable at the End of Transfer Specifies whether to change PID to NAK at the end of transfer when the selected pipe is in the receiving direction. 0: Pipe continued at end of transfer 1: Pipe disabled at end of transfer	R/W
8	CNTMD	Continuous Transfer Mode Specifies whether to use the selected pipe in continuous transfer mode. 0: Non-continuous transfer mode 1: Continuous transfer mode	R/W
9	DBLB	Double Buffer Mode Selects either single- or double-buffer operation for the FIFO buffer used by the selected pipe. 0: Single-buffer operation 1: Double-buffer operation	R/W

Bit	Symbol	Function	R/W
10	BFRE	BRDY Interrupt Operation Specification Specifies the BRDY interrupt generation timing from this controller to the CPU with respect to the selected pipe. 0: BRDY interrupt notification upon transmitting or receiving data 1: BRDY interrupt notification upon reading data	R/W
13:11	—	These bits are read as 0. The write value should be 0.	R/W
15:14	TYPE[1:0]	Transfer Type Specify the transfer type for the pipe selected by the PIPESEL bits (selected pipe). 0 0: Pipe is not in use. 0 1: Bulk transfer 1 0: Interrupt transfer 1 1: Isochronous transfer	R/W

Note: When a USB bus reset is detected, this register value is undefined.

EPNUM[3:0] bits (Endpoint Number)

Specify the endpoint number for the selected pipe in these bits by software.

Setting 0000b indicates that the pipe is not being used.

These bits should be modified while PID is NAK, and the pipe is not selected by the CURPIPE bits.

Before modifying these bits after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Do not make the settings such that the combination of the set values in the DIR and EPNUM bits should be the same for two or more pipes (EPNUM = 0000b (the selected pipe is not in use) can be set for all the pipes).

DIR bit (Transfer Direction)

When this bit is set to 0 by software, this controller uses the selected pipe in the receiving direction, and when this bit is set to 1, this controller uses the selected pipe in the transmitting direction.

This bit should be modified while PID is NAK and the pipe is not selected by the CURPIPE bits.

To modify this bit after completing USB communication using the selected pipe, write 1 and then 0 to ACLRM continuously to clear the FIFO buffer assigned to the selected pipe while the PID and CURPIPE bits are in the abovedescribed state.

Before modifying this bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

SHTNAK bit (Pipe Disable at the End of Transfer)

This bit is valid when pipes 1 to 5 are selected in the receiving direction.

When this bit is set to 1 for the selected pipe in the receiving direction, this controller modifies the PID bits for the selected pipe to NAK on determining the end of the transfer. This controller determines that the transfer has ended on any of the following conditions.

1. A short packet (including a zero-length packet) is successfully received.
2. The transaction counter is used and the number of packets specified for the counter is successfully received.

This bit should be modified while PID is NAK.

Before modifying this bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

This bit should be cleared to 0 for the pipe in the transmitting direction.

CNTMD bit (Continuous Transfer Mode)

This bit is valid when pipes 1 to 5 are selected and the transfer type of the selected pipe is set to bulk.

According to the setting value of this bit, this controller determines transmission/reception completion for the FIFO buffer assigned to the selected pipe. See Table 32.12.

Table 32.12 Relationship between transfer mode settings by CNTMD bit and timings at which reading data or transmitting data from FIFO buffer is enabled

CNTMD bit setting	When reading data or transmitting data is enabled
0	In the receiving direction (DIR = 0), the FIFO buffer is ready for reading in the following case. This controller receives one packet.
	In the transmitting direction (DIR = 1), the FIFO buffer is ready for transmission in either of the following cases. 1. Data of the maximum packet size is written to the FIFO buffer by software (or DMAC). 2. Data of the short packet size (including 0 byte data) is written to the FIFO buffer and then 1 is written to BVAL by software (or DMAC).
1	In the receiving direction (DIR = 0), the FIFO buffer is ready for reading in any of the following cases. 1. The number of the data bytes received in the FIFO buffer assigned to the selected pipe is equal to the number of assigned data bytes ((BUFSIZE + 1) × 64). 2. This controller receives a short packet other than a zero-length packet. 3. This controller receives a zero-length packet when data is already stored in the FIFO buffer assigned to the selected pipe. 4. This controller receives the number of packets equal to the transaction counter value specified for the selected pipe by software.
	In the transmitting direction (DIR = 1), the FIFO buffer is ready for transmission in any of the following cases 1 to 3. 1. The number of the data bytes written to the FIFO buffer by software (or DMAC) is equal to the number of data bytes in a single FIFO buffer plane assigned to the selected pipe. 2. The number of data bytes less than the size of a single FIFO buffer plane (including 0 byte data) assigned to the selected pipe is written to the FIFO buffer and then 1 is written to BVAL by software (or DMAC). 3. The number of data bytes less than the size of a single FIFO buffer plane (including 0 byte data) assigned to the selected pipe is written to the FIFO buffer and then the DENDx_N signal is asserted at the same time as writing the last data by software (or DMAC).

This bit should be modified while PID is NAK and the pipe is not selected by the CURPIPE bits.

To modify this bit after completing USB communication using the selected pipe, write 1 and then 0 to ACLRM continuously to clear the FIFO buffer assigned to the selected pipe while the PID and CURPIPE bits are in the abovedescribed state.

Before modifying this bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

DBLB bit (Double Buffer Mode)

This bit is valid when pipes 1 to 5 are selected.

When this bit is set to 1, this controller assigns two planes of the FIFO buffer size specified by the BUFSIZE bits in PIPEBUF to the selected pipe.

Specifically, the following expression determines the FIFO buffer size assigned to the selected pipe by this controller.

(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

This bit should be modified while PID is NAK and the pipe is not selected by the CURPIPE bits.

To modify this bit after completing USB communication using the selected pipe, write 1 and then 0 to ACLRM continuously by software to clear the FIFO buffer assigned to the selected pipe while the PID and CURPIPE bits are in the above-described state.

Before modifying this bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

BFRE bit (BRDY Interrupt Operation Specification)

This bit is valid when pipes 1 to 5 are selected.

When this bit is set to 1 and the selected pipe is in the receiving direction (the DIR bit is set to 0), this controller detects the transfer completion and generates the BRDY interrupt on having read the pertinent packet.

When the BRDY interrupt is generated with the above conditions, 1 must be written to BCLR. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to BCLR.

When this bit is set to 1 and the selected pipe is in the transmitting direction (the DIR bit is set to 1), this controller does not generate the BRDY interrupt. For details, see the description of the PIPEBRDY interrupt register.

This bit should be modified while PID is NAK and the pipe is not selected by the CURPIPE bits.

To modify this bit after completing USB communication using the selected pipe, write 1 and then 0 to ACLRM continuously to clear the FIFO buffer assigned to the selected pipe while the PID and CURPIPE bits are in the abovedescribed state.

Before modifying this bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

TYPE[1:0] bits (Transfer Type)

Specify the USB transfer type for the pipe selected by the PIPESEL bits (selected pipe) in the TYPE bits.

Table 32.13 lists the selected pipes and transfer types that can be set in the TYPE bits.

Table 32.13 Selected pipes and transfer types that can be set in TYPE bits

Selected pipe	TYPE bits	USB transfer type
Pipe 1 or Pipe 2	01b or 11b	Bulk or isochronous transfer
Pipe 3 to Pipe 5	01b	Bulk transfer
Pipe 6 to Pipe 9	10b	Interrupt transfer

Before setting PID to BUF for the selected pipe (before starting USB communication using the selected pipe), be sure to set these bits to the value other than 00b.

These bits should be modified while the PID bits for the selected pipe are set to NAK. Before modifying these bits after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY is 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

32.3.12.3 PIPEBUF : Pipe Buffer Specification Register

Base address: USBF = 0x9204_1000

Offset address: 0x6A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	BUFSIZE[4:0]					—	—	BUFNMB[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	BUFNMB[7:0]	Buffer number Specify the pipe FIFO buffer number for the selected pipe. (0x04 to 0x80)	R/W
9:8	—	These bits are read as 0. The write value should be 0.	R/W
14:10	BUFSIZE[4:0]	Buffer size Specify the FIFO buffer size for the pipe specified in PIPESEL bits (selected pipe). 0x00: 64 bytes 0x01: 128 bytes ⋮ 0x1F: 2 KB	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.
Note: The bits in this register should be modified while PID is NAK and the pipe is not selected by the CURPIPE bits.
Note: Before modifying the bits of this register after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

BUFNMB[7:0] bits (Buffer number)

The first block number in the FIFO buffer to be allocated for the selected pipe should be set in these bits. The FIFO buffer blocks allocated for the selected pipe by this controller are determined as follows:

Block number: BUFNMB to block number of BUFNMB + (BUFSIZE + 1) × (DBLB + 1) − 1

These bits must be set to a value that does not exceed the size of installed memory (0 [0x00] to 8192 [0x80] for 8 KB memory). Observe the following conditions:

- 0x00 is used exclusively for DCP.
- 0x04 is used exclusively for pipe 6. However, when pipe 6 is not used, 0x04 can be used for other pipes. When pipe 6 is selected, writing to these bits has no effect and 0x04 is automatically assigned by this controller.
- 0x05 is used exclusively for pipe 7. However, when pipe 7 is not used, 0x05 can be used for other pipes. When pipe 7 is selected, writing to these bits has no effect and 0x05 is automatically assigned by this controller.
- 0x06 is used exclusively for pipe 8. However, when pipe 8 is not used, 0x06 can be used for other pipes. When pipe 8 is selected, writing to these bits has no effect and 0x06 is automatically assigned by this controller.
- 0x07 is used exclusively for pipe 9. However, when pipe 9 is not used, 0x07 can be used for other pipes. When pipe 9 is selected, writing to these bits has no effect and 0x07 is automatically assigned by this controller.

BUFSIZE[4:0] bits (Buffer size)

Specify the size of the FIFO buffer for the selected pipe in these bits in terms of blocks, where one block comprises 64 bytes. When the DBLB bit is set to 1 by software, this controller assigns two planes of the FIFO buffer size specified by the BUFSIZE bits to the selected pipe. Specifically, the following expression determines the FIFO buffer size assigned to the selected pipe by this controller.

(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

Set the following value in these bits.

1. When pipes 1 to 5 are selected, any value from 0x00 to 0x1F can be set.
2. When pipes 6 to 9 are selected, only 0x0 should be set.

When used with CNTMD = 1, set an integral multiple of the maximum packet size to the BUFSIZE bits.

32.3.12.4 PIPEMAXP : Pipe Maximum Packet Size Register

Base address: USBF = 0x9204_1000

Offset address: 0x6C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	MXPS[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	MXPS[10:0]*1	Maximum Packet Size Specify the maximum data payload (maximum packet size) of the selected pipe. Pipes 6 to 9 can be set to 0x01 to 0x40 bytes.	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

Note 1. The value after a reset of the MXPS bit is 0x00 when no pipe is selected with the PIPESEL bits in PIPESEL and 0x40 when a pipe is selected with the PIPESEL bits in PIPESEL.

MXPS[10:0] bits (Maximum Packet Size)

Set the maximum data payload (maximum packet size) for the selected pipe in these bits.

For pipes 1 and 2, a value between 1 byte (0x1) to 1024 bytes (0x400) can be set.

For pipes 3 to 5, any value from 8 bytes (0x8), 16 bytes (0x10), 32 bytes (0x20), 64 bytes (0x40) and 512 bytes (0x200) can be set (bits [2:0] are not provided).

The value after a reset is 0x040 (64 bytes).

These bits should be set to the appropriate value for each transfer type based on the USB specification.

Set these bits to 1 while PID is NAK and before setting the CURPIPE bits.

Before modifying these bits after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

While MXPS is 0, do not write to the FIFO buffer or set PID to BUF.

32.3.12.5 PIPEPERI : Pipe Timing Control Register

Base address: USBF = 0x9204_1000

Offset address: 0x6E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	IITV[2:0]	Interval Error Detection Spacing Specify the interval error detection timing for the selected pipe in terms of frames, which is expressed as n-th power of 2.	R/W
11:3	—	These bits are read as 0. The write value should be 0.	R/W
12	IFIS	Isochronous IN Buffer Flush Specifies whether to flush the buffer when the pipe selected by the PIPESEL bits (selected pipe) is used for isochronous IN transfers. 0: The buffer is not flushed 1: The buffer is flushed	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

IITV[2:0] bits (Interval Error Detection Spacing)

Specify the interval error detection timing in terms of frames, which is expressed as n-th power of 2, in these bits.

These bits should be modified while PID is NAK and before setting the CURPIPE bits.

Before modifying these bits after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Before modifying these bits after USB communication has been completed with these bits set to a certain value, set PID to NAK and then set ACLRM to 1 to initialize the interval timer.

The IITV bits are invalid for pipes 3 to 5; set these bits to 0 for these pipes.

These bits can be set when the selected pipe transfer is for isochronous transfers.

When the selected pipe is for isochronous OUT transfers

This controller generates the NRDY interrupt when it fails to receive a data packet within the interval set for (μ) frames by the IITV bits.

This controller generates the NRDY interrupt when this controller fails to receive a data packet because of a CRC error or other errors contained in the packet, or because of the FIFO buffer being full because reading data from the FIFO buffer by software (DMAC) is slow.

This controller generates the NRDY interrupt on receiving an SOF packet. Even if the SOF packet is corrupted, the internal interpolation is used and allows the interrupt to be generated at the timing to receive the SOF packet. However, when the IITV bits are set to the value other than 0, this controller generates the NRDY interrupt on receiving an SOF packet for every interval after starting interval counting operation. When the PID bits are set to NAK by software after starting the

interval timer, this controller does not generate the NRDY interrupt on receiving an SOF packet. The interval counting starts at the different timing depending on the IITV bit setting as follows.

- When IITV = 0: The interval counting starts when the PID bits for the selected pipe are set to BUF. See Figure 32.2.
- When IITV ≠ 0: The interval counting starts on completion of successful reception of the first data packet after the PID bits for the selected pipe have been modified to BUF. See Figure 32.3

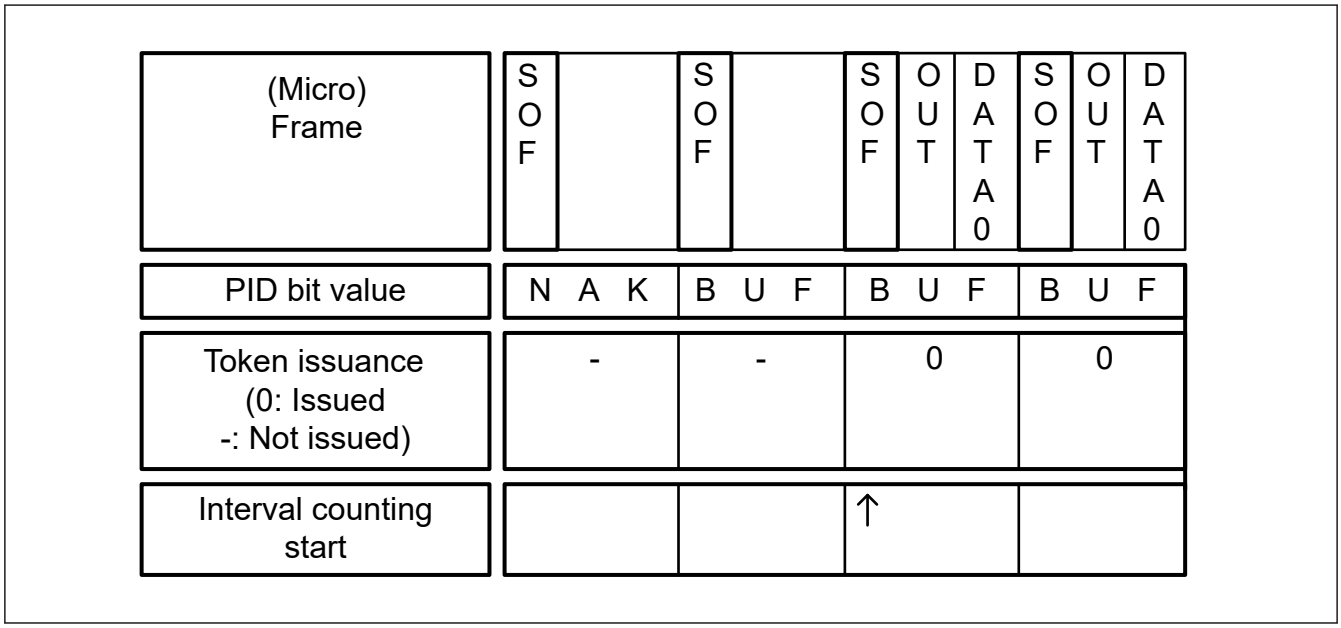

Figure 32.2 Relationship between (μ) frames and expected token reception when IITV = 0

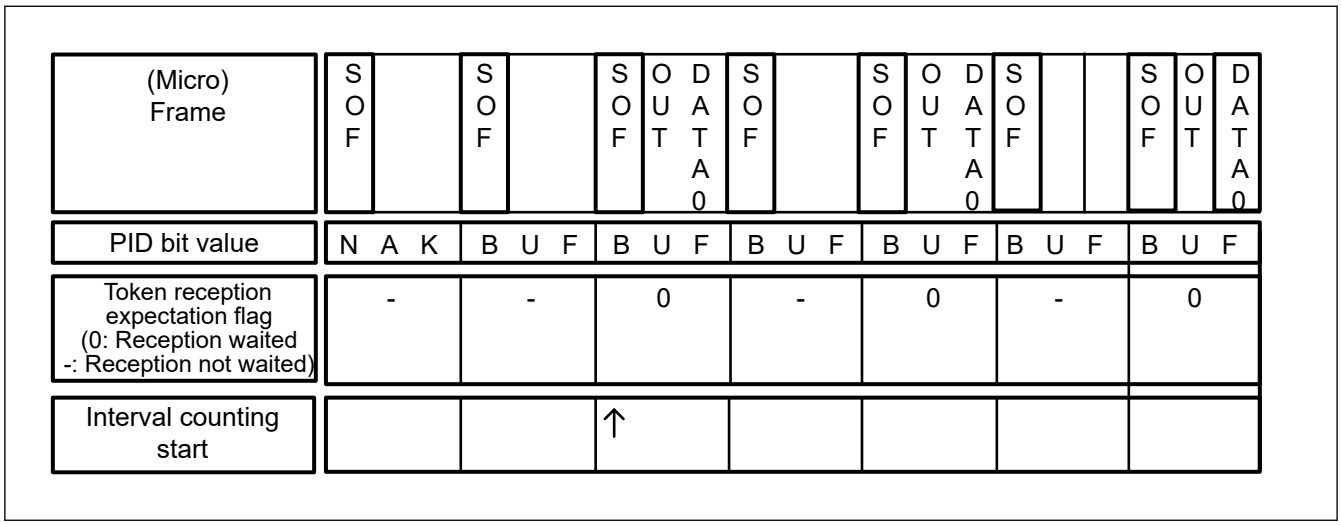

Figure 32.3 Relationship between (μ) frames and expected token reception when IITV = 1

When the selected pipe is for isochronous IN transfers

The IFIS bit should be 1 for this use. When IFIS = 0, this controller transmits a data packet in response to the received IN token irrespective of the IITV bit setting.

When IFIS = 1, this controller clears the FIFO buffer when this controller fails to receive an IN token within the interval set for (μ) frames by the IITV bits in a state in which there is data to be transmitted in the FIFO buffer.

This controller also clears the FIFO buffer when this controller fails to receive an IN token successfully because of a bus error such as a CRC error contained in the token.

This controller clears the FIFO buffer on receiving an SOF packet. Even if the SOF packet is corrupted, the internal interpolation is used and allows the FIFO buffer to be cleared at the timing to receive the SOF packet. The interval counting starts at the different timing depending on the IITV bit setting (similar to the timing during OUT transfers).

The counting conditions for the interval counter are any of the following.

- When a hardware reset is applied to this controller (at this point, the value of the IITV bits is also cleared to 0).
- When the ACLRM bit is set to 1 by software.
- When the controller detects a USB bus reset.

IFIS bit (Isochronous IN Buffer Flush)

When the selected pipe is for isochronous IN transfers, this controller automatically clears the FIFO buffer when this controller fails to receive the IN token from the USB host within the interval set by the IITV bits in terms of (μ) frames.

In double-buffer operation (DBLB = 1), this controller only clears the data in the plane used earlier.

This controller clears the FIFO buffer on receiving the SOF packet immediately after the (μ) frame in which this controller has expected to receive the IN token. Even if the SOF packet is corrupted, this controller also clears the FIFO buffer at the right timing to receive the SOF packet by using the internal interpolation.

When the selected pipe is not for the isochronous transfer, set this bit to 0.

32.3.13 Pipe Control Registers

32.3.13.1 PIPEnCTR : PIPEn Control Register (n = 1 to 5)

Base address: USBF = 0x9204_1000

Offset address: 0x070 + 0x2 × (n - 1)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BSTS	INBUFM	—	—	—	ATREPM	ACLRM	SQCLR	SQSET	SQMON	PBUSY	—	—	—	PID[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PID[1:0]	Response PID Specify the response type for the next transaction of the selected pipe. 0 0: NAK response 0 1: BUF response (depending on the buffer state) 1 0: STALL response 1 1: STALL response	R/W
4:2	—	These bits are read as 0. The write value should be 0.	R/W
5	PBUSY	PIPE Busy Indicates whether or not the selected pipe is being currently used for the USB bus. 0: The pipe is not being currently used for the USB bus. 1: The pipe is being currently used for the USB bus.	R
6	SQMON	Toggle Bit Confirm Sets the expected value of the sequence toggle bit in the next transaction of the selected pipe. 0: DATA0 1: DATA1	R
7	SQSET	Toggle Bit Set Specifies 1 when setting the expected value of the sequence toggle bit in the next transaction of the selected pipe, to DATA1. This bit is read as 0. When writing to this bit, only 1 can be written. 0: Writing has no effect. 1: Specifies DATA1	R/W
8	SQCLR	Toggle Bit Clear Specifies 1 when clearing the expected value of the sequence toggle bit in the next transaction of the selected pipe, to DATA0. This bit is read as 0. When writing to this bit, only 1 can be written. 0: Writing has no effect. 1: Specifies DATA0	R/W

Bit	Symbol	Function	R/W
9	ACLRM	Auto Buffer Clear Mode Enables or disables automatic buffer clear mode for the selected pipe. 0: Disabled 1: Enabled (all buffers are initialized)	R/W
10	ATREPM	Auto Response Mode Enables or disables auto response mode for the selected pipe. 0: Disabled 1: Enabled (a zero-length packet response while sending, NAK response and an NRDY interrupt is issued while receiving)	R/W
12:11	—	These bits are read as 0. The write value should be 0.	R/W
13	—	This bit is read as 0. The write value should be 1.	R/W
14	INBUFM	Transfer Buffer Monitor Indicates the selected FIFO buffer state when the selected pipe is in the transmitting direction. 0: FIFO buffer contains no transmittable data. 1: FIFO buffer contains transmittable data.	R
15	BSTS	Buffer Status Indicates the FIFO buffer state of the selected pipe. 0: Buffer access is disabled. 1: Buffer access is enabled.	R

Note: When a USB bus reset is detected, The PID[1:0] is set to 00b and other bits are undefined.

PID[1:0] bits (Response PID)

Set a response of the controller in each pipe in this bit by the software.

The default value of this bit is NAK. When executing a USB transfer through the selected pipe, change the setting of the PID bits to select BUF. The basic operations (operations when there is no error in the communication packet) of this controller for each value of the PID bit are given in Table 32.14.

If the selected pipe is in USB communication, when the setting of the PID bits is changed from BUF to NAK by software, after writing NAK, to check whether the USB transfer of the selected pipe is actually shifted to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

In following cases, the controller modifies the value of this bit:

1. When the selected pipe is for receiving and when the software has written 1 to the SHTNAK bit of the selected pipe, the controller sets PID = NAK upon identifying the transfer end.
2. For the selected pipe, when the data packet of payload exceeding the maximum packet size is received, the controller sets PID = STALL (11b).
3. When the USB bus reset is detected, the controller sets PID = NAK.

Write 10b to shift from PID = NAK (00b) to PID = STALL.

Write 11b to shift from BUF (01b) to STALL.

First write 10b and then write 00b to shift form STALL (11b) to NAK.

First, shift to NAK and then to BUF to shift from STALL to BUF.

Table 32.14 List of controller operations according to the PID bit (1 of 2)

PID bit value	Transfer type (Type bits value)	Transfer direction (DIR bit value)	Controller operations
00b (NAK)	Bulk (TYPE = 01b) or Interrupt (TYPE = 10b)	Not dependent on setup value	NAK response is sent to the token from the USB host.
	Isochronous (TYPE = 11b)	Reception (DIR = 0)	Does not respond to the token from the USB host.
		Transmission (DIR = 1)	A zero-length packet is sent to the token from the USB host.

Table 32.14 List of controller operations according to the PID bit (2 of 2)

PID bit value	Transfer type (Type bits value)	Transfer direction (DIR bit value)	Controller operations
01b (BUF)	Bulk (TYPE = 01b)	Reception (DIR = 0)	When an OUT token is sent from the USB host, if the FIFO buffer for the selected pipe is ready for reception, the data is received and an ACK or NYET response is returned. A NAK response is returned if not ready. When a PING token is sent from the USB host, if the FIFO buffer of the selected pipe is ready for reception, an ACK response is returned. A NAK response is returned if not ready.
	Interrupt (TYPE = 10b)	Reception (DIR = 0)	For the Out token from the USB host, if the FIFO buffer of the selected pipe is ready for reception, the data is received and an ACK response is sent. A NAK response is returned if not ready.
	Bulk (TYPE = 01b) or Interrupt (TYPE = 10b)	Transmission (DIR = 1)	If the corresponding FIFO buffer is ready for transmission, the data is sent for the token from the USB. A NAK response is returned if not ready.
	Isochronous (TYPE = 11b)	Reception (DIR = 0)	For the Out token from the USB host, if the FIFO buffer of the selected pipe is ready for reception, the data is received. The data is deleted if not ready.
		Transmission (DIR = 1)	If the corresponding FIFO buffer is ready for transmission, the data is sent for the token from the USB. A zero-length packet is sent if not ready.
10b (STALL) or 11b (STALL)	Bulk (TYPE = 01b) or Interrupt (TYPE = 10)	Not dependent on setup value	A STALL response is sent to the token from the USB host.
	Isochronous (TYPE = 11b)	Not dependent on setup value	Returns nothing in response to the token from the USB host.

PBUSY bit (PIPE Busy)

This controller modifies this bit from 0 to 1 upon start of the USB transaction for the selected pipe, and modifies the bit from 1 to 0 upon completion of one transaction.

Reading this bit after PID has been set to NAK allows checking that modification of the pipe settings is possible.

SQMON bit (Toggle Bit Confirm)

This bit indicates the expected value of the sequence toggle bit of the selected pipe.

When the selected pipe is not for the isochronous transfer, this bit is toggled upon normal completion of the transaction. However, this bit is not toggled when a DATA-PID disagreement occurs during the receiving transfer.

SQSET bit (Toggle Bit Set)

Setting this bit to 1 by software allows this controller to set DATA1 as the expected value of the sequence toggle bit of the selected pipe. This bit always indicates 0.

Set this bit to 1 while PID is NAK.

Before setting this bit to 1 after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

SQCLR bit (Toggle Bit Clear)

Setting this bit to 1 by software allows this controller to set DATA0 as the expected value of the sequence toggle bit of the selected pipe. This bit always indicates 0.

Set this bit to 1 while PID is NAK.

Before setting this bit to 1 after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

ACLRM bit (Auto Buffer Clear Mode)

To clear the contents in the FIFO buffer assigned to the selected pipe completely, write 1 and then 0 to this bit continuously.

Table 32.15 shows the contents cleared by writing 1 and 0 to this bit continuously.

Table 32.16 shows the cases in which clearing the contents is necessary.

Table 32.15 Contents cleared by this controller by setting ACLRM = 1

No.	Contents cleared by ACLRM bit manipulation
(1)	All the contents in the FIFO buffer assigned to the selected pipe (all the information in two FIFO buffer planes in double-buffer operation)
(2)	The interval count value when the selected pipe is for isochronous transfer

Table 32.16 Cases where setting ACLRM = 1 is required

No.	Case where clearing is required
(1)	All the contents in the FIFO buffer assigned to the selected pipe are to be cleared.
(2)	The interval counter is to be reset.
(3)	When the BFRE setting is modified
(4)	When the DBLB setting is modified
(5)	When the transaction count function is forcibly terminated

Set this bit to 1 while PID is NAK and before specifying the pipe in CURPIPE bits. Before setting this bit to 1 after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

ATREPM bit (Auto Response Mode)

When the selected pipe is for bulk transfer, this bit can be set to 1.

When this bit is set to 1, this controller responds to the token from the USB host as described below.

1. When the selected pipe is for bulk IN transfer (when TYPE = 01b and DIR = 1)
   When ATREPM = 1 and PID = BUF, this controller transmits a zero-length packet in response to the IN token. This controller updates (toggles) the sequence toggle bit (DATAPID) each time this controller receives the ACK from the USB host (in a single transaction, IN token is received, zero-length packet is transmitted, and then ACK is received). In this case, this controller does not generate the BRDY or BEMP interrupt.
2. When the selected pipe is for bulk OUT transfer (when TYPE = 01b and DIR = 0)
   When ATREPM = 1 and PID = BUF, this controller returns NAK in response to the OUT token (or PING token) and generates the NRDY interrupt.

This bit should be modified while PID is NAK. Before setting this bit to 1 after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

For USB communication in auto response mode, set this bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode.

When the selected pipe is for isochronous transfer, be sure to set this bit to 0.

INBUFM bit (Transfer Buffer Monitor)

When the selected pipe is in the transmitting direction (DIR = 1), this controller sets this bit to 1 when writing to at least one FIFO buffer plane is completed by software (or DMAC).

This controller sets this bit to 0 when this controller completes transmitting the data from the FIFO buffer plane to which all data has been written. In double-buffer operation (DBLB = 1), this controller sets this bit to 0 after this controller has completed transmitting the data from both FIFO buffer planes but before it has completed writing data to a single FIFO buffer plane.

This bit indicates the same value as the BSTS bit when the selected pipe is in the receiving direction (DIR = 0).

BSTS bit (Buffer Status)

This bit indicates whether access from the CPU to the FIFO buffer assigned to the selected pipe is enabled or disabled. The meaning of the BSTS bit depends on the setting of the DIR, BFRE and DCLRM bits as follows.

Table 32.17 BSTS bit operations

DIR bit value	BFRE bit value	DCLRM bit value	Meaning of BSTS bit
0	0	0	1: The received data can be read from the FIFO buffer. 0: The received data has been completely read from the FIFO buffer.
		1	Setting prohibited
	1	0	1: The received data can be read from the FIFO buffer. 0: The BCLR bit has been set to 1 after the received data has been completely read from the FIFO buffer.
		1	1: The received data can be read from the FIFO buffer. 0: The received data has been completely read from the FIFO buffer.
1	0	0	1: The transmit data can be written to the FIFO buffer. 0: The transmit data has been completely written to the FIFO buffer.
		1	Setting prohibited
	1	0	Setting prohibited
		1	Setting prohibited

32.3.13.2 PIPEnCTR : PIPEn Control Register (n = 6 to 9)

Base address: USBF = 0x9204_1000

Offset address: 0x07A + 0x2 × (n - 6)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BSTS	—	—	—	—	—	ACLRM	SQCLR	SQSET	SQMON	PBUSY	—	—	—	PID[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PID[1:0]	Response PID Specify the response type for the next transaction of the selected pipe. 0 0: NAK response 0 1: BUF response (depending on the buffer state) 1 0: STALL response 1 1: STALL response	R/W
4:2	—	These bits are read as 0. The write value should be 0.	R/W
5	PBUSY	PIPE Busy Indicates whether or not the selected pipe is being currently used for the USB bus. 0: The pipe is not being currently used for the USB bus. 1: The pipe is being currently used for the USB bus.	R
6	SQMON	Toggle Bit Confirm Sets the expected value of the sequence toggle bit in the next transaction of the selected pipe. 0: DATA0 1: DATA1	R
7	SQSET	Toggle Bit Set Specifies 1 while clearing the expected value of the sequence toggle bit in the next transaction of the selected pipe to DATA1.This bit is read as 0. When writing to this bit, write 1. 0: Writing has no effect. 1: Specifies DATA1	R/W

Bit	Symbol	Function	R/W
8	SQCLR	Toggle Bit Clear Specifies 1 while clearing the expected value of the sequence toggle bit in the next transaction of the selected pipe to DATA0. This bit is read as 0. When writing to this bit, write 1. 0: Writing has no effect. 1: Specifies DATA0	R/W
9	ACLRM	Auto Buffer Clear Mode Enables or disables automatic buffer clear mode for the selected pipe. 0: Disabled 1: Enabled (all buffers are initialized)	R/W
12:10	—	These bits are read as 0. The write value should be 0.	R/W
13	—	This bit is read as 0. The write value should be 1.	R/W
14	—	This bit is read as 0. The write value should be 0.	R/W
15	BSTS	Buffer Status Indicates the FIFO buffer state of the selected pipe. 0: Buffer access is disabled 1: Buffer access is enabled	R

Note: When a USB bus reset is detected, The PID[1:0] are set to 00b and other bits are undefined.

As for the bits listed below, see the description of each bit in section 32.3.13.1. PIPEnCTR : PIPEn Control Register (n = 1 to 5)

- Response PID Bits (PID[1:0])
- PIPE Busy Bit (PBUSY)
- Buffer Status Bit (BSTS)
- Sequence Toggle Bit Monitor Bit (SQMON)
- Sequence Toggle Bit Set Bit (SQSET)
- Sequence Toggle Bit Clear Bit (SQCLR)

ACLRM bit (Auto Buffer Clear Mode)

To clear all contents from the FIFO buffer allocated to the selected pipe, write 1 and 0 sequentially in the ACLRM bit.

Table 32.18 shows the contents of data to be cleared by the controller when 1 and 0 are written to this bit sequentially.

The cases that require this processing are listed in Table 32.19.

Table 32.18 Contents cleared by the controller when ACLRM = 1

No.	Contents cleared by ACLRM bit manipulation
(1)	Entire contents of the FIFO buffer allocated to the selected pipe

Table 32.19 Cases where setting ACLRM = 1 is required

No.	Cases where clearing is required
(1)	All the contents in the FIFO buffer assigned to the selected pipe are to be cleared.
(2)	The interval counter is to be reset.
(3)	The value of the BFRE bit is changed.
(4)	The transaction count function is forcibly terminated.

The ACLRM bit should be set while PID = NAK and before specifying the pipe in the CURPIPE bits.

Before modifying this bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY is 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

32.3.14 Transaction Counters

32.3.14.1 PIPEnTRE : PIPEn Transaction Counter Enable Register (n = 1 to 5)

Base address: USBF = 0x9204_1000

Offset address: 0x090 + 0x4 × (n - 1)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	TRCLR	Transaction Counter Clear The transaction counter can be cleared to 0 by writing 1 to this bit. This bit is read as 0. When writing to this bit, write 1. 0: Invalid 1: The current counter value is cleared	R/W
9	TRENB	Transaction Counter Enable Enable or disables the transaction counter 0: The transaction counter is disabled 1: The transaction counter is enabled	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

Note: Modify each bit in this register while PID is NAK.
Before modifying each bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

TRCLR bit (Transaction Counter Clear)

When this bit is set to 1 by software, this controller clears the current counter value of the transaction counter corresponding to the selected pipe and then sets this bit to 0.

TRENB bit (Transaction Counter Enable)

For the pipe in the receiving direction, setting this bit is set to 1 by software after setting the total number of the packets to be received in the TRNCNT bits allows the following control on having received the number of packets equal to the set value in the TRNCNT bits.

1. In continuous transmission/reception mode (CNTMD = 1), this module switches the FIFO buffer to the CPU side even if the FIFO buffer is not full on completion of reception.
2. While SHTNAK is 1, this module changes the setting of the PID bits to NAK for the corresponding pipe on having received the number of packets equal to the set value in the TRNCNT bits.
3. While DENDE is 1 and PKTMD is 0, the DEND signal is asserted when the number of packets specified in the TRNCNT bits is received and the last data is to be read.
4. While BFRE is 1, this module asserts the BRDY interrupt on having received the number of packets equal to the set value in the TRNCNT bits and then reading out the last received data.

For the pipe in the transmitting direction, set this bit to 0.

When the transaction counter is not used, set this bit to 0.

When the transaction counter is used, set the TRNCNT bits before setting this bit to 1. Set this bit to 1 before receiving the first packet to be counted by the transaction counter.

32.3.14.2 PIPEnTRN : PIPEn Transaction Counter Register (n = 1 to 5)

Base address: USBF = 0x9204_1000

Offset address: 0x092 + 0x4 × (n - 1)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TRNCNT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TRNCNT[15:0]	Transaction Counter When written to: Specify the total number of reception packets (number of transactions) to be received by the selected pipe. When read from: Indicate the specified number of transactions if TRENB is 0. Indicate the number of currently counted transaction if TRENB is 1.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

TRNCNT[15:0] bits (Transaction Counter)

For the pipe in the receiving direction, setting these bits to 1 by software after setting the total number of the packets to be received in the TRNCNT bits allows the control of the transaction counter clear bit (TRCLR).

When TRENB = 0, these bits indicate the number of transactions set by software.

When TRENB = 1, these bits indicate the number of transactions being currently counted.

This controller increments the value of these bits by one when all of the following conditions are satisfied on receiving the packet.

- TRENB = 1
- (TRNCNT setting ≠ current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the set value in the MXPS bits.

This module clears the value of these bits to 0 when any of the following conditions are satisfied.

When all the following conditions are satisfied:

- TRENB = 1
- (TRNCNT setting ≠ current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the set value in the MXPS bits.

When both of the following conditions are satisfied:

- TRENB = 1
- A short packet is received.

When the following condition is satisfied:

- When the TRCLR bit is set to 1 by software

For the pipe in the transmitting direction, set these bits to 0. When the transaction counter is not used, set these bits to 0.

These bits should be modified while PID is NAK and TRENB is 0.

Before modifying these bits after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

To modify the value of these bits, set TRCLR to 1 before setting TRENB to 1.

32.3.14.3 LPSTS : Low Power Status Register

Base address: USBF = 0x9204_1000

Offset address: 0x102

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	SUSPM	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	—	These bits are read as 0. The write value should be 0.	R/W
14	SUSPM	UTMI SuspendM Control Controls the SuspendM signal to the UTMI. 0: UTMI suspend mode 1: UTMI normal mode	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.

SUSPM bit (UTMI SuspendM Control)

The USBf module controls output of the clock signal from the PLL in the USB-PHY layer. Accordingly, supply of the clock signal to the USBf module is stopped while SUSPM = 0.

After setting this bit to 1, wait for at least 100 µs to allow oscillation of the UTMI clock to become stable.

Writing to this controller is disabled when the SUSPM bit is set to 0 (the UTMI clock is stopped). Reading from the controller area is allowed. However, writing to the registers listed in Table 32.20 is enabled even when the SUSPM bit is set to 0.

Table 32.20 List of registers that can be written by software when SUSPM = 0

Address	Register name
0x8020_1000	SYSCFG0
0x8020_1002	SYSCFG1
0x8020_1032	INTENB1*1
0x8020_1102	LPSTS

Note 1. Bit 0 in the INTENB1 register can be written when SUSPM = 0.

However, the value written to the SYSCFG0 register while the UTMI clock is stopped (SUSPM = 0) is reflected after the UTMI clock oscillation is started (SUSPM = 1).

32.3.15 Next Register Set

32.3.15.1 N0SA_n, N1SA_n : Next Source Address Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x400 + 0x40 × n (N0SA_n)
0x40C + 0x40 × n (N1SA_n)

Bit position:	31	0
Bit field:	SAWD[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	SAWD[31:0]	Source Address or Write Data These bits set the start address of the DMA transfer source in normal mode. These bits set write data in write-only mode.	R/W

Note: When a USB bus reset is detected, this register value is undefined.
Note: The N0SA_n register is overwritten by descriptor read data during a transfer in link mode.

This register is used to set write data in write-only mode (when the WONLY field in the CHCFG_n register = 1). For details, see section 32.15.1.3. Write-Only Mode.

32.3.15.2 N0DA_n, N1DA_n : Next Destination Address Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x404 + 0x40 × n (N0DA_n)
0x410 + 0x40 × n (N1DA_n)

Bit position:	31																												0
Bit field:	DA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DA[31:0]	Destination Address These bits set the start address of the DMA transfer destination.	R/W

Note: When a USB bus reset is detected, this register value is undefined.
Note: The N0DA_n register is overwritten by descriptor read data during a transfer in link mode.

32.3.15.3 N0TB_n, N1TB_n : Next Transaction Byte Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x408 + 0x40 × n (N0TB_n)
0x414 + 0x40 × n (N1TB_n)

Bit position:	31																												0
Bit field:	TB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TB[31:0]	Transaction Byte These bits set the total number of transaction bytes. Do not start a DMA transaction with these bits set to 0.	R/W

Note: When a USB bus reset is detected, this register value is undefined.
Note: The N0TB_n register is overwritten by descriptor read data during a transfer in link mode.

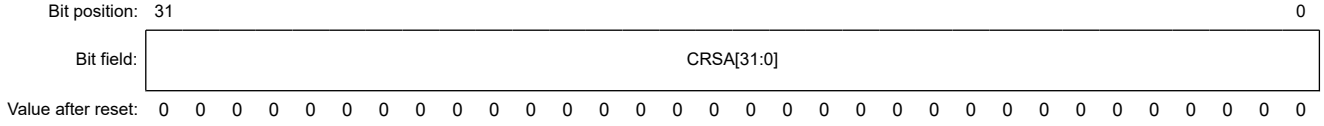
32.3.16 Current Register Set

The current register set indicates the DMA transfer source address, the DMA transfer destination address, and the total number of transfer bytes. The set value is loaded from the Next 0/1 register set (in register mode) or from the descriptor read data (in link mode) by hardware. This current register set cannot be written by software.

32.3.16.1 CRSA_n : Current Source Address Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x418 + 0x40 × n



Bit	Symbol	Function	R/W
31:0	CRSA[31:0]	Source Address These bits indicate the read address of the next DMA transaction. The CRSA[31:0] value is automatically incremented during a DMA transaction, but remains unchanged when the SAD bit in the CHCFG_n register is 1 and is undefined when the WONLY bit in the CHCFG_n register is 1. The initial value of these bits is loaded from the following register. In register mode: The transfer source address is loaded from the Next 0/1 register set. In link mode: The transfer source address is loaded from the descriptor. (Descriptor read data is input to the N0SA_n register by hardware, and is loaded to the CRSA_n register at the beginning of transfer.) The value of these bits is incremented upon completion of a read transfer. Read this register after the ongoing DMA stops (TACT = 0 in the CHSTAT_n register). (Handle the value of these bits during DMA operation as a reference value.)	R

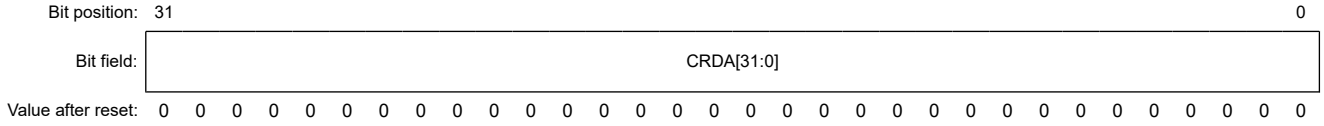
Note: When a USB bus reset is detected, this register value is undefined.

This register indicates the DMA transfer source address of DMA channel n (n = 1, 0).

32.3.16.2 CRDA_n : Current Destination Address Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x41C + 0x40 × n



Bit	Symbol	Function	R/W
31:0	CRDA[31:0]	Destination Address These bits indicate the write address of the next DMA transaction. The CRDA[31:0] value is automatically incremented during a DMA transaction, but remains unchanged when the DAD bit in the CHCFG_n register is 1. The initial value of these bits is loaded from the following register. In register mode: The transfer destination address is loaded from the Next 0/1 register set. In link mode: The transfer destination address is loaded from the descriptor. (Descriptor read data is input to the N0DA_n register by hardware, and is loaded to the CRDA_n register at the beginning of transfer.) The value of these bits is incremented upon completion of a write transfer. Read this register after the ongoing DMA stops (TACT = 0 in the CHSTAT_n register). (Handle the value of these bits during DMA operation as a reference value.)	R

Note: When a USB bus reset is detected, this register value is undefined.

This register indicates the DMA transfer destination address of DMA channel n (n = 1, 0).

32.3.16.3 CRTB_n : Current Transaction Byte Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x420 + 0x40 × n

Bit position:	31																												0
Bit field:	CRTB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CRTB[31:0]	Transaction Byte These bits indicate the remaining number of transfer bytes of the DMA transaction in progress. The CRTB[31:0] value is automatically decremented during a DMA transaction. The initial value of these bits is loaded from the following register. In register mode: The number of transfer bytes is loaded from the Next 0/1 register set. In link mode: The number of transfer bytes is loaded from the descriptor. (Descriptor read data is input to the N0TB_n register by hardware, and is loaded to the CRTB_n register at the beginning of transfer.) The value of these bits is decremented upon completion of a write transfer. Read this register after the ongoing DMA stops (TACT = 0 in the CHSTAT_n register). (Handle the value of these bits during DMA operation as a reference value.)	R

Note: When a USB bus reset is detected, this register value is undefined.

This register indicates the total number of transfer bytes of DMA channel n (n = 1, 0). This register is cleared to 0 at the end of a transfer.

32.3.17 Channel Register Set

32.3.17.1 CHSTAT_n : Channel Status Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x424 + 0x40 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DNUM[7:0]								—	—	—	—	—	SWPRQ	DMARQM	INTM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	MODE	DER	DW	DL	SR	TC	END	ER	SUS	TACT	RQST	EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EN	Enable Indicates that operation of DMA channel n is enabled or disabled. 0: Operation disabled 1: Operation enabled	R
1	RQST	Request Indicates that a transfer request has been received. 0: No DMA transfer request has been received. 1: A DMA transfer request has been received.	R
2	TACT	Transaction Active Indicates that the DMAC is operating to confirm that the channel is completely stopped. For details, see section 32.16.8. Transfer Status. 0: DMA of channel_n is inactive. 1: DMA of channel_n is in progress.	R

Bit	Symbol	Function	R/W
3	SUS	Suspend Indicates that the channel is suspended. For details, see section 32.16.8.2. Suspending a Transfer. 0: Channel_n is not suspended. 1: Channel_n is suspended.	R
4	ER	Error Indicates that an error response was received during a DMA transfer and a USB_FDMAERR interrupt was generated. 0: No error response was received. 1: An error response was received.	R
5	END	USB_FDMAn Interrupted Indicates that a DMA transaction has been completed and an USB_FDMAn interrupt was generated. 0: DMA transfer not completed 1: DMA transfer completed	R
6	TC	Terminal Count Indicates that a DMA transaction has been completed. 0: DMA transfer not completed 1: DMA transfer completed	R
7	SR	Selected Register Set Indicates the selected register set in register mode. 0: Next0 register set 1: Next1 register set	R
8	DL	Descriptor Load Indicates that the internal state is the descriptor read state. This bit remains 1 when a bus error is received during descriptor read. 0: Other than descriptor read 1: (When ER = 0) While the descriptor is read in link mode (When ER = 1) A bus error occurred while the descriptor was read in link mode.	R
9	DW	Descriptor WriteBack Indicates that the internal state is the descriptor write-back state. This bit remains 1 when a bus error is received during descriptor write-back. 0: Other than header write-back in link mode 1: (When ER in the CHSTAT_n register is 0) During header write-back in link mode (When ER in the CHSTAT_n register is 1) A bus error occurred during header write-back in link mode.	R
10	DER	Descriptor Error Indicates that the read descriptor is invalid (LV = 0). (Does not depend on the level of the DIM bit in the CHCFG_n register.) 0: No descriptor error occurred. 1: A descriptor error occurred.	R
11	MODE	DMA Mode Indicates the DMA mode that is specified by the DMS bit in the CHCFG_n register. 0: Register mode 1: Link mode	R
15:12	—	These bits are read as 0.	R
16	INTM	Interrupt Mask Indicates that the USB_FDMAn interrupt is in the temporary mask status. 0: The temporary mask status is cleared. 1: In temporary mask status	R
17	DMARQM	DMAREQ Mask Indicates that a DMA transfer request from the USB control is in the temporary mask status. 0: The temporary mask status is cleared. 1: In temporary mask status	R

Bit	Symbol	Function	R/W
18	SWPRQ	Sweep Request Indicates the forced ejection request status. Indicates the software forced ejection request (activated by the SETSSWPRQ bit in the CHCTRL_n register). 0: The forced ejection request is not asserted. 1: The forced ejection request is asserted.	R
23:19	—	These bits are read as 0.	R
31:24	DNUM[7:0]	Data Number These bits indicate the amount of valid data in the buffer. Data is read from the transfer source, and then the amount of data that has not been written to the transfer destination is displayed (in bytes).	R

This register indicates the status of DMA channel n (n = 1, 0).

When the ER bit in the CHSTAT_n register is set to 1, handle the series of transfers as invalid.

To suspend the ongoing DMA transaction, mask or clear the transfer request or clear the EN bit in the CHSTAT_n register. For details on the procedure, see section 32.16.8.3. Aborting a Transfer.

If a DMA transfer request from the USB control and a transfer request by software (by setting the STG bit in the CHCFG_n register to 1) are used together for the same channel, enabled activation sources cannot be identified. Use only a transfer request in the system.

To make a transfer request by software, make sure that the previously requested DMA transfer operation has been completed (by checking the current register or in other ways), and then set the next STG bit.

EN bit (Enable)

[Setting condition]

- 1 is written to SETEN in the CHCTRL_n register.

[Clearing conditions]

- 1 is written to SWRST in the CHCTRL_n register.
- 1 is written to CLREN in the CHCTRL_n register.
- When an error response is received during a transfer.
- When all DMA transactions are completed in register mode (REN = 0 in the CHCFG_n register)
- When DMA transfer of the last descriptor (LE = 1) is completed in link mode (write-back when WBD = 0)
- When descriptor read operation stops in link mode (LV = 0 and DRRP = 0 in the CHCFG_n register)

RQST bit (Request)

[Setting conditions]

- 1 is written to STG in the CHCTRL_n register.
- When a DMA transfer request is received from the USB control

[Clearing conditions]

- 1 is written to SWRST in the CHCTRL_n register.
- 1 is written to CLRRQ in the CHCTRL_n register.
- When a transfer is performed on the side specified by REQD in the CHCFG_n register in single transfer mode (TM = 0 in the CHCFG_n register)
- When all DMA transactions are completed in register mode (REN = 0 in the CHCFG_n register)
- When DMA transfer of the last descriptor (LE = 1) is completed in link mode
- When descriptor read operation stops in link mode (LV = 0 and DRRP = 0 in the CHCFG_n register)
- When a DMA transaction is completed in link mode with DEM in the CHCFG_n register cleared to 0
- When the master interface receives a bus error

TACT bit (Transaction Active)

[Setting condition]

- 1 is written to SETEN in the CHCTRL_n register (descriptor read start or waiting for a DMA request)

[Clearing condition]

- Idle internal state (EN in the CHSTAT_n register is cleared to 0 and all transfers are completed.)

SUS bit (Suspend)

[Setting condition]

- When the internal state becomes suspended state after 1 is written to SETSUS in the CHCTRL_n register while DMA transfer of channel n is in progress.

[Clearing conditions]

- 1 is written to CLRSUS in the CHCTRL_n register.
- 1 is written to CLREN in the CHCTRL_n register.
- Conditions for clearing EN in the CHSTAT_n register are met.

ER bit (Error)

[Setting condition]

- When an error response is received during a bus cycle.

[Clearing condition]

- 1 is written to SWRST in the CHCTRL_n register.

END bit (USB_FDMAn Interrupted)

[Setting conditions]

- Conditions for setting the TC bit are met when DEM in the CHCFG_n register is 0.
- When LV = 0 in the header, DRRP = 0 in the CHCFG_n register, and DIM = 0 during the descriptor read operation in link mode.

[Clearing conditions]

- 1 is written to CLREND in the CHCTRL_n register.
- 1 is written to SWRST in the CHCTRL_n register.

TC bit (Terminal Count)

[Setting conditions]

- When transfers for the total number of transfer bytes specified in the CRTB register are completed in register mode.
- When transfers for the total number of transfer bytes specified in the CRTB register are completed in link mode while WBD = 1 in the descriptor's header.
- When descriptor write-back is completed in link mode while WBD = 0 in the descriptor's header.

[Clearing conditions]

- 1 is written to CLRTC in the CHCTRL_n register.
- 1 is written to SWRST in the CHCTRL_n register.

SR bit (Selected Register Set)

[Setting condition]

- 1 is written to the RSEL bit in the CHCFG_n register to set it.

[Clearing condition]

- 0 is written to the RSEL bit in the CHCFG_n register to clear it.

DL bit (Descriptor Load)

[Setting condition]

- When descriptor read starts in link mode

[Clearing conditions]

- Descriptor read is completed with an OK response in link mode.
- 1 is written to SWRST in the CHCTRL_n register. If 1 is retained with an error response, this bit can be cleared to 0 only with the SWRST bit.

DW bit (Descriptor WriteBack)

[Setting condition]

- When header write-back starts in link mode.

[Clearing conditions]

- Header write-back is completed with an OK response in link mode.
- 1 is written to SWRST in the CHCTRL_n register. If 1 is retained with an error response, this bit can be cleared to 0 only with the SWRST bit.

DER bit (Descriptor Error)

[Setting condition]

- LV of the read descriptor is 0 when DRRP in the CHCFG_n register is 0 in link mode.

[Clearing conditions]

- 1 is written to the CLRDER bit in the CHCTRL_n register.
- 1 is written to the SWRST bit in the CHCTRL_n register.

INTM bit (Interrupt Mask)

[Setting condition]

- 1 is written to the SETINTM bit in the CHCTRL_n register.

[Clearing conditions]

- 1 is written to the CLRINTM bit in the CHCTRL_n register.
- 1 is written to the SWRST bit in the CHCTRL_n register.

DMARQM bit (DMAREQ Mask)

[Setting condition]

- 1 is written to the SETDMARQM bit in the CHCTRL_n register to set it.

[Clearing conditions]

- Header write-back in link mode is completed with an OK response.
- 1 is written to the CLRDMARQM bit in the CHCTRL_n register.
- 1 is written to the SWRST bit in the CHCTRL_n register.

SWPRQ bit (Sweep Request)

[Setting condition]

- When SETSSWPRQ in the CHCTRL_n register is asserted

[Clearing conditions]

- The amount of data in the buffer becomes 0 because of forced ejection.

- 1 is written to the CLRHSWPRQM bit in the CHCTRL_n register.
- 1 is written to the SWRST bit in the CHCTRL_n register.

DNUM[7:0] bits (Data Number)

[Increment condition]

- When DMA read transfer is completed.

[Decrement condition]

- When DMA write transfer is completed.

[Clearing conditions]

- Conditions for clearing the EN bit are met.
- 1 is written to the SWRST bit in the CHCTRL_n register.

32.3.17.2 CHCTRL_n : Channel Control Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x428 + 0x40 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CLRDMARQM	SETDMARQM	CLRINTM	SETINTM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	SETSWPRQ	—	SETREN	—	—	CLRSUS	SETSUS	CLRDER	CLRTC	CLRENDD	CLRRQ	SWRST	STG	CLREN	SETEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SETEN	Set Enable Enables DMA transfer of DMA channel n. If this bit is set together with the SWRST bit, clearing by the SWRST bit takes precedence, and a transfer does not start. 0: No effect 1: DMA transfer is enabled. (The EN bit in the CHSTAT_n register is set)	W
1	CLREN	Clear Enable Clears the EN bit in the CHSTAT_n register. For details, see section 32.16.8.3. Aborting a Transfer. 0: No effect 1: DMA transfer is disabled. (The EN bit in the CHSTAT_n register is cleared)	W
2	STG	Software Trigger Activates the software (setting the internal transfer request). If this bit is set together with the SWRST bit, clearing by the SWRST bit takes precedence. 0: No effect 1: A transfer request is set by software. (The RQST bit in the CHSTAT_n register is set)	W
3	SWRST	Software Reset Clears each bit in the CHSTAT_n register. (For details on bits to be cleared, see descriptions of each bit.) Set this bit to 1 when the EN bit and the TACT bit are 0. 0: No effect 1: Clears each bit in the CHSTAT_n register	W

Bit	Symbol	Function	R/W
4	CLRRQ	Clear Request Clears the RQST bit in the CHSTAT_n register. 0: No effect 1: Clears the RQST bit in the CHSTAT_n register	W
5	CLREND	Clear End Clears the END bit in the CHSTAT_n register, and clears USB_FDMAn to low level. 0: No effect 1: Clears the END bit in the CHSTAT_n register	W
6	CLRTC	Clear TC Clears the TC bit in the CHSTAT_n register. 0: No effect 1: Clears the TC bit in the CHSTAT_n register	W
7	CLRDER	Clear DER Clears the DER bit in the CHSTAT_n register, and clears USB_FDMAn to low level. 0: No effect 1: Clears the DER bit in the CHSTAT_n register	W
8	SETSUS	Set Suspend Setting this bit to 1 when the EN bit in the CHSTAT_n register is 1 suspends the ongoing DMA transfer. 0: No effect 1: Suspends the ongoing DMA transfer	W
9	CLRSUS	Clear Suspend Setting this bit to 1 when the SUS bit in the CHSTAT_n register is 1 clears the suspended state. 0: No effect 1: Clears the suspended status of the ongoing DMA transfer	W
11:10	—	The write value should be 0.	W
12	SETREN	Set Register Set Enable Sets the REN bit in the CHCFG_n register. 0: No effect 1: Sets the REN bit in the CHCFG_n register to 1	W
13	—	The write value should be 0.	W
14	SETSSWPRQ	Set Software Sweep Request Forcibly ejects the data in the buffer to the transfer destination. See section 32.16.3. Forced Ejection Request. If the transfer destination asserts a hardware request (REQD = 1), forced ejection is not available (disabled by hardware). 0: No effect 1: Writes the buffer data (that has not been written to the transfer destination) to the transfer destination	W
15	—	The write value should be 0.	W
16	SETINTM	Set Interrupt Mask Temporarily masks USB_FDMAn and sets the INTM bit in the CHSTAT_n register to 1. 0: No effect 1: Masks USB_FDMAn	W
17	CLRINTM	Clear Interrupt Mask Clears the NT_DMA [n] pin output mask status, and clears the INTM bit in the CHSTAT_n register to 0. 0: No effect 1: Clears the mask status set by the SETINTM bit	W
18	SETDMARQM	SET DMAREQ Mask Temporarily masks a DMA transfer request from the USB control, and sets the DMARQM bit in the CHSTAT_n register to 1. 0: No effect 1: Masks a DMA transfer request from the USB control	W

Bit	Symbol	Function	R/W
19	CLRDMARQM	Clear DMAREQ Mask Clears the temporary mask status of the DMA transfer request from the USB control, and clears the DMARQM bit in the CHSTAT_n register to 0. 0: No effect 1: Clears the mask status set by the SETDMARQM bit	W
31:20	—	The write value should be 0.	W

The CHCTRL_n register controls DMA transfer of DMA channel n (n = 1, 0). This register is used to activate each function, and it does not retain written values.

32.3.17.3 CHCFG_n : Channel Configuration Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x42C + 0x40 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DMS	REN	RSW	RSEL	SBE	DIM	—	DEM	WONLY	TM	DAD	SAD	DDS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SDS[3:0]				DRRP	AM[2:0]			—	LVL	HIEN	LOEN	REQD	—	—	SEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SEL	Terminal Select Selects the FIFO channel to be used on the USB control side. 0: D0FIFO is used 1: D1FIFO is used	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	REQD	Request Direction Specifies whether the USB control side is source or destination. 0: The USB control side is source (initial value) 1: The USB control side is destination	R/W
4	LOEN	Sets the transfer request signal between the USB control and the DMAC. Always set this bit to 0.	R/W
5	HIEN	Sets the transfer request signal between the USB control and the DMAC. Always set this bit to 1.	R/W
6	LVL	Sets the transfer request signal between the USB control and the DMAC. Always set this bit to 1.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
10:8	AM[2:0]	These bits set the transfer request signal between the USB control and the DMAC. Always set these bits to 000b.	R/W
11	DRRP	Descriptor Read Repeat Switches operation when LV in the header is 0 after reading the descriptor. (See Figure 32.22.) 0: Sets the DER bit in the CHSTAT_n register to stop operation (initial value). 1: Reads the same descriptor continuously until LV becomes 1. When LV = 1, DMA transfer using the descriptor value starts. The descriptor read interval is controlled by the DSCITVL register.	R/W

Bit	Symbol	Function	R/W
15:12	SDS[3:0]	Source Data Size These bits set the DMA transfer size. When SDS[3] is set to 0, transfer mode is changed to normal mode. When SDS[3] is set to 1, transfer mode is changed to skip mode. Transfer size is set by SDS[2:0]. (For settable values, see Table 32.21.) 0 0 0: 8 bits (initial value) 0 0 1: 16 bits 0 1 0: 32 bits 0 1 1: 64 bits 1 0 0: 128 bits 1 0 1: 256 bits 1 1 0: 512 bits 1 1 1: 1024 bits	R/W
19:16	DDS[3:0]	Destination Data Size These bits set the DMA transfer size. When the USB control side is transfer destination, use the normal mode. When DDS[3] is set to 0, transfer mode is changed to normal mode. When SDS[3] is set to 1, transfer mode is changed to skip mode. Transfer size is set by DDS[2:0]. (For settable values, see Table 32.21.) 0 0 0: 8 bits (initial value) 0 0 1: 16 bits 0 1 0: 32 bits 0 1 1: 64 bits 1 0 0: 128 bits 1 0 1: 256 bits 1 1 0: 512 bits 1 1 1: 1024 bits	R/W
20	SAD	Source Address Direction Sets the count direction of the transfer source address of DMA channel n. When the USB control side is transfer source, set this bit to 1 (fixed). When using the skip mode on the transfer source side or when the transfer source is beat-unaligned, do not specify SAD = 1 (fixed). 0: Increment (initial value) 1: Fixed	R/W
21	DAD	Destination Address Direction Sets the count direction of the transfer destination address of DMA channel n. When the USB control side is transfer destination, set this bit to 1 (fixed). When using the skip mode on the transfer destination side or when the transfer destination is beat-unaligned, do not specify DAD = 1 (fixed). 0: Increment (initial value) 1: Fixed	R/W
22	TM	Sets the transfer request signal between the USB control and the DMAC. Always set this bit to 0.	R/W
23	WONLY	Write Only Mode Sets the write-only mode. For details, see section 32.15.1.3. Write-Only Mode. 0: Normal operation (initial value) 1: Write-only mode	R/W
24	DEM	USB_FDMAn Mask Masks USB_FDMAn interrupt detection. When this bit is 1 at USB_FDMAn timing, USB_FDMAn and END in the CHSTAT_n register are not asserted. In register mode, the DEM bit is automatically cleared to 0. In link mode, this bit is not cleared. 0: Does not mask USB_FDMAn interrupt detection (initial value) 1: Masks USB_FDMAn interrupt detection	R/W
25	—	This bit is read as 0. The write value should be 0.	R/W
26	DIM	Descriptor Interrupt Mask Sets masking for USB_FDMAn when LV = 0 after the descriptor's header is read. 0: Does not mask USB_FDMAn (initial value) 1: Masks USB_FDMAn	R/W

Bit	Symbol	Function	R/W
27	SBE	Sweep Buffer Enable Selects whether to sweep (by writing) the read data in the buffer before aborting the transfer when EN in the CHSTAT_n register is cleared to 0 during a DMA transaction. Sweep mode can be used only when REQD = 0. 0: Does not sweep buffer data and aborts the transfer (initial value) 1: Sweeps buffer data and aborts the transfer	R/W
28	RSEL	Register Set Select Selects the next register set to be executed next. This bit is valid only in register mode. When RSW = 1, this bit is automatically reversed upon completion of a DMA transaction. 0: Executes Next0 register set (initial value) 1: Executes Next1 register set	R/W
29	RSW	Register Select Switch The RSEL bit is automatically reversed upon completion of a DMA transaction. This bit is valid only in register mode. 0: Does not reverse the RSEL bit upon completion of a DMA transaction (initial value) 1: Reverses the RSEL bit upon completion of a DMA transaction	R/W
30	REN	Register Set Enable Performs DMA transaction of the next register set selected by the RSEL bit continuously after the current DMA transaction is completed. This bit is valid only in register mode. 0: Does not perform DMA transaction continuously 1: Performs DMA transaction continuously	R/W
31	DMS	DMA Mode Select Sets DMA mode. 0: Register mode (initial value) 1: Link mode	R/W

The CHCFG_n register controls DMA transfer of DMA channel n (n = 1, 0).

The settable size ranges of the SDS[2:0] and DDS[2:0] bits depend on the data bus width, number of implemented buffers, and alignment type of addresses to be accessed (beat-aligned or beat-unaligned). The following table shows the settable size ranges. These ranges are specified to prevent this controller from malfunctioning. Set appropriate values according to the module to be accessed.

Table 32.21 Settable size ranges of SDS[2:0] and DDS[2:0] bits

Data bus width [bit]	Number of buffers	Transfer address	Settable values of SDS[2:0] and DDS[2:0] bits	
32	16	Beat-aligned	8 to 32 bits 128 to 512 bits	(000b to 010b) (100b to 110b)
		Beat-unaligned	8 to 32 bits 128 to 256 bits	(000b to 010b) (100b to 101b)
		Beat-unaligned	8 to 32 bits	(000b to 010b)

If both transfer source and destination or either of these is beat-unaligned, set the SDS[2:0] and DDS[2:0] bits to values within the settable ranges for the beat-unaligned addresses from among the CHCFG_n register settings.

- Even when beat-aligned setting is made at the beginning of DMA transaction, if a skip transfer is used, beat-aligned setting may change to beat-unaligned setting during the DMA transaction. In this case, make beat-unaligned setting from the beginning.
- If the software cannot distinguish beat-aligned or beat-unaligned setting, use the beat-unaligned setting range.

DEM bit (USB_FDMAn Mask)

[Clearing condition]

A DMA transaction is completed when DEM = 1.

RSEL bit (Register Set Select)

[Transition condition]

A DMA transaction is completed when RSW = 1.

REN bit (Register Set Enable)

[Setting conditions]

- 1 is written to this bit.
- 1 is written to the SETREN bit in the CHCTRL_n register.

[Clearing conditions]

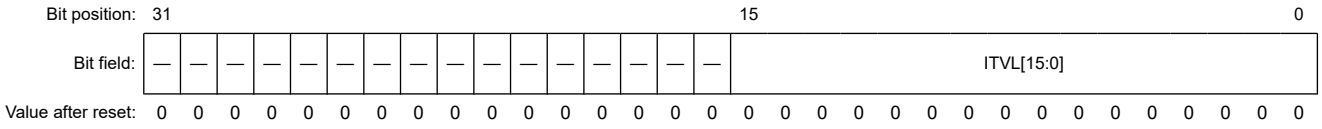
- 0 is written to this bit.
- A DMA transaction is completed when REN = 1.

To re-set the REN bit during a DMA transaction, use the SETREN bit in the CHCTRL_n register.

32.3.17.4 CHITVL_n : Channel Interval Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x430 + 0x40 × n



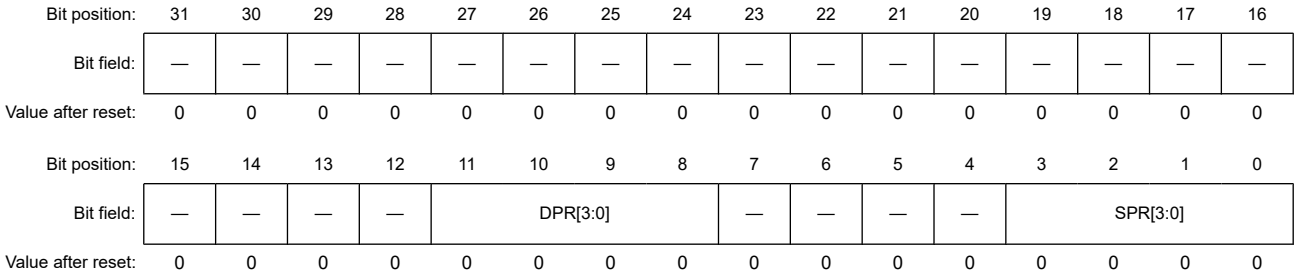
Bit	Symbol	Function	R/W
15:0	ITVL[15:0]	Interval These bits set the DMA transfer interval.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The CHITVL_n register sets the DMA transfer interval of DMA channel n (n = 1, 0).

32.3.17.5 CHEXT_n : Channel Extension Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x434 + 0x40 × n



Bit	Symbol	Function	R/W
3:0	SPR[3:0]	Source PROT These bits set the value to be output to the MHPROT[3:0] pins during DMA read transfer.	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
11:8	DPR[3:0]	Destination PROT These bits set the value to be output to the MHPROT[3:0] pins during DMA write transfer.	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The CHEXT_n register is an extension register for DMA channel n.

32.3.18 Link Register Set

The link register set is used to set and display the descriptor address in link mode.

When the descriptor address is set in the NXLA_n register by software to activate the DMAC, the NXLA_n register value is loaded to the CRLA_n register by hardware and the descriptor is read. The DMAC starts a DMA transaction according to the read descriptor value. The NXLA_n register value is automatically updated by the next link address value in the read descriptor to be used as the descriptor address for the next DMA transaction.

32.3.18.1 NXLA_n : Next Link Address Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x438 + 0x40 × n

Bit position:	31																												0
Bit field:	NXLA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	NXLA[31:0]	Next Link Address These bits set the address of the link destination. Because the two lower-order bits are fixed to 0, only word-aligned addresses can be set.	R/W

The NXLA_n register sets the link address of DMA channel n (n = 1, 0).

32.3.18.2 CRLA_n : Current Link Address Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x43C + 0x40 × n

Bit position:	31																												0
Bit field:	CRLA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CRLA[31:0]	Current Link Address These bits display the address of the descriptor that is being executed.	R

The CRLA_n register displays the link address of DMA channel n (n = 1, 0).

32.3.19 Skip Register Set

The skip register set is used for settings for skip (scatter/gather) transfer.

32.3.19.1 SCNT_n : Source Continuous Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x600 + 0x20 × n

Bit position:	31																												0
Bit field:	SCNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SCNT[31:0]	Source Continuous These bits set the size (in bytes) of continuous access space for access to the transfer source address.	R/W

The SCNT_n register sets the space size for continuous access to the transfer source address of DMA channel n (n = 1, 0).

Use this register together with the SSKP_n register (see Figure 32.4).

When using this mode, set the SDS[3] bit in the CHCFG_n register to 1.

When performing a skip transfer on the transfer source side, do not set the SAD bit in the CHCFG_n register to 1 (fixed). In addition, do not perform a skip transfer when SCNT_n is set to 0x00000000.

32.3.19.2 SSKP_n : Source Skip Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x604 + 0x20 × n

Bit position:	31																												0
Bit field:	SSKP[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SSKP[31:0]	Source Skip These bits set the skip amount (in bytes) during access to the source address.	R/W

The SSKP_n register sets the skip amount for skipping the next source address after accessing the data size set by the SCNT_n register during access to the source address of DMA channel n (n = 1, 0).

Use this register together with the SCNT_n register (see Figure 32.4).

When using this mode, set the SDS[3] bit in the CHCFG_n register to 1.

When performing a skip transfer on the transfer source side, do not set the SAD bit in the CHCFG_n register to 1 (fixed).

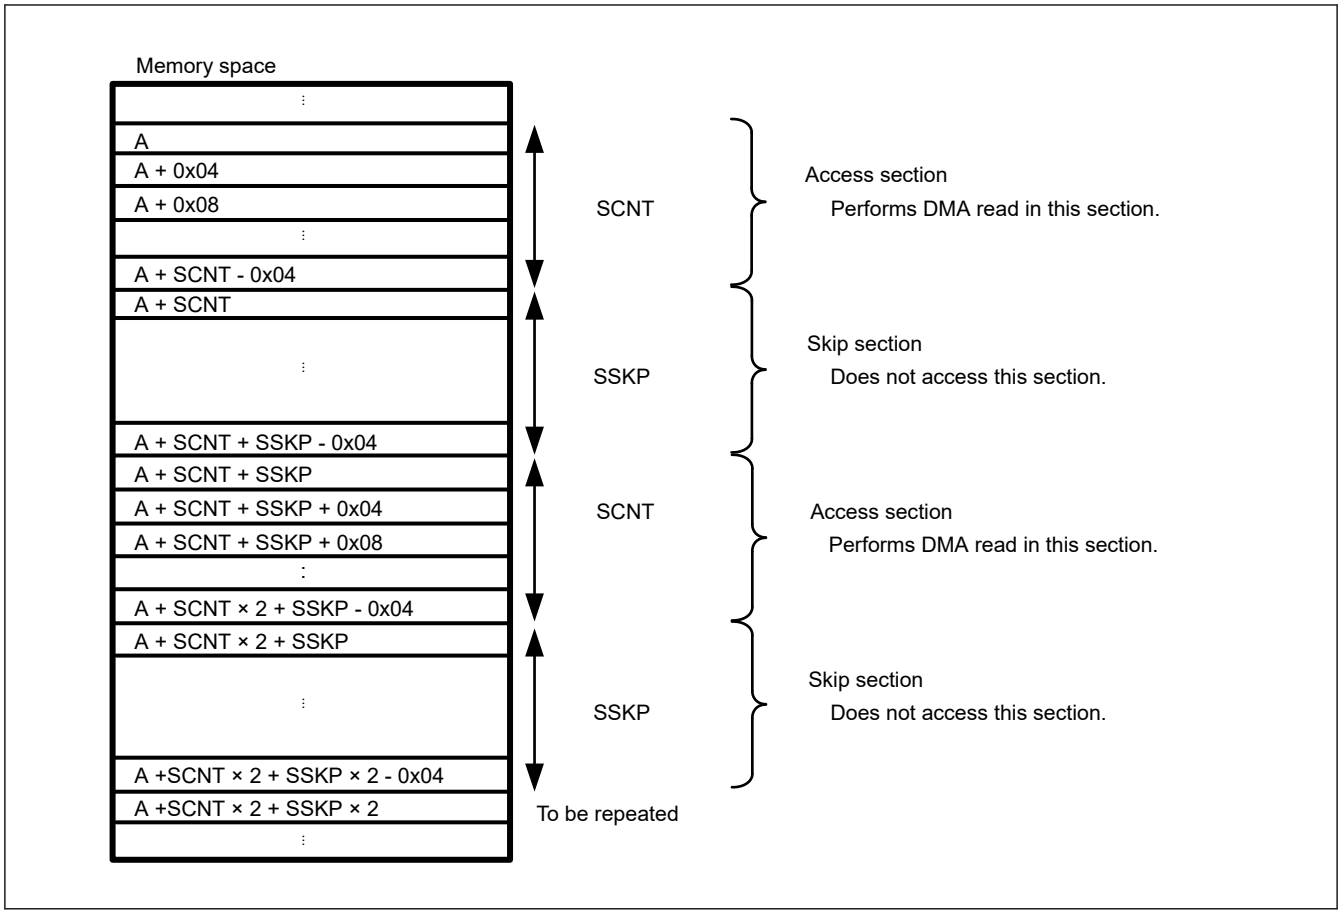


Figure 32.4 Relationship between SSKP and SCNT

The SCNT and SSKP_n values can be set regardless of the source address and the set value of the SDS field in the CHCFG_n register. The DMAC accesses a memory space with the size set in the SDS field, and acquires only valid data into the buffer. For details, see section 32.17.1.1. Read Access.

32.3.19.3 DCNT_n : Destination Continuous Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x608 + 0x20 × n

Bit position:	31																												0
Bit field:	DCNT[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DCNT[31:0]	Destination Continuous These bits set the space size (in bytes) for continuous access during an access to the destination address.	R/W

The DCNT_n register sets the space size for continuous access during an access to the destination address of DMA channel n (n = 1, 0).

Use this register together with the DSKP_n register (see Figure 32.5).

When using this mode, set the DDS[3] bit in the CHCFG_n register to 1.

When performing a skip transfer on the transfer destination side, do not set the DAD bit in the CHCFG_n register to 1 (fixed). In addition, do not perform a skip transfer when DCNT is set to 0x00000000.

32.3.19.4 DSKP_n : Destination Skip Register n (n = 0, 1)

Base address: USBF = 0x9204_1000

Offset address: 0x60C + 0x20 × n

Bit position:	31																												0
Bit field:	DSKP[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DSKP[31:0]	Destination Skip These bits set the skip amount (in bytes) during access to the destination address.	R/W

The DSKP_n register sets the skip amount for skipping the next destination address after accessing the data size set by the DCNT_n register during access to the destination address of DMA channel n (n = 1, 0).

Use this register together with the DCNT_n register (see Figure 32.5).

When using this mode, set the DDS[3] bit in the CHCFG_n register to 1.

When performing a skip transfer on the transfer destination side, do not set the DAD bit in the CHCFG_n register to 1 (fixed).

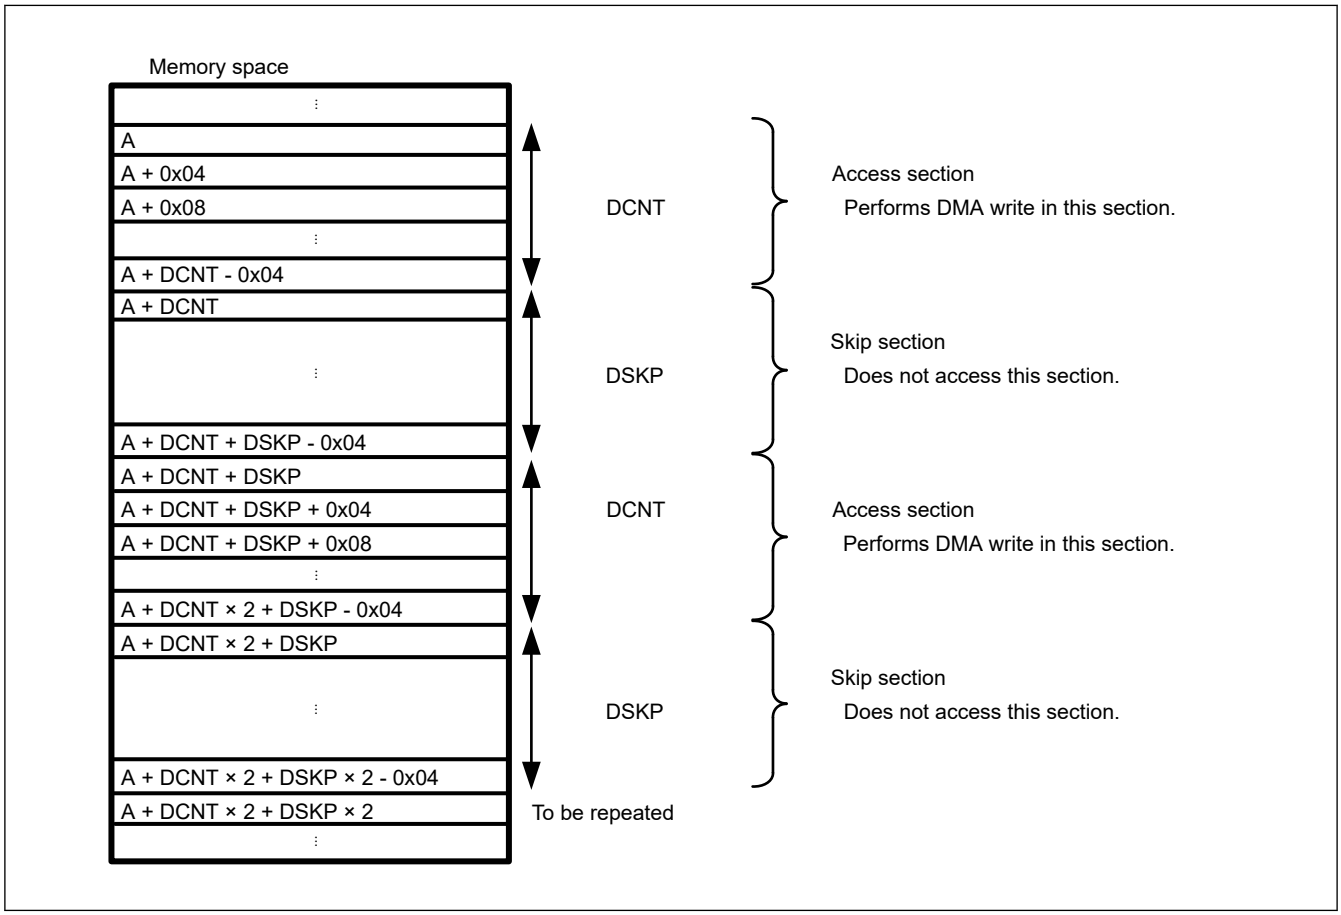

Figure 32.5 Relationship between DSKP and DCNT

The DCNT and DSKP_n values can be set regardless of the destination address and the set value of the DDS field in the CHCFG_n register. The DMAC performs write access only to the specified space with the size equal to or smaller than the value set in the DDS field. For details, see section 32.17.1.2. Write Access.

32.3.20 DMA Register Set

The following registers are common to all channels.

32.3.20.1 DCTRL : DMA Control Register

Base address: USBF = 0x9204_1000

Offset address: 0x700

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	LWPR[3:0]				—	—	—	—	LDPR[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PR	Priority Sets transfer priority control mode. See section 32.16.2. DMA Channel Priority Control. 0: Fixed priority mode 1: Round-robin mode	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W
19:16	LDPR[3:0]	Link Descriptor PROT These bits set the value to be output to the MHPROT[3:0] pins during descriptor read in link mode.	R/W
23:20	—	These bits are read as 0. The write value should be 0.	R/W
27:24	LWPR[3:0]	Link WriteBack PROT These bits set the value to be output to the MHPROT[3:0] pins during descriptor writeback in link mode.	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

The DCTRL register sets the transfer type for descriptor access and the arbitration between channels.

32.3.20.2 DSCITVL : Descriptor Interval Register

Base address: USBF = 0x9204_1000

Offset address: 0x704

Bit position:	31								15							8								0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DITVL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
15:8	DITVL[7:0]	Descriptor Interval These bits set the descriptor read interval. The descriptor is read again with an interval of (DITVL × 256) cycles.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The DSCITVL register sets the descriptor read interval.

By setting the DRRP bit in the CHCFG_n register to 1, the descriptor is continuously read until it reaches LV = 1. This register sets the read interval.

32.3.20.3 DSTAT_EN : DMA Status EN Register

Base address: USBF = 0x9204_1000

Offset address: 0x710

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EN1	EN0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EN0	Channel 0 EN Displays the EN bit status of DMA channel 0.	R
1	EN1	Channel 1 EN Displays the EN bit status of DMA channel 1.	R
31:2	—	These bits are read as 0.	R

The DSTAT_EN register displays the EN bit status of all channels.

Writing data to this register does not change the value of each bit.

32.3.20.4 DSTAT_ER : DMA Status ER Register

Base address: USBF = 0x9204_1000

Offset address: 0x714

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ER1	ER0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ER0	Channel 0 ER Displays the ER bit status of DMA channel 0.	R
1	ER1	Channel 1 ER Displays the ER bit status of DMA channel 1.	R
31:2	—	These bits are read as 0.	R

The DSTAT_ER register displays the ER bit status of all channels.

Writing data to this register does not change the value of each bit.

32.3.20.5 DSTAT_END : DMA Status END Register

Base address: USBF = 0x9204_1000

Offset address: 0x718

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	END1	END0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	END0	Channel 0 END Displays the END bit status of DMA channel 0.	R
1	END1	Channel 1 END Displays the END bit status of DMA channel 1.	R
31:2	—	These bits are read as 0.	R

The DSTAT_END register displays the END bit status of all channels.

Writing data to this register does not change the value of each bit.

32.3.20.6 DSTAT_TC : DMA Status TC Register

Base address: USBF = 0x9204_1000

Offset address: 0x71C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TC1	TC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TC0	Channel 0 TC Displays the TC bit status of DMA channel 0.	R
1	TC1	Channel 1 TC Displays the TC bit status of DMA channel 1.	R
31:2	—	These bits are read as 0.	R

The DSTAT_TC register displays the TC bit status of all channels.

Writing data to this register does not change the value of each bit.

32.3.20.7 DSTAT_SUS : DMA Status SUS Register

Base address: USBF = 0x9204_1000

Offset address: 0x720

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SUS1	SUS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SUS0	Channel 0 SUS Displays the SUS bit status of DMA channel 0.	R
1	SUS1	Channel 1 SUS Displays the SUS bit status of DMA channel 1.	R
31:2	—	These bits are read as 0.	R

The DSTAT_SUS register displays the SUS bit status of all channels.

Writing data to this register does not change the value of each bit.

32.4 Operation

32.4.1 System Controls and Oscillation Controls

This section describes the register operations required for initial settings of this module, and the registers necessary for power consumption control. The startup sequence is as follows.

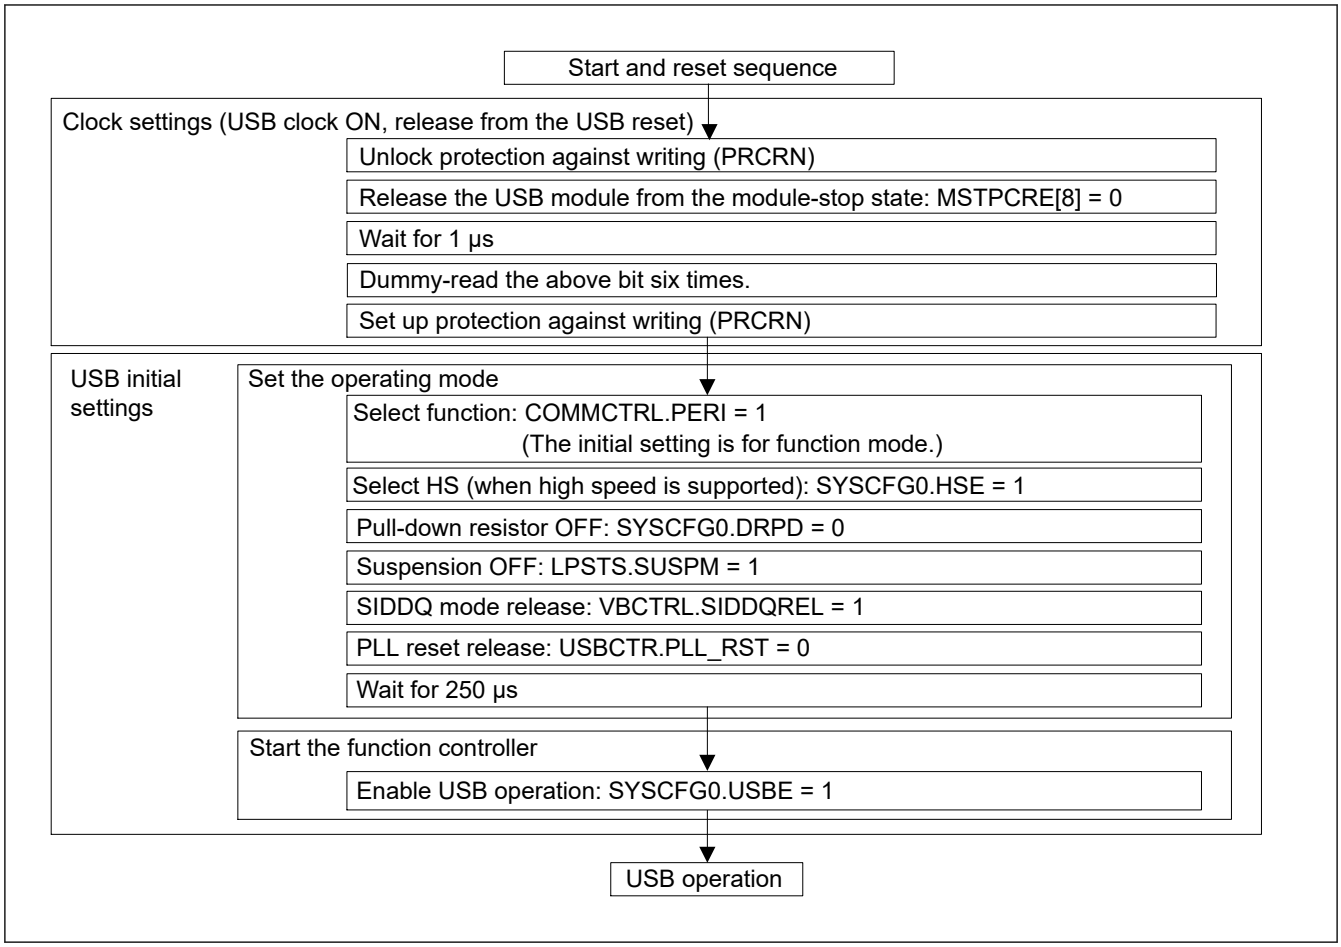

Figure 32.6 Startup sequence

32.4.2 Resets

Table 32.22 lists the types of reset for this controller. For the initial states of the registers following the reset operations, see .

Table 32.22 Types of reset

Name	Operation
Hardware reset	Low level input from the RES# pin
USB bus reset	Automatically detected by this module from the D+ and D- lines

32.4.3 USB Data Bus Resistor Controller

This controller controls the pull-up resistors for the D+ signal of the USB2.0-PHY port.

Make pull-up setting for the D+ signal using the DPRPU and DRPD bits of the SYSCFG0 register.

Confirm the connection to the USB Host before setting the DPRPU bit of the SYSCFG0 register to 1 to pull up D+.

This controller incorporates termination resistors for the D+ and D− signals (in high-speed operation mode) and output resistors (in full-speed operation mode). The switching of the internal resistors following the connection to the PC is automatically done by the controller during reset handshake, suspend, and resume processing.

If the DPRPU bit of the SYSCFG0 register is set to 0 during communication with the PC, the controller disables the pull-up resistors (or termination resistors) of the USB data lines, so that it can notify the host controller of the disconnection of the device.

32.4.4 Notes on Stopping Clocks

- The PHY clock can be stopped with the SUSPM register in suspend mode.

- If a clock is to be stopped while the controller is in USB suspended state, however, it is necessary to resume the supply of the clock during resume processing. The resumption of the PHY clock need be accomplished within 5.5 ms after a resume interrupt occurs.
- When the USB function is not in use, place the USB module in the module-stop state (MSTPCRE[8] = 1).

32.5 Interrupt Functions

32.5.1 Overview of Interrupt Functions

Table 32.23 lists the interrupt functions of this controller.

Table 32.23 List of interrupt functions

Bit	Interrupt name	Interrupt source	Related status
VBINT	VBUS interrupt	When a change in the state of the USB_VUBUSIN input pin has been detected (low to high or high to low).	VBSTS
RESM	Resume interrupt	When a change in the state of the USB bus has been detected in the suspended state (J-state to K-state or J-state to SE0)	—
SOFR	Frame number update interrupt	If SOFRM = 0: When an SOF packet with a different frame number is received. If SOFRM = 1: When an SOF packet for a μ frame number of 0 cannot be received due to a corrupted packet.	—
DVST	Device state transition interrupt	When transition in device state is detected: A USB bus reset detected The suspended state detected Set Address request received Set Configuration request received	DVSQ
CTRT	Control transfer stage transition interrupt	When a stage transition is detected in control transfer: Setup stage completed Control write transfer status stage transition Control read transfer status stage transition Control transfer completed A control transfer sequence error occurred	CTSQ
BEMP	Buffer empty interrupt	When the buffer becomes empty after all data in the buffer memory has been transmitted. When a packet exceeding the maximum packet size is received.	PIPEBEMP
NRDY	Buffer not ready interrupt	When a token is received when PID = BUF and the buffer memory is not ready to transmit or receive data. When a CRC error or bit stuff error occurs while receiving data in isochronous transfer. When an interval error occurs while receiving data in isochronous transfer.	PIPENRDY
BRDY	Buffer ready interrupt	When the buffer is ready (readable or writable).	PIPEBRDY

Table 32.24 shows operations for a USBf interrupt output from this controller. In case more than one interrupt source is generated, the USBf interrupt output method can be set by using the INTL bit in the SOFCFG register. Set the USBf interrupt output operation according to the user system.

Table 32.24 Operations for USBf Interrupt (USB_FI)

INTL setting	USBf interrupt output pin operation	
	When one interrupt source is generated	When more than one interrupt source is generated
Edge sense (INTL = 0)	Holds the pin low until the interrupt source is cleared.	Negated (L pulse output) for 40 clock cycles at 60 MHz when one source is cleared.
Level sense (INTL = 1)	Holds the pin low until the interrupt source is cleared.	Holds the pin low until all sources are cleared.

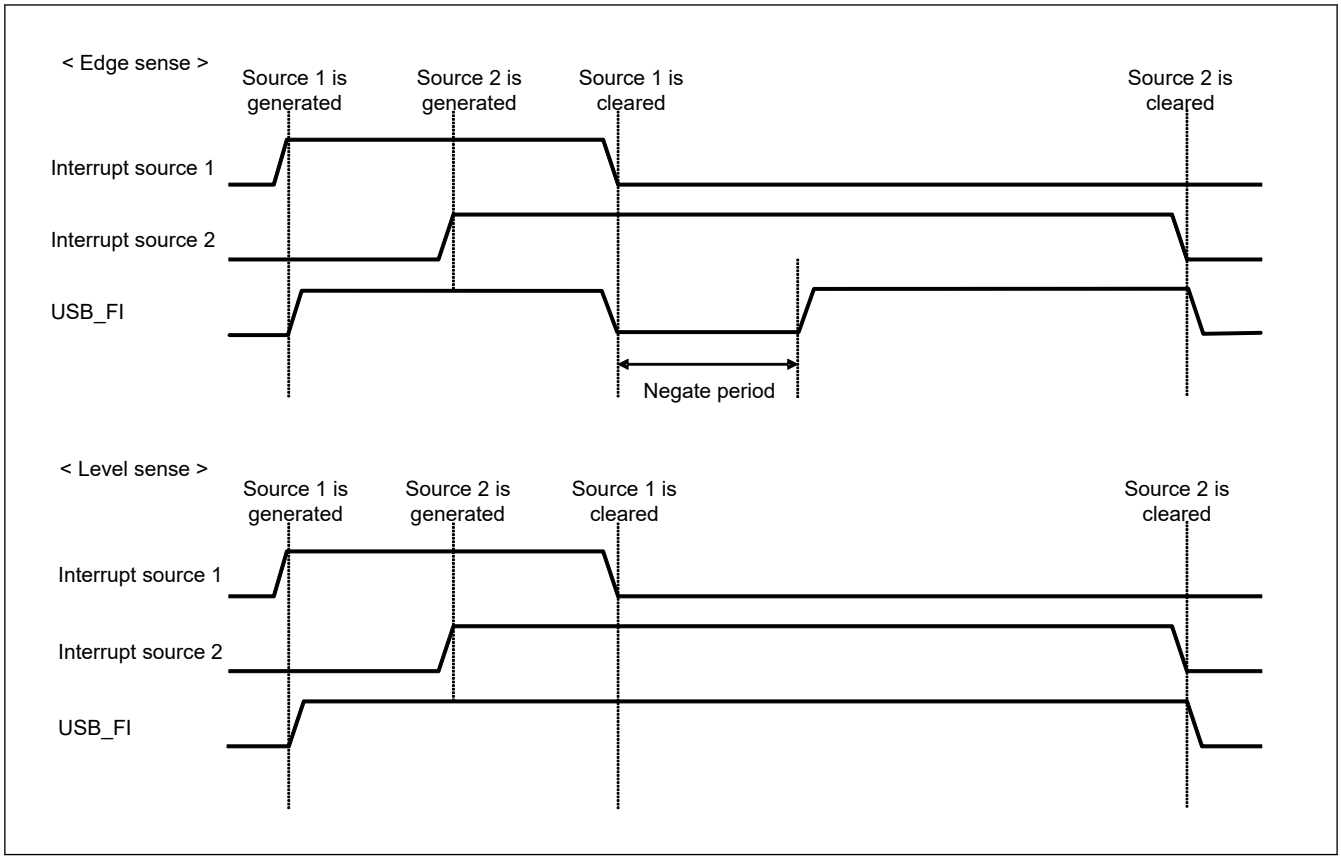

Figure 32.7 USBf interrupt output operation diagram

Figure 32.8 shows the interrupt configurations for the controller.

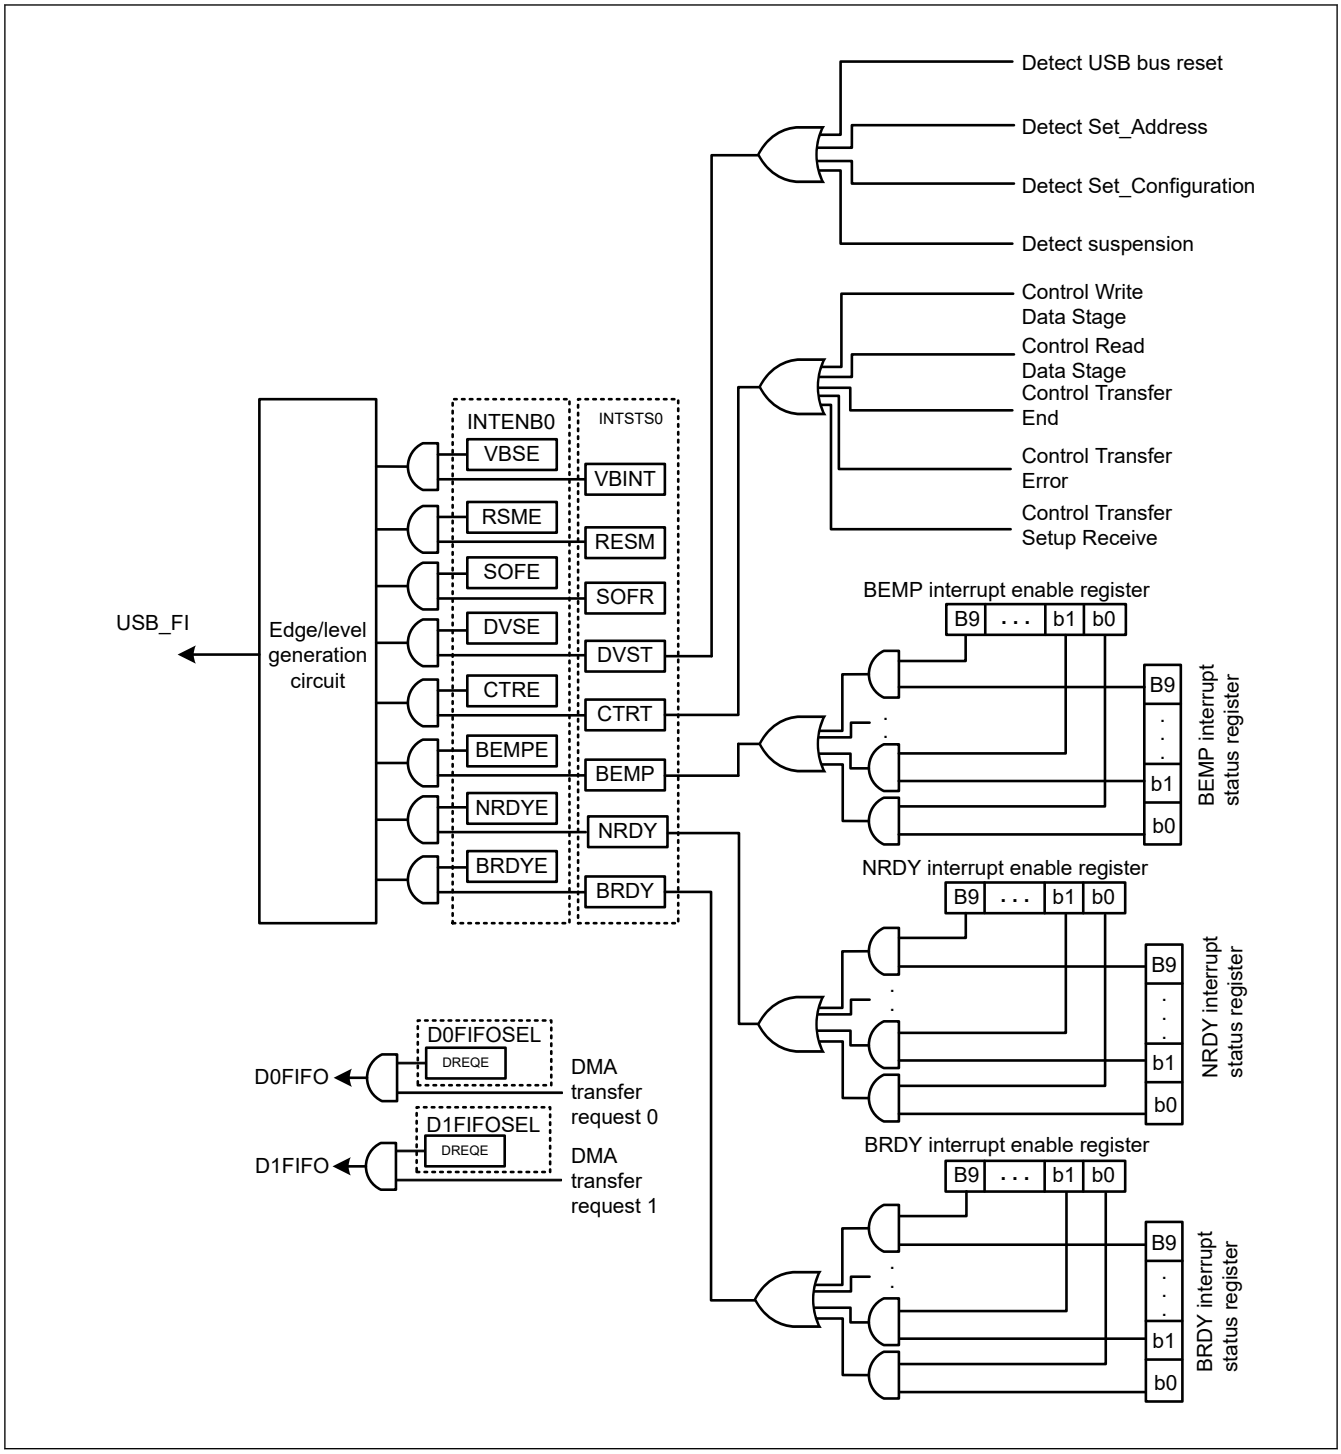

Figure 32.8 Interrupt configuration diagram

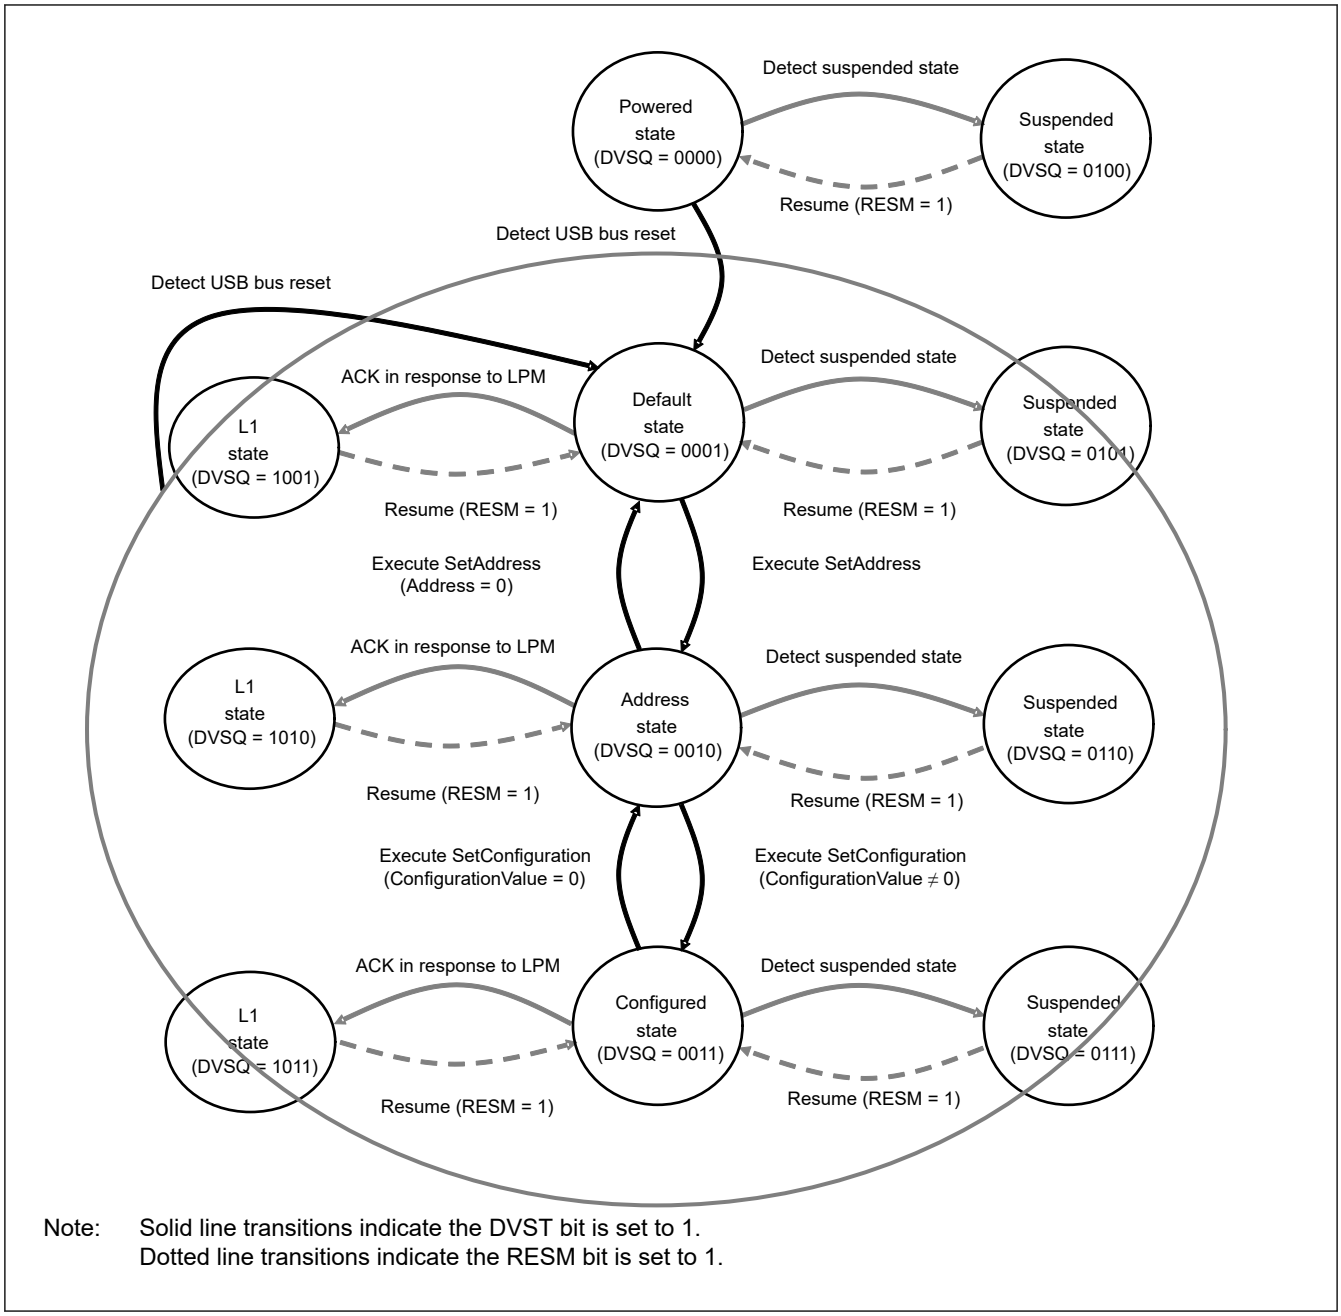
32.5.2 Device State Transition Interrupt

Figure 32.9 shows a diagram of how this module handles the device state transitions. The controller monitors the device states and generates the device state transition interrupts. However, recovery from the suspended state (resume signal detection) is detected by the resume interrupt. The device state transition interrupts can be enabled or disabled individually by setting the INTENB0 register. The device state after a transition can be confirmed using the DVSQ bits in the INTSTS0 register.

When making a transition to the default state, the device state transition interrupt is generated after the reset handshake protocol has been completed.



Note: Solid line transitions indicate the DVST bit is set to 1.
Dotted line transitions indicate the RESM bit is set to 1.

Figure 32.9 Device state transitions

32.5.3 Control Transfer Stage Transition Interrupt

Figure 32.10 shows a diagram of how this module handles the control transfer stage transition. The controller monitors the control transfer sequence and generates the control transfer stage transition interrupts. The control transfer stage transition interrupts can be enabled or disabled individually in the INTENB0 register. The control transfer stage after a transition can be confirmed in the CTSQ bits in the INTSTS0 register.

The control transfer sequence errors are described below. If an error occurs, the PID bits in DCPCTR are set to 1xb (STALL).

1. During control read transfers
   (a) At the IN token of the data stage, an OUT or PING token is received when there have been no data transfers at all.
   (b) An IN token is received at the status stage.
   (c) A packet is received at the status stage for which the data packet is DATAPID = DATA0.
2. During control write transfers

(a) At the OUT token of the data stage, an IN token is received when there have been no ACK response at all.

(b) A packet is received at the data stage for which the first data packet is DATAPID = DATA0.

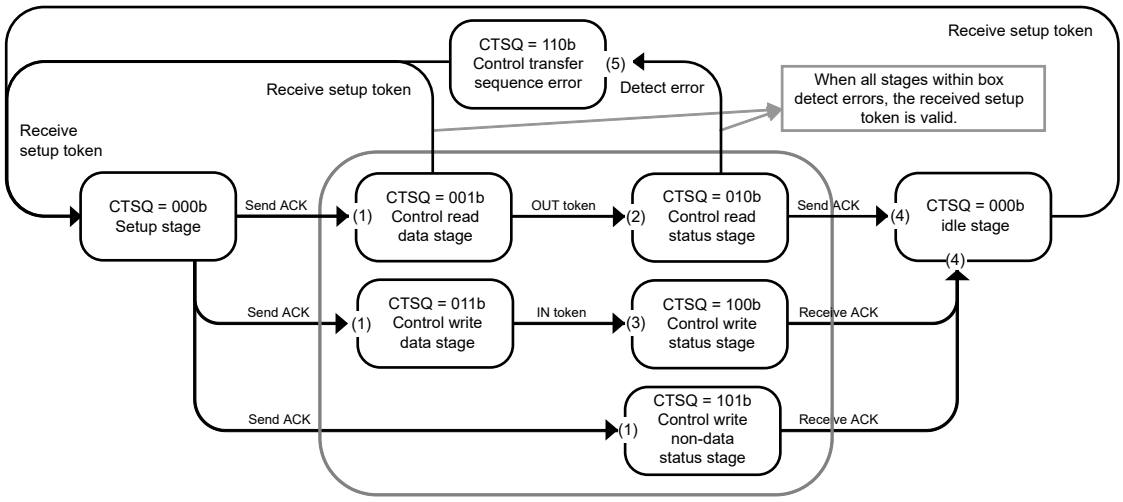
(c) At the status stage, an OUT or PING token is received.

3. During control write no-data transfers

(a) At the status stage, an OUT or PING token is received.

Note that in the control write transfer data stage, if the number of received data is more than the USB request wLength value, the control transfer sequence error cannot be recognized. Also, in the control read transfer status stage, when a packet other than a zero-length packet is received, an ACK response is returned and the transfer is successfully completed.

When a CTRT interrupt is generated due to a sequence error (SERR = 1), the value of CTSQ = 110b is retained until CTRT = 0 is written by the user system (clearing the interrupt state). Therefore, while CTSQ = 110b is retained, the CTRT interrupt for the completion of the setup stage is not generated, even when a new USB request is received. Events occurring after the setup stage are saved by the controller and the CTRT interrupt is generated after the interrupt state is cleared by software.



Note: CTRT interrupt
(1) Setup stage end
(2) Control read transfer status stage transition
(3) Control write transfer status stage transition
(4) Control transfer complete
(5) Control transfer sequence error

Figure 32.10 Control transfer stage transition

32.6 Pipe Control

Table 32.25 provides a list of pipe settings for the controller. In USB data transfers, data transmission is executed in logic pipes called endpoints. This controller comes with ten pipes for data transfer. Each pipe can be set to meet the requirements of the user system.

Table 32.25 Pipe settings

Register name	Bit name	Setting	Remarks
PIPECFG	TYPE	Specifies the transfer type	Can be set for pipes 1 to 9.
	BFRE	Selects BRDY interrupt mode	Can be set for pipes 1 to 5.
	DBLB	Selects double buffer configuration	Can be set for pipes 1 to 5.
	CNTMD	Selects continuous transfer or noncontinuous transfer	Can be set for pipes 1 and 2 only in bulk transfers. Can be set for pipes 3 to 5.
	DIR	Selects transfer direction	Set to IN or OUT
	EPNUM	Endpoint number	Can be set for pipes 1 to 9. Set to a value other than 0x0 when a pipe is in use.
	SHTNAK	Disables pipe when transfer is completed.	Can be set for pipes 1 and 2 only in bulk transfers. Can be set for pipes 3 to 5.
PIPEBUF	BUFSIZE	Buffer memory size	Cannot be set for DCP (fixed to 256 bytes). Up to 2 KB can be set for pipes 1 to 5. Cannot be set for pipes 6 to 9 (fixed to 64 bytes).
	BUFNMB	Buffer memory number	Cannot be set for DCP (fixed at areas 0x00 to 0x03). Can be set for pipes 1 to 5 (specifiable in area ranging from 0x08 to 0x80). Cannot be set for pipes 6 to 9 (fixed at areas ranging from 0x04 to 0x07).
DCPMAXP PIPEMAXP	MXPS	Maximum packet size	Setting conforming to the USB standard
PIPEPERI	IFIS	Buffer flush	Can be set for pipes 1 and 2 only in isochronous transfers. Cannot be set for pipes 3 to 5. Cannot be set for pipes 6 to 9.
	IITV	Interval counter	Can be set for pipes 1 and 2 only in isochronous transfers. Cannot be set for pipes 3 to 5. Cannot be set for pipes 6 to 9.
DCPCTR PIPExCTR	BSTS	Buffer status	DCP state switched between receive and transmission buffer by ISEL bit
	INBUFM	IN buffer monitor	Available only for pipes 3 to 5.
	ATREPM	Auto response mode	Can be set for pipes 1 to 5.
	ACLRM	Auto buffer clear	Can be set for pipes 1 to 9.
	SQCLR	Sequence clear	Clears data toggle bit.
	SQSET	Sequence set	Sets data toggle bit.
	SQMON	Sequence check	Monitors data toggle bit.
	PBUSY	Pipe busy check	—
	PID	Response PID	—
PIPExTRE	TRENB	Transaction count enable	Can be set for pipes 1 to 5.
	TRCLR	Current transaction counter clear	Can be set for pipes 1 to 5.
PIPExTRN	TRNCNT	Transaction counter	Can be set for pipes 1 to 5.

32.6.1 Maximum Packet Size Setting

The MXPS bits in DCPMAXP and PIPEMAXP are used to specify the maximum packet size for each pipe. DCP and PIPE1 to PIPE5 can be set to any of the maximum packet sizes defined by the USB Specification. For PIPE6 to PIPE9, 64 bytes are the upper limit of the maximum packet size. The maximum packet size should be set before beginning the transfer (PID = BUF).

DCP: 64 should be set when using high-speed operation.

DCP: Select and set 8, 16, 32, or 64 when using full-speed operation.

Pipes 1 to 5: 512 should be set when using high-speed bulk transfer.

Pipes 1 to 5: Select and set 8, 16, 32, or 64 when using full-speed bulk transfer.

Pipes 1 to 2: Set a value between 1 and 1024 when using high-speed isochronous transfer.

Pipes 1 to 2: Set a value between 1 and 1023 when using full-speed isochronous transfer.

Pipes 6 to 9: Set a value between 1 and 64.

The high bandwidth transfers used with interrupt transfers and isochronous transfers are not supported.

32.6.2 Response PID

Set the response PID for each pipe with the PID bits of the DCPCTR and PIPExCTR registers.

1. Response PID setting
   The response PID specifies the response to a transaction from the Host.
   (a) NAK setting: Always sends a NAK response when a transaction is issued.
   (b) BUF setting: Responds to the transaction in accordance with the buffer memory state.
   (c) STALL setting: Always sends a STALL response when a transaction is issued.

   Regardless of the value set in the PID bit, an ACK is always sent as a response to a setup transaction and the USB request is stored in corresponding registers.
   Based on the results of the transaction, the controller may trigger the PID bits to be written.
   The controller will trigger a write event to the PID bit in the following cases.
2. Hardware setting of response PID
   (a) NAK setting:
      (i) When SETUP token is received normally (only DCP)
      (ii) In bulk transfers when the SHTNAK bit of the PIPECFG register is set to 1 and short packet is received.
      (iii) In bulk transfers when SHTNAK bit is set to 1 and the transaction counter is completed.
   (b) BUF setting: The BUF cannot be written by the controller.
   (c) STALL setting:
      (i) When a maximum packet size over error is detected in the received data packet
      (ii) When a control transfer sequence error is detected

32.6.3 Pipe Control Register Switching Procedures

The following bits in the pipe control registers can be re-written only when USB transmission is disabled (PID = NAK). Figure 32.11 shows the procedure for switching the pipe control register from the USB transmission enabled (PID = BUF) state.

Registers for which settings are prohibited when the USB transmission is enabled (PID = BUF):

- All bits of the DCPMAXP register
- Bits SQCLR and SQSET of the DCPCTR register
- All bits of the PIPECFG, PIPEBUF, PIPEMAXP and PIPEPERI registers
- ATREPM, ACLRM, SQCLR, and SQSET bits of the PIPExCTR register
- All bits of the PIPExTRE and PIPExTRN registers

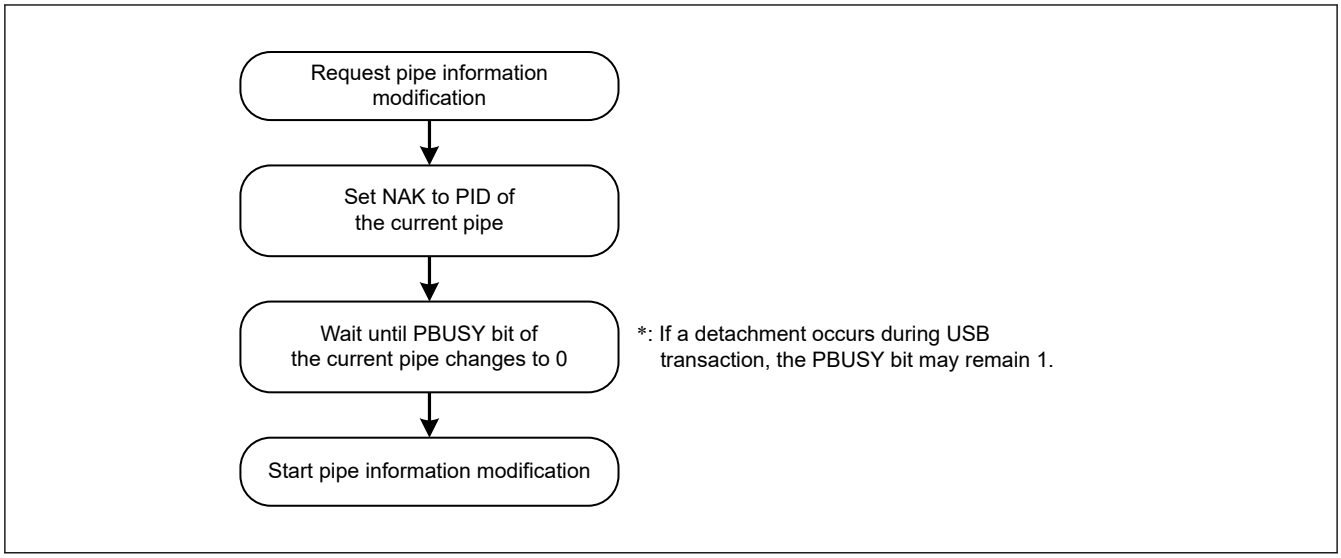


Figure 32.11 Procedure for changing pipe information from USB transmission enabled (PID = BUF) state

In addition, the following bits of the pipe control registers can only be re-written with pipe information that is not set in the CURPIPE bits of CPU/DMA0/DMA1-FIFO ports.

- Register for which settings are prohibited during setting of the CURPIPE bits in the FIFO port register:
  - All bits of the DCPMAXP register
  - All bits of the PIPECFG, PIPEBUF, PIPEMAXP and PIPEPERI registers
  - Bit ACLRM of the PIPExCTR register

When modifying information of a pipe, specify other pipe number in the CURPIPE bits. Also, after setting the DCP pipe information, clear the buffer using the BCLR bit.

32.6.4 Data PID Sequence Bit

When a normal data transfer occurs in the control transfer data stage, bulk transfer or interrupt transfer, the controller automatically toggles the data PID sequence bit. The next data PID sequence bit for data transfer can be confirmed in the SQMON bit in the DCPCTR or PIPExCTR registers. The sequence bit is switched in the ACK handshake receive timing when data is sent or in the ACK handshake send timing when data is received. The data PID sequence bit can also be modified for the SQCLR and SQSET bits of the DCPCTR and PIPExCTR registers.

In control transfers, the controller automatically sets the sequence bit for stage transitions. DATA1 is established at the end of the setup stage. In the status stage, the controller does not reference the sequence bit and returns a response with PID = DATA1. Therefore, the bit does not need to be set with software. Note that the data PID sequence bit must be set with software when a ClearFeature request is received.

Finally, the sequence bit cannot be manipulated through the SQSET bit for the isochronous transfer setup pipe.

32.7 FIFO Buffers

This section describes the operation of the FIFO buffers in this controller.

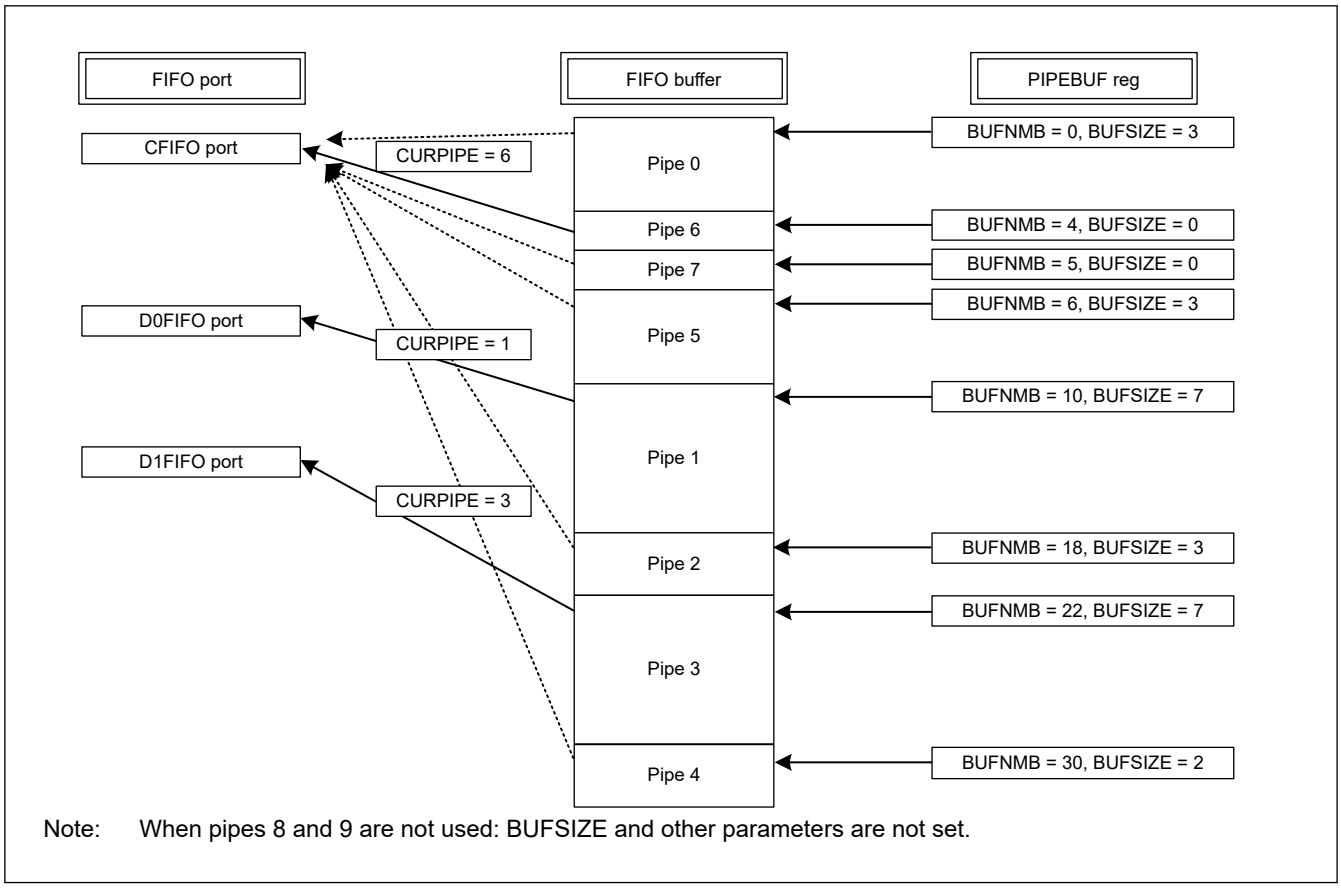
32.7.1 FIFO Buffer Allocation

Figure 32.12 shows an example of memory map for the FIFO buffers of this controller. The FIFO buffer area is shared by the CPU controlling the user system and this controller. The access right of the FIFO buffers may be given to the user system (CPU side) or to this controller (SIE side).

An independent FIFO buffer area is allocated for each pipe. The memory area is made up of memory blocks of 64 bytes and defined by the starting block number (1 block is 64 bytes long) and the number of blocks (specified by the BUFNMB and BUFSIZE bits of the PIPEBUF register). If the CNTMD bit of the PIPExCFG register is set to continuous transfer mode, the value specified in the BUFSIZE bits must be an integral multiple of the maximum packet size. If the double buffer configuration is selected through the DBLB bit of the PIPExCFG register, two planes of memory area the size of which is specified by the BUFSIZE bits of the PIPEBUF register are allocated to a single pipe.

Two FIFO ports are used to access an FIFO buffer (data read/write). The pipe to be assigned to an FIFO port is designated by specifying the pipe number in the CURPIPE bits of the CFIFOSEL or DxFIFOSEL register.

The FIFO buffer state of each pipe can be confirmed by using the BSTS and INBUFM bits of the DCPCTR and PIPExCTR registers. The access right of a FIFO port can be confirmed by using the FRDY bit of the CFIFOCTR or DxFIFOCTR register.



Note: When pipes 8 and 9 are not used: BUFSIZE and other parameters are not set.

Figure 32.12 Example of FIFO buffer memory map

32.7.2 Clearing FIFO Buffers

Table 32.26 shows a list of modes of clearing the FIFO buffers by this controller. The FIFO buffers can be cleared by the 3 bits that are listed in the table.

Table 32.26 List of FIFO buffer clearing modes

Bit name	BCLR	DCLRM	ACLRM
Register	CFIFOCTR register DxFIFOCTR register	DxFIFOSEL register	PIPExCTR register
Function	The FIFO buffer on the CPU side is cleared.	The FIFO buffer is automatically cleared after the data is read from the designated pipe.	The buffer is automatically cleared to discard all the received packets.
Clearing method	Write 1 to clear.	1: Mode valid 0: Mode invalid	1: Mode valid 0: Mode invalid

32.8 FIFO Port Function

This section describes FIFO port functions. Table 32.27 lists settings of FIFO port functions of this controller. If writing data is continued until the buffer becomes full (up to the maximum packet size in discontinuous transfer mode) during the data write access, the FIFO port automatically enters the state where data can be transmitted to the USB bus. To make data with a size less than the buffer full (the maximum packet size in discontinuous transfer mode) transmittable, write completion must

be set by the BVAL bit in the CFIFOCTR or DxFIFOCTR register. Furthermore, to transmit a zero-length packet, clear the buffer by the BCLR bit in the CFIFOCTR or DxFIFOCTR register and set write completion by the BVAL bit.

When all data has been read during the read access, the FIFO port automatically enters the state where a new packet can be received. However, when a zero-length packet is received (DTLN = 0), the data cannot be read. In that case, clear the buffer by the BCLR bit in the CFIFOCTR or DxFIFOCTR register. The receive data length is checked by the DTLN bits in the CFIFOCTR or DxFIFOCTR register.

Table 32.27 FIFO Port function settings

Register name	Bit name	Function	Notes
C/DxFIFOSEL	RCNT	DTLN read mode selection	
	REW	Buffer memory rewind (re-read, re-write)	
	DCLRM	Automatic clearing of buffer memory after specified pipe received data is read	DxFIFO only
	DREQE	DREQ signal assertion	DxFIFO only
	MBW	FIFO port access bit width	
	BIGEND	FIFO port endian selection	
	ISEL	FIFO port access direction	DCP only
	CURPIPE	Current pipe selection	
C/DxFIFOCTR	BVAL	Buffer memory write completion	
	BCLR	Clearing of CPU-side buffer memory	
	FRDY	Monitoring of FIFO port ready	
	DTLN	Confirmation of received data length	

32.8.1 FIFO Port Selection

Table 32.28 shows the list of pipes that can be selected in each FIFO port. The pipes to be accessed are selected with the CURPIPE bits of the CFIFOSEL or DxFIFOSEL register. After selecting the pipes, confirm that the value of the CURPIPE bits written was read correctly (if the previous pipe number is read out, this indicates the controller is still changing the pipe), then confirm that FRDY = 1 and access the FIFO port. Figure 32.13 shows the procedure for switching pipes for access to the FIFO port.

Also, select the bus width for the FIFO port access with the MBW bit. The buffer memory access direction is determined by the ISEL bit for DCP, and the DIR bit of the PIPExCFG register for all other pipes.

Table 32.28 FIFO port access by pipe

Pipe	Access method	Usable ports
DCP	CPU access	CFIFO port register
Pipes 1 to 9	CPU access	CFIFO port register
	DMA access	DxFIFO port register

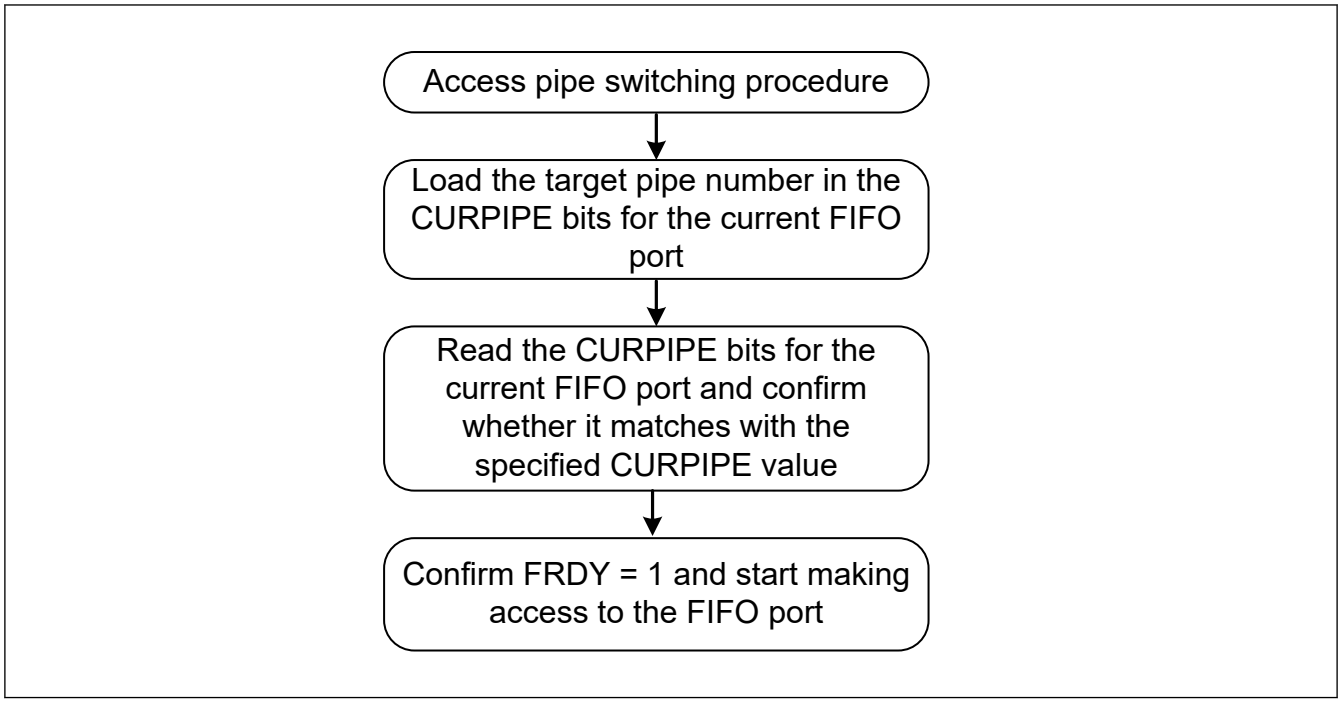


Figure 32.13 Pipe switching procedure for FIFO port access

32.8.2 DxFIFO Automatic Clear Mode (DxFIFO Port Read Direction)

When a data read event of the controller buffer memory is completed with setting the DCLRM bit of the DxFIFOSEL register to 1, the buffer memory of the corresponding pipe is automatically cleared.

Table 32.29 shows the correspondence between packet reception and buffer memory clearing by software in each setting.

As indicated in Table 32.29, the buffer clear conditions differ according to the set value of the BFRE bit, even for states in which clear is normally required, using the DCLRM bit eliminates the need for clearing of the buffer by software, enabling DMA transfers without the use of software.

Note that this function only supports the buffer memory read direction setting.

Table 32.29 Correspondence of packet reception and buffer memory clearing by software

Buffer state when packet is received	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	Clearing not required	Clearing not required	Clearing not required	Clearing not required
Zero-length packet received	Clearing required	Clearing required	Clearing not required	Clearing not required
Normal short packet received	Clearing not required	Clearing required	Clearing not required	Clearing not required
Transaction count end	Clearing not required	Clearing required	Clearing not required	Clearing not required

32.8.3 BRDY Interrupt Timing Selection

The BFRE bit of the PIPECFG register can be set so that the BRDY interrupt is not generated when a data packet of maximum packet size is received.

When using a DMA transfer, this function enables an interrupt to be generated only when the last data is received. The last data indicates either a short packet reception or the transaction count end. By setting BFRE = 1, the BRDY interrupt will be generated after the received data is read. By reading the DTLN bit of the DnFIFOCTR register, the receive data length of last data packet received just before the BRDY interrupt was generated can be confirmed.

Table 32.30 shows the timing of the BRDY interrupt.

Table 32.30 BRDY interrupt generation timing

Buffer state when packet is received	BFRE = 0	BFRE = 1
Buffer full (normal packet received)	When packet is received	No interrupt generated
Zero-length packet received	When packet is received	When packet is received
Normal short packet received	When packet is received	When read event of data received from buffer memory is completed
Transaction count end	When packet is received	When read event of data received from buffer memory is completed

The BFRE bit function is only valid in reading direction of the buffer memory. When in writing direction, fix the BFRE bit to 0.

32.9 Control Transfer (DCP)

Data transfers of the data stage of control transfers are done using the default control pipe (DCP). The DCP buffer memory is a 64 byte single buffer, and is a fixed area that is shared for both control reading and control writing. The buffer memory can be accessed only through the CFIFO port.

32.9.1 Setup Stage

The controller always responds with an ACK when it receives a normal setup packet. The controller operations in the setup stage are as follows.

1. When a new setup packet is received, the controller sets the following bits.
   (a) Sets the VALID bit of the INTSTS0 register to 1.
   (b) Sets the PID bits of the DCPCTR register to NAK.
   (c) Sets the CCPL bit of the DCPCTR register to 0.
2. When a data packet is received following the setup packet, the USB request parameters are stored in the following registers: USBREQ, USBVAL, USBINDX and USBLENG.

Always set VALID = 0 before the response process to a control transfer. While VALID = 1, PID = BUF will not be set and the data stage cannot be completed.

The function of the VALID bit allows the controller to temporarily stop a request in-process when it receives a new USB request during a control transfer, and respond to the newest request.

In addition, the controller automatically judges the direction bit (bmRequestType bit 8) and the request data length (wLength) of the received USB request and determines whether it is a control read transfer, control write transfer or control write no-data transfer, and then handles the stage transition. If the sequence is incorrect, a sequence error for the control transfer stage transition interrupt is generated and is notified to the software. For more information concerning the controller stage management, see Figure 32.10.

32.9.2 Data Stage

Use the DCP for data transfers in response to receiving a USB request. Before accessing the DCP buffer memory, set the access direction in the ISEL bit of the CFIFOSEL register.

The transaction is executed by setting the PID bits of the DCPCTR register to BUF.

Data transfer completion is detected by the BRDY and BEMP interrupts. Use the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

For control write transfers in high-speed operation, a NYET handshake is sent in accordance with the buffer memory state.

32.9.3 Status Stage

When the setting of the PID bits of the DCPCTR register is BUF, set the CCPL bit to 1 to complete the control transfer.

After the above settings, the controller automatically executes the status stage in accordance with the data transfer direction fixed in the setup stage. The detailed process is as follows.

1. Control read transfers:

The controller receives a zero-length packet from the USB host and sends an ACK response.

2. Control write transfers and no-data control transfers:
   The controller sends a zero-length packet and receives an ACK response from the USB host controller.

32.9.4 Control Transfer Automatic Response

The controller automatically sends a response to a normal SET_ADDRESS request. If one of the following errors occurs, a response must be sent by software.

1. bmRequestType ≠ 0x00
2. wIndex ≠ 0x00
3. wLength ≠ 0x00
4. wValue > 0x7F
5. DVSQ = 011b (configured)

All requests other than the SET_ADDRESS request must be responded to by software.

32.10 Bulk Transfer (Pipes 1 to 5)

The user can select the buffer memory usage method (single/double buffer, continuous/non-continuous transfer mode) for bulk transfer. The maximum size that can be set for the buffer memory is 2 KB. The controller manages the buffer memory state and automatically responds to PING packets and NYET handshakes.

32.10.1 NYET Handshake Control

Table 32.31 shows the list of responses to a token received in a bulk or control transfer. When an OUT token is received in a bulk or control transfer and there is only enough open space for one packet in the buffer memory, the controller sends a NYET response. However, when a short packet is received, the controller sends an ACK response instead of a NYET response, even under these conditions.

Table 32.31 List of responses to received tokens

PID bits setting	Buffer memory state	Received token	Response	Notes
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY*1	OUT/PING	ACK	When OUT token is received, data packet is received.
	RCV-BRDY*2	OUT	NYET	Data packet is received.
	RCV-BRDY*2	OUT (Short)	ACK	Data packet is received.
	RCV-BRDY*2	PING	ACK	
	RCV-NRDY*3	OUT/PING	NAK	
	TRN-BRDY*4	IN	DATA0/1	Data packet is transmitted.
	TRN-NRDY*5	IN	NAK	

Note 1. RCV-BRDY: Buffer memory has enough space for 2 packets or more when an OUT or PING token is received.
Note 2. RCV-BRDY: Buffer memory has only enough space for one packet when an OUT token is received.
Note 3. RCV-NRDY: Buffer memory has not enough space when a PING token is received.
Note 4. TRN-BRDY: Buffer memory has data for transmission when an IN token is received.
Note 5. TRN-NRDY: Buffer memory does not have data for transmission when an IN token is received.

32.11 Interrupt Transfer (Pipes 6 to 9)

This controller executes an interrupt transfer in accordance with the period managed by the host controller. The controller ignores (no response) PING packets in interrupt transfers. In addition, the controller does not send a NYET handshake, but responds with ACK, NAK or STALL.

The controller does not support high-bandwidth interrupt transfers.

32.12 Isochronous Transfer (Pipes 1 and 2)

The controller provides the following functions for isochronous transfers.

1. Isochronous transfer error information notification
2. Interval counter (IITV bit setting)
3. Isochronous IN transfer data setup control (IDLY function)
4. Isochronous IN transfer buffer flush function (IFIS bit setting)
5. SOF pulse output function

The controller does not support high-bandwidth isochronous transfers.

32.12.1 Isochronous Transfer Error Detection

The controller manages isochronous transfer errors by software and therefore has the following error information detection functions. Table 32.32 and Table 32.33 describe the procedure in which errors are confirmed and the interrupts that are generated.

1. PID error
   When PID of the received packet is corrupted
2. CRC error and bit stuffing error
   When an error occurs in CRC of the received packet or when the bit stuffing is corrupted
3. Maximum packet size over
   This indicates the data size of the received packet is larger than the value set for the maximum packet size.
4. Overrun and underrun
   When there is no data in the buffer memory when an IN token is received in an IN-direction (send) transfer When there is no empty space in the buffer memory when an OUT token is received in an OUT-direction (receive) transfer
5. Interval error
   The following will generate interval errors.
   (a) When an IN token could not be received in the interval frame of an isochronous IN transfer
   (b) When an OUT token could not be received in the interval frame of an isochronous OUT transfer

Table 32.32 Errors detected in token reception/transmission

Detection priority	Error type	Generated interrupts and states at time of error detection
1	PID error	No interrupt generated (ignored as corrupted packet)
2	CRC error or bit stuffing error	No interrupt generated (ignored as corrupted packet)
3	Overrun or underrun errors	NRDY interrupt is generated and OVRN bit is set. A zero-length packet is sent in response to an IN token. A data packet is not received in response to an OUT token.
4	Interval error	NRDY interrupt generated

Table 32.33 Errors detected in data packet reception

Detection priority	Error type	Generated interrupts and states
1	PID error	No interrupt generated (ignored as corrupted packet)
2	CRC error or bit stuffing error	NRDY interrupt is generated and CRCE bit is set.
3	Maximum packet size over error	BEMP interrupt is generated and PID is set to STALL.

32.12.2 DATA-PID

This controller does not support high-bandwidth transfers. The following occurs in response to a received PID.

1. IN direction:
   (a) DATA0: Transmitted as PID of the data packet
   (b) DATA1: Not transmitted
   (c) DATA2: Not transmitted
   (d) mDATA: Not transmitted
2. OUT direction (in full-speed operation):
   (a) DATA0: Received successfully as PID of the data packet
   (b) DATA1: Received successfully as PID of the data packet
   (c) DATA2: The packet is ignored.
   (d) mDATA: The packet is ignored.
3. OUT direction (in high-speed operation):
   (a) DATA0: Received successfully as PID of the data packet
   (b) DATA1: Received successfully as PID of the data packet
   (c) DATA2: Received successfully as PID of the data packet
   (d) mDATA: Received successfully as PID of the data packet

32.12.3 Interval Counter

32.12.3.1 Overview of Operation

The isochronous transfer interval can be set in the IITV bit of the PIPEPERI register. Table 32.34 shows the functions of the interval counter.

Table 32.34 Interval counter functions

Transfer direction	Function	Detection conditions
IN	Transfer buffer flush function	Cannot successfully receive IN token in interval frame during isochronous IN transfer.
OUT	Notifies that a token not being received	Cannot successfully receive OUT token in interval frame during isochronous OUT transfer.

Since the interval counting is performed upon reception of SOF or by the complemented SOF, the isochronism can be maintained even if the SOF is damaged. Frame intervals are set as 2^{IITV} (μ) frames.

32.12.3.2 Interval Counter Initialization

The controller initializes the interval counter under the following conditions.

1. Hardware reset
   Initializes the IITV bit.
2. Clearing of the buffer memory by the ACLRM bit
   This initializes the counter but not the IITV bit.
3. USB bus reset

After the interval counter is initialized and a packet is successfully transferred, the interval count starts under the following conditions.

1. SOF is received after data is sent in response to an IN token when PID = BUF.
2. SOF is received after data is received in response to an OUT token when PID = BUF.

Note that the interval counter is not initialized in the following conditions.

1. When the PID is set to NAK or STALL
   The interval timer is not stopped at this time. The transaction will be attempted at the next interval.

2. USB bus reset or USB suspend
   The IITV bit is not initialized at this time. When the SOF is received, the count starts from the value before the reception.

32.12.4 Isochronous Transfer Transmission Data Setup

In the isochronous data transmission by this controller, after data is written to the buffer memory, the data packet can be sent out in the next frame after the SOF packet is detected. This function, called the isochronous transfer transmission data setup, allows specification of the frame that started transmission.

When the buffer memory is used for double buffering and writing to both buffers has been completed, only transfer from the first buffer to have received data can proceed. Therefore, even when several IN tokens are received in the same frame, only one packet of data is sent by the buffer memory.

When an IN token is received, if the buffer memory is ready for transmission, the data is transferred and a normal response is returned. However, if the buffer memory is not ready for transmission, a zero-length packet is sent and an underrun error occurs.

Figure 32.14 shows an example of transmission using the isochronous transfer transmission data setup function with this controller when IITV = 0 (for each frame) is set.

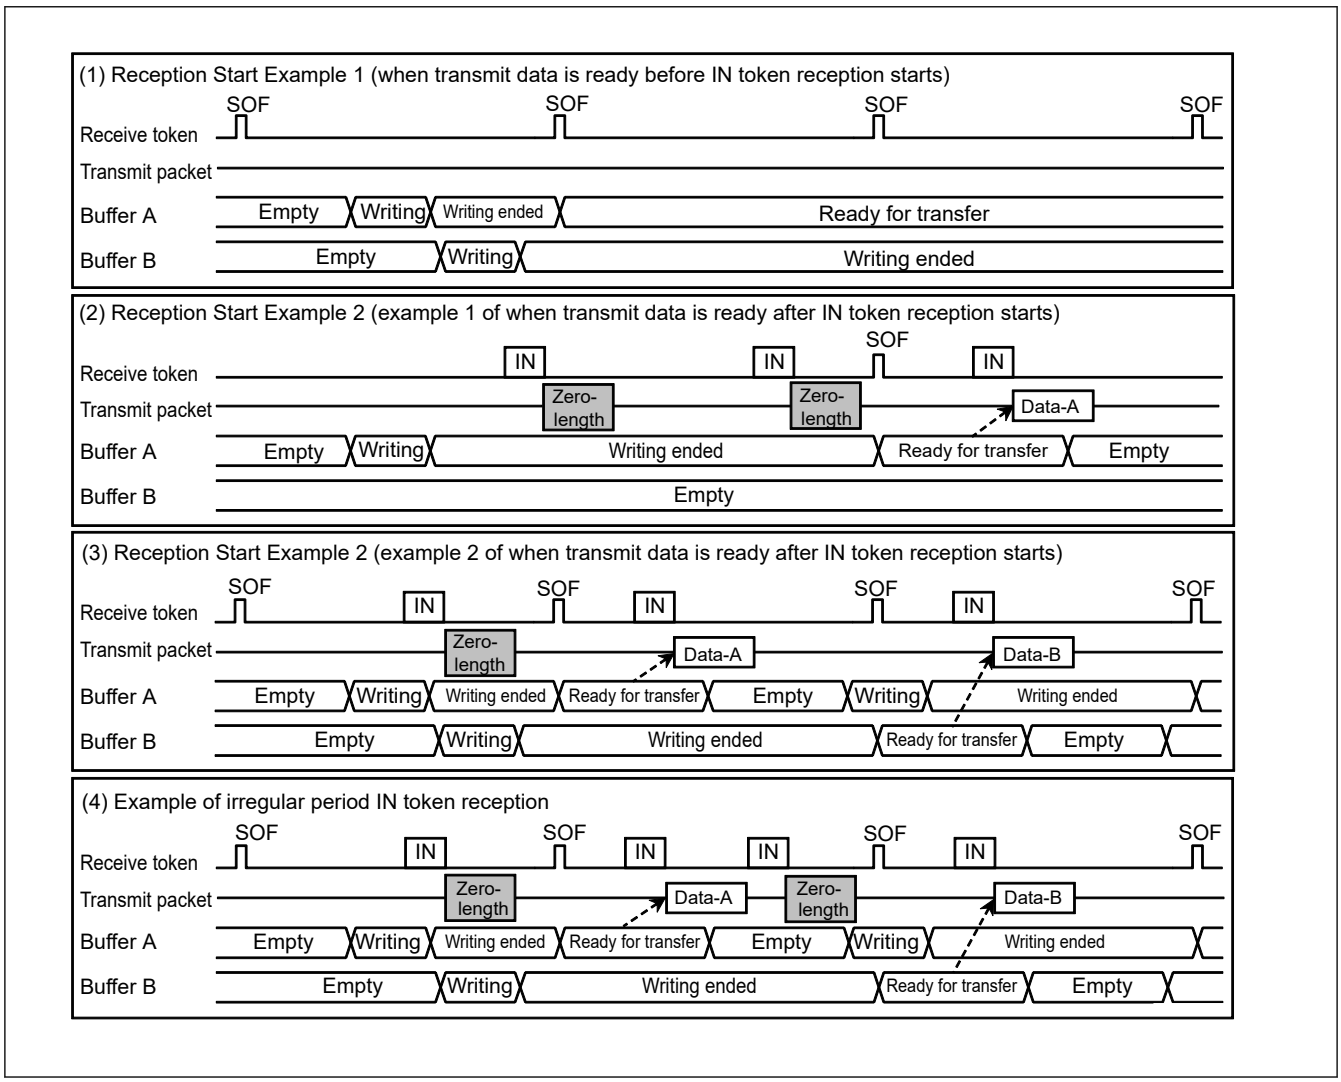

Figure 32.14 Example of data setup function operation

32.12.5 Isochronous Transfer Transmission Buffer Flush

When an SOF packet or a µSOF packet of the next frame is received without receiving an IN token in the interval frame during isochronous data transmission, this controller operates as if a corrupted IN token was received, and clears the buffer which is ready for transmission, making that buffer ready for writing.

If a double buffer is being used and writing to both buffers has been completed, data are considered to have been sent from the buffer memory that was cleared in the same interval frame, and transmission is enabled for the buffer memory that is not discarded with SOF or µSOF packets reception.

The timing at which the buffer flush function is activated varies depending on the setting of the IITV bits.

1. When IITV = 0
   The buffer flush operation proceeds from the first frame after the pipe becomes valid.
2. When IITV ≠ 0
   The buffer flush operation proceeds after the first successful transaction.

Figure 32.15 shows an operation example of the buffer flush function of this controller. When an unanticipated token is received prior to the interval frame, this controller sends the written data or a zero-length packet as an underrun error according to the data setup state.

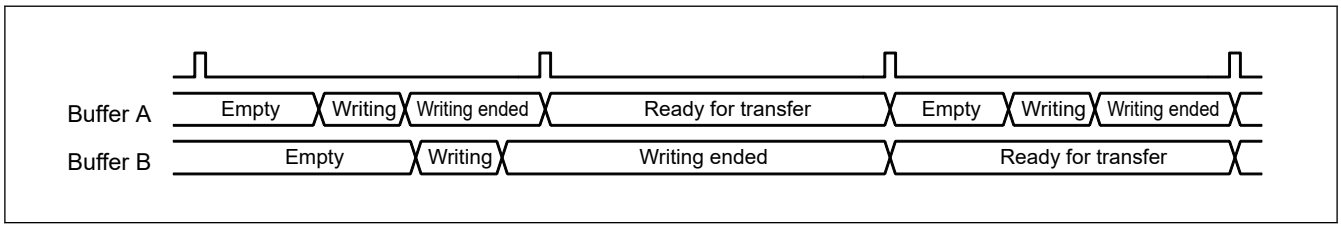

Figure 32.15 Buffer flush function operation example

Figure 32.16 shows an example of an interval error generated in the controller. There are five types of interval errors, as listed below. Timing 1 in the figure shows when the interval error occurs and how the buffer flush function operates.

When an interval error occurs during an IN transfer, the buffer flush function goes into operation; during an OUT transfer, the NRDY interrupt is generated.

Use the OVRN bit to determine whether an error is an NRDY interrupt, such as a receive packet error, or an overrun error.

Responses to the tokens in the shaded boxes are executed in accordance to the buffer memory state.

1. IN direction:
   (a) If the buffer is ready for transfer, data is transferred as a normal response.
   (b) If the buffer is not ready for transfer, a zero-length packet is sent and an underrun error occurs.
2. OUT direction:
   (a) If the buffer is ready for reception, data is received as a normal response.
   (b) If the buffer is not ready for reception, data is discarded and an overrun error occurs.

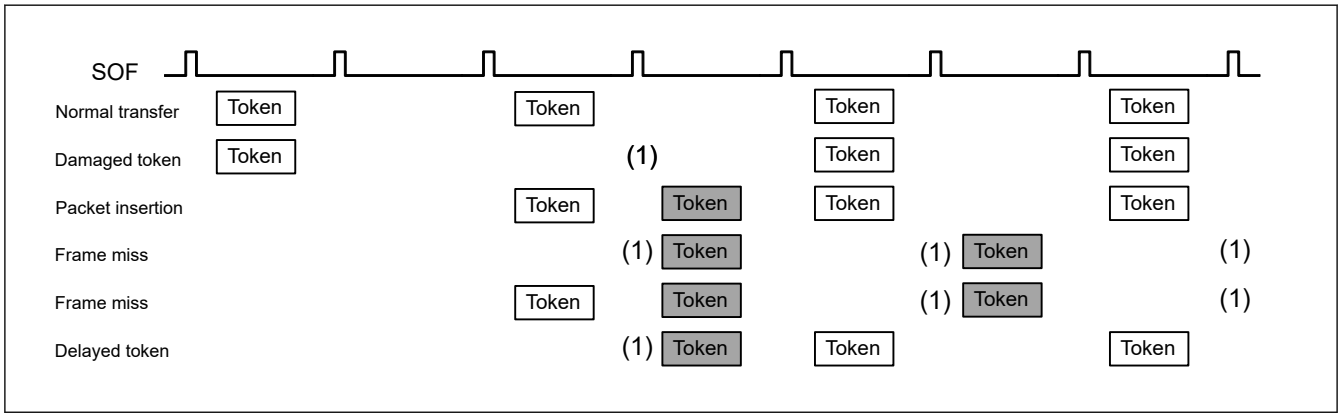

Figure 32.16 Example of interval error when IITV = 1

32.13 SOF Interpolation

If an SOF packet could not be received at intervals of 1 ms (in full-speed operation) or 125 µs (in high-speed operation) because of corruption or missing, this controller interpolates the SOF. The SOF interpolation operation begins when both the USBE and SUSPM bits have been set to 1 and an SOF packet is received. The interpolation is initialized under the following conditions.

1. Hardware reset
2. USB bus reset
3. Suspended state detected

The SOF interpolation operates according to the following specifications.

1. The frame interval (125 µs or 1 ms) is based on the results of the reset handshake protocol.
2. The interpolation does not operate until the SOF packet is received.
3. After a first SOF packet is received, interpolation of another SOF packet proceeds after a 125-µs or 1-ms interval counted in cycles of the internal clock running at 48 MHz clock has elapsed.
4. Interpolation is performed in the previous reception intervals after the 2nd and subsequent SOF packets are received.
5. Interpolation is not performed in the suspended state or during reception of a USB bus reset.
   When the controller goes to the suspended state in high-speed operation, interpolation continues for 3 ms from the last packet.

The SOF interpolation works for the following.

1. Updating of the frame number or micro-frame number
2. SOFR interrupt and µSOF lock
3. SOF pulse output
4. Isochronous transfer interval count

When an SOF packet is lost during full-speed operation, the FRNM bit of the FRMNUM register is not updated.

When a µSOF packet is lost during high-speed operation, the UFRNM bit of the UFRMNUM register is updated.

However, when a µSOF packet when µFRNM = 000b is lost, the FRNM bit is not updated. At this time, even if µSOF packets when µFRNM ≠ 000b are received successfully, the FRNM bit is not updated.

32.14 Link Power Management Processing

The Link Power Management standard redefines the existing suspended state as L2 state, and further defines L1 state that enables transitions and recovery with lower latency than the L2 (suspended) state.

The following table shows comparison between L2 (suspended) and L1.

Table 32.35 Comparison between L2 (suspended) and L1

Item	L1	L2 (suspended)
Transition	LPM transaction	3 ms idle
Recovery due to host	(Host) The host can specify the minimum drive period (75 µs to 1.175 ms). (Device) 10 µs K drive	(Host) Min 20 ms K drive (Device) 10 ms K drive
Recovery due to device	(Device) 50 µs K drive (Host) 60 µs to 990 µs K drive (Device) 10 µs K drive	(Device) 1 ms to 15 ms K drive (Host) Min 20 ms K drive (Device) 10 ms K drive
Signaling	Low and full speed idle	Low and full speed idle

The following describes the transition (to L1 state) processing and recovery processing.

32.14.1 Descriptor

When the GetDescriptor command is received, the own descriptor must be sent back.

It is necessary to change the contents of the descriptor to be returned depending on whether to respond to the transition to L1 and recovery processing because of the LPM transaction, as shown in the table below.

Table 32.36 Relationship between response to LPM and descriptor

Response to LPM	bcdUSB	Provision of USB2.0Ex.Desc	LPM of USB2.0Ex.Desc	Response when LPM is received	Remarks
Does not respond	0x0200	Not provided	—	Not Respond	Standard operation when the descriptor does not respond to LPM
	0x0201	Provided	LPM = 0	STALL	Clear declaration that the descriptor does not respond to LPM. In this case, no response must be avoided and STALL must be sent in response.
Responds	0x0201	Provided	LPM = 1	ACK or NYET	Standard operation when the descriptor responds to LPM

Whether to respond to the transition to L1 and recovery processing is declared with the LPM bit in the USB2.0 extension descriptor. To provide the USB2.0 extension descriptor, a value of 0x0201 or larger must be set for the bcdUSB field of the device descriptor.

If the descriptor does not respond to LPM, the USB2.0 extension descriptor is not provided and the bcdUSB field is set to 0x0200. In this case, even if LPM token is received, ignore it.

If the descriptor does not respond to LPM, it is also possible to set the bcdUSB field to 0x0201 and clear the LPM bit in the USB2.0 extension descriptor to 0 (does not respond). In this case, however, LPM cannot be ignored and STALL must be sent in response. When the descriptor responds to LPM, set the bcdUSB field to 0x0201 and set the LPM bit in the USB2.0 extension descriptor to 1 (responds). This enables acknowledgment of NYET or ACK response to the LPM token.

32.14.2 Basic Processing

The following processing is required.

1. Send no response, ACK, NYET, or STALL response to the LPM token received from the host in accordance with the own state.
2. If re-transmission of LPM token is not detected for 8 µs after an ACK response was sent, a transition to the L1 state is made.
3. Detect the K drive of the host and perform the processing for recovery to the idle state.
4. Perform the processing for recovery to the idle state by remote wakeup.

For step 1, hardware receives the LPM token, it sends the response. Hardware performs processing in step 2 in addition to re-transmission control and transition to the L1 state.

A transition to the L1 state can be checked by a DVST interrupt.

For step 3, a RESM interrupt is generated by detecting the K drive of the host in the L1 state.

For step 4, setting the WKUP bit to 1 by software gives an instruction to start remote wakeup to the hardware. In the specifications, software clears this bit at the time of recovery from the L2 state, but hardware clears this bit at the time of recovery from the L1 state.

32.14.3 HIRD Value Negotiation

The HIRD value included in the LPM token indicates the host K period for recovery from the L1 state. It is supposed that the desired HIRD value may vary depending on applicable applications. It is supposed that a small HIRD value is desired for applications focusing on improvement in transfer efficiency, but a large HIRD value is desired for applications focusing on low power consumption.

According to the L1NEGOMD and HIRDTHR bits in the L1CTRL register, an ACK response is returned if the received HIRD value is within the desired range. Otherwise, a NYET response is returned to request the host to correct the HIRD value.

Note: Using this HIRD value negotiation function requires that the negotiation processing be also supported on the host side.

32.15 DMA Mode

32.15.1 Register Mode/Link Mode

With the DMS bit in the CHCFG_n register, DMA mode can be switched between register mode and link mode.

Table 32.37 DMA mode setting

DMS(CHCFG)	Mode	Description
0	Register Mode	Performs a DMA transfer with the values set for the next register set.
1	Link Mode	Accesses the descriptor area and performs a DMA transfer with the value set for the descriptor. Repeats descriptor read and DMA transfer unless you set the descriptor or use the control register to stop them.

32.15.1.1 Register Mode

In register mode, you can perform a DMA transfer using the value set in the internal register. You can set two sets (Next0 register set and Next1 register set) of transfer source addresses, the transfer destination addresses, and the numbers of transfer bytes.

You can select the next register set to perform a transfer, or use two next register sets for continuous transfer.

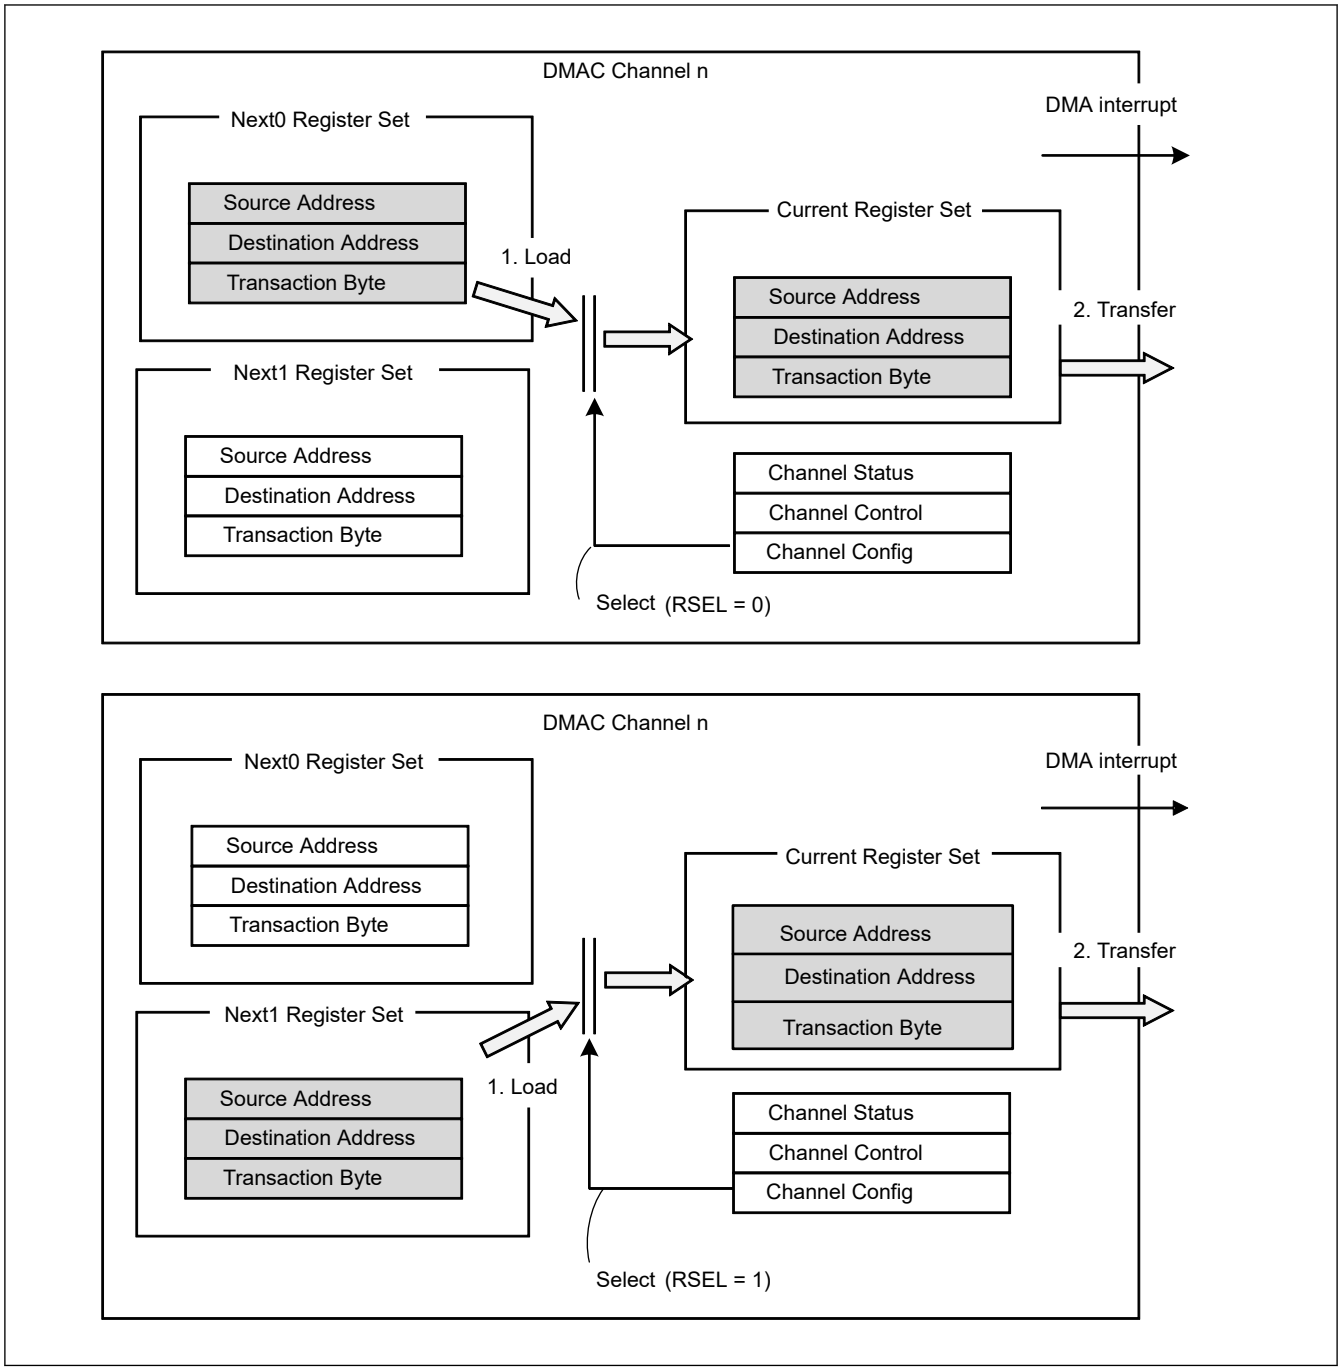

Figure 32.17 Overview of register normal mode

The above figure illustrates operation when Next0 register set is executed (above) and operation when Next1 register set is executed (below).

(1) Operation Flow in Register Mode

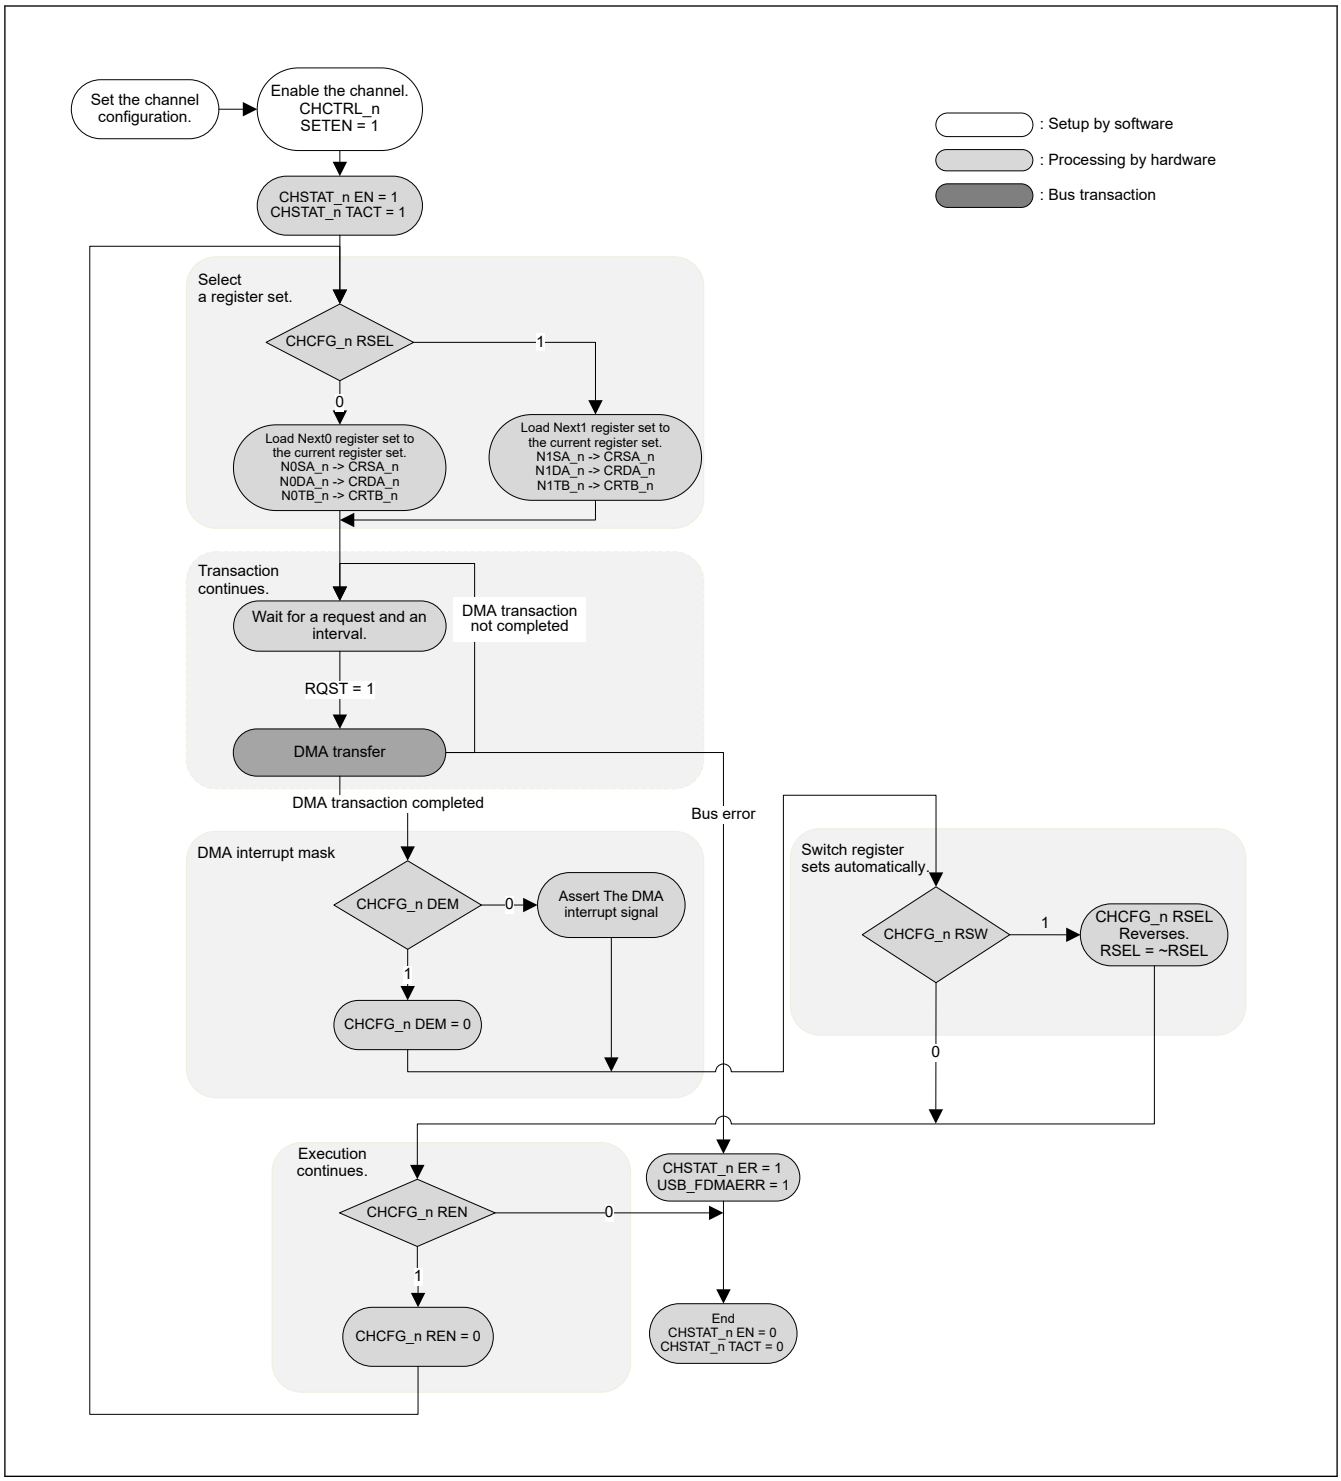

Figure 32.18 Register mode flow

<Description of register mode flow>

1. Channel setting (set channel configuration)
   Set Next0 or Next1 register set (the transfer destination address, the transfer source address, and the total number of transfer bytes). Also set the USB-controlled FIFO channels and the amount of transfer used for channel register set. (See section 32.16. DMA Transfer.)
2. Selecting register set

When 1 is written to the SETEN bit in the CHCTRL_n register, the EN bit and the TACT bit in the CHSTAT_n register are set to 1, and the set value of the next register set selected by the RSEL bit in the CHCFG_n register is loaded to the current register set.

3. DMA transaction (processing transaction)
   A DMA transaction is performed according to the set value. For details on transfer, see section 32.16. DMA Transfer.
4. Making USB_FDMAn (USB_FDMAn mask)
   The USB_FDMAn is masked according to the set DEM bit value in the CHCFG_n register. When DEM = 1, the USB_FDMAn is masked. Immediately after that, the DEM bit is automatically cleared to 0.
5. Switching register sets automatically
   Switching to the other next register set is determined according to the set RSW bit value in the CHCFG_n register.
6. Continuous execution
   Whether to perform DMA transfers continuously is determined according to the set REN bit value in the CHCFG_n register. When REN = 0, the EN bit and the TACT bit in the CHSTAT_n register are cleared to 0, and the DMAC stops operation. When REN = 1, DMA transfers are continued. Immediately after that, the REN bit is automatically cleared to 0.

(2) Setting Register Mode

Register mode settings

Select the register set to execute.

Table 32.38 Register mode settings

DMS (CHCFG_n)	RSEL (CHCFG_n)	Description
0	0	Executes Next0 register set.
	1	Executes Next1 register set.

USB_FDMAn mask settings

The USB_FDMAn can be masked.

Table 32.39 USB_FDMAn mask settings

DEM (CHCFG_n)	Description
0	When a DMA transaction is completed, the USB_FDMAn is asserted.
1	Even if a DMA transaction is completed, the USB_FDMAn is not asserted. Upon completion of a DMA transaction, the DEM bit is cleared to 0 by hardware.

Settings for executing register sets automatically

After a DMA transaction is completed, another DMA transaction can be performed successively.

Table 32.40 Settings for automatic execution of register sets

REN (CHCFG_n)	Description	Remarks
0	When a DMA transaction of the register set that is set in the RSEL bit is completed, the EN bit is cleared to 0 and the DMA operation ends.	Set this value if you want to perform a DMA transaction once.
1	After a DMA transaction is completed, a DMA transfer is performed for the register set that was selected to be performed successively. When the successive transfer is performed, the REN bit is cleared to 0.	Set this value if you want to perform DMA transactions for register sets successively.

Settings for switching register sets automatically

After a DMA transaction is completed, the register set to be used for the next DMA transaction can be switched.

Table 32.41 Settings for automatic switching of register sets

RSW (CHCFG_n)	Description	Remarks
0	After a DMA transaction is completed, register sets are not switched.	Set this value when you want to use only one register set.
1	When a DMA transaction is completed while REN = 1, the RSEL bit is reversed automatically and the other register set is selected.	Set this value when you want to switch register sets.

(3) Register Mode Setting Examples

Using the Next0 register set only

Table 32.42 Register mode setting example 1

DMS (CHCFG_n)	RSEL (CHCFG_n)	DEM (CHCFG_n)	RSW (CHCFG_n)	REN (CHCFG_n)
0 (Register mode)	0 (Next0)	0 (Do not mask)	0 (Do not switch)	0 (Continuous execution not in progress)

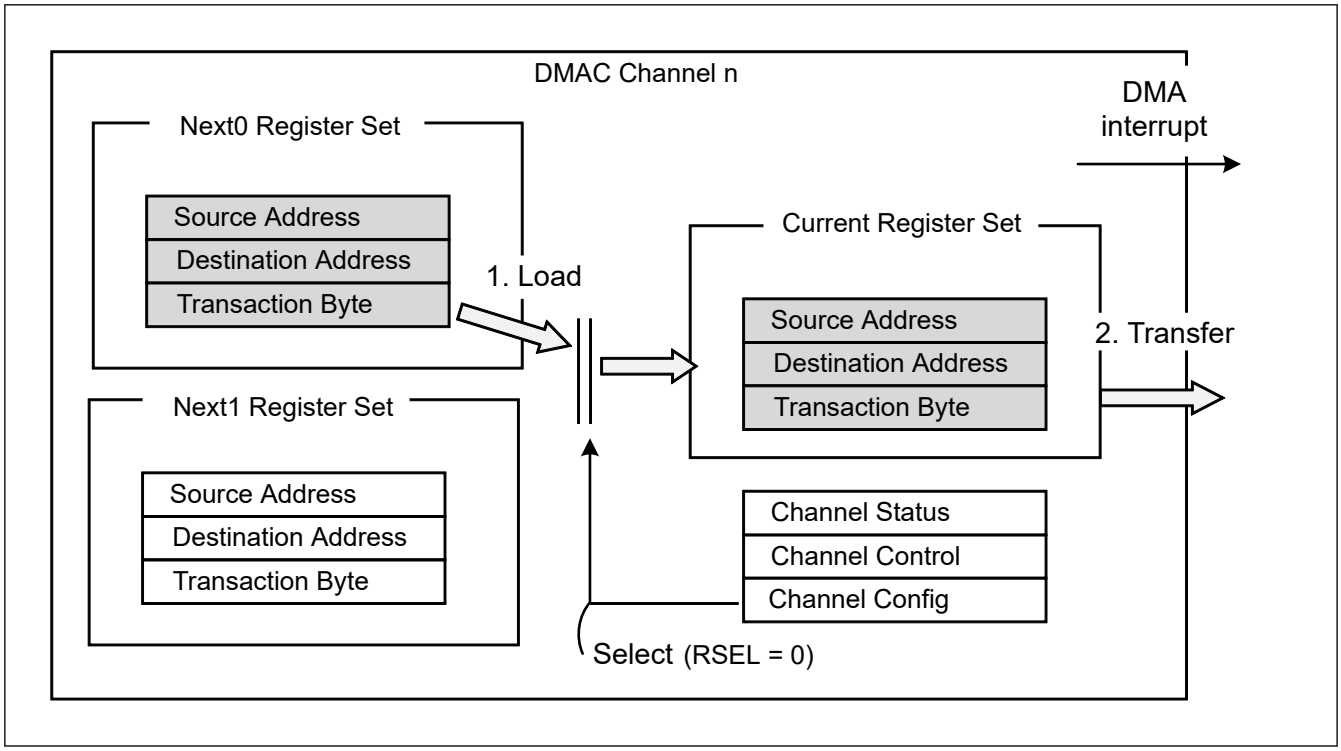

Figure 32.19 Register mode setting example 1

1. Writing 1 to the SETEN bit in the CHCTRL_n register sets the EN bit in the CHSTAT_n register to 1, and loads Next0 register set to the current register set.
2. According to the values set for the current register set and the channel register set, a DMA transaction is performed.
3. Because the DEM bit in the CHCFG_n register is 0, USB_FDMAn is asserted after a DMA transaction is completed.
4. Because the REN bit in the CHCFG_n register is 0, the EN bit in the CHSTAT_n register is cleared to 0, and the operation ends.

Using two register sets successively

Table 32.43 Register mode setting example 2

DMS (CHCFG_n)	RSEL (CHCFG_n)	DEM (CHCFG_n)	RSW (CHCFG_n)	REN (CHCFG_n)
0 (Register mode)	0 (Next0)	1 (Mask)	1 (Switch)	1 (Continuous execution in progress)

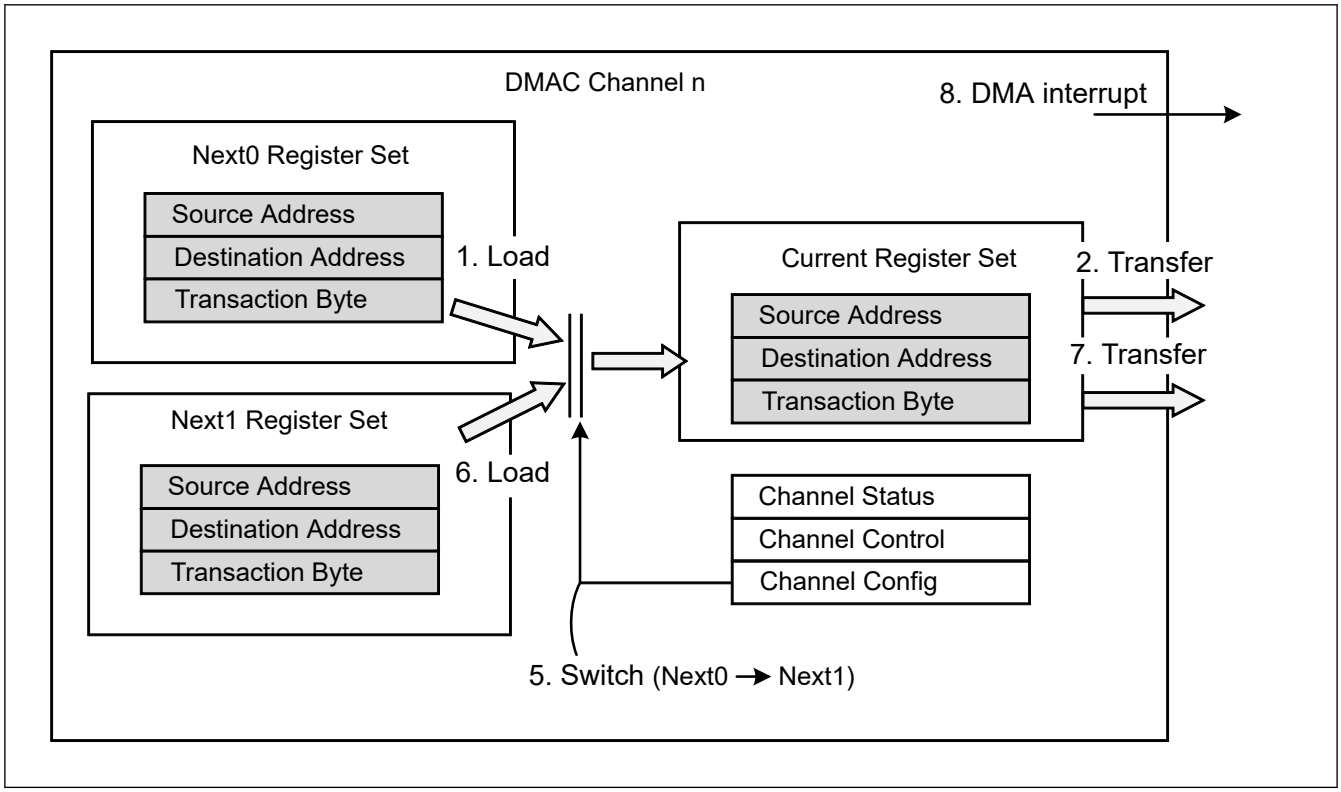

Figure 32.20 Register mode setting example 2

1. Writing 1 to the SETEN bit in the CHCTRL_n register sets the EN bit in the CHSTAT_n register to 1, and loads Next0 register set to the current register set.
2. According to the values of the current register set and the channel register set, a DMA transaction is performed.
3. Because the DEM bit in the CHCFG_n register is 1, USB_FDMAn is not asserted after a DMA transaction is completed, and the DEM bit is automatically cleared to 0.
4. Because the REN bit in the CHCFG_n register is 1, DMA transactions are performed successively, and the REN bit is automatically cleared to 0.
5. Because the RSW bit in the CHCFG_n register is 1, the register set to be executed next is switched (RSEL = 0 → 1).
6. Loads Next1 register set to the current register set.
7. According to the values of the current register set and the channel register set, DMA transactions are performed.
8. Because the DEM bit in the CHCFG_n register is 0, USB_FDMAn is asserted after a DMA transaction is completed.
9. Because the REN bit in the CHCFG_n register is 0, the EN bit in the CHSTAT_n register is cleared to 0, and the operation ends.

32.15.1.2 Link Mode

In link mode, a DMA transaction is performed by reading a descriptor in an external memory area as a setting value. The DMAC incorporates the next link address (NXLA_n) register and the current link address (CRLA_n) register for each channel. Each of them is used to set the address of the descriptor to be executed next and to display the descriptor address of the current DMA transaction respectively.

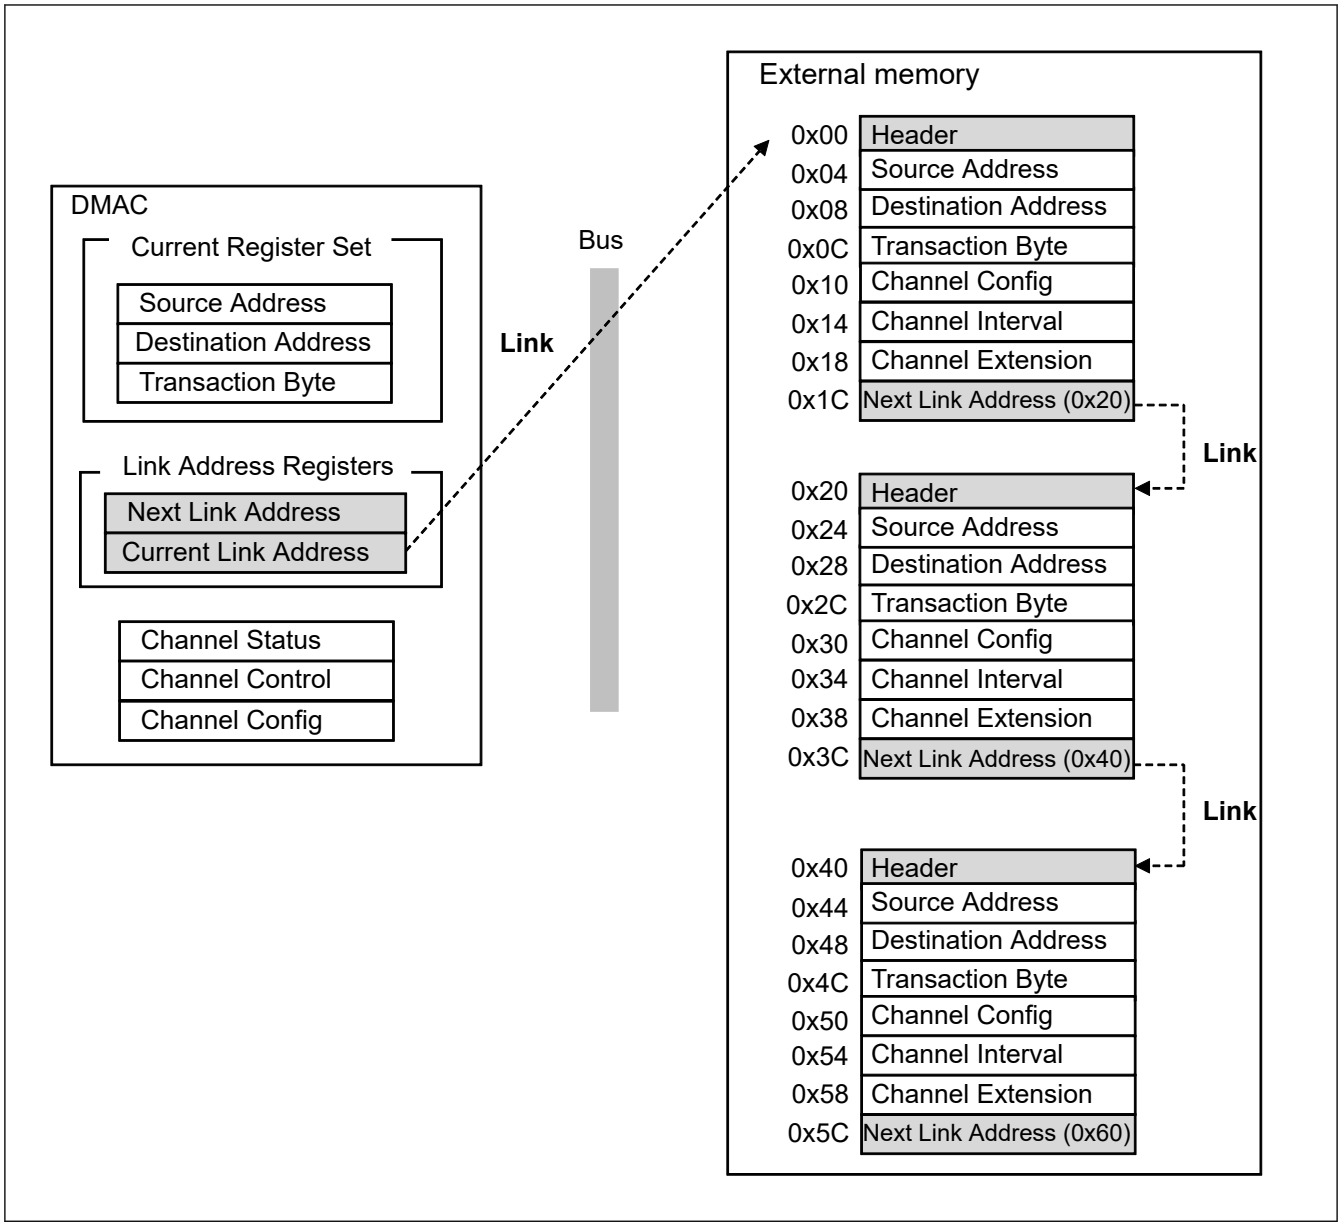

Figure 32.21 Overview of link mode

(1) Link Mode Operation Flow

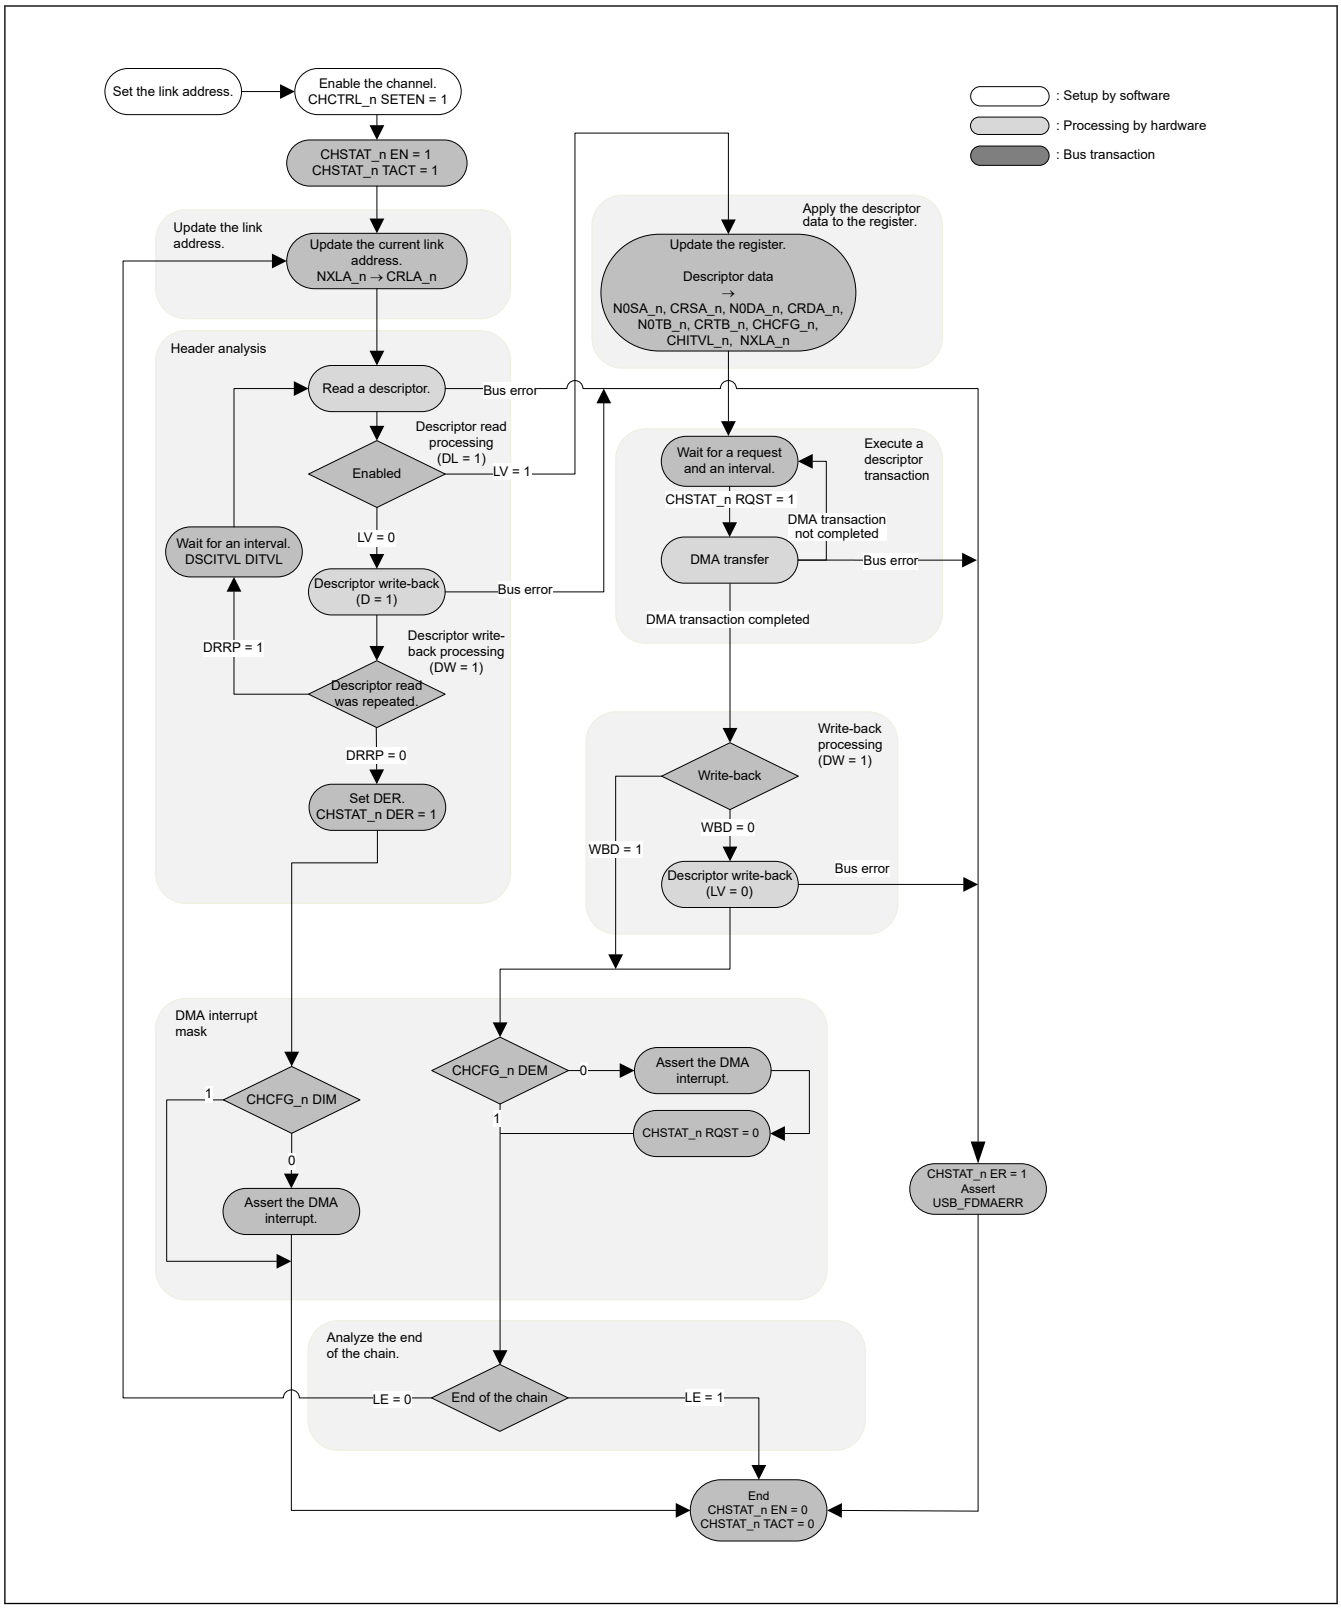

Figure 32.22 Link mode operation flow

Description of Link Mode Operation Flow

1. Channel setting
   Set the start address of the link destination in the NXLA_n register.

2. Updating the link address
   Writing 1 to the SETEN bit in the CHCTRL_n register sets the EN bit and the TACT bit in the CHSTAT_n register to 1, and loads the link address set for the NXLA_n register to the CRLA_n register.
3. Descriptor read and header judgment
   The DMAC starts reading a descriptor and checks the header contents. When LV = 0, 1 is written back to the D bit in the header. After that, when the DRRP bit in the CHCFG_n register = 1, the same descriptor is read again after the number of cycles set in the DSCITVL register elapsed. When DRRP = 0, DER in the CHSTAT_n register is set to 1. This indicates the end state (EN = 0 and TACT = 0 in the CHSTAT_n register). At that time, if the DIM bit in the CHCFG_n register is 0, USB_FDMAn is asserted.
4. Descriptor setting
   When LV = 1, the read descriptor data is loaded to the current register set and the channel register set. In addition, the next link destination is loaded to the NXLA_n register.
5. DMA transaction
   According to the set values, a DMA transaction is performed. For details on transfers, see section 32.16. DMA Transfer.
6. Writing back of header
   When WBD in the header = 0, the DMAC writes LV = 0 back to the header area.
7. USB_FDMAn mask
   When the DEM bit in the CHCFG_n register is 0, USB_FDMAn is asserted.
8. Link end judgment
   When LE in the header = 1, the EN bit and the TACT bit in the CHSTAT_n register are cleared to 0, and the DMAC stops operation. When LE = 0, the current register set is updated and the next descriptor read is started.

(2) Register Settings

Link mode settings

When using link mode, set the DMS bit in the CHCFG_n register to 1.

Table 32.44 Link mode settings

DMS (CHCFG_n)	Description
1	Operates in link mode.This bit cannot be modified by using a descriptor.

LINK address settings

As registers that indicate the link destination, the next link address (NXLA_n) register and the current link address (CRLA_n) register are available.

To start link mode, set the link destination in the NXLA_n register.

The NXLA_n register is updated to the next link after a descriptor is read. In addition, the CRLA_n register indicates the link address of the currently executed descriptor.

Table 32.45 Link address register set

Register	Description
Next link address register (NXLA_n)	Sets and displays the next link destination. Before starting link mode, set the address of the link destination in this register.
Current link address register (CRLA_n)	Displays the currently executed link destination. This register is read-only.

(3) Descriptor Settings

The DMAC supports multiple descriptor formats. To switch formats, use the DSCFM field of bits [31:28] in the first word (header) of a descriptor.

The following table shows the relationship between the DSCFM bit value and descriptor formats.

Table 32.46 Descriptor format

DSCFM	Descriptor size	Next link address	Channel extension	Channel interval	Channel config	Transaction size	Destination address	Source address	Header
0x3	Four words	Y	— (Reload)	— (Reload)	— (Reload)	— (Header)	Y	Y	Y (with STS)
0x1	Eight words	Y	Y	Y	Y	Y	Y	Y	Y (without STS)
Other than above	If DSCFM is set to a value other than 1 and 3, operation is not guaranteed. Do not set a value other than 0x1 and 0x3 for DSCFM.								

Table 32.47 Description of availability

Field	Availability	Description	Remarks
Header	Y(with STS)	Indicates that the STS field of [15:0] in the header is enabled. The value set in the STS field is used as the total number of transfer bytes (transaction size).	—
	Y(without STS)	The STS field of [15:0] in the header is disabled. The transaction size of the descriptor is used as the total number of transfer bytes.	—
Source address	Y	Specifies the source address.	—
Destination address	Y	Specifies the destination address.	—
Transaction size	Y	Specifies the transaction size.	—
	— (Header)	Omits the transaction size. The value set in the STS field in the header is used as the total number of transfer bytes (transaction size).	Because the STS field is 16 bits, up to 65,535 bytes can be set.
Channel config Channel interval Channel extension	Y	Specifies the channel config, channel interval, and channel extension.	—
	— (Reload)	Omits the channel config, channel interval, and channel extension. Inherits the previous setting values (of the CHCFG_n, CHITVL_n, and CHEXT_n registers at that time).	—
Next link address	Y	Specifies the next descriptor address (next link address) to be read after a DMA transfer of this descriptor.	—

The DMAC interprets data obtained through descriptor read in order. If a value less than eight words is specified in the DSCFM field, place descriptor data marked with Y in Table 32.46 in memory.

Table 32.48 Descriptor placement example

	Address (link address + n)							
DSCFM	+ 0x1C	+ 0x18	+ 0x14	+ 0x10	+ 0x0C	+ 0x08	+ 0x04	+ 0x00
0x3	—	—	—	—	Next link address	Destination address	Source address	Header
0x1	Next link address	Extension	Interval	Config	Transaction byte	Destination address	Source address	Header

Header

The header indicates descriptor states as shown below.

This area is read by the DMAC before starting a DMA transfer in link mode. Furthermore, the transfer status is written back by the DMAC after the DMA transfer.

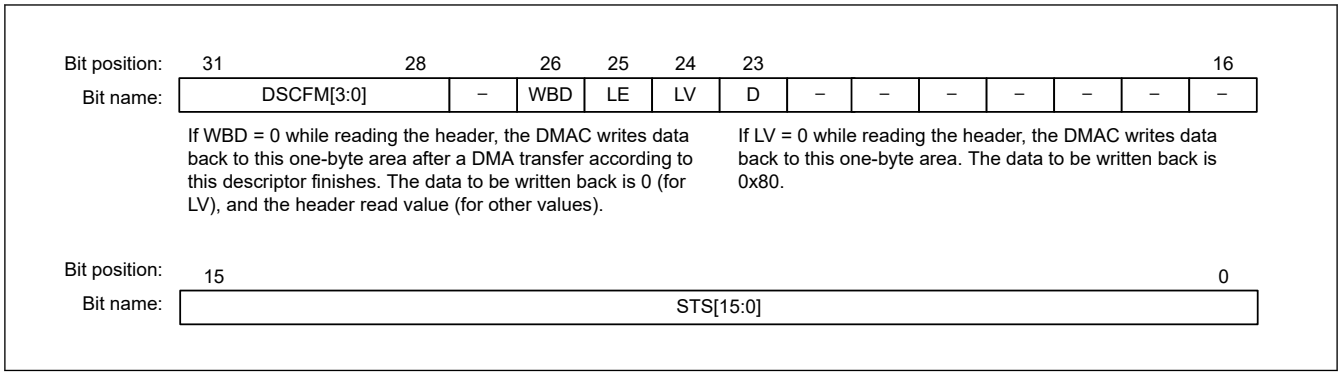

Figure 32.23 Header area

Table 32.49 Header area

Bit position	Bit name	Description
15:0	STS	Short Transaction Size When DSCFM = 0x3, these bits set the transaction size in bytes. Up to 65535 bytes can be set. When DSCFM = 0x3, do not set the STS bits to 0. If 0 is set, the operation is not guaranteed.
22:16	—	A reserved area. Set 0.
23	D	Descriptor Error Indicates an access error of a descriptor. When LV = 0 while a descriptor is being read, the DMAC writes 1 back to this bit. 0: No descriptor error 1: LV = 0 during descriptor read
24	LV	Link Valid Indicates that this descriptor is enabled. When WBD = 0, the DMAC writes 0 after the DMA transaction written in the descriptor is completed. Set 1 when setting header. 0: The descriptor is disabled. 1: The descriptor is enabled.
25	LE	Link End Indicates that the link ends with the DMA transaction of this descriptor. To indicate the end of the link, set this bit to 1. 0: The link continues. 1: The link ends.
26	WBD	Write Back Disable Masks write-back execution of the LV bit. When this bit is 1, the DMAC does not perform writeback operation. 0: The LV bit is written back to 0. 1: The LV bit is not written back.
27	—	A reserved area. Set 0.
31:28	DSCFM	Descriptor Format Specifies the descriptor format (descriptor length and combination). For details, see Table 32.46.

If descriptors are added sequentially while the DMAC is operating, an access of the CPU to set the LV bit to 1 and an access of the DMAC to write 1 back to the D bit may conflict. Because of this, the data that was written first is overwritten by the data that was written later.

To avoid this problem, the byte lane of the D bit and the byte lane of the LV bit are placed differently to separate write areas. The DMAC uses the byte write method to write back the D bit. Therefore, the CPU must set LV = 1 by using the byte write method.

Setting descriptors other than header

Data in descriptors except header has the same specifications as an on-chip register. For details on the on-chip register specifications, see section 32.3. Register Descriptions.

Setting AHB during descriptor access

The MHPROT pin output during the descriptor access can be set in the LWPR and LDPR fields in the DCTRL register. Set it according to the access destination for which descriptor is placed.

Descriptor areas and DMA transfer areas

Figure 32.24 provides an overview of descriptor areas and DMA transfer areas which the DMAC accesses.

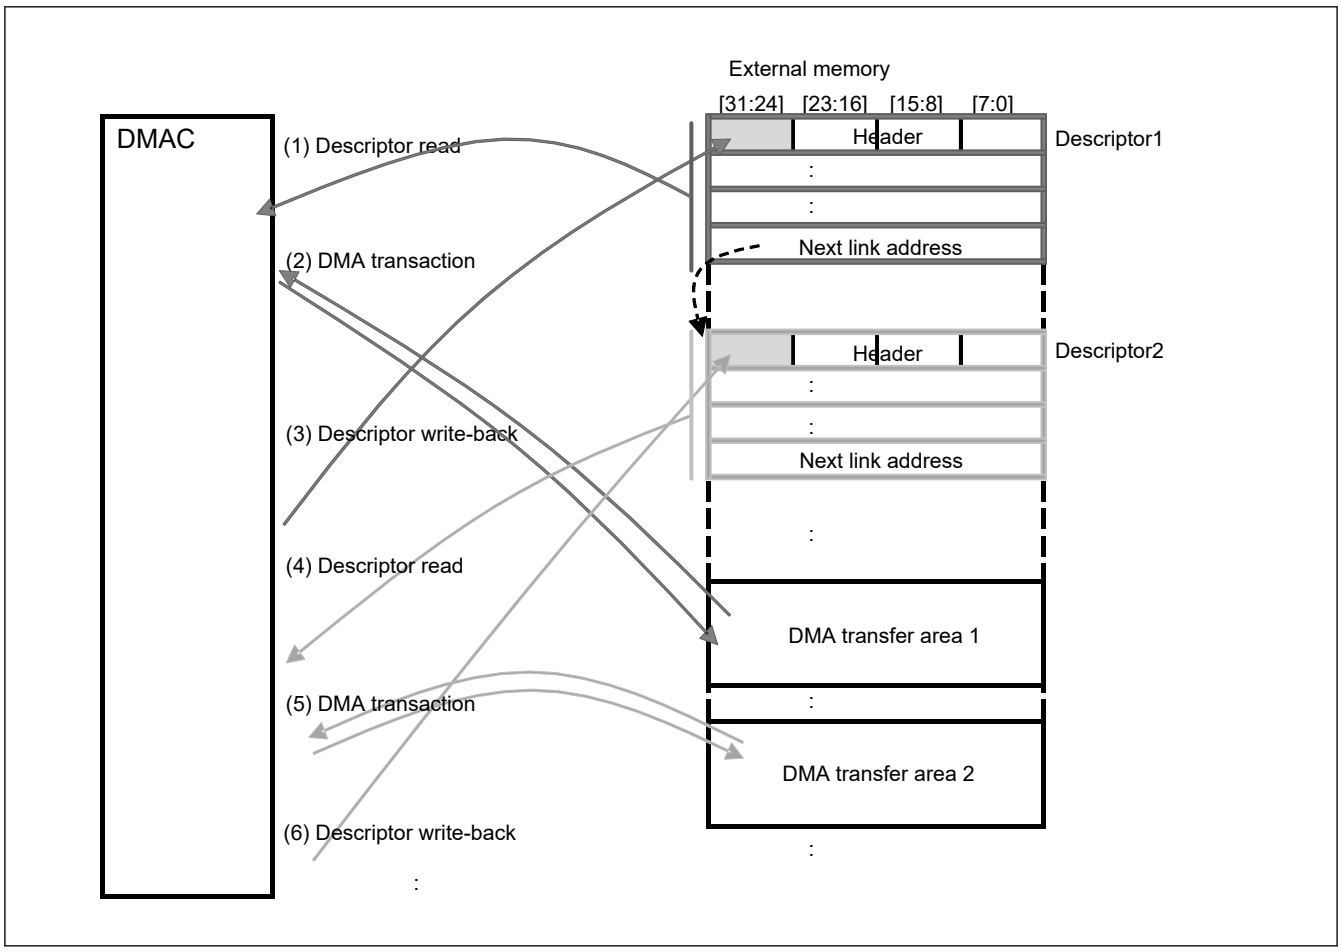

Figure 32.24 Overview of descriptor areas and DMA transfer areas

1. Descriptor read
   Loads the value set for the on-chip NXLA_n register to the CRLA_n register, and then reads the descriptor from the external memory space (descriptor 1) indicated by the CRLA_n register.
2. DMA transaction
   When the LV bit in the header of the descriptor is 1, performs a DMA transfer according to the descriptor information.
3. Descriptor write-back
   If the WBD bit in the header is 0 after a DMA transfer for the set number of bytes, data (LV bit = 0 and the data that was read in step 1 in other fields) is written back to header[31:24] of descriptor 1 with a byte size.
4. Descriptor read
   If the LE bit in the header of the descriptor that was read in step 1 is 0, reads the next descriptor from the address (descriptor 2) indicated by the next link address in the descriptor.
5. DMA transaction
   When the LV bit in the header of the descriptor is 1, performs a DMA transfer according to the descriptor information.
6. Descriptor write-back
   If the WBD bit in the header is 0 after a DMA transfer for the set number of bytes, data (LV bit = 0 and the data that was read in step 4 in other fields) is written back to header[31:24] of descriptor 2 with a byte size.

Hereafter, repeats steps 4 through 6.

When LE in the header is 1 and WBD = 0, a DMA transfer is performed with the descriptor settings, and 0 is written back to the LV bit in the header, and then operation ends.

When LE in the header is 1 and WBD = 1, a DMA transfer is performed with the descriptor settings, and then operation ends (without write-back).

When the LV bit in the header is 0, 1 is written back to the D bit in the header. After that, if the DRRP bit in the CHCFG_n register is 1, the descriptor is read again after the interval specified in the DITVL field in the DSCITVL_n register. When DRRP = 0, the operation stops.

Notes on descriptors

- In link mode, settings can be changed by reading a descriptor, but the timing for changing settings and for a hardware request cannot be synchronized. For this reason, when using a hardware request, set the AM, LVL, HIEN, LOEN, and SEL bits in the CHCFG_n register to 1 before setting the SETEN bit in the CHCTRL_n register. Besides, do not change these bits in a descriptor.
- In a descriptor, the settings of the DMS field in the CHCFG_n register cannot be changed (always link mode). In addition, settings of the REN, RSW, and RSEL fields in the CHCFG_n register can be changed in the descriptor, but that does not affect the operation.
- The DMAC references the DSCFM field and the LV bit in the header to determine if the descriptor is enabled or disabled. Therefore, initialize (DSCFM = 0x1 or 0x3 and LV = 1) the memory area equivalent to the DSCFM field and the LV bit of the descriptor before the DMAC accesses the memory area.
- If you want to set the next descriptor in the memory while the DMAC is operating, write 1 to the LV bit after setting the descriptors after header (source address, destination address, ... next link address). This is to avoid DMA transfer using descriptor values (source address, destination address, and so on) before the setting if descriptor settings by the CPU and descriptor read of the DMAC conflict and descriptor read by the DMAC interrupts descriptor settings by the CPU.
- If you want to keep the information written back to the D bit in the header, perform a byte access to write 1 to the LV bit in the header.

(4) LINK Configuration Example

In link mode, descriptors can be configured as shown below.

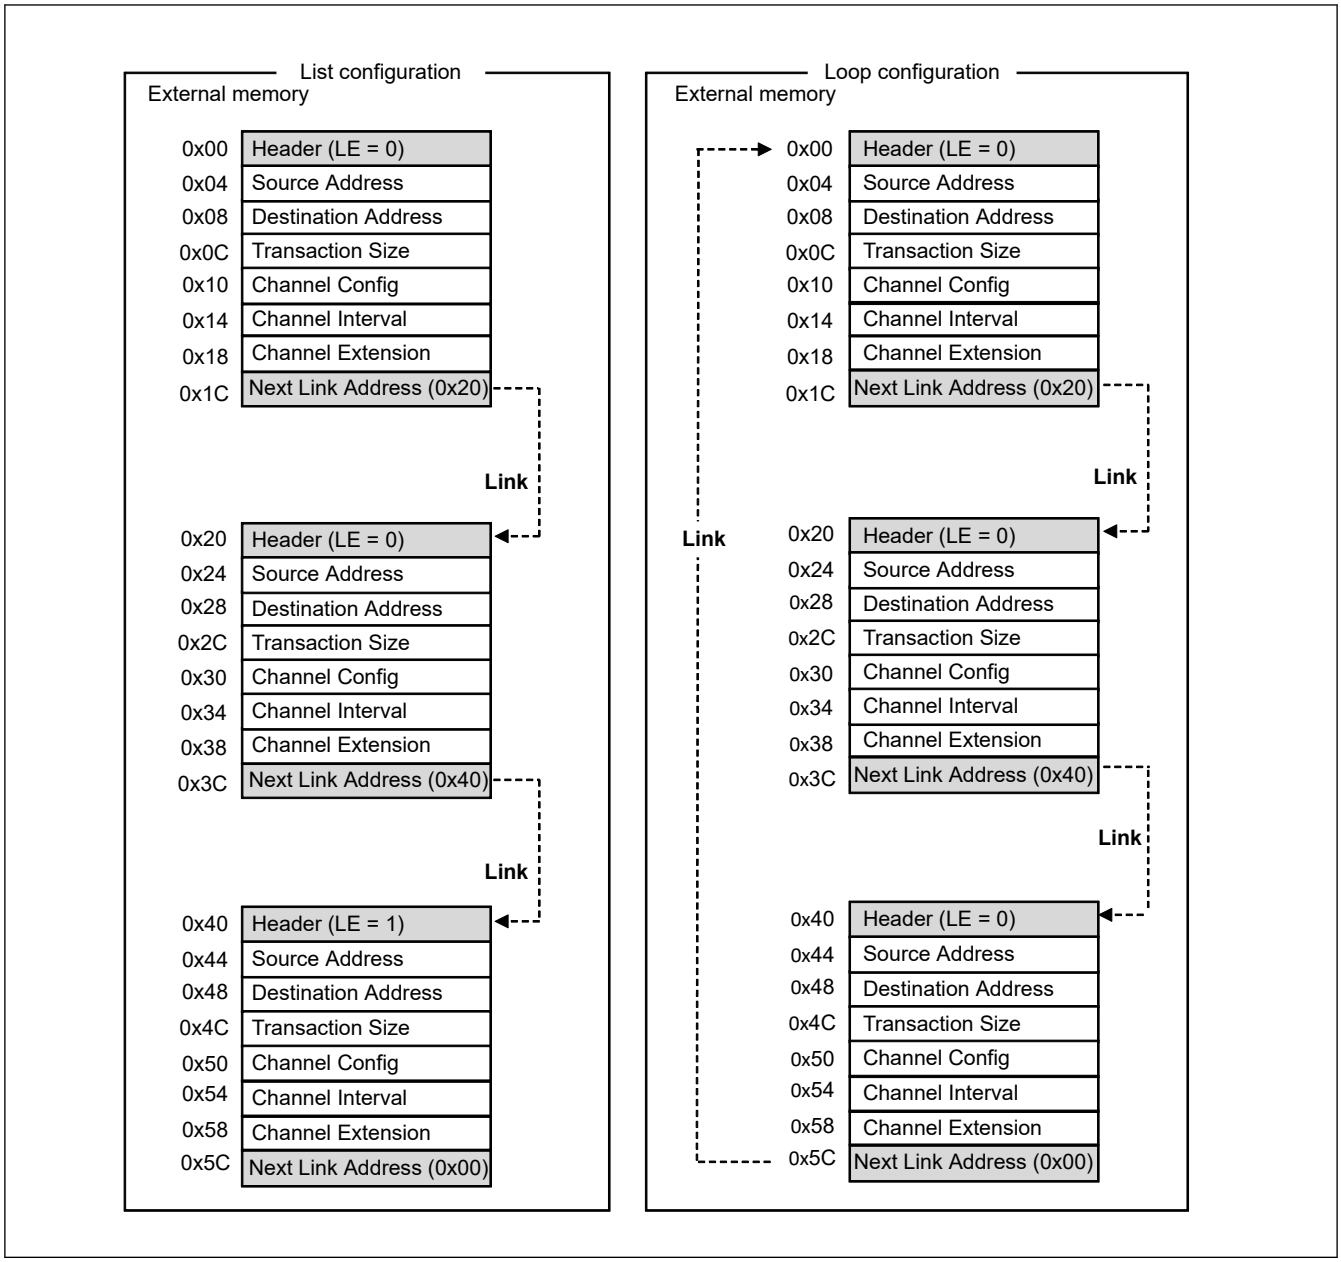

Figure 32.25 Link mode configuration example

List configuration

Writing 1 to the LE bit in the header of the last descriptor terminates the link.

Loop configuration

Setting the link destination of the last descriptor to the address of the previous descriptor configures descriptors in a loop. To terminate the loop, modify the LE bit in the header to 1 before the DMAC reads a descriptor, or follow the procedure to suspend a transfer.

32.15.1.3 Write-Only Mode

Setting the WONLY bit in the CHCFG_n register to 1 enables write-only mode.

Table 32.50 Write-only mode settings (1 of 2)

WONLY(CHCFG)	Mode	Description
0	Normal mode	Performs DMA transfers with the values set for the next register set.

Table 32.50 Write-only mode settings (2 of 2)

WONLY(CHCFG)	Mode	Description
1	Write-only mode	Performs DMA write transfers only without performing DMA read transfers.

In write-only mode, read operation for DMA transfers is not performed (descriptor read is performed in the same way as normal mode). In register mode, use the values set for the NxSA_n register (x = 0 when RSEL = 0, and x = 1 when RSEL = 1) as write data. In link mode, use the value in the SA field of a descriptor as write data.

Use this mode for initializing a memory area.

32.16 DMA Transfer

This section describes basic operation of DMA transfer.

32.16.1 Transfer Mode

Only single transfer mode is supported.

When a DMA transfer request from the USB control is accepted, a DMA transfer is performed on the side (transfer source or transfer destination) indicated by the REQD bit in the CHCFG_n register to assert the internal DMA acknowledge signal from the internal USB control to the DMAC control. Each time a transfer request is accepted, transfer proceeds. This operation is repeated until it reaches the transfer size loaded to the CRTB_n register. (Arbitration between channels is performed for each DMA transfer.)

The DMA acknowledge timing differs depending on the setting for the REQD bit in the CHCFG_n register or settings for the transfer size (DDS[2:0] and SDS[2:0] in the CHCFG_n register). For details, see section 32.16.7. Differences in Operation According to the Transfer Data Size.

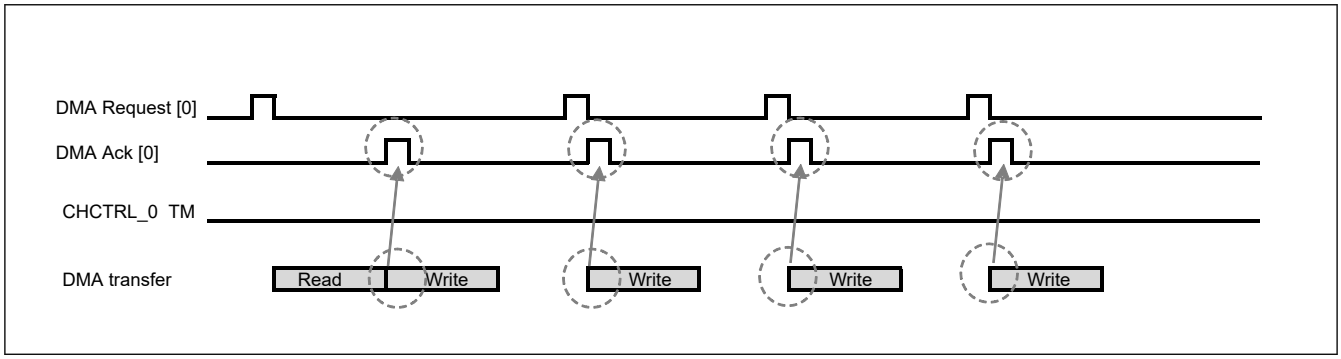

Figure 32.26 Single transfer mode (REQD = 1, SDS > DDS)

32.16.2 DMA Channel Priority Control

As an arbitration method between channels, fixed priority mode and round-robin mode are supported. To select a mode, use the PR bit in the DCTRL register. When the PR bit is 0, fixed priority mode is selected. When the PR bit is 1, round-robin mode is selected.

Table 32.51 Priority control settings

Mode	PR (DCTRL)	Description	Application
Fixed priority	0	Controls requests in fixed priority (high: CH0 > CH1: low) mode.	Use this mode if channels have priority.
Round-robin	1	Controls requests in round-robin mode.	Use this mode if you want to execute requests equally.

32.16.2.1 Fixed Priority Mode

In fixed priority mode, the priority among channels is fixed as shown below.

[High] CH0 > CH1 [Low]

If DMA transfer requests are generated in multiple channels simultaneously, a DMA transfer request with a smaller channel number takes precedence. The following figure provides an example where another DMA transfer request with higher priority is generated during a DMA transfer in fixed priority mode.

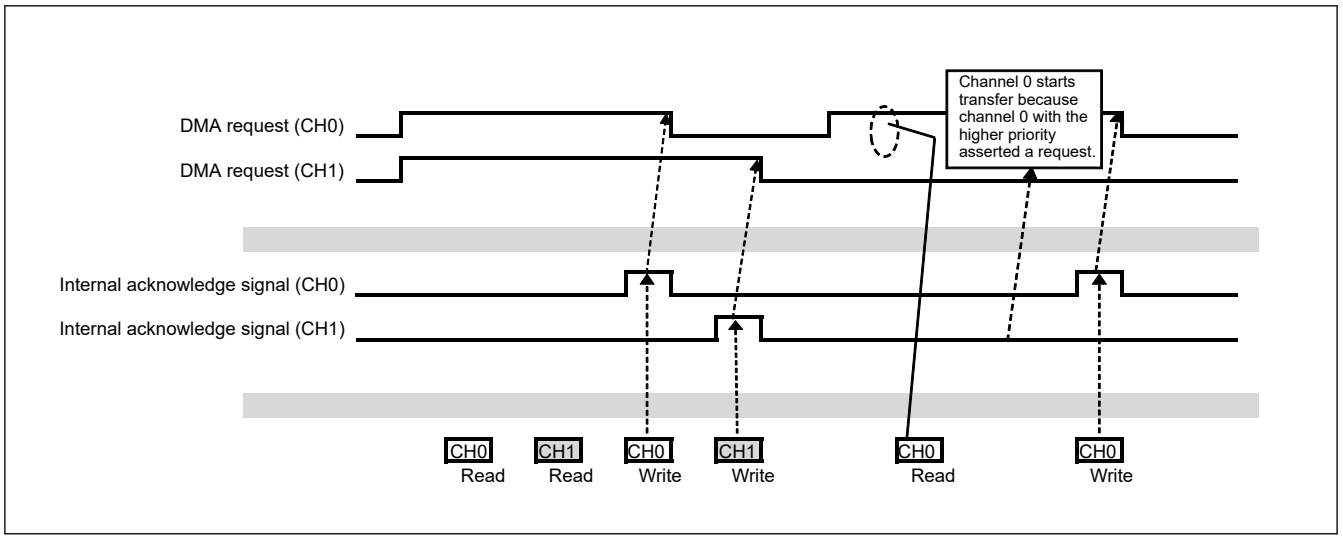

Figure 32.27 Fixed priority mode (four channels, REQD = 1)

Note: Channel 0 is handled with the highest priority, but the transfer with the next highest priority is performed to increase the bus usage rate while the transfer of channel 0 switches.

32.16.2.2 Round-Robin Mode

In round-robin mode, priority is changed each time a transfer of each channel is accepted so that the lowest priority is given to the channel in which the last transfer is performed.

The priority immediately after a reset is the same as the one in fixed priority mode as shown below.

[High] CH0 > CH1 [Low]

In this state, if no transfer request is generated in DMA channel 0, but a request is generated in DMA channel 1, a transfer of DMA channel 1 is performed. The priority after the transfer is shown below.

[High] CH1 > CH0 [Low]

The following figure provides an example of a DMA transfer in round-robin mode.

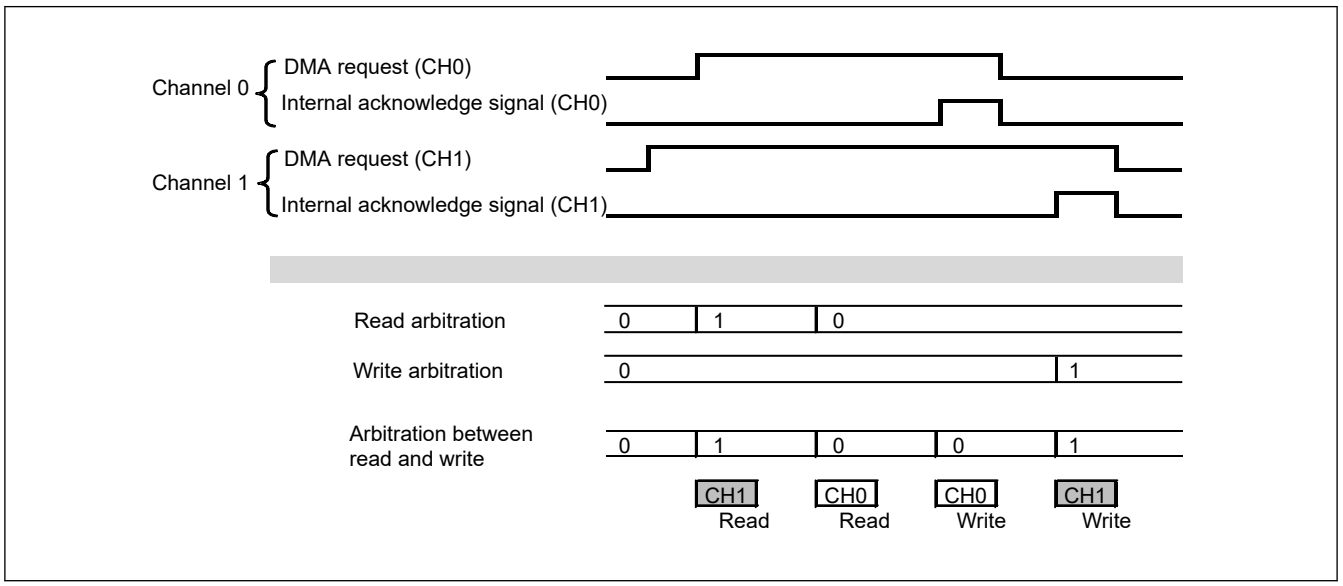

Figure 32.28 Round-robin mode (two channels, REQD = 1)

Note: In the DMAC, arbitration between read channels and arbitration between write channels are performed. As a result of these arbitrations, further arbitration is performed, and a bus access is issued.

32.16.3 Forced Ejection Request

When a forced ejection request is input, data that is not yet transferred in a buffer is transferred to the DMA transfer destination address. After data is flushed, the DMA transfer resumes.

The following describes notes on forced ejection requests:

- If a forced ejection request conflicts with a USB control DMA transfer request, the forced ejection takes precedence, and then the DMA transfer is performed.
- When the transfer destination is a system on the USB control side (the REQD bit in the CHCFG_n register = 1), the unit on the DMA transfer destination side receives data even if the USB control side does not request a DMA transfer. Therefore, a malfunction, such as buffer overflow, may occur. Because of this, when REQD =1, no forced ejection is performed by hardware.
- Differences from flush mode described in (2) Aborting a Transfer (with Buffer Flush: SBE = 1) (The EN bit is cleared to 0 when the SBE bit in the CHCFG_n register = 1.)
  Flush mode: The DMAC stops operation after data in a buffer is written.
  Forced ejection request: A DMA transfer continues after flush operation ends.

32.16.3.1 Software Forced Ejection Request

For software forced ejection requests, use the SETSSWPRQ bit in the CHCTRL_n register. To make a forced ejection request, write 1 to the SETSSWPRQ bit. The DMAC outputs data in a buffer to the DMA transfer destination.

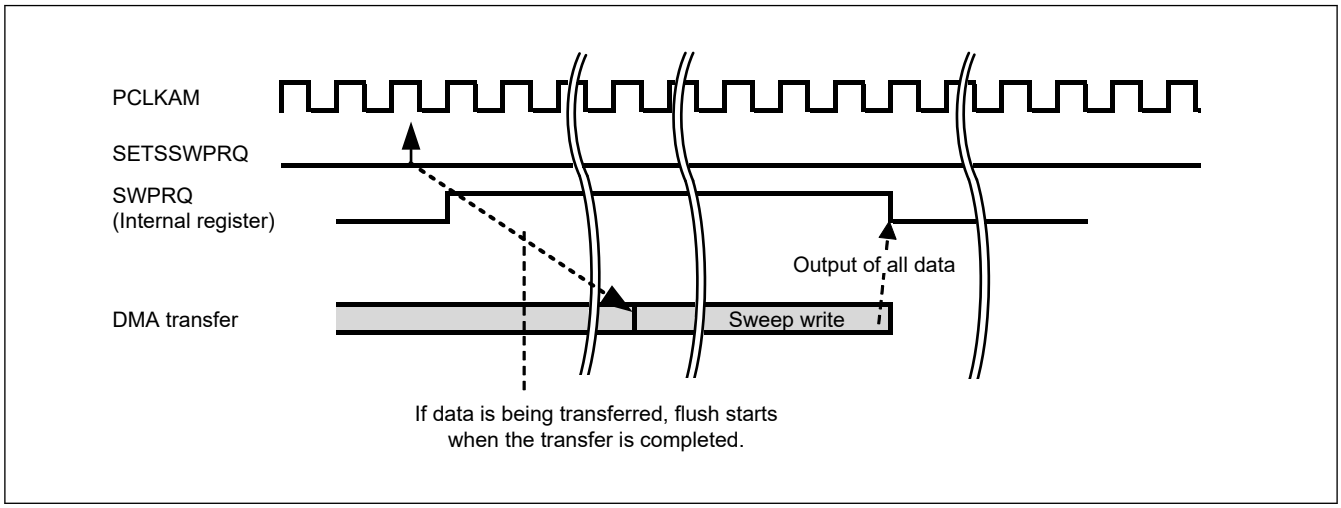

Figure 32.29 Software forced ejection timing

32.16.4 DMA Transfer Completion Interrupt (USB_FDMAn)

The USB_FDMAn[1:0] interrupt request signals indicate that a DMA transaction is completed.

Each bit of USB_FDMAn[1:0] corresponds to each channel.

When a transfer for the total number of transfer bytes loaded to the CRTB_n register is completed with an OKAY response, the END bit in the CHSTAT_n register is set to 1. If the DEM bit in the CHCFG_n register = 0 at this time, USB_FDMAn is asserted to high level (n = 1, 0). (When write-back is performed in link mode, this pin is asserted after the write-back operation.)

In addition, when the DRRP bit in the CHCFG_n register = 0 in link mode and the header of the read descriptor is LV = 0, the DER bit in the CHSTAT_n register is set to 1. If the DIM bit in the CHCFG_n register = 0 at this time, USB_FDMAn is asserted to high level.

Use these signals to detect a transfer completion interrupt in the interrupt controller.

Table 32.52 USB_FDMAn assert conditions

Source	Condition	USB_FDMAn mask signal
DMA transaction completed	When a transfer for the total number of transfer bytes loaded to the CRTB_n register is completed with an OKAY response (after write-back when write-back is performed in link mode)	DEM bit in the CHCFG_n register
Descriptor invalid	When the header of the read descriptor is LV = 0 while DRRP and DIM in the CHCFG_n register are 0 in link mode	DIM bit in the CHCFG_n register

32.16.5 DMA Error Interrupt (USB_FDMAERR)

If an error response is received during a DMA transfer or descriptor access, this module determines it as an error and aborts the transfer. When an error response is received, the EN bit in the CHSTAT_n register for channel n where a transfer is in progress is cleared to 0 and the ER bit is set to 1 (n = 1, 0). In addition, high level is output from the USB_FDMAERR pin.

The USB_FDMAERR signal cannot be masked.

Data for a series of error transfers is not guaranteed. Be sure to perform the following procedure to retry the transfer from the beginning.

1. Set the SWRST bit in the CHCTRL_n register to 1.
2. Set each register again.

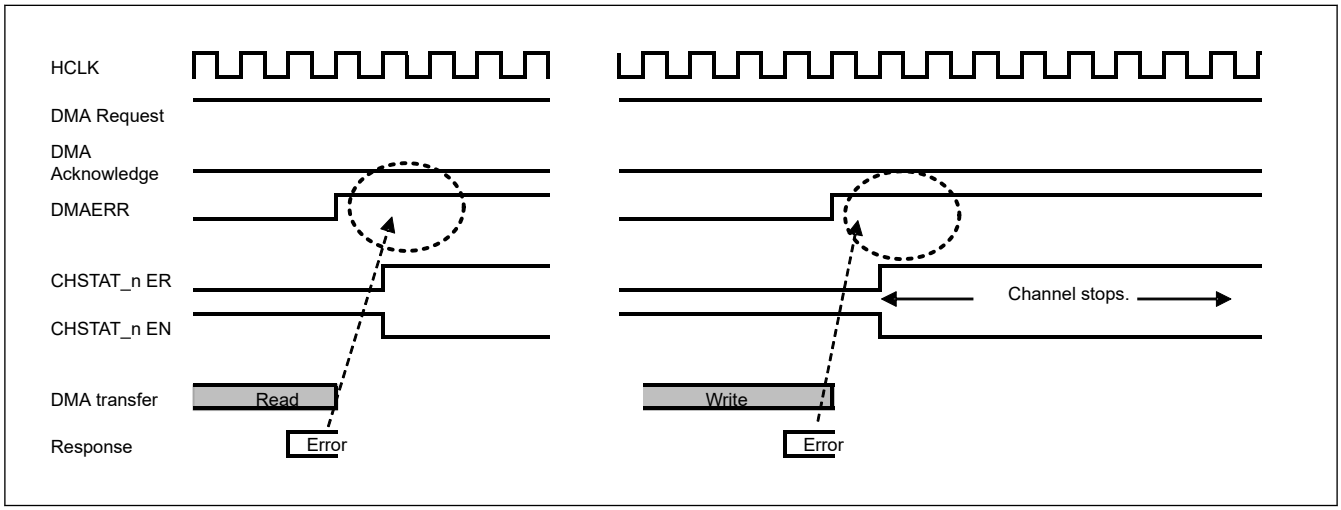

Figure 32.30 Transfer stop timing due to an error response (ERROR)

Note: The USB_FDMAERR pin output is not asserted even if an error occurs during an access to the slave of this controller.

32.16.6 Interval Count Function

By the setting for the ITVL field in the CHITVL_n register, the execution interval of DMA transfers can be adjusted. This function is used to avoid occupation of a bus by the DMAC. Until the count value becomes 0, no DMA transfer for the next DMA request is performed.

The following figure provides an operation example.

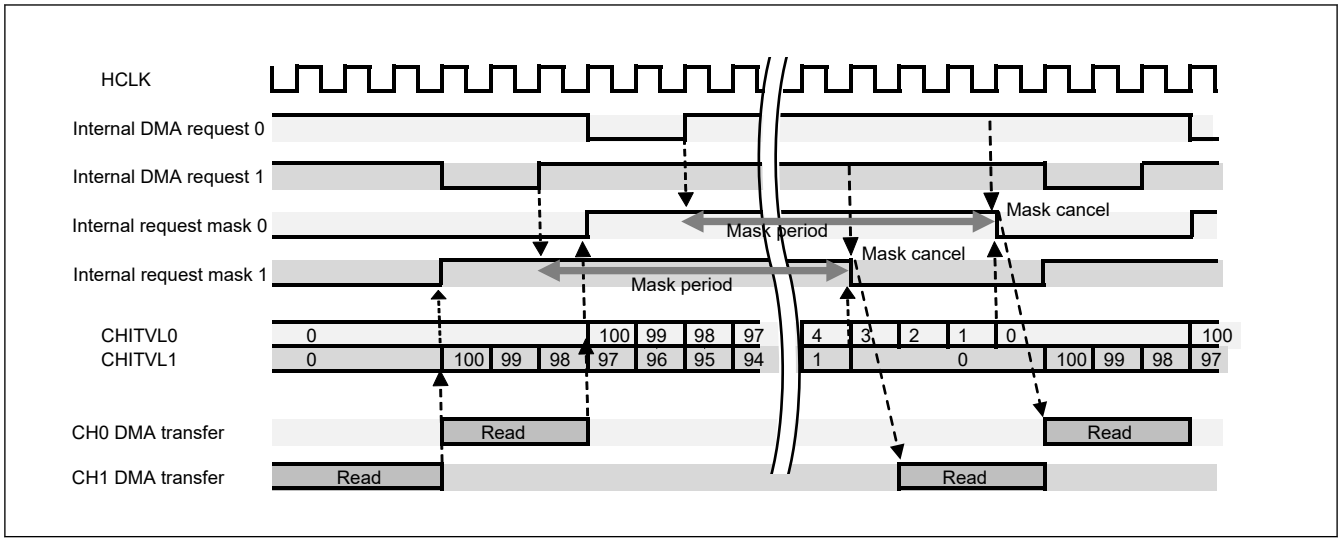

Figure 32.31 Interval count (REQD = 0, SDS < DDS)

An interval is inserted after a transfer specified by the REQD bit in the CHCFG_n register.

The following figure shows the relationship between the setting values for the REQD, SDS, and DDS bits in the CHCFG_n register and the cycles applied to intervals.

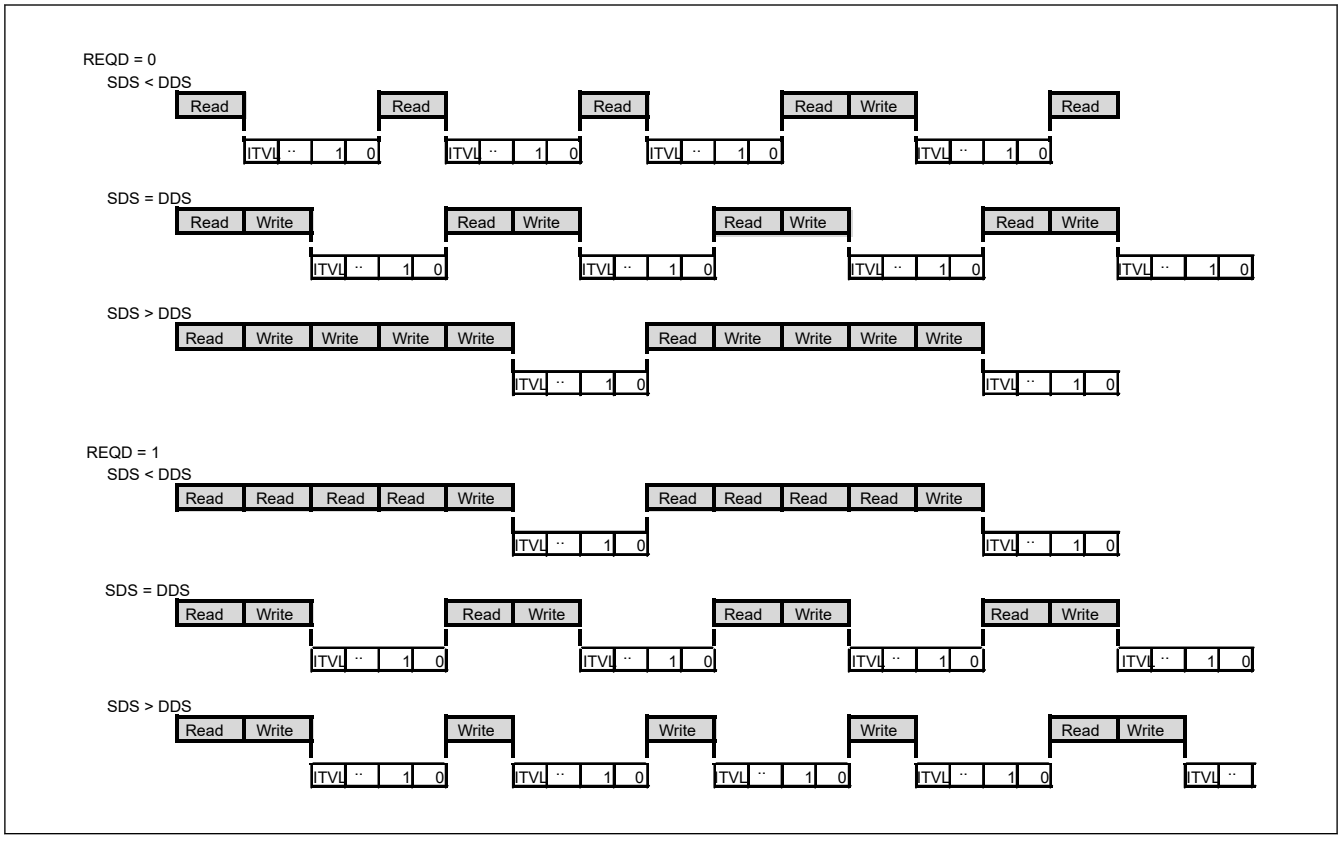

Figure 32.32 DMA transfer settings and interval counts

32.16.7 Differences in Operation According to the Transfer Data Size

32.16.7.1 When the Transfer Data Size on the Transfer Source Side is Small

When read operation for the transfer data size on the transfer destination side is completed, write operation to the transfer destination starts.

The following figure shows the timing chart (rising edge detection) when the transfer source data size is 8 bits and the transfer destination data size is 32 bits (SDS = 0 and DDS = 2 in the CHCFG_n register).

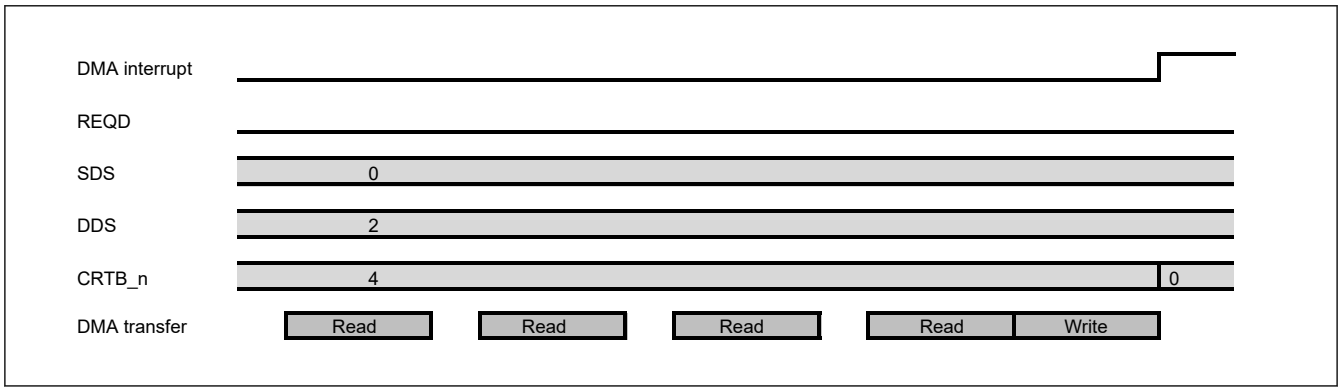

Figure 32.33 When the data size on the transfer source size is small (LVL = 0, HIEN = 1, REQD = 0, SDS < DDS in CHCFG_n)

32.16.7.2 When the Transfer Data Size on the Transfer Destination is Small

Because the transfer data size on the transfer source side is large, after a single read operation of the transfer source, write operation to the transfer destination is performed a few times. The following figure shows the timing chart (rising edge detection) when the transfer source data size is 64 bits and the transfer destination data size is 16 bits (SDS = 3 and DDS = 1 in the CHCFG_n register).

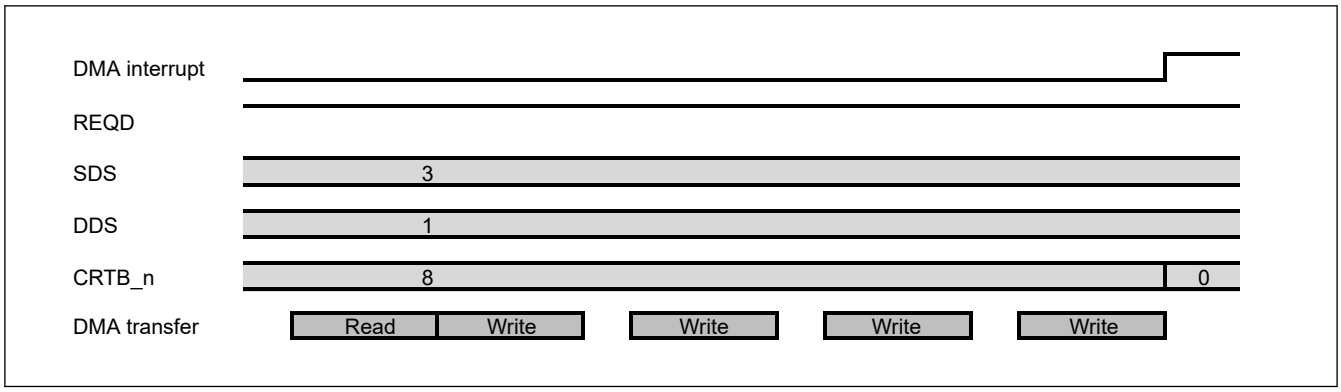

Figure 32.34 When the data size on the transfer destination side is small (LVL = 0, HIEN = 1, REQD = 1, SDS > DDS in CHCFG_n)

32.16.7.3 When Transfer Data Sizes on the Transfer Source Side and the Transfer Destination Side are Equal

Each time a DMA transfer request is detected, read operation is performed on the transfer source side and write operation is performed on the transfer destination side. The following figure shows the timing chart (rising edge detection) when the transfer source data size and the transfer destination data size are 8 bits (SDS = 0 and DDS = 0 in the CHCFG_n register).

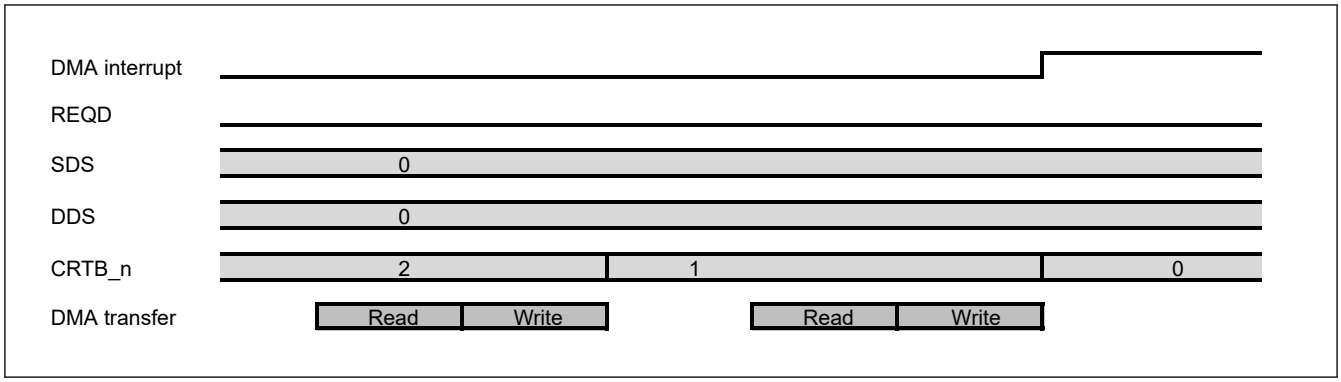

Figure 32.35 When transfer data sizes on the transfer source side and the transfer destination side are equal (LVL = 0, HIEN = 1, REQD = 0, and SDS = DDS in CHCFG_n)

32.16.8 Transfer Status

The CHSTAT_n register indicates the transfer status of each channel.

32.16.8.1 Transfer Status

The TACT bit in the CHSTAT_n register indicates that channel n is operating. Writing 1 to the SETEN bit in the CHCTRL_n register sets 1. The TACT bit remains 1 during an access to a descriptor or waiting for a DMA request.

The TACT bit is cleared when the EN bit in the CHSTAT_n register is cleared (for details on clearing conditions, see section 32.3.17.1. CHSTAT_n : Channel Status Register n (n = 0, 1), and the ongoing DMA transfer is completed.

The TACT bit is not cleared when the EN bit is not cleared (when the REN bit in the CHCFG_n register = 1 in register mode or the next descriptor access is performed in link mode) even if a DMA transaction finishes.

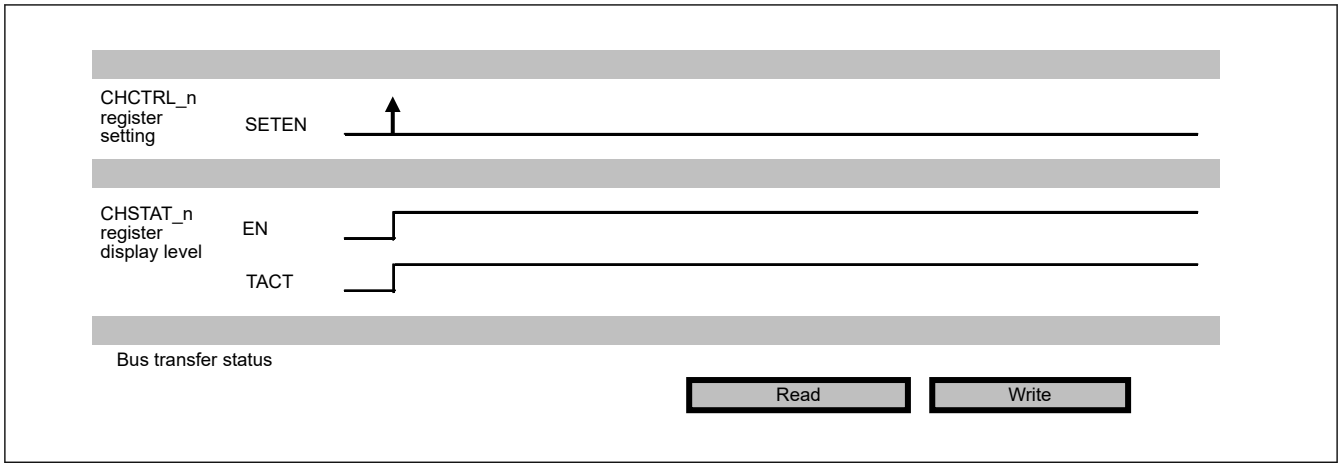

Figure 32.36 DMAC status example 1 (hardware request)

32.16.8.2 Suspending a Transfer

A DMA transfer can be suspended using the SETSUS bit in the CHCTRL_n register. At that time, if there is an active bus cycle, the DMA transfer is suspended after the bus cycle finishes. Writing 1 to the CLRSUS bit in the CHCTRL_n register resumes from the suspended state.

To check whether the transfer is suspended, set the SETSUS bit in the CHCTRL_n register, and then make sure that the SUS bit in the CHSTAT_n register or the SUS bit in the DSTAT_SUS register of the applicable channel is set to 1.

32.16.8.3 Aborting a Transfer

If 1 is written to the CLREN bit in the CHCTRL_n register during a DMA transaction, the DMA transaction of the channel can be aborted. As processing after aborting the transaction, you can use the SBE bit in the CHCFG_n register to select a mode to flush data remaining in a buffer when the transaction is aborted or a mode that does not flush buffer data. SBE = 0 (mode not to flush data) is selected by default.

When this mode (flush data) is enabled, if an ongoing transfer is aborted when the CLREN bit in the CHCTRL_n register = 1, data remaining in the buffer of the DMAC is flushed and the operation stops.

(1) Aborting a Transfer (without Buffer Flush: SBE = 0)

If 1 is written to the CLREN bit in the CHCTRL_n register during a DMA transfer, the DMA transfer is aborted and then stopped. The timing to stop the transfer depends on the set REQD bit value. After the transfer stops, write 1 to the SWRST bit in the CHCTRL_n register to clear the contents of the DMAC, and then make settings for the next transfer.

- When the TACT bit in the CHSTAT_n register is cleared to 0, you can confirm that the channel has completely stopped.
- If a DMA transfer is aborted, USB_FDMAn is not asserted.
- When the REQD bit in the CHCFG_n register = 0, the transfer stops when the next read operation is completed. (However, if data that can be written is remaining in the buffer, the data is written and then the transfer stops.)
- When the REQD bit in the CHCFG_n register = 1, the transfer stops when the next write operation is completed.

(2) Aborting a Transfer (with Buffer Flush: SBE = 1)

If 1 is written to the CLREN bit in the CHCTRL_n register during a DMA transfer, the DMA transfer is aborted. When the REQD bit in the CHCFG_n register = 0, already read data is flushed (written), and then the DMA transfer stops. When REQD = 1, flush mode cannot be used by hardware.

After the transfer stops, set the SWRST bit in the CHCTRL_n register to clear the contents of the DMAC, and then make settings for the next transfer.

- When the TACT bit in the CHSTAT_n register is cleared to 0, you can confirm that the channel has completely stopped.

(3) Checking Channel Stop

Even if 1 is written to the CLREN bit in the CHCTRL_n register, and the EN bit in the CHSTAT_n register is cleared to 0, if a transfer is already in progress on the bus, the DMAC cannot stop the transfer immediately. To check that DMA has completely stopped, make sure that the EN bit is 0 and the TACT bit in the CHSTAT_n register is 0.

(4) Transfer Aborting Procedure

The following describes the procedure for aborting a transfer:

1. Write 1 to the CLREN bit in the CHCTRL_n register.
2. When the SBE bit in the CHCFG_n register = 0, the transfer stops according to the REQD bit value in the CHCFG_n register. If SBE = 1 at this time, flush mode is enabled.
3. Read the CHSTAT_n register and confirm that the TACT bit is 0. When TACT = 0, DMA has completely stopped. When TACT = 1, continue polling until the TACT bit is cleared to 0.
4. If you want to perform the next DMA transfer after a transfer is aborted, be sure to set the SWRST (software reset) bit in the CHCTRL_n register to 1 before the next transfer starts.

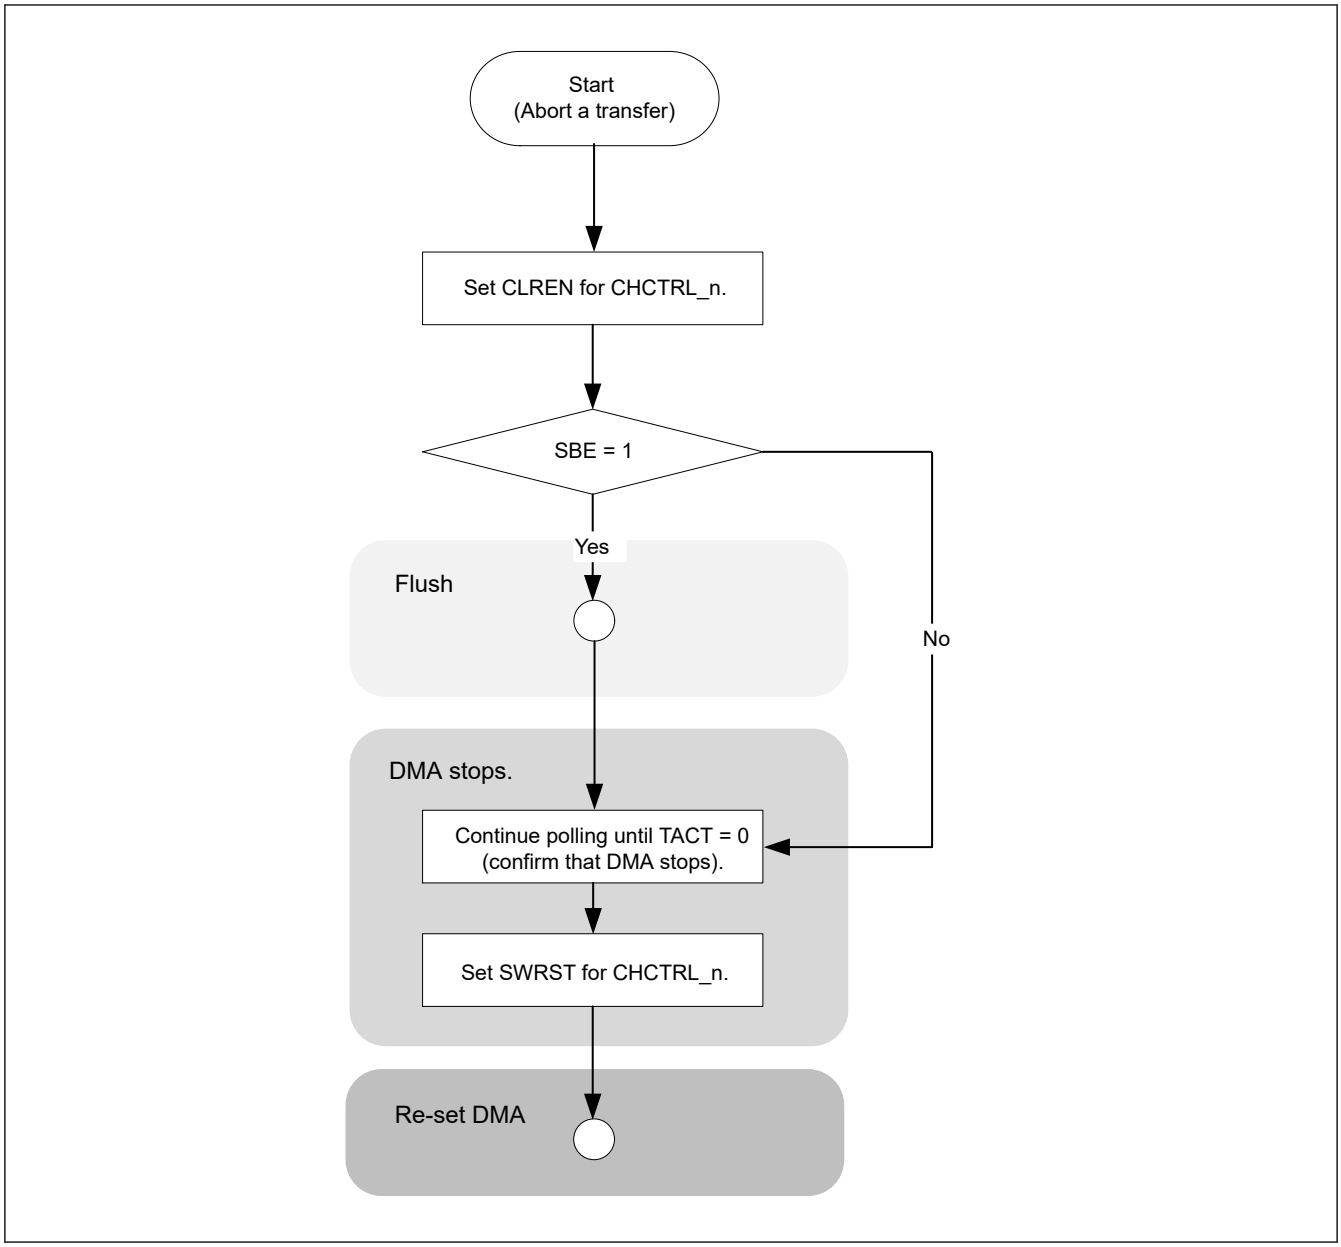

Figure 32.37 Transfer aborting flow

32.17 Access Type

32.17.1 AHB Master DMA Transfer Combinations

32.17.1.1 Read Access

The DMA read access issuance type has the following features.

- Read access is made to a beat-aligned space (including the source address indicated in the CRSA_n register) with the size specified by the SDS[2:0] bits in the CHCFG_n register. Beat-unaligned transfer is not performed for the bus. An unnecessary area may be read depending on the set values of the CRSA_n register and each SKIP register. In this case, necessary data in the read data is loaded to a buffer.
- The size and the burst length are determined by the value set for the SDS[2:0] field.
  When the value set for the SDS[2:0] field is equal to or smaller than the bus width:

Size:	SDS[2:0] set value

Burst type: Single

When the value set for the SDS[2:0] field is larger than the bus width:

Size: Bus width

Burst type: Fixed-length burst (burst length = SDS[2:0] set value/bus width)

The following table shows AHB bus access types.

Table 32.53 DMA read transfer combinations

SDS	Source address	AHB transfer					
		First transfer			Second transfer		
		Address	Size	Burst	Address	Size	Burst
0 (8 bits)	—	addr	8	Single	—	—	—
1 (16 bits)	2-byte align	{addr[31:1], 0b}	16	Single	—	—	—
	2-byte unalign				{addr[31:1], 0b} + 0x2	16	Single
2 (32 bits)	4-byte align	{addr[31:2], 00b}	32	Single	—	—	—
	4-byte unalign				{addr[31:2], 00b} + 0x4	32	Single
4 (128 bits)	16-byte align	{addr[31:4], 0x0}	32	INCR4	—	—	—
	16 bytes				{addr[31:4], 0x0} + 0x10	32	INCR4
5 (256 bits)	32-byte align	{addr[31:5], 0x00}	32	INCR8	—	—	—
	32 bytes				{addr[31:5], 0x00} + 0x20	32	INCR8
6 (512 bits)	64-byte align	{addr[31:6], 0x00}	32	INCR16	—	—	—
	64 bytes				{addr[31:6], 0x00} + 0x40	32	INCR16

Note: If the transfer becomes EBT during the burst transfer, remaining transfer is performed by 32-bit INCR.

32.17.1.2 Write Access

The DMA write access issuance type has the following features.

- Write access is made from the destination address (indicated in the CRDA_n register) to a beat-aligned boundary with the size specified by the DDS[2:0] bits in the CHCFG_n register.
- The size and the burst length are determined by the value set for the DDS[2:0] field.
  When the value set for the DDS[2:0] field is equal to or smaller than the bus width:

  Size: DDS[2:0] set value

  Burst type: Single

  When the value set for the DDS[2:0] field is larger than the bus width:

  Size: Bus width

  Burst type: Fixed-length burst (burst length = DDS[2:0] set value/bus width)
- Write access to any space other than the specified space is not performed. In the following cases, write access is made with a combination of sizes smaller than the value set for the DDS[2:0] field.
  - When the destination address is beat-unaligned with the value set for the DDS[2:0] field
  - When an access with the DDS field size is made over the SKIP boundary
  - When the DDS[2:0] size is larger than the remaining number of transfer bytes

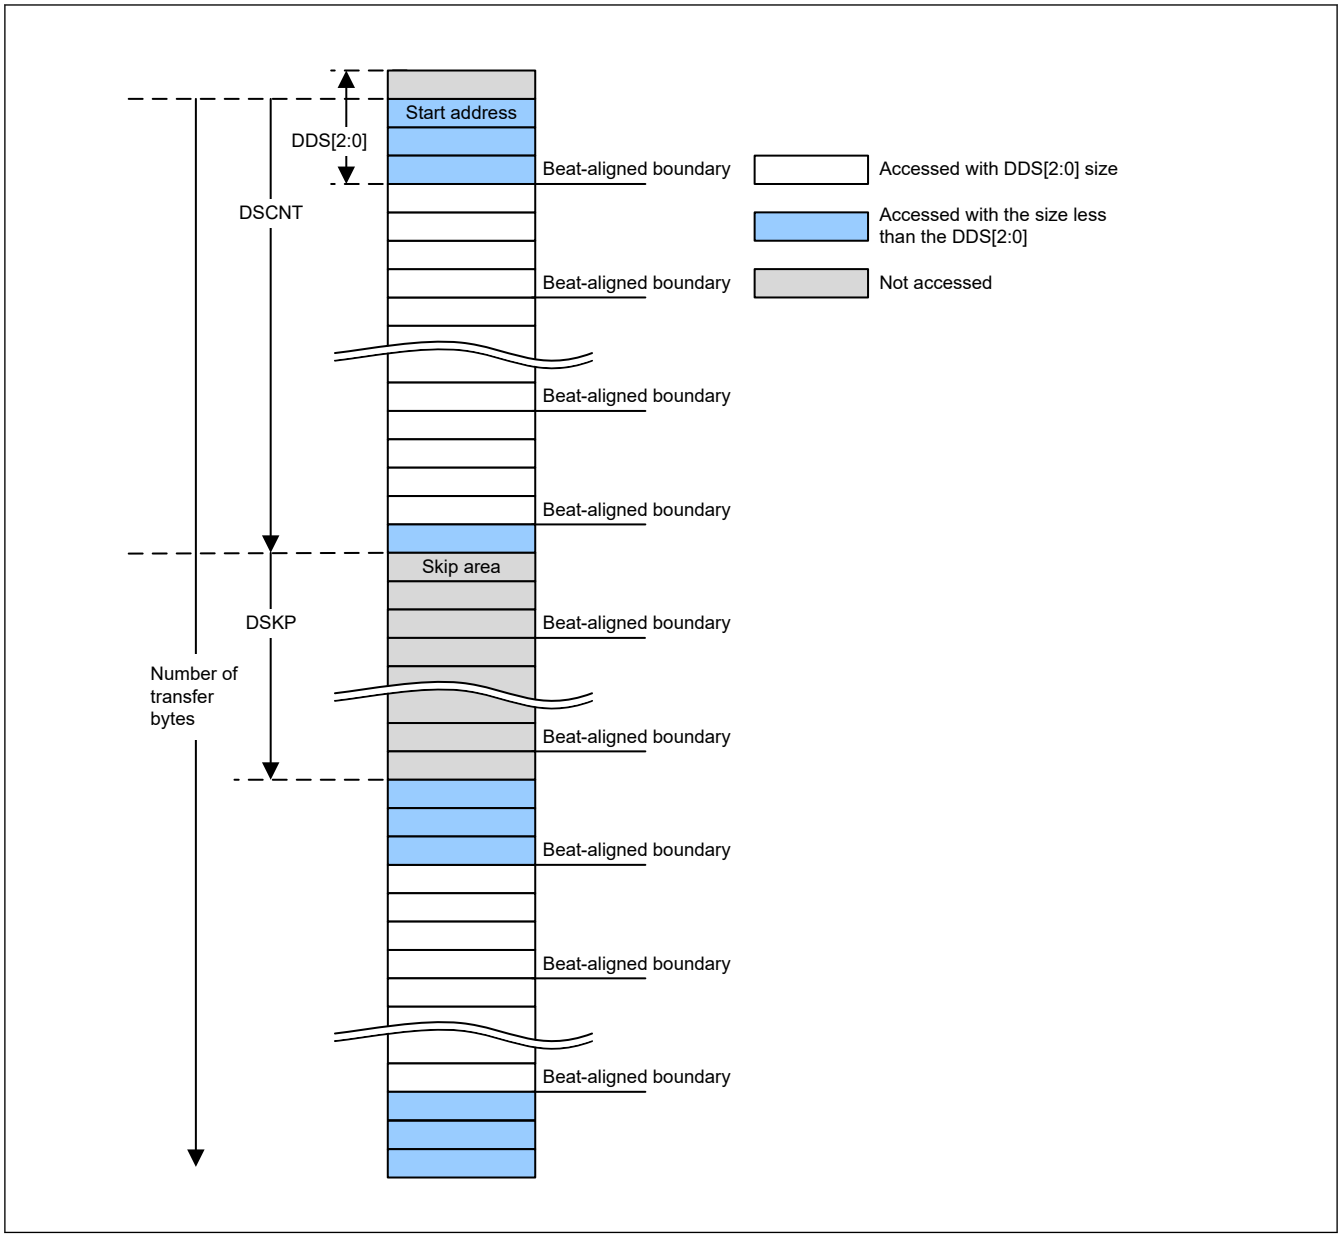

Figure 32.38 Example of DMA write access space and access type

33. Serial Communications Interface (SCI, SCIE)

33.1 Overview

This LSI has six independent serial communications interface (SCI) channels and 12 independent serial communications interface for encoder interface (SCIE) channels. The SCI is configurable to six asynchronous and synchronous serial interfaces:

- Asynchronous interfaces (UART and Asynchronous Communications Interface Adapter (ACIA))
- 8-bit clock synchronous interface
- Simple I2C (master-only)
- Simple SPI
- Smart card interface
- Manchester mode

The smart card interface complies with the ISO/IEC 7816-3 standard for electronic signals and transmission protocol. Each SCI has FIFO buffers to enable continuous and full-duplex communication, and the data transfer speed can be configured independently using a baud rate generator.

The SCIE is configurable to Asynchronous, Clock synchronous, and Manchester mode only. Note that wording, SCI, stands for both SCI and SCIE in this chapter except significant difference.

Table 33.1 lists the SCI specifications, Figure 33.1 shows a block diagram of SCI channel n, and Table 33.2 lists the I/O pins.

Table 33.1 SCI specifications (1 of 3)

Item	Specifications
Number of channels	6 channels (ch0 to ch4 in NONSAFETY and ch5 in SAFETY) 12 channels for encoder (8 in LLPP0 and 4 in LLPP1)
Serial communication modes	• Asynchronous • Clock synchronous • Smart card interface (This mode is not supported in SCIE.) • Simple I2C (This mode is not supported in SCIE.) • Simple SPI (This mode is not supported in SCIE.) • Manchester mode
Transfer speed	Bit rate specifiable with the baud rate generator
Full-duplex communications	• Transmitter: Continuous transmission possible using double-buffering • Receiver: Continuous reception possible using double-buffering
Half-duplex communication	Possible by using TXD pins
Data transfer	Selectable as LSB-first or MSB-first transfer
RXD/TXD polarity	Selectable polarity for TXD and RXD independently
Interrupt sources	• Transmit end, transmit data empty, receive data full, receive error, receive data ready, and address match • Completion of generation of a start condition, restart condition, or stop condition (for simple I2C mode)
RS-485 driver control function	Output DE pin to enable transmission mode of external transceiver
Loopback function	Self-diagnosis of communication function inside module supported
Synchronizing circuit bypass function	Bus clock (PCLKM) can be used as operation clock (PCLKSCIn) when bypass function is enabled.
Module-stop function	Module-stop state can be set for each channel

Table 33.1 SCI specifications (2 of 3)

Item		Specifications
Asynchronous mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Reception sampling timing adjustment	Adjustable reception sampling timing from default timing
	Transmission timing adjustment	Adjustable timing of transmission wave edge by register
	Parity	Even parity, odd parity, or no parity
	Receive error detection	Parity, overrun, and framing errors
	Hardware flow control	Transmission and reception controllable with CTSn# and RTSn# pins
	Transmission/reception	Selectable to 1-stage register or 16-stage FIFO
	Address match	Interrupt request/event output can be issued upon detecting a match between received data and the value in the compare match register.
	Start-bit detection	Selectable to low level or falling edge detection
	Break detection	Breaks from framing errors detectable by reading register
	Clock source	Selectable to internal or external clock
	Double-speed mode	Baud rate generator double-speed mode is selectable.
	Multi-processor communications function	Serial communication enabled between multiple processors
	Noise cancellation	Digital noise filters included on signal paths from RXDn pin inputs
Clock synchronous mode	Data length	8 bits
	Reception sampling timing adjustment	Adjustable reception sampling timing to backward from default timing in case internal clock used
	Receive error detection	Overrun error
	Clock source	Selectable to internal clock (master mode) or external clock (slave mode)
	Double-speed mode	Baud rate generator double-speed mode is selectable.
	Hardware flow control	Transmission and reception controllable with CTSn# and RTSn# pins
	Transmission/reception	Selectable to 1-stage register or 16-stage FIFO
Smart card interface mode	Error processing	Error signal can be automatically transmitted on detecting a parity error during reception.
		Data can be automatically retransmitted on receiving an error signal during transmission.
	Data type	Both direct and inverse convention supported
Simple I2C mode	Transfer format	I2C bus format (MSB-first only)
	Operating mode	Master (single-master operation only)
	Transfer rate	Up to 400 kbps
	Noise cancellation	The signal paths from input on the SCLn and SDAn pins incorporate digital noise filters and provide an adjustable interval for noise cancellation.

Table 33.1 SCI specifications (3 of 3)

Item		Specifications
Simple SPI mode	Data length	8 bits
	Error detection	Overrun error
	Clock source	Selectable to internal clock (master mode) or external clock (slave mode)
	Double-speed mode	Baud rate generator double-speed mode is selectable.
	Reception sampling timing adjustment	Adjustable reception sampling timing to backward from default timing in case internal clock used
	SS input pin function	High impedance state can be invoked on the output pins by driving the SSn# pin high.
	Clock settings	Configurable between four clock phase and clock polarity settings
	Transmission/reception	Selectable to 1-stage register or 16-stage FIFO
Manchester mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Receive error detection	Parity, overrun, framing, Manchester errors, Preface, Start Bit, SYNC
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission
	Clock source	Only internal clock can be used. (The setting of external clock is prohibited because it is not the object of operation guarantee.)
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Multi-processor communication function	Serial communication among multiple processors
	Noise cancellation	The signal paths from input on the RxDn pins incorporate digital noise filters
	Manchester encoding/decoding function	Function to perform Manchester encoding/decoding of transmission/reception data and communicate using Manchester code
	Preface setting/detection function	The function outputs the configured the preface pattern and detects it.
	Start Bit setting/detection function	The function outputs the configured the Start Bit pattern and detects it.
	Reception retiming function	Function to perform timing correction for each bit center edge by using Manchester code having edge at bit center
Bit rate modulation function		Error reduction through correction of outputs from the baud rate generator

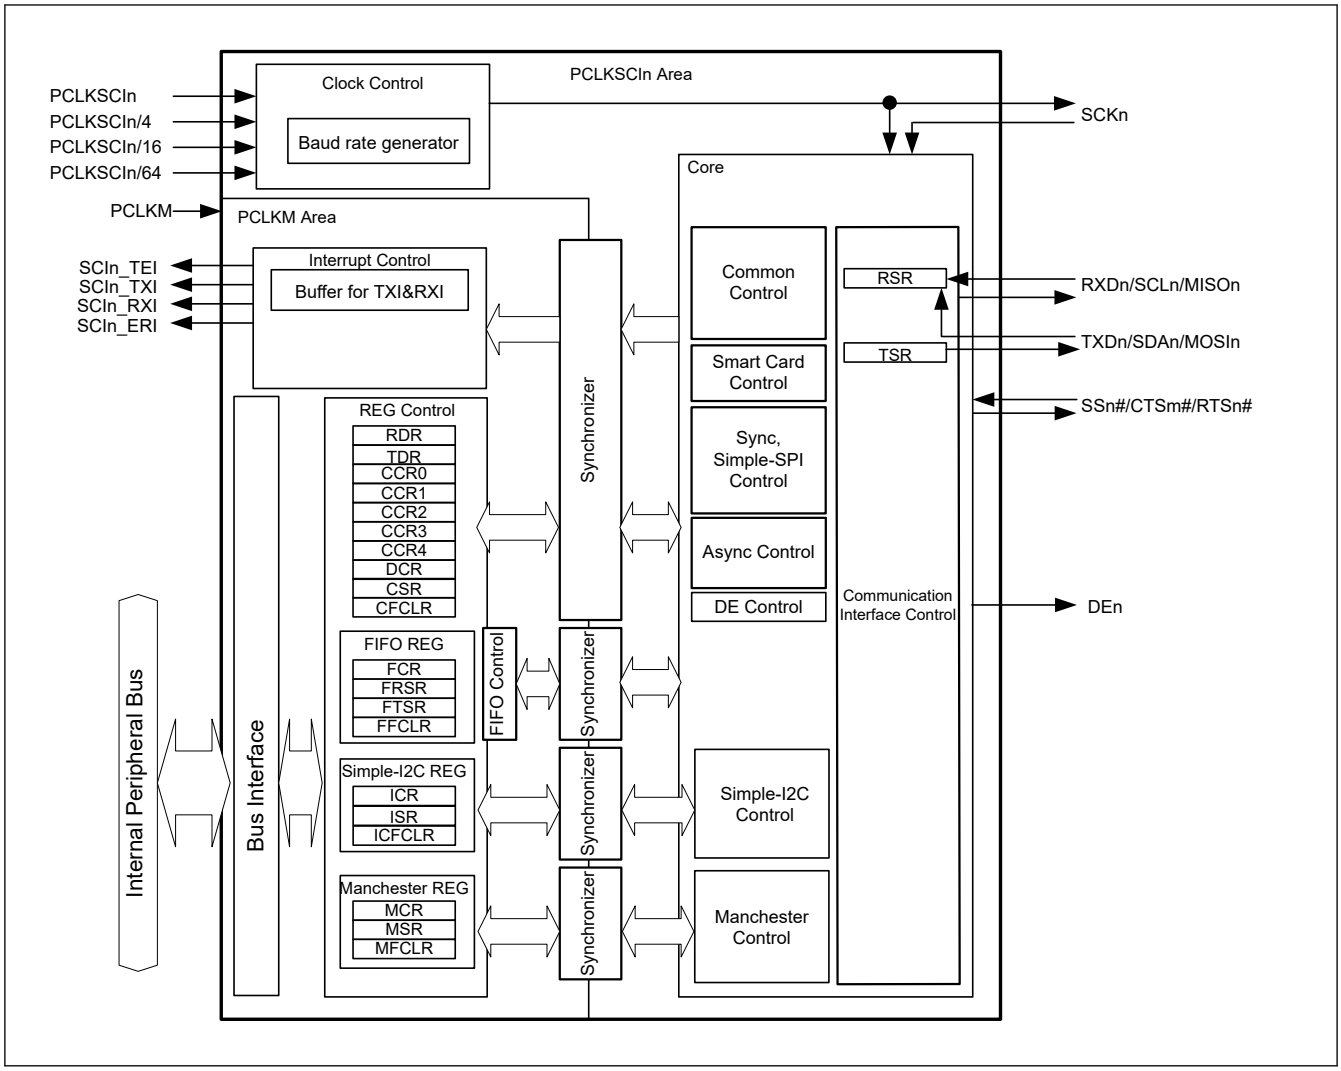

Figure 33.1 SCI block diagram

Table 33.2 SCI input/output pins

Channel	Pin name	I/O	Function
SCIn	SCKn	I/O	SCIn clock input/output
	RXDn	Input	SCIn receive data input
	SCLn	I/O	SCIn I2C clock input/output
	MISOn	I/O	SCIn data input (master), data output (slave)
	TXDn	Output	SCIn transmit data output
	SDAn	I/O	SCIn I2C data input/output
	MOSIn	I/O	SCIn data output (master), data input (slave)
	SSn#	Input	SCIn chip select input, active-low
	RTSn#	Output	SCIn transfer start control output, active-low
	CTSn#	Input	SCIn transfer start control input, active-low
	DEn	Output	SCIn Driver Enable output
SCIEm	SCKEm	Output	SCIEm clock output for encoder
	RXDEm	Input	SCIEm receive data input for encoder
	TXDEm	Output	SCIEm transmit data output for encoder
	DEEm	Output	SCIEm Driver Enable output for encoder

Note: n = 0 to 5, m = 0 to 11

Note 1. Access from Cortex-R52 CPU0 and CPU1 is not protected by TrustZone. This slave access control is applied to access from other masters.

33.3 Register Descriptions

This section explains each register specification.

Table 33.5 shows a list of registers/bits that can not be rewritten during communication. Also, check the notes on register rewriting described in section 33.18. Usage Notes.

Table 33.5 Bits that cannot be rewritten during communication

Register	Bit	Write constraint
CCR0	RE	In Clock synchronous mode, Simple-SPI and Simple-I2C, 1 can be written only when TE = 0 and RE = 0. After setting TE or RE to 1, only 0 can be written in TE and RE.
CCR0	TE	
CCR0	IDSEL	Writable only when TE = 0 and RE = 0.
CCR0	SSE	Writable only when TE = 0 and RE = 0.
CCR1	CTSE	Writable only when TE = 0 and RE = 0.
CCR1	CTSPEN	Writable only when TE = 0 and RE = 0.
CCR1	PE	Writable only when TE = 0 and RE = 0.
CCR1	PM	Writable only when TE = 0 and RE = 0.
CCR1	TINV	Writable only when TE = 0 and RE = 0.
CCR1	RINV	Writable only when TE = 0 and RE = 0.
CCR1	SPLP	Writable only when TE = 0 and RE = 0.
CCR1	SHARPS	Writable only when TE = 0 and RE = 0.
CCR1	NFCS[2:0]	Writable only when TE = 0 and RE = 0.
CCR1	NFEN	Writable only when TE = 0 and RE = 0.
CCR2	All bits	Writable only when TE = 0 and RE = 0.
CCR3	All bits	Writable only when TE = 0 and RE = 0.
CCR4	All bits	Writable only when TE = 0 and RE = 0.
ICR	IICDL[4:0]	Writable only when TE = 0 and RE = 0.
ICR	IICINTM	Writable only when TE = 0 and RE = 0.
ICR	IICCSC	Writable only when TE = 0 and RE = 0.
FCR	All bits	Writable only when TE = 0 and RE = 0.
MCR	All bits	Writable only when TE = 0 and RE = 0.
DCR	All bits	Writable only when TE = 0 and RE = 0.

33.3.1 RSR : Receive Shift Register

RSR is a shift register which is used to receive serial data input from the RXDn pin and converts it into parallel data. When one frame of data has been received, it is automatically transferred to the RDR register.

The RSR register cannot be directly accessed by the CPU.

33.3.2 RDR : Receive Data Register

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	FER	PER	—	—	ORER	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	FFER	FPER	DR	MPB	RDAT[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	RDAT[8:0]	Serial receive data RDAT is a 9-bit register for storing received data. Received data is stored in [6:0] when 7-bit data is selected, in [7:0] when 8-bit data is selected, and in [8:0] when 9-bit data is selected. And 0 is stored in the unused bit.	R
9	MPB	Multi-processor flag 0: Data transmission cycles 1: ID transmission cycles	R
10	DR	Receive data ready flag FRSR.DR can be read.	R
11	FPER	FIFO parity error flag (Valid only in Asynchronous mode) 0: There is no parity error in the data read from the receive FIFO. 1: There is parity error in the data read from the receive FIFO.	R
12	FFER	FIFO framing error flag (Valid only in Asynchronous mode) 0: There is no framing error in the data read from the receive FIFO. 1: There is framing error in the data read from the receive FIFO.	R
23:13	—	These bits are read as 0.	R
24	ORER	Overrun Error flag CSR.ORER can be read.	R
26:25	—	These bits are read as 0.	R
27	PER	Parity error flag CSR.PER can be read.	R
28	FER	Framing error flag CSR.FER can be read.	R
31:29	—	These bits are read as 0.	R

In FIFO mode (CCR3.FM = 1), this register has 16-stage FIFO structure.

RDAT[8:0] bits (Serial receive data)

After one frame of data is received, the received data is transferred from the RSR register to this registers, thus allowing the RSR register to receive the next data.

The RSR and RDR registers have a double-buffered structure to enable continuous reception.

Read RDR only once when a receive data full interrupt (RXI) request is issued. Without reading received data from RDR, if the next one frame is received, an overrun error occurs.

In FIFO mode, continuous reception is executed until 16 stages are stored. If data is read when there is no received data in the receive FIFO (RDR), the value is undefined. When the receive FIFO (RDR) are full of received data, subsequent serial receive data is lost.

The CPU cannot write to RDR.

"0" is stored in the bit position which is not received (RDR.bit8 or RDR.bit7) at the time of 7 bit or 8 bit communication of Asynchronous and Manchester mode.

FFER and FPER store error information of received data only in FIFO mode. When not FIFO, 0 is stored in RDR.bit 12 and bit 11.

MPB bit (Multi-processor flag)

In asynchronous mode and Manchester mode, during multi-processor communication (CCR3.MP = 1), the value of the multi-processor bit corresponding to the received data (RDAT[8:0]) can be read.

FPER bit (FIFO parity error flag)

Indicates whether the data read from the receive FIFO has a parity error.

FFER bit (FIFO framing error flag)

Indicates whether the data read from receive FIFO has a framing error.

33.3.3 TDR : Transmit Data Register

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TSYNC	—	—	MPBT	TDAT[8:0]								
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
8:0	TDAT[8:0]	Serial transmit data TDAT is a 9-bit register for setting transmit data. Transmit data is set in [6:0] when 7-bit data is selected, in [7:0] when 8-bit data is selected, and in [8:0] when 9-bit data is selected. When byte access, write TDR[15:8] and then write TDR[7:0].	R/W
9	MPBT	Multi-processor transfer bit flag Value of the multi-processor bit in the transmission frame. This bit is use in Asynchronous mode and Manchester mode. When writing to this bit when not used, write the initial value. 0: Data transmission cycles 1: ID transmission cycles	R/W
11:10	—	These bits are read as 1. The write value should be 1.	R/W

Bit	Symbol	Function	R/W
12	TSYNC	Transmit SYNC Data Bit It is valid when MCR.SBSEL = 1 and MCR.SYNSEL = 1 in Manchester mode. When writing to this bit when not used, write the initial value. 0: The Start Bit is transmitted as DATA SYNC. 1: The Start Bit is transmitted as COMMAND SYNC.	R/W
31:13	—	These bits are read as 1. The write value should be 1.	R/W

In FIFO mode (CCR3.FM = 1), this register has 16-stage FIFO structure.

TDAT[8:0] bits (Serial transmit data)

The TDR is a 9-bit register for storing transmit data.

When empty space is detected in the TSR register, the transmit data stored in the TDR registers is transferred to TSR, and transmitting is started.

The TSR and TDR registers have a double-buffer structure to realize continuous transmission. When the next data to be transmitted is stored in TDR after one frame of data has been transmitted, the transmitting operation is continued by transfer to the TSR register.

In FIFO mode, when the SCI detects that the transmit shift register (TSR) is empty, it transmits data in the transmit FIFO (TDR) into TSR and starts serial transmission. Continuous serial transmission is executed until there is no transmit data left in the transmit FIFO (TDR).

When transmit FIFO is full of transmit data (16 frames), no more data can be written. If new data is written, the data is ignored.

Write transmit data to the TDR only once, after TXI interrupt is issued when CCR0.TE is 1. And when using bytes access, write TDR[15:8] and then write TDR[7:0].

MPBT bit (Multi-processor transfer bit flag)

Selects the multi-processor bit of transmit frame.

TSYNC bit (Transmit SYNC Data Bit)

When Manchester mode and MCR.SBSEL = 1 and MCR.SYNSEL=1, the type of SYNC selected according to this bit becomes the Start Bit of the transmission frame.

33.3.4 TSR : Transmit Shift Register

TSR is a shift register that transmits serial data. TSR cannot be directly accessed by the CPU.

To perform serial data transmission, the SCI first automatically transfers transmit data from TDR to TSR, and then sends the data to the TXDn pin.

33.3.5 CCR0 : Common Control Register 0

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	SSE	—	—	TEIE	TIE	—	—	—	RIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	IDSEL	DCME	MPIE	—	—	—	TE	—	—	—	RE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RE	Receive Enable In clock synchronous mode and simple-SPI mode, receive only setting is prohibited (TE = 0 and RE = 1 setting prohibited). 0: Serial reception is disabled. 1: Serial reception is enabled.	R/W*1
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	TE	Transmit Enable 0: Serial transmission is disabled. 1: Serial transmission is enabled.	R/W*1
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	MPIE	Multi-Processor Interrupt Enable (Valid in asynchronous mode and Manchester mode when CCR3.MP = 1.) This bit should set 0 in smart card interface mode. When the data with the multiprocessor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and non-multiprocessor reception is resumed. If you want to continue receiving operation using the multiprocessor function, set this bit to 1 sufficiently earlier than receiving the STOP bit of the next received frame. (Consider the synchronization delay time.) 0: Non-Multi-Processor reception 1: Multi-Processor reception	R/W*2
9	DCME	Data Compare Match Enable (Valid only in asynchronous mode) 0: Address match function is disabled. 1: Address match function is enabled.	R/W*2
10	IDSEL	ID frame select (Valid only in asynchronous mode with multi-processor mode) 0: All data is to be compared. 1: The data with RDR.MPB = 1 is to be compared.	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
16	RIE	Receive Interrupt Enable 0: RXI and ERI interrupt requests are disabled. 1: RXI and ERI interrupt requests are enabled.	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	TIE	Transmit Interrupt Enable 0: TXI interrupt request is disabled. 1: TXI interrupt request is enabled.	R/W
21	TEIE	Transmit End Interrupt Enable This bit should set 0 in smart card interface mode. 0: TEI interrupt request is disabled. 1: TEI interrupt request is enabled.	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
24	SSE	SSn# Pin Function Enable (Valid in Simple-SPI mode.) In slave mode (CCR3.CKE[1:0] = 1xb), set 1 to this bit. 0: SSn# pin function is disabled. 1: SSn# pin function is enabled.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. In clock-synchronous mode (CCR3.MOD[2:0] = 010b), simple-SPI mode (CCR3.MOD[2:0] = 011b), and simple-I^{2}C mode (CCR3.MOD[2:0] = 100b), 1 can be written only when TE = 0 and RE = 0. After setting TE or RE to 1, only 0 can be written in TE and RE. In other modes, writing is enabled under any condition.

Note 2. This bit is cleared by hardware. Note that unintentional setting of this bit may be occurred by read-modify-write operation.

RE bit (Receive Enable)

Enables or disables serial receive operation.

When this bit is set to 1, serial reception becomes possible after the synchronization delay time has elapsed in asynchronous mode or the synchronous clock input in clock synchronous mode or the neg-edge of RxD in manchester mode or start bit in smart-card-interface mode.

Note that CCR3 should be set prior to setting the RE bit to 1 in order to designate the reception format.

Except smart-card-interface-mode, even if reception is halted by setting the RE bit to 0, the CSR.RDRF, FER, PER, ORER, MSR.MER, SBER, SYER, PFER, FRSR.DR flags are not affected and the previous values are retained. In smart-card-interface-mode, even if reception is halted by setting the RE bit to 0, the CSR.FER, PER, ORER flags are not affected and the previous value is retained. Also, to stop the reception operation, synchronization delay time will be required from when the RE bit is set to 0 until the reception operation is stopped.

TE bit (Transmit Enable)

Enables or disables serial transmission.

When this bit is set to 1, serial transmission becomes possible after the synchronization delay time has elapsed. After the synchronization delay time, transmission is started by writing transmit data to TDR. Note that CCR3 should be set prior to setting the TE bit to 1 in order to designate the transmission format. In addition, the synchronization delay time is required until the transmission control circuit is stopped after the TE bit is set to 0.

MPIE bit (Multi-Processor Interrupt Enable)

When this bit is set to 1 and the data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags (CSR.RDRF, ORER, FER, FRSR.DR, MSR.MER, SYER, PFER, SBER) are not set.

When the data with the multi-processor bit set to 1 is received, the MPIE is automatically cleared to 0, and normal reception is resumed. For details, see section 33.5. Multi-Processor Communication Function. If you want to continue receiving operation using the multiprocessor function, set this bit to 1 sufficiently earlier than receiving the STOP bit of the next received frame.

When the receive data includes the MPB bit set to 0, the receive data is not transferred from the RSR to the RDR, a receive error is not detected, and setting the flags ORER, FER, MER, SYER, PFER, and SBER to 1 is disabled.

When the receive data includes the MPB bit set to 1, the MPIE bit is automatically cleared to 0, the RXI and ERI interrupt requests are enabled (if CCR0.RIE is set to 1), and setting the flags ORER, FER, MER, SYER, PFER, and SBER to 1 is enabled.

MPIE should be set to 0 if multi-processor communications function is not to be used.

DCME bit (Data Compare Match Enable)

It can select whether the Address match function (data compare match function) uses or not.

When DCME is 1, if SCI detects the match to the comparison data (CCR4.CMPD) with receive data, DCME is cleared automatically, and after that, SCI operation mode will be receive mode without data compare match function.

See section 33.4.6. Address Match (receive data match detection) Function.

The write value should be 0 other than asynchronous mode.

IDSEL bit (ID frame select)

It can select whether it's compared in spite of the value of MPB bit or it's compared only the data of MPB bit = 1 (ID frame) when the Address match function is valid. Please set at the same time as DCME.

RIE bit (Receive Interrupt Enable)

Enables or disables RXI and ERI interrupt requests.

RXI and ERI interrupt request is disabled by setting the RIE bit to 0.

An ERI interrupt request can be canceled by reading 1 from the CSR.ORER, FER, or PER and then setting the flag to 0, or setting the RIE bit to 0.

In the case of Manchester mode, the MER, SYER, PFER, and SBER flags are also the cause of ERI interrupt request, so the same processing is necessary. For details of these flags, see section 33.3.12. MCR : Manchester Control Register and section 33.3.18. MSR : Manchester Status Register.

TIE bit (Transmit Interrupt Enable)

Enables or disables a TXI interrupt request.

A TXI interrupt request is disabled by setting the TIE bit to 0. At the beginning of transmission, set 1 to CCR0.TE and CCR0.TIE simultaneously. Then the TXI interrupt request is generated.

TEIE bit (Transmit End Interrupt Enable)

Enables or disables a TEI interrupt request.

A TEI interrupt request is disabled by setting the TEIE bit to 0.

In simple I2C mode, the TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STI). In this case, the TEIE bit can be used to enable or disable the STI.

SSE bit (SSn# Pin Function Enable)

Set this bit to 1 if the SSn# pin is to be used in control of transmission and reception (in simple SPI mode). Set this bit to 0 in any other mode. Do not set both the SSE and CTSE (even if this setting is made, operation is the same as that when these bits are set to 0).

In the slave mode (CCR3.CKE[1:0] = 10b or 11b), SSE should be set 1.

In the master mode (CCR3.CKE[1:0] = 00b or 01b) and single-master, the SSn# pin on the master side is not required to control reception and transmission, so SSE should be set 0.

33.3.6 CCR1 : Common Control Register 1

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	NFEN	—	NFCS[2:0]			—	—	—	SHARPS	—	—	—	SPLP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	RINV	TINV	—	—	PM	PE	—	—	SPB2IO	SPB2DT	—	—	CTSPEN	CTSE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	CTSE	CTS Enable 0: CTS function is disabled (RTS output function is enabled). 1: CTS function is enabled.	R/W
1	CTSPEN	CTS external pin Enable 0: 1-pin mode, CTS and RTS share 1 pin. 1: 2-pin mode, CTS and RTS have dedicated pins.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	SPB2DT	Serial port break data select The output level of TXD pin is selected when CCR0.TE = 0.*1 0: Low level is output in TXD pin, when TINV = 0. High level is output in TXD pin, when TINV = 1. 1: High level is output in TXD pin, when TINV = 0. Low level is output in TXD pin, when TINV = 1.	R/W
5	SPB2IO	Serial port break I/O This bit selects output or not output of TXD pin when the CCR0.TE = 0.*1 0: The value of SPB2DT bit is not output in TXD pin. 1: The value of SPB2DT bit is output in TXD pin.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
8	PE	Parity Enable (Valid only in asynchronous mode and Manchester mode. In Smart Card Interface mode, set 1 to this bit.) 0: Parity bit addition is not performed, when transmitting. Parity bit checking is not performed, when receiving. 1: The parity bit is added, when transmitting. The parity bit is checked, when receiving.	R/W
9	PM	Parity Mode (Valid only when PE = 1) 0: Selects even parity 1: Selects odd parity	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
12	TINV	TXD invert 0: Transmit data is not inverted and output to TXD.*2 1: Transmit data is inverted and output to TXD.	R/W
13	RINV	RXD invert 0: Received data from RXD is not inverted and input.*2 1: Received data from RXD is inverted and input.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
16	SPLP	Loopback Control This function is available in asynchronous mode, Manchester mode, and clock synchronous mode. 0: Normal mode 1: Loopback mode	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	SHARPS	Half-duplex communication select In the simple I2C mode or in the simple SPI mode, this bit should be set 0. 0: The TXD pin and the RXD pin independent 1: Half-duplex communication using TXD pin	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
26:24	NFCS[2:0]	Noise Filter Clock Select (Valid in asynchronous mode, Manchester mode, and simple-I2C mode.) Select for the noise filter's clock source. In simple-I2C mode, 000b setting is prohibited. "The baud rate generator source clock" means the clock selected by CCR2.CKS[1:0]. 0 0 0: The base clock signal divided by 1. 0 0 1: The baud rate generator source clock divided by 1. 0 1 0: The baud rate generator source clock divided by 2. 0 1 1: The baud rate generator source clock divided by 4. 1 0 0: The baud rate generator source clock divided by 8. Others: Setting prohibited	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W
28	NFEN	Digital Noise Filter Function Enable (Valid in asynchronous mode, Manchester mode, and simple-I2C mode) Noise filter function is available for RXD only in asynchronous mode and Manchester mode, for SCL and SDA inputs in simple-I2C mode. 0: Noise filter disabled 1: Noise filter enabled	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. You should use this bit in asynchronous mode and Manchester mode only. Not guaranteed in other mode.
Note 2. RINV/TINV should be set 0b in smart card interface mode and simple I2C mode.

CTSE bit (CTS Enable)

Set this bit to 1 if the SSn# pin is to be used for CTS input. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, and simple I2C mode. Do not set both the CTSE and SSE bits (even if this setting is made, operation is the same as that when these bits are set to 0).

CTSPEN bit (CTS external pin Enable)

When CTSE is 1, select the terminals usage method when using the CTS and RTS functions.

SPB2DT bit (Serial port break data select), SPB2IO bit (Serial port break I/O)

The TXD pin status decided by combination of CCR0.TE bit, CCR1.SPB2IO bit and CCR1.SPB2DT bit is indicated in Table 33.6.

Table 33.6 TXD pin status

CCR0.TE	CCR1.SPB2IO	CCR1.SPB2DT	TXD pin status (When CCR1.TINV = 0)
0	0	x	Hi-Z (initial value)
0	1	0	Low level output
0	1	1	High level output
1	x	x	Serial transmission data is output.

PE bit (Parity Enable)

When PE bit to 1, the parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

In the multiprocessor format, the parity bit is not added or checked regardless of this bit setting.

PM bit (Parity Mode)

Selects the parity mode for transmission and reception (even or odd). In multi-processor mode, this bit is invalid.

For details on the usage of this bit in smart card interface mode, see section 33.7.2. Data Format (Except in Block Transfer Mode).

TINV bit (TXD invert), RINV bit (RXD invert)

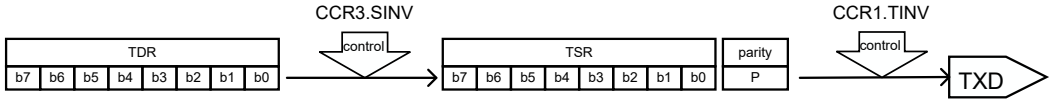
The data of RDR is controlled by RINV and CCR3.SINV. And the data from TXD pin is controlled by TINV and CCR3.SINV. The control by RINV/TINV are done to communication pins (RXD/TXD), so they can control not only data-bits but also other bits (start bit, stop bit, parity bit). For details, see Figure 33.2.

During half-duplex communication and slave operation in simple SPI mode, use the TXD pin for reception, so set the inversion control of the received data with the TINV bit.

Note: Description and timing charts in this chapter assumes CCR1.TINV = 0 and CCR1.RINV = 0 when TINV and RINV value are not specified.

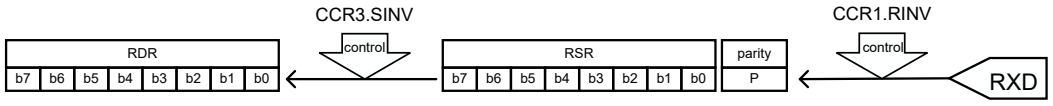
The receive/transmit data control (Data size = 8 bits, Even parity, MSB first)

The transmit data is controlled by CCR1.TINV and CCR3.SINV.



CCR3. SINV	CCR1. TINV	TDR	TSR	Parity (even)	TxD waveform
0	0	0xBE	0xBE	0	
0	1	0xBE	0xBE	0	
1	0	0xBE	0x41	0	
1	1	0xBE	0x41	0	

The received data is controlled by CCR1.RINV and CCR3.SINV.



CCR3. SINV	CCR1. TINV	RDR	RSR	parity (even)	RxD waveform
0	0	0xBE	0xBE	0	
1	0	0x41	0xBE	0	
0	1	0xBE	0xBE	0	
1	1	0x41	0xBE	0	

Figure 33.2 Example of the receive/transmit data control

SPLP bit (Loopback Control)

When SPLP = 1, TXD is connected to RXD internally.

Transmit data can be inverted and received by TINV = 1.

Set to 0 in asynchronous mode with external clock and clock synchronous mode slave.

SHARPS bit (Half-duplex communication select)

Setting this bit to 1 enables half-duplex communication using the TXD pin. However, it cannot be used in Simple-SPI mode, Simple-I2C mode, and Smart Card Interface mode.

NFCS[2:0] bits (Noise Filter Clock Select)

These bits select the sampling clock for the digital noise filter.

To use the noise filter in asynchronous mode and Manchester mode, set these bits from 000b to 100b. In simple I2C mode, set the bits to a value in the range from 001b to 100b.

NFEN bit (Digital Noise Filter Function Enable)

This bit enables or disables the digital noise filter function. When the function is enabled, noise cancellation is applied to the RXDn input in asynchronous mode and Manchester mode, and noise cancellation is applied to the SDAn and SCLn input in simple I2C mode. In any mode other than above, set the NFEN bit to 0.

33.3.7 CCR2 : Common Control Register 2

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

3	—	This bit is read as 0. The write value should be 0.	R/W
4	BGDM	Baud Rate Generator Double-Speed Mode Select Valid in asynchronous/clock-synchronous/simple-SPI/Manchester mode and CCR3.CKE[1] = 0. 0: Baud rate generator outputs the clock with single frequency. 1: Baud rate generator outputs the clock with doubled frequency.	R/W
5	ABCS	Asynchronous Mode Base Clock Select (Valid only in Asynchronous mode and Manchester mode) 0: Selects 16 base clock cycles for 1-bit period. 1: Selects 8 base clock cycles for 1-bit period.	R/W
6	ABCSE	Asynchronous Mode Extended Base Clock Select (Valid only in asynchronous mode and CCR3.CKE[1] = 0) 0: Clock cycles for 1-bit period are decided with combination between CCR2.BGDM and CCR2.ABCS. 1: 6 base clock cycles for 1-bit period and doubled frequency is output from the baud rate generator.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
15:8	BRR[7:0]	Bit rate setting BRR is an 8-bit register that adjusts the bit rate.	R/W
16	BRME	Bit Rate Modulation Enable 0: Bit rate modulation function is disabled. 1: Bit rate modulation function is enabled.	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
21:20	CKS[1:0]	Clock Select 0 0: PCLKSCIn clock (n = 0)*2 0 1: PCLKSCIn/4 clock (n = 1)*2 1 0: PCLKSCIn/16 clock (n = 2)*2 1 1: PCLKSCIn/64 clock (n = 3)*2	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
31:24	MDDR[7:0]	Modulation Duty setting MDDR corrects the bit rate adjusted by the BRR register.	R/W

Note 1. S is the value of S in Table 33.8.
Note 2. n is the decimal notation of the value of n in Table 33.8.

BCP[2:0] bits (Base Clock Pulse)

The BCP[2:0] bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode.

For details, see section 33.7.4. Receive Data Sampling Timing and Reception Margin.

BGDM bit (Baud Rate Generator Double-Speed Mode Select)

The BGDM bit is valid when the baud rate generator is selected as the clock source (CCR3.CKE[1] = 0) in asynchronous mode, Manchester mode, clock synchronous mode, simple-SPI mode. When external clock is selected (CCR3.CKE[1] = 1), set it to 0. For the clock output from the baud rate generator, either single or doubled frequency can be selected. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.

Set this bit to 0 in modes other than asynchronous mode or Manchester mode or clock synchronous mode or simple-SPI.

ABCS bit (Asynchronous Mode Base Clock Select)

Selects the clock cycles for 1-bit period.

Set it to 0 in modes other than asynchronous mode and Manchester mode.

ABCSE bit (Asynchronous Mode Extended Base Clock Select)

The pulse number for a base clock at 1-bit period is 6 and the clock of a double frequency is output from baud rate generator. Only when the bit rate is set to 6 dividing frequency of the bus clock, please use this bit and set CCR2.CKS[1:0] = 00b and BRR = 0.

Set it to 0 in modes other than asynchronous mode. Even in asynchronous mode, set it to 0 when using external clock.

Table 33.7 Base clock cycle number per 1-bit

ABCSE bit	ABCS bit	BGDM bit	The base clock cycles / 1 bit	The frequency of the baud rate generator
0	0	0	16	×1
0	0	1	16	×2
0	1	0	8	×1
0	1	1	8	×2
1	x	x	6	×2

BRR[7:0] bits (Bit rate setting)

BRR is an 8-bit register that adjusts the bit rate.

SCI has independent baud rate generator control, different bit rates can be set for each. Table 33.8 shows the relationship between the setting (N) in the BRR and the bit rate (B) for asynchronous mode, multiprocessor transfer, Manchester mode, clock synchronous mode, smart card interface mode, simple SPI mode, and simple I2C mode.

Table 33.8 Relationship between N setting in BRR and bit rate B

Mode	BGDM bit	ABCS bit	ABCSE bit	BRR[7:0] setting	Error (%)
Asynchronous, Multiprocessor transfer, Manchester	0	0	0	$N = \frac{PCLKSCIn \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	$Error = \{\frac{PCLKSCIn \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)} - 1\} \times 100$
	1	0	0	$N = \frac{PCLKSCIn \times 10^6}{32 \times 2^{2n-1} \times B} - 1$	$Error = \{\frac{PCLKSCIn \times 10^6}{B \times 32 \times 2^{2n-1} \times (N+1)} - 1\} \times 100$
	0	1	0		
	1	1	0	$N = \frac{PCLKSCIn \times 10^6}{16 \times 2^{2n-1} \times B} - 1$	$Error = \{\frac{PCLKSCIn \times 10^6}{B \times 16 \times 2^{2n-1} \times (N+1)} - 1\} \times 100$
	x	x	1*2	$N = \frac{PCLKSCIn \times 10^6}{12 \times 2^{2n-1} \times B} - 1$	$Error = \{\frac{PCLKSCIn \times 10^6}{B \times 12 \times 2^{2n-1} \times (N+1)} - 1\} \times 100$
Clock synchronous, Simple-SPI	0	0	0	$N = \frac{PCLKSCIn \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	—
	1	0	0	$N = \frac{PCLKSCIn \times 10^6}{4 \times 2^{2n-1} \times B} - 1$	—
Smart card interface				$N = \frac{PCLKSCIn \times 10^6}{S \times 2^{2n+1} \times B} - 1$	$Error = \{\frac{PCLKSCIn \times 10^6}{B \times S \times 2^{2n+1} \times (N+1)} - 1\} \times 100$
Simple-I2C*1				$N = \frac{PCLKSCIn \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	—

Note: B: Bit rate (bps)
N: BRR setting for baud rate generator (0 ≤ N ≤ 255)
PCLKSCIn: Operating frequency (MHz)
n and S: Determined by the settings of the CCR2 registers as listed in the table below. Please be careful about 2^{2n+1} is used in the expression for Smart card interface, 2^{2n-1} is used in other modes.
Note 1. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I2C mode satisfy the I2C standard.
Note 2. In Manchester mode, only ABCSE = 0 can be selected.

Table 33.9 Calculating widths at high and low level for SCL

Mode	SCL	Formula (result in seconds)
I^2C	Width at high level (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 7 \times \frac{1}{PCLKSCIn \times 10^6}$
	Width at low level (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 8 \times \frac{1}{PCLKSCIn \times 10^6}$

Table 33.10 Clock source settings

CCR2 setting	Clock source	n
CKS[1:0] = 00b	PCLKSCIn clock	0
CKS[1:0] = 01b	PCLKSCIn/4 clock	1
CKS[1:0] = 10b	PCLKSCIn/16 clock	2
CKS[1:0] = 11b	PCLKSCIn/64 clock	3

Table 33.11 Base clock settings in smart card interface mode (1 of 2)

CCR2 setting	Base clock cycles for 1-bit period	S
BCP[2:0] = 000b	93 clock cycles	93
BCP[2:0] = 001b	128 clock cycles	128
BCP[2:0] = 010b	186 clock cycles	186
BCP[2:0] = 011b	512 clock cycles	512

Table 33.11 Base clock settings in smart card interface mode (2 of 2)

CCR2 setting	Base clock cycles for 1-bit period	S
BCP[2:0] = 100b	32 clock cycles	32
BCP[2:0] = 101b	64 clock cycles	64
BCP[2:0] = 110b	372 clock cycles	372
BCP[2:0] = 111b	256 clock cycles	256

Table 33.12 lists examples of N settings in BRR in asynchronous mode and Manchester mode. Table 33.13 and Table 33.18 list the maximum bit rate settable for each operating frequency. Examples of BRR (N) settings in clock synchronous mode and simple SPI mode are listed in Table 33.15. Examples of BRR (N) settings in smart card interface mode are listed in Table 33.17. Examples of BRR (N) settings in simple I2C mode are listed in Table 33.19. In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, see section 33.7.4. Receive Data Sampling Timing and Reception Margin. Table 33.14 and Table 33.16 list the maximum bit rates with external clock input. Table 33.20 lists the minimum widths at high and low level for SCL at various bit rates.

When either the asynchronous mode base clock select bit (ABCS) or the baud rate generator double-speed mode select bit (BGDM) is set to 1 in asynchronous mode and Manchester mode, the bit rate becomes twice that listed in Table 33.12.

When both of those registers are set to 1, the bit rate becomes four times the listed value.

Table 33.12 Examples of BRR settings for various bit rates (asynchronous mode and Manchester mode)

Bit rate (bps)	PCLKSCIn = 75 MHz			PCLKSCIn = 80 MHz			PCLKSCIn = 96 MHz			PCLKSCIn = 100 MHz			PCLKSCIn = 125 MHz		
	n	N	Error (%)	n	N	Error (%)	n	N	Error (%)	n	N	Error (%)	n	N	Error (%)
9600	0	243	0.06	—	—	—	—	—	—	—	—	—	—	—	—
19200	0	121	0.06	0	129	0.16	0	155	0.16	0	162	-0.15	0	202	0.22
38400	0	60	0.06	0	64	0.16	0	77	0.16	0	80	0.47	0	101	-0.27
57600	0	40	-0.76	0	42	0.94	0	51	0.16	0	53	0.47	0	67	-0.27
115200	0	19	1.73	0	21	-1.36	0	25	0.16	0	26	0.47	0	33	-0.27

Note: This is an example when CCR2.ABCS = 0, CCR2.BGDM = 0 and CCR2.ABCSE = 0.
When either ABCS bit or BGDM bit is set to 1, the bit rate doubles.
When both ABCS = 1 and BGDM = 1, the bit rate increases four times.

Table 33.13 Maximum bit rate for each operating frequency (asynchronous mode and Manchester mode) (1 of 2)

PCLKSCIn (MHz)	BGDM bit	ABCS bit	ABCSE bit	n	N	MAX baud rate (baud)
75	0	0	0	0	0	2,343,750
		1	0	0	0	4,687,500

BRME bit (Bit Rate Modulation Enable)

Enables and disables the bit rate modulation function. The bit rate generated by baud rate generator is evenly corrected when this function is enabled.

Set to 0 in Clock-synchronous mode, Simple-SPI mode, Smart Card Interface mode, and Manchester mode.

CKS[1:0] bits (Clock Select)

These bits select the clock source for the baud rate generator.

For the relationship between the settings of these bits and the baud rate, refer to BRR explanation.

MDDR[7:0] bits (Modulation Duty setting)

When the BRME bit is set to 1, the bit rate generated by the baud rate generator is evenly corrected according to the settings of MDDR (M/256). The relationship between the MDDR setting (M) and the bit rate (B) is given in Table 33.21.

The initial value of MDDR is 0xFF. Bit 7 in this register is fixed to 1.

Table 33.21 Relationship between MDDR setting (M) and bit rate (B) using bit rate modulation function

Mode*1	BGDM bit	ABCS bit	ABCSE bit	BRR setting	Error (%)
Asynchronous Multiprocessor transfer	0	0	0	$N = \frac{\mathrm{PCLKSCIn} \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$	$\mathrm{Error} = \{\frac{\mathrm{PCLKSCIn} \times 10^6}{B \times 64 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\} \times 100$
	1	0	0	$N = \frac{\mathrm{PCLKSCIn} \times 10^6}{32 \times 2^{2n-1} \times (256/M) \times B} - 1$	$\mathrm{Error} = \{\frac{\mathrm{PCLKSCIn} \times 10^6}{B \times 32 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\} \times 100$
	0	1	0		
	1	1	0	$N = \frac{\mathrm{PCLKSCIn} \times 10^6}{16 \times 2^{2n-1} \times (256/M) \times B} - 1$	$\mathrm{Error} = \{\frac{\mathrm{PCLKSCIn} \times 10^6}{B \times 16 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\} \times 100$
	x	x	1	$N = \frac{\mathrm{PCLKSCIn} \times 10^6}{12 \times 2^{2n-1} \times (256/M) \times B} - 1$	$\mathrm{Error} = \{\frac{\mathrm{PCLKSCIn} \times 10^6}{B \times 12 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\} \times 100$
Simple-I2C*2				$N = \frac{\mathrm{PCLKSCIn} \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$	

Note: B: Bit rate (bps)
M: MDDR setting (128 ≤ M ≤ 255)
N: BRR setting for bound rate generator (0 ≤ N ≤ 255)
PCLKSCIn: Operating frequency (MHz)
n and S: Determined by the settings of the CCR2.BCP[2:0] and CKS[1:0] as listed in Table 33.10 and Table 33.11.
Please be careful about 2^{2n+1} is used in the expression for Smart card interface, 2^{2n-1} is used in other modes.

Note 1. Do not use this function in Clock-synchronous mode, Simple-SPI mode, Smart card Interface mode, and Manchester mode.

Note 2. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I2C mode satisfy the I2C standard.

Table 33.22 lists examples of N settings in BRR and M settings in MDDR in asynchronous mode.

Table 33.22 Examples of BRR and MDDR settings for various bit rates (asynchronous mode)

Bit rate (bps)	PCLKSCIn = 75 MHz					PCLKSCIn = 80 MHz					PCLKSCIn = 96 MHz					PCLKSCIn = 100 MHz					PCLKSCIn = 125 MHz				
	n	N	M	BGDM bit	Error (%)	n	N	M	BGDM bit	Error (%)	n	N	M	BGDM bit	Error (%)	n	N	M	BGDM bit	Error (%)	n	N	M	BGDM bit	Error (%)
38400	0	35	151	0	0.00	0	58	232	0	0.00	0	46	154	0	-0.00	0	47	151	0	0.00	0	59	151	0	0.00
57600	0	23	151	0	0.00	0	39	236	0	0.03	0	47	236	0	0.03	0	31	151	0	0.00	0	39	151	0	0.00
115200	0	11	151	0	0.00	0	19	236	0	0.03	0	23	236	0	0.03	0	15	151	0	0.00	0	19	151	0	0.00
230400	0	5	151	0	0.00	0	9	236	0	0.03	0	11	236	0	0.03	0	7	151	0	0.00	0	9	151	0	0.00
460800	0	2	151	0	0.00	0	4	236	0	0.03	0	5	236	0	0.03	0	3	151	0	0.00	0	4	151	0	0.00

Note: In this example when CCR2.ABCS = 0 and CCR2.ABCSE = 0.
CCR2.BRME = 0 (M = 256) disables the bit rate modulation function.

33.3.8 CCR3 : Common Control Register 3

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	BLK	GM	—	—	CKE[1:0]		—	—	DEN	FM	MP	MOD[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RXDESEL	STP	SINV	LSBF	—	—	CHR[1:0]		BPEN	—	—	—	—	—	CPOL	CPHA
Value after reset:	0	0	0	1	0	0	1	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
0	CPHA	Clock Phase Select (Valid in Clock-synchronous mode and Simple-SPI mode. Set this bit only when CCR0.TE = 0 and RE = 0.) 0: Data is sampled at an odd edge and changes at an even edge. (Clock is delayed.) 1: Data changes at an odd edge and is sampled at an even edge. (Clock is not delayed.)	R/W
1	CPOL	Clock Polarity Select (Valid in Clock-synchronous mode and Simple-SPI mode. Set this bit only when CCR0.TE = 0 and RE = 0.) 0: SCKn in idle state is 0. 1: SCKn in idle state is 1.	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W
7	BPEN	Synchronizer bypass enable This bit controls whether to bypass the synchronizer circuit between the bus clock and operation clock. When BPEN = 1, PCLKSPIn (operation clock) is input from PCLKM (Bus clock) and the synchronization circuit is bypassed. See section 7, Clock Generation Circuit. 0: Synchronizer circuit is not bypassed. 1: Synchronizer circuit is bypassed.	R/W
9:8	CHR[1:0]	Character Length (Valid in Asynchronous mode and Manchester mode)*1 Select the data length for transmission and reception. 0 0: Transmit/receive in 9-bit data length 0 1: Transmit/receive in 9-bit data length 1 0: Transmit/receive in 8-bit data length (initial value) 1 1: Transmit/receive in 7-bit data length*2	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
12	LSBF	LSB First select Set this bit to 0 in simple I2C mode. 0: MSB first 1: LSB first	R/W
13	SINV	Transmitted/Received Data Invert The level of communication pins (RXD/TXD) are controlled by combination of this bit and CCR1.TINV/RINV. For details, see Figure 33.2. Set this bit to 0 in simple-I2C mode. 0: TDR contents are transmitted to TSR as they are. RSR contents are stored to RDR as they are. 1: TDR contents are inverted before being transmitted to TSR. RSR contents are inverted and stored to RDR.	R/W
14	STP	Stop Bit Length (Valid in Asynchronous mode and Manchester mode) 0: 1 stop bit 1: 2 stop bits	R/W

Bit	Symbol	Function	R/W
15	RXDESEL	Asynchronous Start Bit Edge Detection Select (Valid only in asynchronous mode) 0: The low level on the RXDn pin is detected as the start bit. 1: A falling edge on the RXDn pin is detected as the start bit.	R/W
18:16	MOD[2:0]	Communication mode select Select the SCI communication mode. 0 0 0: Asynchronous mode (Multi-processor mode) 0 0 1: Smart card interface mode 0 1 0: Clock synchronous mode 0 1 1: Simple SPI mode 1 0 0: Simple I2C mode 1 0 1: Manchester mode Others: Setting prohibited	R/W
19	MP	Multi-Processor Mode (Valid in Asynchronous mode and Manchester mode) 0: Multi-processor communications function is disabled. 1: Multi-processor communications function is enabled.	R/W
20	FM	FIFO Mode select (Valid in Asynchronous mode (including multi-processor mode), Clock synchronous mode, Simple SPI mode) 0: Non-FIFO mode (TDR and RDR registers are non-FIFO). 1: FIFO mode (TDR and RDR registers are FIFO).	R/W
21	DEN	Driver enable (Valid only in Asynchronous mode) 0: RS-485 Driver control function disable. 1: RS-485 Driver control function enable.	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
25:24	CKE[1:0]	Clock enable In the case of asynchronous mode When using the external clock 16 times the bit rate should be input from the SCKn pin when CCR2.ABCS bit is 0. Input a clock signal with a frequency 8 times the bit rate when the CCR2.ABCS bit is 1. 0 0: The baud rate generator The SCKn pin is available for use as an I/O port in accord with the I/O port settings. 0 1: The baud rate generator The clock with the same frequency as the bit rate is output from the SCKn pin. 1 x: External clock In case of Manchester mode 0 0: On-chip baud rate generator The SCKn pin functions as I/O port Others: Prohibited In the case of Clock synchronous mode, Simple-SPI 0 x: Internal clock (Master operation) The SCKn pin functions as the clock output pin. 1 x: External clock (Slave operation) The SCKn pin functions as the clock input pin. In the case of Smart card interface mode When CCR3.GM = 0 0 0: Output disabled (The SCKn pin can be used for other peripherals.) 0 1: Clock output 1 x: Setting prohibited When CCR3.GM = 1 0 0: Output fixed low 1 0: Output fixed high x 1: Clock output	R/W
27:26	—	These bits are read as 0. The write value should be 0.	R/W
28	GM	GSM Mode (Valid only in Smart card interface mode) 0: Non-GSM mode operation 1: GSM mode operation	R/W

Bit	Symbol	Function	R/W
29	BLK	Block Transfer Mode (Valid only in Smart card interface mode) 0: Non-block transfer mode operation 1: Block transfer mode operation	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. In other than asynchronous mode and Manchester mode, this bit setting is invalid and a fixed data length of 8 bits is used.
Note 2. LSB first is fixed and the MSB (bit 7) in TDR is not transmitted in transmission.

CPHA bit (Clock Phase Select)

This bit selects the phase of the clock signal output through the SCKn pin. For details, see Figure 33.101.

Set the bit to 1 in other than simple SPI mode and clock synchronous mode.

CPOL bit (Clock Polarity Select)

This bit selects the polarity of the clock signal output through the SCKn pin. For details, see Figure 33.101.

Set the bit to 1 in other than simple SPI mode and clock synchronous mode.

BPEN bit (Synchronizer bypass enable)

The synchronization circuit can be bypassed by this bit only when the same clock is input to the bus clock and the operation clock (PCLKSCIn). For details, see section 33.16. Synchronizer Bypass Function.

CHR[1:0] bits (Character Length)

Selects the data length for transmission and reception.

Except of asynchronous mode and Manchester mode, a fixed data length of 8 bits is used.

LSBF bit (LSB First select)

Select whether to transmit/receive data in MSB first or LSB first.

SINV bit (Transmitted/Received Data Invert)

SINV can invert the transmit data-bit from TDR to TSR, and also can invert the received data from RSR to RDR. This bit does not affect the logic level of the parity bit. To invert the parity bit, invert the CCR1.PM.

STP bit (Stop Bit Length)

Selects the stop bit length in transmission.

In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

RXDESEL bit (Asynchronous Start Bit Edge Detection Select)

Selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data receiving operation depends on the settings of this bit. Set this bit to 1 when reception should be stopped while a break occurs or when reception should be started without retaining the RXDn pin input at high level for the period of one data frame or longer after completion of the break.

Set this bit to 0 in modes except of asynchronous mode.

MOD[2:0] bits (Communication mode select)

Selects the SCI communication mode.

Table 33.23 Relationship between communication mode selection bits (MOD[2:0]), other operation mode setting bits (1 of 2)

Communication mode	Asynchronous		SMIF*1	Clock synchronous	Simple SPI	Simple I2C	Manchester	
CCR3.MOD[2:0]	000b		001b	010b	011b	100b	101b	
CCR3.MP	0	1	—	—	—	—	0	1

Table 33.23 Relationship between communication mode selection bits (MOD[2:0]), other operation mode setting bits (2 of 2)

Communication mode	Asynchronous								SMIF*1	Clock synchronous		Simple SPI		Simple I2C	Manchester
CCR3.FM	0		1		0		1		—	0	1	0	1	—	—
CCR3.DEN	0	1	0	1	0	1	0	1	—	—		—		—	—
CCR0.SSE	—								—	—		0	1	—	—

Note: '— ' means setting prohibited.
Note 1. Smart card interface

MP bit (Multi-Processor Mode)

Disables/enables the multi-processor communications function. The settings of the PE bit and PM bit are invalid in multi-processor mode.

FM bit (FIFO Mode select)

When FM = 1, the TDR register / RDR register switches to FIFO mode.

DEN bit (Driver enable)

Select RS-485 Driver control function disable or enable.

CKE[1:0] bits (Clock enable)

These bits select the clock source and SCKn pin function.

In smart card interface mode, these bits control the clock output from the SCKn pin.

In GSM mode, clock output can be dynamically switched. For details, see section 33.7.8. Clock Output Control.

GM bit (GSM Mode)

Setting this bit to 1 allows GSM mode operation.

In GSM mode, the CSR.TEND flag set timing is put forward to 11.0 etu (elementary time unit = 1-bit transfer time) from the start and the clock output control function is appended. For details, see section 33.7.6. Serial Data Transmission (Except in Block Transfer Mode) and section 33.7.8. Clock Output Control.

BLK bit (Block Transfer Mode)

Setting this bit to 1 allows block transfer mode operation.

For details, see section 33.7.3. Block Transfer Mode.

33.3.9 CCR4 : Common Control Register 4

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x18

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	AET	ATT[2:0]			AJD	AST[2:0]			—	—	—	—	—	—	ATEN	ASEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CMPD[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	CMPD[8:0]	Compare Match Data (Valid only in Asynchronous mode) Set the compare data pattern for address match function.	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
16	ASEN	Adjust receive sampling timing enable (Valid in Asynchronous mode using internal clock, Clock-synchronous mode operating as master, Simple-SPI mode operating as master) 0: Adjust sampling timing disable. 1: Adjust sampling timing enable.	R/W
17	ATEN	Adjust transmit timing enable (Valid only in asynchronous mode using internal clock) 0: Adjust transmit timing disable. 1: Adjust transmit timing enable.	R/W
23:18	—	These bits are read as 0. The write value should be 0.	R/W
26:24	AST[2:0]	Adjustment value for receive Sampling Timing This bit enables only when ASEN is 1. In asynchronous mode using internal clock The sampling timing of RXDn pin is adjusted from the middle of bit by the following formula. Adjustment sampling timing = base clock × the setting value of AST[2:0]. In Clock-synchronous mode and Simple-SPI mode using internal clock The RxD sampling timing can be adjusted by delaying 1 to 4 PCLKSCIn. 0 0 0: 1 PCLKSCIn delay 0 0 1: 2 PCLKSCIn delay 0 1 0: 3 PCLKSCIn delay 0 1 1: 4 PCLKSCIn delay Others: Setting prohibited	R/W
27	AJD	Adjustment Direction for receive sampling timing (Valid in Asynchronous mode using internal clock) This bit enables only when ASEN is 1. Adjustment direction for RxD receive sampling timing is determined by this bit. For details, see section 33.4.10. The function of adjust receive sampling timing (Asynchronous Mode). 0: The sampling timing is adjusted backward to the middle of bit. 1: The sampling timing is adjusted forward to the middle of bit.	R/W
30:28	ATT[2:0]	Adjustment value for Transmit timing (Valid in Asynchronous mode using internal clock) This bit enables only when ATEN is 1. The selected edge timing of TxD is adjusted by the following formula. Adjustment edge timing = base clock × the setting value of ATT[2:0] This setting timing is limited by setting the base clock cycles. For details, see section 33.4.11. The function of adjust transmit timing (Asynchronous Mode).	R/W
31	AET	Adjustment edge for transmit timing (Valid in Asynchronous mode using internal clock) The adjustable edge is set by this bit. This bit enables only when ATEN = 1. For details, see section 33.4.11. The function of adjust transmit timing (Asynchronous Mode). 0: Adjust the rising edge timing, when CCR1.TINV = 0. Adjust the falling edge timing, when CCR1.TINV = 1. 1: Adjust the falling edge timing, when CCR1.TINV = 0. Adjust the rising edge timing, when CCR1.TINV = 1.	R/W

Note: If the description in this document and the timing chart do not specify the ASEN / ATEN setting value, it means that the reception sampling adjustment function / transmission timing adjustment function are OFF (CCR4.ASEN = 0, CCR4.ATEN = 0).

CMPD[8:0] bits (Compare Match Data)

Set the comparison data for receive data, when Address match function is enabled (CCR0.DCME = 1). CCR4.CMPD[8:0] should be written while CCR0.DCME is 0.

For the comparison data, it can select length from 3 types, they are CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.

ASEN bit (Adjust receive sampling timing enable)

When this bit is 1, the receive sampling timing adjustment function is enabled. Control is different in Asynchronous mode, Clock-synchronous mode, and Simple-SPI mode.

In Asynchronous mode using internal clock, see section 33.4.10. The function of adjust receive sampling timing (Asynchronous Mode) in details.

In Clock-synchronous mode as master, Simple-SPI mode operating as master, see section 33.9.7. Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with Internal Clock Used in details. Only the digital delay of the master mode receive sampling clock (MRCLK) can be controlled by this bit.

ATEN bit (Adjust transmit timing enable)

When this bit is 1, the transmission timing adjustment function is enabled. The transmission timing adjustment function can adjust the edge timing of the waveform output from the TXD pin. See section 33.4.11. The function of adjust transmit timing (Asynchronous Mode) in details.

AST[2:0] bits (Adjustment value for receive Sampling Timing)

When ASEN = 1, the receive sampling timing can be adjusted according to this bit setting value.

In Asynchronous mode using internal clock.

The sampling timing of RXD pin is adjusted from the middle of bit by the following formula. This setting value is limited by setting the base clock cycles. For details, see section 33.4.10. The function of adjust receive sampling timing (Asynchronous Mode).

Adjustment sampling timing = base clock × the setting value of AST[2:0].

In Clock-synchronous mode and Simple-SPI mode using internal clock

The RxD sampling timing can be adjusted by delaying 1 to 4 PCLKSCIn. For details, see section 33.9.7. Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with Internal Clock Used.

000: 1 PCLKSCIn delay

001: 2 PCLKSCIn delay

010: 3 PCLKSCIn delay

011: 4 PCLKSCIn delay

1xx: Setting prohibited

AJD bit (Adjustment Direction for receive sampling timing)

Set the RXD pin sampling timing adjustment direction from the bit center to the rear or front. See section 33.4.10. The function of adjust receive sampling timing (Asynchronous Mode) for details.

ATT[2:0] bits (Adjustment value for Transmit timing)

The edge timing of the TXD pin specified by the AET bit is adjusted by the base clock × ATT[2:0] setting value. The upper limit of the adjustment time that can be set is limited by the number of base clock cycles. See section 33.4.11. The function of adjust transmit timing (Asynchronous Mode) for details.

AET bit (Adjustment edge for transmit timing)

Set the TXD pin edge for timing adjustment. See section 33.4.11. The function of adjust transmit timing (Asynchronous Mode) for details.

33.3.10 ICR : Simple I2C Control Register

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	IICSCLS[1:0]		IICSDAS[1:0]		—	IICSTPREQ	IICRSTAREQ	IICSTAREQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	IICACKT	—	—	—	IICCSC	IICINTM	—	—	—	IICDL[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	IICDL[4:0]	SDA Delay Output Select (Cycles below are of the clock signal from the baud rate generator.) 0x00: No output delay 0x01: 0 to 1 cycle 0x02: 1 to 2 cycles 0x03: 2 to 3 cycles 0x04: 3 to 4 cycles 0x05: 4 to 5 cycles ⋮ 0x1E: 29 to 30 cycles 0x1F: 30 to 31 cycles	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	IICINTM	I2C Interrupt Mode Select 0: Use ACK/NACK interrupts. 1: Use reception and transmission interrupts.	R/W
9	IICCSC	Clock Synchronization 0: No synchronization with the clock signal 1: Synchronization with the clock signal	R/W
12:10	—	These bits are read as 0. The write value should be 0.	R/W
13	IICACKT	ACK Transmission Data 0: ACK transmission 1: NACK transmission and reception of ACK/NACK	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
16	IICSTAREQ	Start Condition Generation 0: A start condition is not generated. 1: A start condition is generated. *1 *3 *4 *5	R/W
17	IICRSTAREQ	Restart Condition Generation 0: A restart condition is not generated. 1: A restart condition is generated. *2 *3 *4 *5	R/W
18	IICSTPREQ	Stop Condition Generation 0: A stop condition is not generated. 1: A stop condition is generated. *2 *3 *4 *5	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W
21:20	IICSDAS[1:0]	SDA Output Select 0 0: Serial data output 0 1: Generate a start, restart, or stop condition. 1 0: Output the low level on the SDAn pin. 1 1: Place the SDAn pin in the high-impedance state.	R/W

Bit	Symbol	Function	R/W
23:22	IICSCLS[1:0]	SCL Output Select 0 0: Serial clock output 0 1: Generate a start, restart, or stop condition. 1 0: Output the low level on the SCLn pin. 1 1: Place the SCLn pin in the high-impedance state.	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. In the bus free state, perform the start condition generation.
Note 2. In the bus busy state, perform restart or stop condition generation when the SCLn pin after acknowledgment described in section 33.8. Simple I2C mode in Figure 33.71 and Figure 33.72 is low level.
Note 3. Do not set more than one from among the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.
Note 4. Execute the generation of a condition after the value of the IICSTIF flag is 0.
Note 5. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

IICDL[4:0] bits (SDA Delay Output Select)

These bits are used to set a delay for output on the SDAn pin relative to the falling edge of the output on the SCLn pin. The available delay settings range from no delay to 31 cycles, with the clock signal from the baud rate generator as the base. The signal obtained by frequency-dividing PCLKSCIn by the divisor set in CCR2.CKS[1:0] is supplied as the clock signal from the baud rate generator.

Set these bits to 0x00 unless operation is in simple I2C mode. In simple I2C mode, set these bits from 0x01 to 0x1F.

IICINTM bit (I2C Interrupt Mode Select)

This bit selects the sources of interrupt requests in simple I2C mode.

IICCSC bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SCLn clock signal is to be synchronized when the SCLn pin has been placed at the low level in the case of a wait inserted by the other device, etc.

The SCLn clock signal is not synchronized if the IICCSC bit is 0. The SCLn clock signal is generated in accord with the rate selected in the BRR regardless of the level being input on the SCLn pin.

Set the IICCSC bit to 1 except during debugging.

IICACKT bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set this bit to 1 when ACK and NACK bits are received.

IICSTAREQ bit (Start Condition Generation)

When a start condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTAREQ bit to 1.

If you want to generate the start condition after generating the stop condition, start the generation of the start condition with a half cycle period of the bit rate from the stop condition generation interrupt request output.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the start condition

IICRSTAREQ bit (Restart Condition Generation)

When a restart condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICRSTAREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the restart condition

IICSTPREQ bit (Stop Condition Generation)

When a stop condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTPREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of stop condition

IICSDAS[1:0] bits (SDA Output Select)

These bits control output from the SDAn pin.

IICSCLS[1:0] bits (SCL Output Select)

These bits control output from the SCLn pin.

33.3.11 FCR : FIFO Control Register

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x24

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	RSTRG[4:0]					RFRST	—	—	RTRG[4:0]				
Value after reset:	0	0	0	1	1	1	1	1	0	0	0	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TFRST	—	—	TTRG[4:0]					—	—	—	—	—	—	—	DRES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DRES	Receive data ready error select (Valid in Asynchronous mode) This bit select the interrupt request for a reception data ready detection. 0: reception data full interrupt (RXI) 1: receive error interrupt (ERI)	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
12:8	TTRG[4:0]	Transmit FIFO data trigger number (Valid in Asynchronous mode (including multi-processor mode), Clock-synchronous mode, Simple-SPI mode) Trigger number must be set 15 or less. When DMAC transfer is used, set TTRG[4:0] = 0x0F. 0x00: Trigger number 0 ⋮ 0x0F: Trigger number 15 Others: Setting prohibited	R/W
14:13	—	These bits are read as 0. The write value should be 0.	R/W
15	TFRST	Transmit FIFO Data Register Reset This bit enables only when CCR3.FM is 1. The read value is always 0. 0: It is invalid. It does not affect the operation. 1: The number of data stored in transmit FIFO (TDR register) are made 0.	W

Bit	Symbol	Function	R/W
20:16	RTRG[4:0]	Receive FIFO data trigger number (Valid in Asynchronous mode (including multi-processor mode), Clock-synchronous mode, Simple-SPI mode) Trigger number must be set 15 or less. When DMAC transfer is used, set RTRG[4:0] = 0x00. 0x00: Trigger number 0 ⋮ 0x0F: Trigger number 15 Others: Setting prohibited	R/W
22:21	—	These bits are read as 0. The write value should be 0.	R/W
23	RFRST	Receive FIFO Data Register Reset This bit enables only when CCR3.FM is 1. The read value is always 0. 0: It is invalid. It does not affect the operation. 1: The number of data stored in receive FIFO (RDR register) are made 0.	W
28:24	RSTRG[4:0]	RTS# Output Active Trigger Number Select (Valid in Asynchronous mode (including multi-processor mode), Clock-synchronous mode) These bits enable only when CCR3.FM = 1 and CCR1.CTSE = 0 and CCR0.SSE = 0. Trigger number must be set 15 or less. 0x00: Trigger number 0 ⋮ 0x0F: Trigger number 15 Others: Setting prohibited	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

DRES bit (Receive data ready error select)

Select whether the detection of receive data ready (FRSR.DR = 1) is the cause of RXI interrupt request or the cause of ERI interrupt request.

TTRG[4:0] bits (Transmit FIFO data trigger number)

The TDRE flag is set to 1 when the quantity of transmit data in the transmit FIFO (TDR register) is equal to or less than the specified transmit triggering number. If CCR0.TIE = 1, TXI interrupt request is occurred.

Note: In case the trigger number is set 16 or more, unexpected TXI interrupt will occur.

TFRST bit (Transmit FIFO Data Register Reset)

When the TFRST bit is set to 1, the number of the transmission data stored in transmit FIFO (TDR register) is made 0.

RTRG[4:0] bits (Receive FIFO data trigger number)

The CSR.RDRF flag is set to 1 when the quantity of receive data in the receive FIFO (RDR register) is equal to or greater than the specified receive triggering number. If CCR0.RIE = 1, RXI interrupt request is occurred. When FCR.RTRG is set to 0, RDRF bit is set if the quantity of data in receive FIFO is greater than or equal to 1.

Note: In case the trigger number is set 16 or more, unexpected RXI interrupt will occur.

RFRST bit (Receive FIFO Data Register Reset)

When the RFRST bit is set to 1, the number of the reception data stored in receive FIFO (RDR register) is made 0.

RSTRG[4:0] bits (RTS# Output Active Trigger Number Select)

When the quantity of receive data stored in the receive FIFO (RDR register) is equal to or greater than this number, the RTS# signal is in the High state. When FCR.RSTRG is set to 0, RTS# is in the high state if the quantity of data in receive FIFO is greater than or equal to 1.

Note: In case the trigger number is set 16 or more, RTS# will go to High state at unexpected timing.

33.3.12 MCR : Manchester Control Register

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

31:27	—	These bits are read as 0. The write value should be 0.	R/W

RMPOL bit (Polarity of Received Manchester Code)

This bit sets the polarity of the received Manchester code. For details, see section 33.6.7. Serial Data Reception in Manchester mode.

TMPOL bit (Polarity of Transmit Manchester Code)

This bit sets the polarity of the transmit Manchester code. For details, see section 33.6.6. Serial Data Transmission in Manchester Mode.

ERTEN bit (Manchester Edge Retiming Enable)

This bit sets the receive retiming function in Manchester mode.

For information on the receive retiming function, see section 33.6.9. Receive Retiming.

SYNVAL bit (SYNC value Setting)

This bit is valid when the SYNSEL bit of this register is set to 0.

The SYNC type can be set by combining this bit and the SBSEL bit.

For the start bit area determined by the combination of this bit and the SBSEL bit, see Figure 33.44 and Figure 33.45.

SYNSEL bit (SYNC Select)

This bit is valid when the SBSEL bit of this register is set to 1. This bit determines the destination to be referred to for setting the SYNC type of the start bit area added to Manchester frames.

When this bit is set to 0, the SYNVAL bit of this register is referred to.

When this bit is set to 1, the TSYNC bit in the TDR register is referred to.

SBSEL bit (Start Bit Select)

This bit sets the start bit area in Manchester frames.

When this bit is set to 1, the start bit area added to each frame consists of three bits, and the SYNSEL and SYNVAL bits in this register are valid.

When this bit is set to 0, the start bit area added to each frame consists of one bit.

TPLEN[3:0] bits (Transmit preface length)

These bits set the preface bit length of the transmit data in Manchester mode.

The settable range is 0x0 to 0xF (0d to 15d). 0x0 disables the transmit preface, which is not added.

TPPAT[1:0] bits (Transmit preface pattern)

These bits set one of the four preface patterns in Manchester mode. For the transmit data when the TPPAT bits are set, see Figure 33.43.

When these bits are set to 00b, the preface area is set to all zeros.

When these bits are set to 01b, the preface area is set to the zero-one-zero-one pattern.

When these bits are set to 10b, the preface area is set to the one-zero-one-zero pattern.

When these bits are set to 11b, the preface area is set to all ones.

RPLEN[3:0] bits (Receive Preface Length)

These bits set the preface bit length of the received frames in Manchester mode.

The settable range is 0x0 to 0xF (0d to 15d). 0x0 disables the receive preface, which is not added. When 0x1 to 0xF is set, the set value is handled as the receive preface bit length.

RPPAT[1:0] bit (Receive Preface Pattern)

These bits set one of the four preface patterns in Manchester mode. For the transmit and receive data when the TPPAT bits are set, see Figure 33.43.

When these bits are set to 00b, the preface area is handled as all zeros.

When these bits are set to 01b, the preface area is handled as the zero-one-zero-one pattern.

When these bits are set to 10b, the preface area is handled as the one-zero-one-zero pattern.

When these bits are set to 11b, the preface area is handled as all ones.

PFEREN bit (Preface Error Enable)

This bit specifies whether to handle a preface error as an interrupt source.

When it is set to 0, a preface error is not handled as an interrupt source. When it is set to 1, a preface error is handled as an interrupt source.

SYEREN bit (Receive SYNC Error Enable)

This bit specifies whether to handle a receive SYNC error as an interrupt source.

When it is set to 0, a receive SYNC error is not handled as an interrupt source. When it is set to 1, a receive SYNC error is handled as an interrupt source.

SBEREN bit (Start Bit Error Enable)

This bit specifies whether to handle a start bit error as an interrupt source.

When it is set to 0, a start bit error is not handled as an interrupt source. When it is set to 1, a start bit error is handled as an interrupt source.

33.3.13 DCR : Driver Control Register

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x30

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	DENGT[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	DEAST[4:0]					—	—	—	—	—	—	—	DEPOL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DEPOL	Driver effective polarity select (Valid only in Asynchronous mode) 0: The DE signal is active high. 1: The DE signal is active low.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
12:8	DEAST[4:0]	Driver Assertion Time (Valid only in Asynchronous mode) Set the driver assertion time. When CCR3.DEN = 1, the following driver assertion time is inserted in addition to the normal transmission waiting time. Driver assertion time = DEAST[4:0] set value × base clock period Setting DEAST[4:0] = 0x00 is prohibited.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
20:16	DENGT[4:0]	Driver negate time (Valid only in Asynchronous mode) Set the driver negation time. When CCR3.DEN = 1, the following driver negate time is inserted after STOP bit transmission end. Driver negate time = DENGT[4:0] set value × base clock period Setting DENGT[4:0] = 0x00 is prohibited.	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

DEPOL bit (Driver effective polarity select)

Select the active level of the DE signal.

DEAST[4:0] bits (Driver Assertion Time)

Set the driver assertion time (= time from the activation of the DE (Driver Enable) signal to the start of the start bit). It is expressed in base clock units (1/6, 1/8, or 1/16 bit period).

DENGT[4:0] bits (Driver negate time)

Set the driver negation time (= time from the end of the last stop bit of the transmitted message until the DE (Driver Enable) signal is disabled). It is expressed in base clock units (1/6, 1/8, or 1/16 bit period).

If the transmission data is written during the driver negate time, transmit starting operation is different depends on the writing timing. (The DE signal remains valid, and transmission of the start bit may start after the transmission wait time has elapsed. Also, the DE signal may become invalid once, and start bit transmission may start after the DEAST time + transmission wait time has elapsed.)

33.3.14 CSR : Common Status Register

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x48

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit field:	RXDMON	—	—	—	—	—	—	—	—	—	—	ERS	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0.	R
4	ERS	Error Signal Status Flag (Valid only in Smart card interface mode) 0: Error signal Low not responded 1: Error signal Low responded	R
14:5	—	These bits are read as 0.	R
15	RXDMON	Serial input data monitor The state of the RXD pin without synchronizing by bus clock is shown. 0: RXD pin is the Low level, when CCR1.RINV = 0. RXD pin is the High level, when CCR1.RINV = 1. 1: RXD pin is the High level, when CCR1.RINV = 0. RXD pin is the Low level, when CCR1.RINV = 1.	R
16	DCMF	Data Compare Match Flag (Valid only in Asynchronous mode) 0: No matched 1: Matched	R
17	DPER	Data Compare Match Parity Error Flag (Valid only in Asynchronous mode) 0: No parity error occurred at address match detection. 1: A parity error has occurred at address match detection.	R
18	DFER	Data Compare Match Framing Error Flag (Valid only in Asynchronous mode) 0: No framing error occurred at address match detection. 1: A framing error has occurred at address match detection.	R
23:19	—	These bits are read as 0.	R
24	ORER	Overrun Error Flag 0: No overrun error occurred. 1: An overrun error has occurred.	R
25	—	This bit is read as 0.	R
26	MFF	Mode Fault Error Flag (Valid only in Simple-SPI mode) 0: No mode fault error 1: Mode fault error	R
27	PER	Parity Error Flag 0: No parity error occurred (Non-FIFO mode) No parity error in all received data in receive FIFO (FIFO mode) 1: A parity error has occurred (Non-FIFO mode) One or more parity errors occurred in received data in receive FIFO (FIFO mode)	R

Bit	Symbol	Function	R/W
28	FER	Framing Error Flag 0: No framing error occurred (Non-FIFO mode) No framing error in all received data in receive FIFO (FIFO mode) 1: A framing error has occurred (Non-FIFO mode) One or more framing errors occurred in received data in receive FIFO (FIFO mode)	R
29	TDRE	Transmit Data Empty Flag 0: Transmit data is in TDR register (Non-FIFO mode) The quantity of transmit data written in transmit FIFO exceeds the specified transmit triggering number. (FIFO mode) 1: No transmit data is in TDR register (Non-FIFO mode) The quantity of transmit data written in transmit FIFO is equal to or less than the specified transmit triggering number. (FIFO mode)	R
30	TEND	Transmit End Flag 0: A character is being transmitted or standing by for transmission. 1: Character transfer has been completed.	R
31	RDRF	Receive Data Full Flag 0: No received data is in RDR register (Non-FIFO mode) The quantity of receive data written in receive FIFO falls below the specified receive triggering number (FIFO mode) 1: Received data is in RDR register (Non-FIFO mode) The quantity of receive data written in receive FIFO is equal to or greater than the specified receive triggering number (FIFO mode)	R

ERS bits (Error Signal Status Flag)

[Setting condition]

- When an error signal LOW is sampled.

[Clearing condition]

- When write 1 to CFCLR.ERSC.

DCMF bit (Data Compare Match Flag)

Indicates that SCI detects the match to the comparison data (CCR4.CMPD) with receive data.

Clearing the CCR0.RE bit to 0 does not affect the DCMF flag, which retains its previous state.

[Setting condition]

- Matched to the comparison data (CCR4.CMPD) with receive data, while CCR0.DCME = 1.

[Clearing condition]

- When write 1 to CFCLR.DCMFC.

DPER bit (Data Compare Match Parity Error Flag)

It indicates that a parity error occurred at Address Match detection (reception data match detection).

Clearing the CCR0.RE bit to 0 does not affect the DPER flag, which retains its previous state.

[Setting condition]

- When a parity error was detected by the frame in which an address match was detected.

[Clearing condition]

- When write 1 to CFCLR.DPERC.

DFER bit (Data Compare Match Framing Error Flag)

It indicates that a framing error occurred at Address Match detection (reception data match detection).

Clearing the CCR0.RE bit to 0 does not affect the DFER flag, which retains its previous state.

[Setting condition]

- When a stop bit of the frame in which an Address Match was detected is 0.
  When it is a 2-stop mode, the 1st bit of stop bit judges only whether it's 1 and does not check the 2nd bit of stop bit.

[Clearing condition]

- When write 1 to CFCLR.DFERC.

ORER bit (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

Clearing the CCR0.RE bit to 0 does not affect the ORER flag, which retains its previous state. In simple-I2C mode, this bit is not use.

[Setting condition with Non-FIFO mode (CCR3.FM = 0)]

- When the next data is received before reading out RDR with no-error reception data stored in RDR.
  In RDR, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, reception data is not forwarded to RDR register.
  Note that, in clock synchronous mode and simple-SPI mode, serial reception will be stop.

[Setting condition with FIFO mode (CCR3.FM = 1)]

- When the next serial reception is completed while the receive FIFO is full of N_{FIFO} (= 16) receive data.
  (N_{FIFO}: Indicates the number of available FIFO stages)

[Clearing condition]

- When write 1 to CFCLR.ORERC.

MFF bit (Mode Fault Error Flag)

This bit indicates mode fault errors. In a multi-master mode, determine the mode fault error occurrence by reading the MFF flag.

[Setting condition]

- Input on the SSn# pin being at the low level during master operation (CCR3.CKE[1:0] = 00b or 01b) in simple SPI mode.

[Clearing condition]

- When write 1 to CFCLR.MFFC.

PER bit (Parity Error Flag)

Indicates that a parity error has occurred during reception and the reception ends abnormally.

Clearing the CCR0.RE bit to 0 does not affect the PER flag, which retains its previous state.

When performing parity check in asynchronous mode, set the address match function disabled (CCR0.DCME = 0). In

Clock-synchronous mode, Simple-SPI mode, and Simple-I2C mode, this bit not used.

[Setting condition]

- When a parity error is detected during reception.
  In FIFO select mode, when one or more parity error is detected in receive FIFO data.
  Although receive data when the parity error occurs is transferred to RDR, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When write 1 to CFCLR.PERC.

FER bit (Framing Error Flag)

Indicates that a framing error has occurred during reception and the reception ends abnormally.

Clearing the CCR0.RE bit to 0 does not affect the FER flag, which retains its previous state.

When performing framing check in asynchronous mode, set the address match function disabled (CCR0.DCME = 0).

In Clock-synchronous mode, Simple-SPI mode, and Simple-I2C mode, this bit not used.

[Setting condition]

- When 0 is sampled as the stop bit during reception.
  In FIFO select mode, when one or more framing error is detected in receive FIFO data.
  In Manchester mode, when both sampling results (1⁄4 and 3⁄4 sampling points) are not 1 for 1 stop bit.
  In 2-stop-bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked. Note that although receive data when the framing error occurs is transferred to RDR, no RXI interrupt request occurs. In addition, when the FER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When write 1 to CFCLR.FERC.

TDRE bit (Transmit Data Empty Flag)

[Non-FIFO selected (CCR3.FM = 0)]

Indicates the presence of transmit data in the TDR register.

The condition of CCR0.TE = 0 has priority over the condition of 0.

If other conditions that become 1 and conditions that become 0 are satisfied at the same time, the TDRE flag is set to 0.

[Setting condition]

- When CCR0.TE is 0.
- When data is transmitted from the TDR register to the TSR register.

[Clearing condition]

- When write 1 to CFCLR.TDREC.
- When the transmission data is written to the TDR register during CCR0.TE = 1.

[FIFO selected (CCR3.FM = 1)]

- Indicates that data has been transferred from the transmit FIFO (TDR) into the transmit shift register (TSR), the quantity of data in transmit FIFO has fallen below the specified transmit triggering number.
  When the condition which becomes 1 and the condition which becomes 0 were formed at the same time, TDRE flag will be 0. After that, when the number of data stored in transmit FIFO is judged, and if that is equal to or less than TTRG value, TDRE is set to 1 after 1 PCLKM.

[Setting condition]

- When the quantity of transmit data written in transmit FIFO is equal to or less than the specified transmit triggering number.[*1]

[Clearing condition]

- When write 1 to CFCLR.TDREC.
- When the transmission data is written to transmit FIFO by the DMAC (except ch5).

Note 1. The transmit FIFO is 16-stage FIFO, the maximum number of data that can be written when the TDRE flag is 1 is "N_{FIFO} (= 16) - FTSR.T[5:0]". Even if data any more is written, data is discarded.

TEND bit (Transmit End Flag)

[Non-FIFO selected (CCR3.FM = 0), and Not Smart card interface mode (CCR3.MOD[2:0] ≠ 001b)]

Indicates completion of transmission.

[Setting condition]

- When CCR0.TE is 0.
- When the CCR0.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at transmission of the tail-end bit of a character.

- When the TDR register is not updated at the end of DE negate time with DE control function enable (CCR3.DEN = 1).

[Clearing condition]

- After the synchronization delay time has elapsed since the transmission data was written to the TDR register during CCR0.TE = 1.
- When write 1 to CFCLR.TDREC during CCR0.TE = 1.

[Non-FIFO selected (CCR3.FM = 0), and Smart card interface mode (CCR3.MOD[2:0] = 001b)]

With no error signal from the receiving side, this bit is set to 1 when next data is ready to be transferred to the TDR register.

[Setting condition]

- When CCR0.TE is 0.
- When the CCR0.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When ERS flag is 0 and TDR register is not updated after 1-byte transmission + fixed time, the set timing is determined by setting CCR3 register as listed below.
  - When GM = 0 and BLK = 0, 12.5 etu after the start of transmission
  - When GM = 0 and BLK = 1, 11.5 etu after the start of transmission
  - When GM = 1 and BLK = 0, 11.0 etu after the start of transmission
  - When GM = 1 and BLK = 1, 11.0 etu after the start of transmission

[Clearing condition]

- After the synchronization delay time has elapsed since the transmission data was written to the TDR register during CCR0.TE = 1.
- When write 1 to CFCLR.TDREC during CCR0.TE = 1.

[FIFO selected (CCR3.FM = 1)]

Indicates that the transmit FIFO does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

- TEND is set to 1 when transmit FIFO does not contain transmit data when the last bit of a one-byte serial character is transmitted.
- When the TDR register is not updated at the end of DE negate time with DE control function enable (CCR3.DEN = 1).

[Clearing condition]

- After the synchronization delay time has elapsed since the transmission data was written to the TDR register during CCR0.TE = 1.

RDRF bit (Receive Data Full Flag)

[Non-FIFO selected (CCR3.FM = 0)]

Indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing condition]

- When write 1 to CFCLR.RDRFC.
- When a data is read from the RDR register.

[FIFO selected (CCR3.FM = 1)]

Indicates that receive data has been transferred to the receive FIFO data register (RDR), and the quantity of data in receive FIFO is equal to or greater than the specified receive triggering number. When FCR.RTRG is set to 0, RDRF is set if receive FIFO is not empty.

[Setting condition]

RDRF is set to 1 when the quantity of receive data in receive FIFO is equal to or greater than the specified receive triggering number.*1

[Clearing condition]

- When write 1 to CFCLR.RDRFC.
- When the reception data is read from receive FIFO by the DMAC (except ch5).
  When setting condition and clearing condition are occurred at the same time, RDRF flag will be 0. After that, if the data count in receive FIFO is equal to or greater than RTRG value, RDRF is set to 1 after 1 PCLKM.

Note 1. Since the receive FIFO is N_{FIFO} (= 16) stage, the maximum quantity of data that can be read when RDRF is 1 is equal to FRSR.R[5:0]. Further data can be read, but the value is undefined.

Note: Except when interrupting communication, RDRF and TDRE should not be cleared by CFCLR register.

33.3.15 ISR : Simple I2C Status Register

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x4C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IICSTIF	—	—	IICACKR
Value after reset:	0	0	0	0	0	0	0	0	0	0	x	x	0	x	0	0

Bit	Symbol	Function	R/W
0	IICACKR	ACK Reception Data Flag 0: ACK received 1: NACK received	R
1	—	This bit is read as 0.	R
2	—	The read value is undefined.	R
3	IICSTIF	Issuing of Start, Restart, or Stop Condition Completed Flag 0: There are no requests for generating conditions or a condition is being generated. 1: A start, restart, or stop condition is completely generated.	R
4	—	The read value is undefined.	R
5	—	The read value is undefined.	R
31:6	—	These bits are read as 0.	R

IICACKR bit (ACK Reception Data Flag)

Received ACK and NACK bits can be read from this bit.

The IICACKR flag is updated at the rising of SCLn clock for the ACK/NACK receiving bit.

IICSTIF bit (Issuing of Start, Restart, or Stop Condition Completed Flag)

After generating a condition, this bit indicates that the generation is completed. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ, do it after clearing the IICSTIF flag.

When the IICSTIF flag is 1 while CCR0.TEIE = 1, an STI request is output.

[Setting condition]

Completion of the generation of a start, restart, or stop condition (when setting condition and clearing condition are occurred at the same time, IICSTIF will be 0).

[Clearing condition]

- Writing 1 to ICFCLR.IICSTIFC bit
- When operation is not in simple-I2C
- Writing 0 to CCR0.TE bit

33.3.16 FRSR : FIFO Receive Status Register

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)

Bit field:	—	—	FNUM[5:0]						—	—	PNUM[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	R[5:0]						—	—	—	—	—	—	—	DR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DR	Receive Data Ready flag 0: Receiving is in progress, or no received data has remained in receive FIFO after normally completed receiving. (Receive FIFO is empty.) 1: The following receive data does not come for a fixed period after storing data below the threshold.	R
7:1	—	These bits are read as 0.	R
13:8	R[5:0]	Receive FIFO Data Count (Valid in Asynchronous mode (including multi-processor), Clock synchronous mode, Simple-SPI mode, when CCR3.FM is 1.) Indicate the quantity of data in receive FIFO.	R
15:14	—	These bits are read as 0.	R
21:16	PNUM[5:0]	Parity Error Count (Valid only in Asynchronous mode) Indicates the quantity of data with a parity error among the data in receive FIFO.	R
23:22	—	These bits are read as 0.	R
29:24	FNUM[5:0]	Framing Error Count (Valid only in Asynchronous mode) Indicates the quantity of data with a framing error among the data in receive FIFO.	R
31:30	—	These bits are read as 0.	R

DR bit (Receive Data Ready flag)

Indicates that the quantity of data stored in the receive FIFO falls below the specified receive triggering number, and that no next data has been received yet after the elapse of 15 etu from the last stop bit in asynchronous mode. This bit is valid only asynchronous mode (including multi-processor mode) and FIFO selected. In other modes, this bit does not set to 1.

[Setting conditions]

DR is set to 1 when both of the following conditions are met.

- Data in receive FIFO is less than the specified receive triggering number, and no next data is received after the elapse of 15 etu[*1] from the last stop bit.
- CSR.FER, PER flags are 0.

[Clearing conditions]

- When all receive data in the receive FIFO is read and 1 is written to FFCLR.DRC.
- When CCR3.FM bit is 0.

Note 1. This is equivalent to one and a half (1.5) frames in the 8-bit format with one stop bit (etu: elementary time unit).

R[5:0] bits (Receive FIFO Data Count)

Indicate the quantity of receive data stored in receive FIFO.

0x00 means no receive data. N_{FIFO} (= 16) means receive FIFO is full.

PNUM[5:0] bits (Parity Error Count)

Indicate the quantity of data with parity error in the received FIFO.

FNUM[5:0] bits (Framing Error Count)

Indicate the quantity of data with framing error in the received FIFO.

33.3.17 FTSR : FIFO Transmit Status Register

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x54

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	T[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	T[5:0]	Transmit FIFO Data Count (Valid in Asynchronous mode (including multi-processor), Clock synchronous mode, Simple-SPI mode, when CCR3.FM is 1.) Indicate the quantity of non-transmitted data stored in transmit FIFO.	R
31:6	—	These bits are read as 0.	R

T[5:0] bits (Transmit FIFO Data Count)

Indicate the quantity of non-transmitted data stored in transmit FIFO.

0x00 means no un-transmit data. N_{FIFO} (= 16) means transmit FIFO is full.

33.3.18 MSR : Manchester Status Register

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000
SCIEi = 0x9003_0000 + 0x0400 × i (i = 0 to 7)
SCIEj = 0x9013_0000 + 0x0400 × (j - 8) (j = 8 to 11)

Offset address: 0x58

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	RSYNC	—	MER	—	SBER	SYER	PFER
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PFER	Preface Error flag This bit is set when a preface error (pattern mismatch) is detected 0: No preface error detected 1: Preface error detected	R
1	SYER	SYNC Error flag This bit is set when no edge is detected in the adjustable range during receive retiming 0: No receive SYNC error detected 1: Receive SYNC error detected	R
2	SBER	Start Bit Error flag This bit is set when a pattern mismatch in the start bit area is detected 0: No start bit error detected 1: Start bit error detected	R
3	—	This bit is read as 0.	R
4	MER	Manchester Error Flag Valid for Manchester mode only 0: No Manchester error occurred 1: Manchester error has occurred	R
5	—	This bit is read as 0.	R
6	RSYNC	Receive SYNC data bit It is valid when MCR.SBSEL = 1 in Manchester mode, 0 is read otherwise. 0: The received the Start Bit is DATA SYNC 1: The received the Start Bit is COMMAND SYNC	R
31:7	—	These bits are read as 0.	R

PFER bit (Preface Error flag)

This bit indicates that a preface error was detected when receiving frames in Manchester mode.

Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the PFER flag is not affected and retains its previous value.

[Setting condition]

When detecting a preface error when receiving frames in Manchester mode.

The following operations are performed when a preface error occurs.

<When MCR.PFEREN = 1>

The received data is not transferred to the RDR register and no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the PFER flag is being set to 1, the subsequently received data is not transferred to the RDR register.

<When MCR.PFEREN = 0>

The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the PFER flag being set to 1.

[Clearing condition]

Write 1 to MFCLR.PFERC.

SYER bit (SYNC Error flag)

This bit indicates that a receive SYNC error was detected when receiving frames in Manchester mode with MCR.ERTEN = 1 (Manchester edge retiming enabled).

Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the SYER flag is not affected and retains its previous value.

[Setting condition]

When detecting a receive SYNC error when receiving frames in Manchester mode.

The following operations are performed when a receive SYNC error occurs.

<When MCR.SYEREN = 1>

Although the received data is transferred to the RDR register, no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the SYER flag is being set to 1, the subsequently received data is not transferred to the RDR register.

<When MCR.SYEREN = 0>

The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SYER flag being set to 1.

[Clearing condition]

Write 1 to MFCLR.SYERC.

SBER bit (Start Bit Error flag)

This bit indicates that a start bit error was detected when receiving frames in Manchester mode.

Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the SBER flag is not affected and retains its previous value.

[Setting condition]

When detecting a start bit error when receiving frames in Manchester mode

The following operations are performed when a start bit error occurs.

<When MCR.SBEREN = 1>

The received data is not transferred to the RDR register and no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the SBER flag is being set to 1, the subsequently received data is not transferred to the RDR register.

<When MCR.SBEREN = 0>

The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SBER flag being set to 1.

[Clearing condition]

Write 1 to MFCLR.SBERC.

MER bit (Manchester Error Flag)

When data is received in Manchester mode, Manchester error is detected, and it is displayed. Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the MER flag is not affected and retains its previous value.

[Setting conditions]

When receiving in Manchester mode and detecting Manchester code error in data area of received frame.

Received data when an error occurs is transferred to the RDR register, but the RXI interrupt request is not generated and the ERI interrupt request is generated.

When the Manchester error flag is set to 1, subsequent receive data is not transferred to the RDR register.

For details on Manchester error, see section 33.6.11. Errors in Manchester Mode.

[Clearing condition]

Write 1 to MFCLR.MERC.

RSYNC bit (Receive SYNC data bit)

When Manchester mode (CCR3.MOD[2:0] = 101b) and MCR.SBSEL = 1, this bit indicates the type of SYNC of the received the Start Bit. For other settings, it is fixed to 0.

33.3.19 CFCLR : Common Flag Clear Register

Base address: SCIn = 0x8000_5000 + 0x0400 × n (n = 0 to 4)
SCI5 = 0x8100_5000

31:5	—	The write value should be 0.	W

33.4 Asynchronous Mode

Figure 33.3 shows the general format for asynchronous serial communications.

One frame consists of a start bit (low level), transmit/receive data, a parity bit, and stop bits (high level).

In asynchronous serial communications, the communications line is held in the mark state (high level) when not communicating.

The SCI monitors the communications line. When the SCI detects a start bit, it starts serial communication. The detection condition of the start bit changes according to the CCR3.RXDESEL setting. SCI regards space (Low level) as a start bit when CCR3.RXDESEL is 0. SCI regards a fall edge as a start bit when RXDESEL is 1.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and the receiver also have a double-buffered structure (it has also FIFO mode), so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

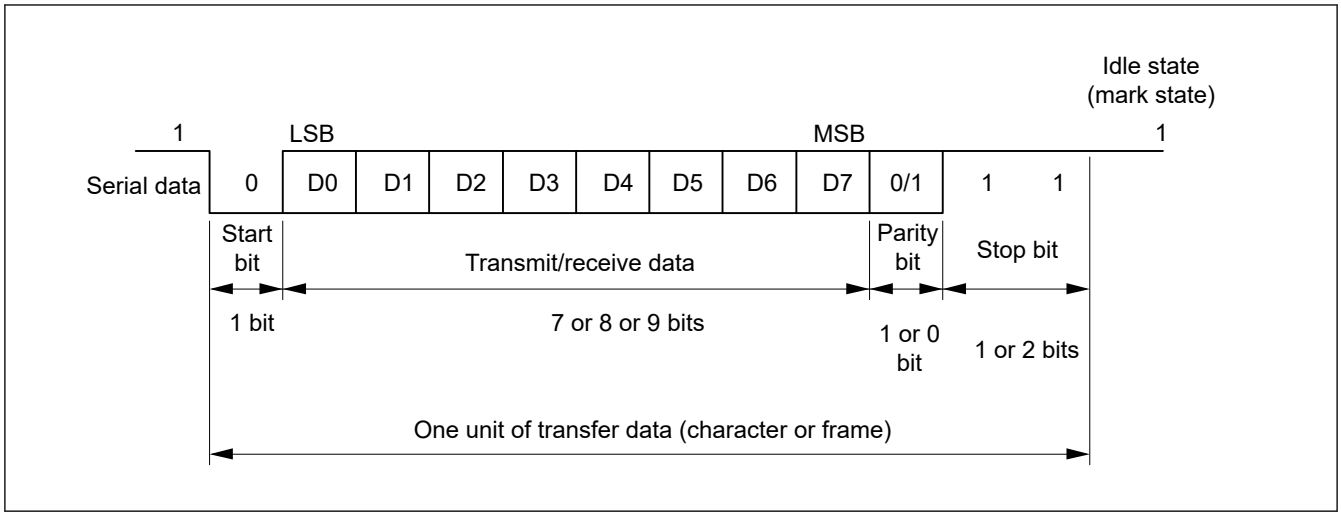

Figure 33.3 Data format in asynchronous serial communications (example with 8-bit data, parity, 2 stop bits)

33.4.1 Serial Data Transfer Format

Table 33.24 lists the serial data transfer formats that can be used in asynchronous mode. Any of 18 transfer formats can be selected according to the CCR1 and CCR3 settings.

For details of multi-processor function, see section 33.5. Multi-Processor Communication Function.

Table 33.24 Serial transfer formats (asynchronous mode) (1 of 2)

[Symbol explanation]

St : Start bit
STP : Stop bit
P : Parity bit
MPB : Multi-processor bit

33.4.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times[*1] the bit rate. In reception, the SCI samples the falling edge of the start bit using the base clock and performs internal synchronization[*2]. When sampling timing does not adjust ("CCR4.ASEN = 0b" or "CCR4.ASEN = 1b and CCR4.AST[2:0] = 000b"), receive data is sampled at the rising edge of the 8th pulse[*1] of the base clock, data is latched at the middle of each bit, as shown in Figure 33.4. Thus, the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left|(0.5 - \frac{1}{2N}) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100[\%] \cdots \text{Equation (1)}$$

M: Reception margin

N: Ratio of bit rate to clock

(N = 16, when CCR2.ABCSE = 0 and CCR2.ABCS = 0, N = 8, when CCR2.ABCS = 1, N = 6, when CCR2.ABCSE = 1)

D: Duty cycle of clock (D = 0.5 to 1.0)

L: Frame length (L = 9 to 13)

F: Absolute value of clock frequency deviation

Assuming values of N = 16, F = 0 and D = 0.5 in formula (1), the reception margin is determined by the formula below.

$$M = \{0.5 - 1/(2 \times 16)\} \times 100(\%) = 46.875\%$$

However, this is only the computed value, and a margin of 20% to 30% should be allowed in system design.

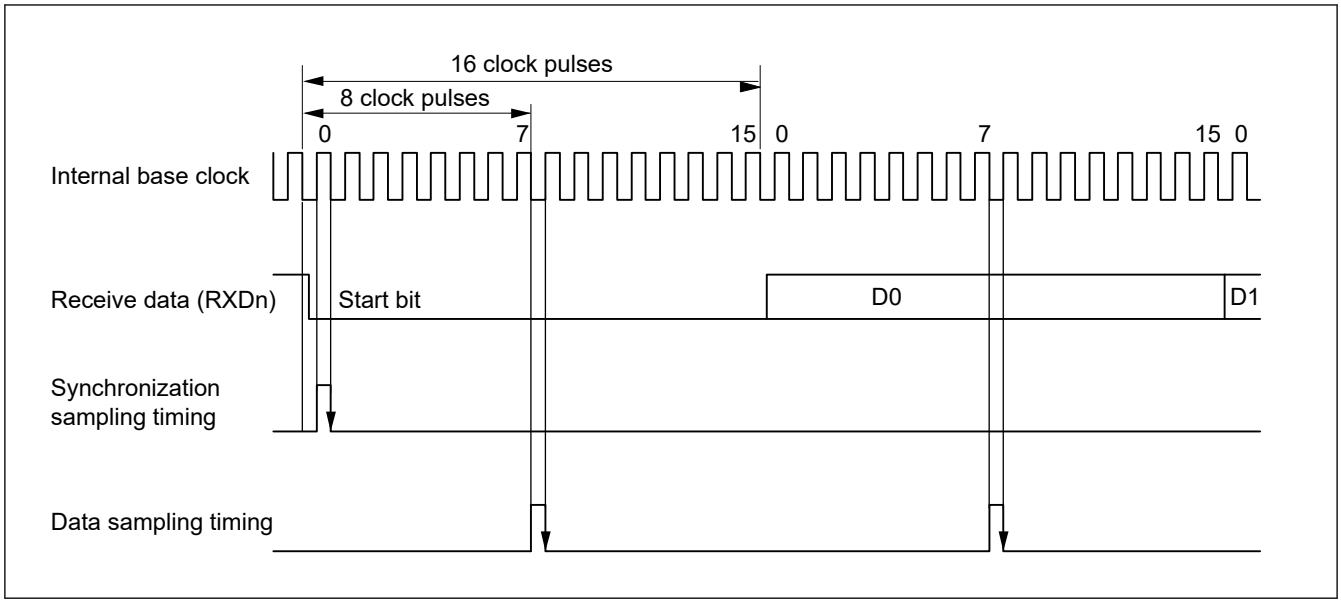

Figure 33.4 Receive data sampling timing in asynchronous mode

Note 1. This is an example when CCR2.ABCS = 0 and CCR2.ABCSE = 0. When CCR2.ABCS = 1 and CCR2.ABCS = 0, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock. When CCR2.ABCSE is 1, a sextuple frequency of a bit rate is a base clock and receive data is sampled at the rising edge of the 3rd pulse of the base clock.

Note 2. The determination condition of the start bit is as follows.

In the case of the function of adjust sampling timing is OFF (CCR4.ASEN = 0):

The determination condition of a start bit is that Low beyond half bit length continues. It is same as the sampling timing.

In Figure 33.4, the low period should be kept over 8 cycles to detect a start bit. If Low period does not keep over 8 cycles, the module judges this as a noise. So, the module does not start reception and wait start bit.

In the case of the function of adjust sampling timing is ON (CCR4.ASEN = 1):

The determination condition of a start bit is that Low keeps up until the sampling timing.

Adjusting the sampling timing forward (CCR4.AJD = 1) increases the possibility of erroneously determining a noise as the start bit.

33.4.3 Clock

Either an internal clock generated by the baud rate generator or an external clock input to the SCKn pin can be selected as the SCI's transfer clock, according to the setting of CCR3.CKE[1:0]. When an external clock is input to the SCKn pin, the clock frequency should be 16 times the bit rate (when CCR2.ABCS = 0) and 8 times the bit rate (when CCR2.ABCS = 1).

When the SCI is operated on an internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is such that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 33.5.

If you selected an internal clock, the SCK pin is outputted after CCR0.TE is set to 1 or CCR0.RE is set to 1.

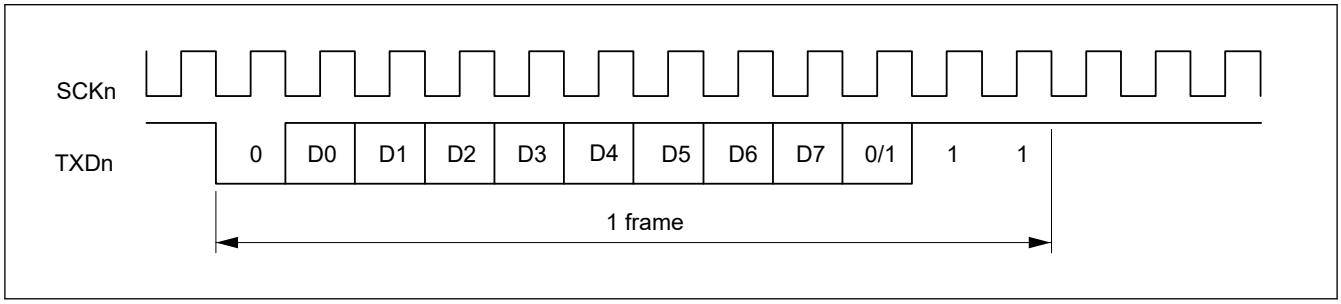

Figure 33.5 Phase relationship between output clock and transmit data (asynchronous mode: CHR[1:0] = 10b, PE = 1, MP = 0, STP = 1)

33.4.4 Double-Speed Operation and frequency of 6 times the bit rate

When CCR2.ABCS is set to 1, the SCI operates on the bit rate twice that in the case where ABCS is set to 0. And when CCR2.BGDM is set to 1, the cycle of the base clock is halved and the bit rate is doubled from that in the case where BGDM is set to 0. When CCR3.CKE[1] is set to 0 and the baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the SCI to operate on a bit rate four times that in the case ABCS = 0 and BGDM = 0.

When CCR2.ABCSE is set to 1, the number of base clock pulses are 6 during a period of 1 bit, and the base clock frequency is half. And SCI works 16/3 times of bit rate compared with a case of CCR2.ABCS = 0, CCR2.BGDM = 0 and CCR2.ABCSE = 0.

As shown by Formula (1) in section 33.4.2. Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, the reception margin decreases when CCR2.ABCS is set to 1 or CCR2.ABCSE is set to 1. Therefore, if the desired bit rate can be obtained with CCR2.ABCS set to 0 and/or CCR2.ABCSE set to 0, it is recommended to use the SCI with CCR2.ABCS set to 0 and/or CCR2.ABCSE set to 0.

33.4.5 CTS and RTS Function

The CTS function is the transmission control function by the CTSn# pin. Setting the CCR1.CTSE bit to 1 enables the CTS function. For the functions of CTS and RTS, you can select the alternate setting that uses either function with one terminal or the dedicated setting that uses each function independently with two terminals. This setting is done with the CCR1.CTSPEN bit.

When the CTS function is enabled, placing the low level on the CTSn# pin, causes transmission to start.

Even if the CTSn# pin goes high after transmission starts, the frame being transmitted is not affected and transmission will continue.

The RTS function is the transmission request function by the RTSn# pin. In the RTS function, the RTSn# pin output low level, when reception becomes possible. Conditions for output of the low and high levels are shown below.

[Conditions of low-level output]

(1) Non-FIFO selected when all of the following conditions are satisfied.

- CCR0.RE is 1
- When in receivable state
- There are no received data yet to be read
- CSR.ORER, FER, PER flags are all 0

(2) FIFO selected when all of the following conditions are satisfied.

- CCR0.RE is 1
- When the quantity of receive data written in receive FIFO (RDR) are less than the setting value of FCR.RSTRG[4:0]
- CSR.ORER (RDR.ORER) is 0

[Condition for high-level output]

When the conditions of low-level output have not been satisfied.

33.4.6 Address Match (receive data match detection) Function

The address match function can be used only for the asynchronous mode.

If CCR0.DCME is set to 1,[*2] when one frame of data has been received, SCI compares that receive data with the data which is set to CCR4.CMPD. If SCI detects the match to the comparison data (CCR4.CMPD[*1]) with receive data, SCI can issue RXI interrupt request.

If CCR3.MP bit is set to 0, this comparative target in communication data is valid only data field in receive format. In multi-processor mode (CCR3.MP = 1), if CCR0.IDSEL bit is set to 1, the reception data at which MPB bit is 1 detects address match or unmatch, and the reception data at which MPB bit is 0 detects always unmatch. If CCR0.IDSEL bit is set to 0, SCI detects address match or unmatch despite the value of the MPB bit of the reception data at every reception complete.

Until SCI detects the match to the comparison data (CCR4.CMPD) with receive data, the communication data is skipped (discarded), and SCI can not detect parity error, framing error.

When SCI detects the match, the CCR0.DCME is automatically cleared, and CSR.DCMF is set to 1. If CCR0.IDSEL bit is set to 1 at this time, CCR0.MPIE bit is automatically cleared. If CCR0.IDSEL bit is set to 0 at this time, CCR0.MPIE bit is kept. At the same time, if CCR0.RIE is set to 1, SCI issues RXI interrupt request.

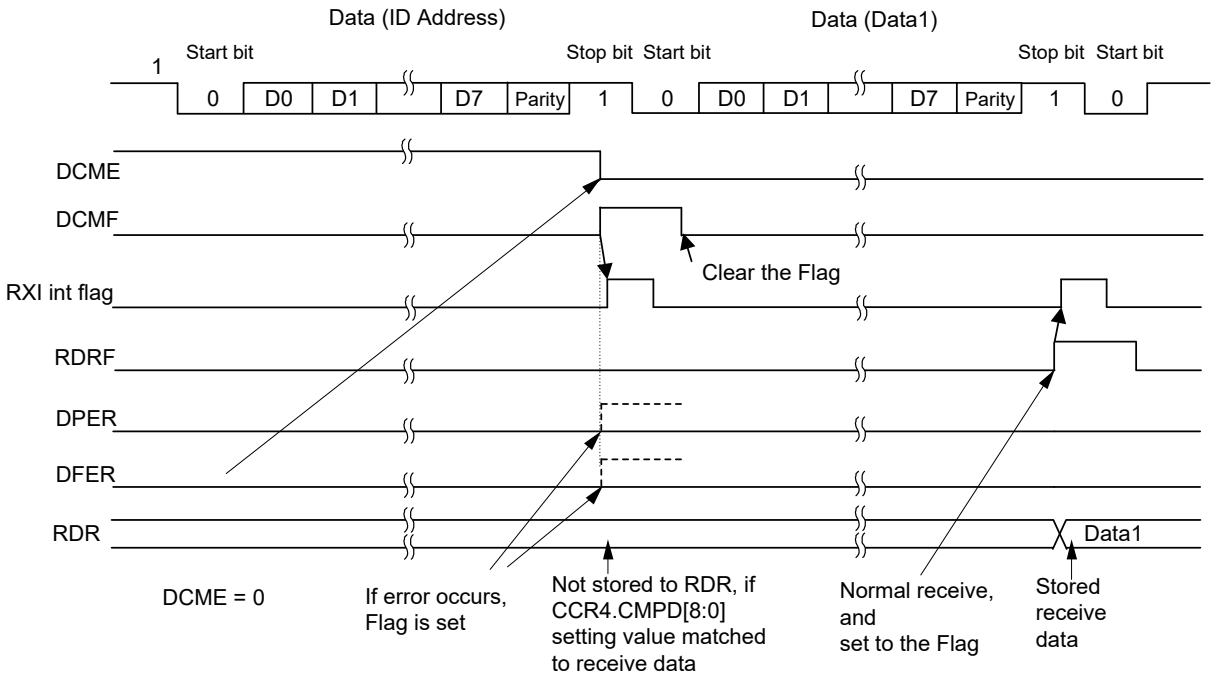
If SCI detects framing error in comparative receive data which is detected the match, CSR.DFER is set to 1, and if SCI detects parity error in that frame, CSR.DPER is set to 1. That comparative receive data and MPB bit are not stored to RDR register, and CSR.RDRF is retained to 0.

After SCI detects the match, and the CCR0.DCME is automatically cleared, it receives next data continuously in current register setting.

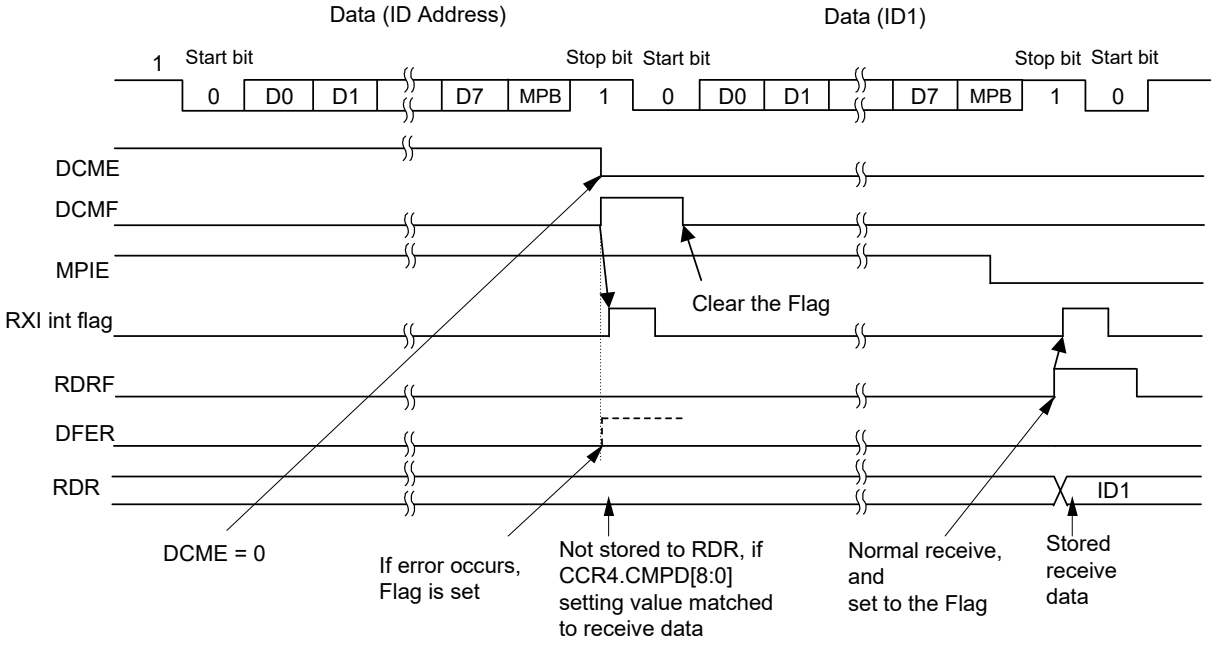
When CSR.DFER flag or CSR.DPER flag is set, the address much is not detected. Before making the address match function effective, please be sure to set CSR.DFER and CSR.DPER flag as 0.

Figure 33.6 and Figure 33.7 show the address match function example.

Note 1. This comparative target can select one length of 3 types, they are CMPD[6:0] with 7-bit length enable, CMPD[7:0] with 8-bit, and CMPD[8:0] with 9-bit length.
Note 2. Set the CCR0.DCME bit to 1 before receiving the start bit of the received frame that performs address matching.

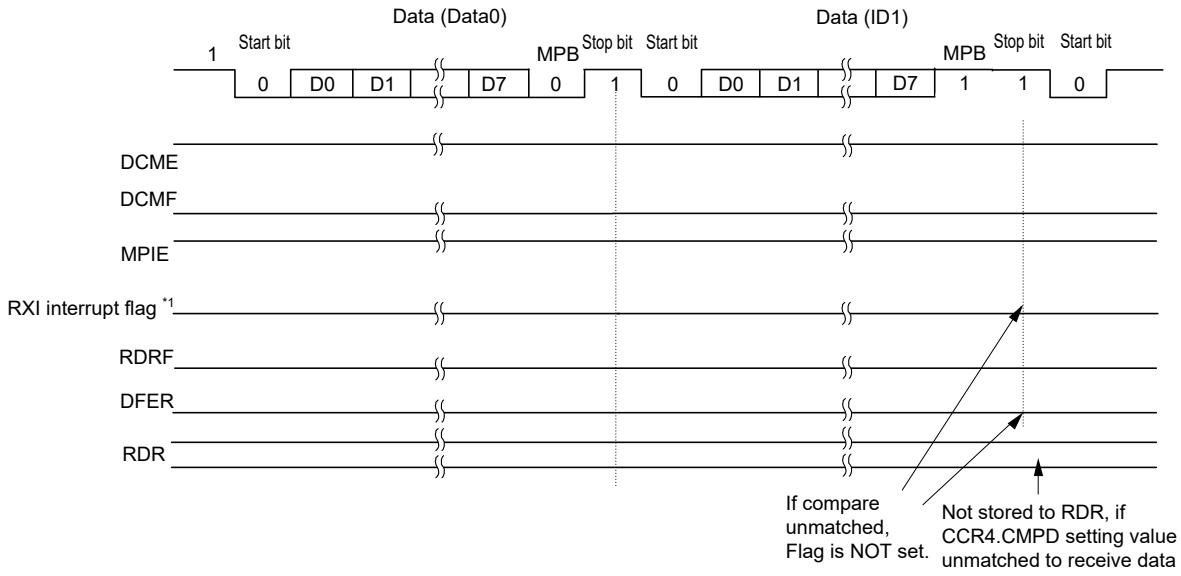


(a) Example of Compare matched between receive data and CCR4.CMPD[8:0] (8-bit length/parity/Normal mode)

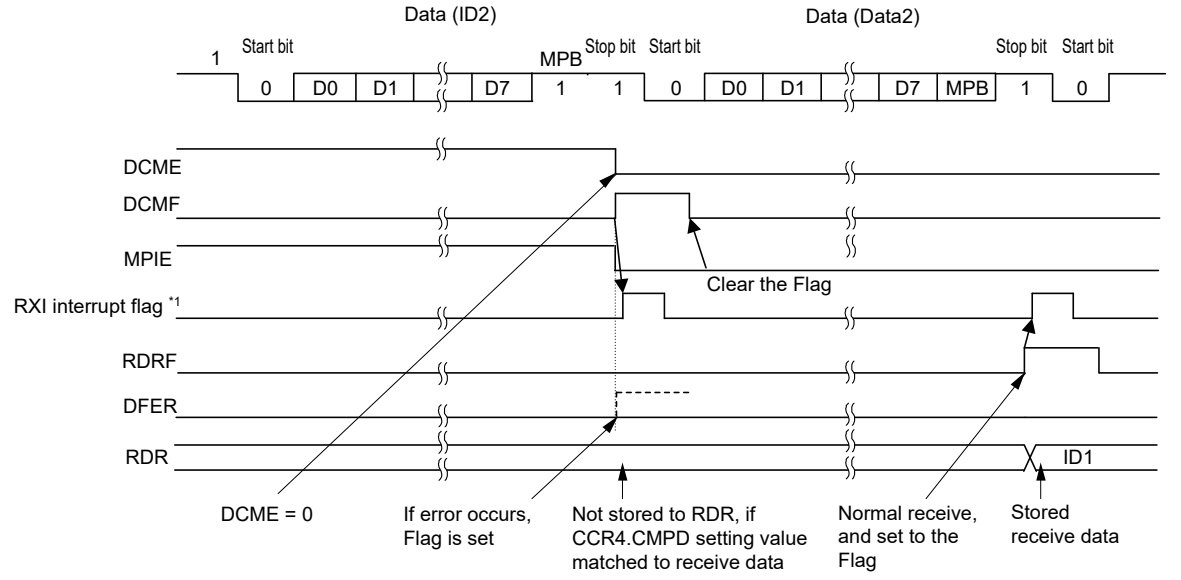


(b) Example of Compare matched between receive data and CCR4.CMPD[8:0] (8-bit length/Multi-processor mode)

Figure 33.6 Example of addresss match (1) non-multi-processor mode / 8-bit data



(a) Example of Compare unmatched between receive data and CCR4.CMPD (8-bit length / IDSEL = 1 / Multi-processor mode)



(b) Example of Compare matched between receive data and CCR4.CMPD (8-bit length / IDSEL = 1 / Multi-processor mode)

Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.7 Example of address match (2) multi-processor mode / 8bit-data

33.4.7 SCI Initialization (Asynchronous Mode)

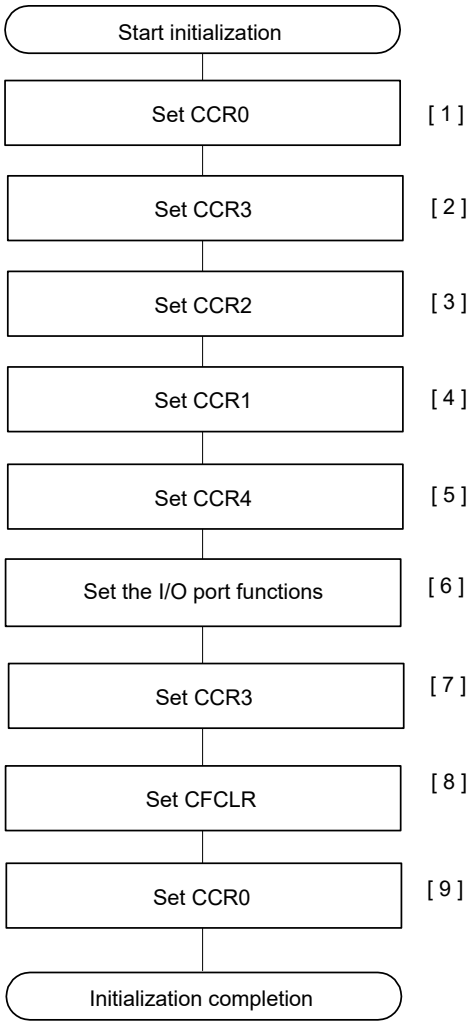
Before transmitting and receiving data, start by writing 0 to CCR0.TE and CCR0.RE (or writing the initial value to CCR0) and then continue through the Procedure (select to Non-FIFO or FIFO) for SCI given in Figure 33.8 or Figure 33.9. Whenever the operating mode or transfer format is changed, CCR0.TE and CCR0.RE must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied even during initialization.

Note that setting the CCR0.RE bit to 0 initializes neither the ORER, FER, PER, RDRF, DR and RDAT. When FIFO selected, even if the TE bit is set as 0, the TEND flag is not initialized, so please be careful.

Please be also careful at the time of change in the operation mode.

Moreover, note that switching the value of the CCR0.TE bit from 0 to 1 while the CCR0.TIE bit is 1 leads to the generation of a TXI interrupt request.



[1] Set the following bits of CCR0 to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set up following function and communication mode.
Driver control function for RS-485
FIFO no-use
Multi-Processor mode
Communication mode (MOD[2:0] = 000b)
Transmission / reception format
Clock enable (Leave the initial value in this step when outputting the clock)
Leave unused bits at their initial values.

[3] Set up the bit-rate-modulation function*1 *2, select clock, set bit rate*2.

[4] Set up the Noise-filter function, the loop-back function, communication terminal status, the parity check function, and the CTS/RTS function.

[5] Set up the adjust sampling timing function and the adjust transmit timing function.

[6] Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.

[7] Set clock enable bit (CKE[1:0]) at this step when outputting the clock. After this register setting, a clock will be output immediately.

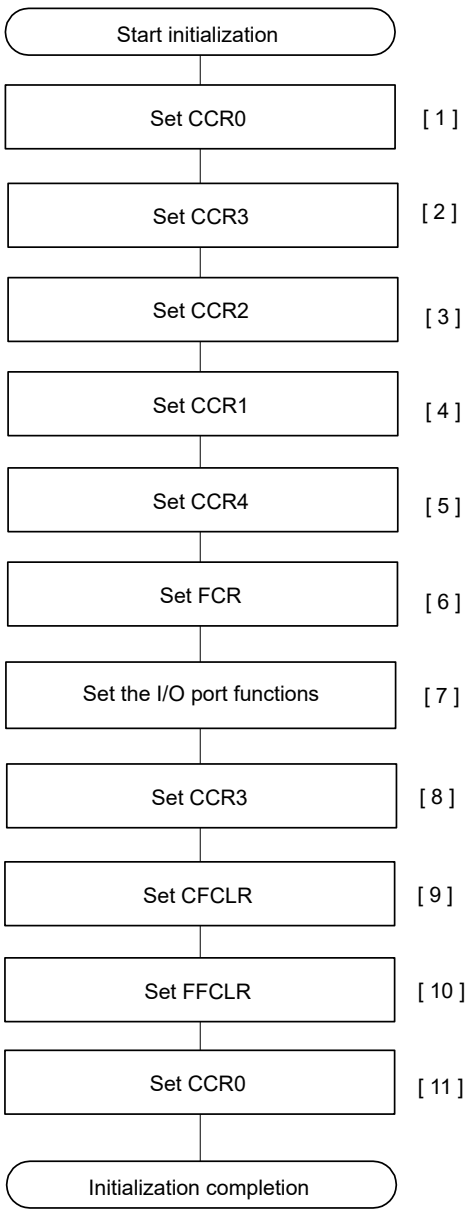
[8] Write 1 to the following bits and clear the corresponding flag.
CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
If it's initialization flow after a reset, you can skip this step.

[9] Set the TE or RE bit to 1.
To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time.
Setting the TE and RE bits allows TXDn and RXDn to be used.

Note 1. If you do not use the bit rate modulation function, you do not need to set it.

Note 2. If you use an external clock, you do not need to set it.

Figure 33.8 Sample SCI initialization flowchart (asynchronous mode/non-FIFO selected)



Note 1. If you do not use the bit rate modulation function, you do not need to set it.
Note 2. If you use an external clock, you do not need to set it.

[1] Set the following bits of CCR0 to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set up following function and communication mode.
Driver control function for RS-485
FIFO use
Multi-Processor mode
Communication mode (MOD[2:0] = 000b)
Transmission / reception format
Clock enable (Leave the initial value in this step when outputting the clock)
Leave unused bits at their initial values.

[3] Set up the bit-rate-modulation function*1 *2, select clock, set bit rate*2.

[4] Set up the Noise-filter function, the loop-back function, communication terminal status, the parity check function, and the CTS/RTS function.

[5] Set up the adjust sampling timing function and the adjust transmit timing function.

[6] Set the TFRST and RFRST to 1 to empty FIFO.
Set the DRES, TTRG[4:0], RTRG[4:0], and RSTRG[4:0] bits

[7] Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.

[8] Set clock enable bit (CKE[1:0]) at this step when outputting the clock. After this register setting, a clock will be output immediately.

[9] Write 1 to the following bits and clear the corresponding flag.
CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
If it's initialization flow after a reset, you can skip this step.

[10] Write 1 to the FFCLR.DRC and clear the corresponding flag.
If it's initialization flow after a reset, you can skip this step.

[11] Set the TE or RE bit to 1.
To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time.
Setting the TE and RE bits allows TXDn and RXDn to be used.

Figure 33.9 Sample SCI initialization flowchart (asynchronous mode/FIFO selected)

Figure 33.10 shows an example of the timing when data is transmitted after reset is released, and SCI is set to asynchronous mode according to Figure 33.8 or Figure 33.9. As shown in the figure, when the pin function is set to the TXD pin, the CCR0.TE bit is 0, so the pin is high impedance. When transmit data is written after setting the CCR0.TE bit to 1, data transmission starts. There is a transmission wait time from writing TDR to data transmission starts. In asynchronous mode, TXD is high during this period.

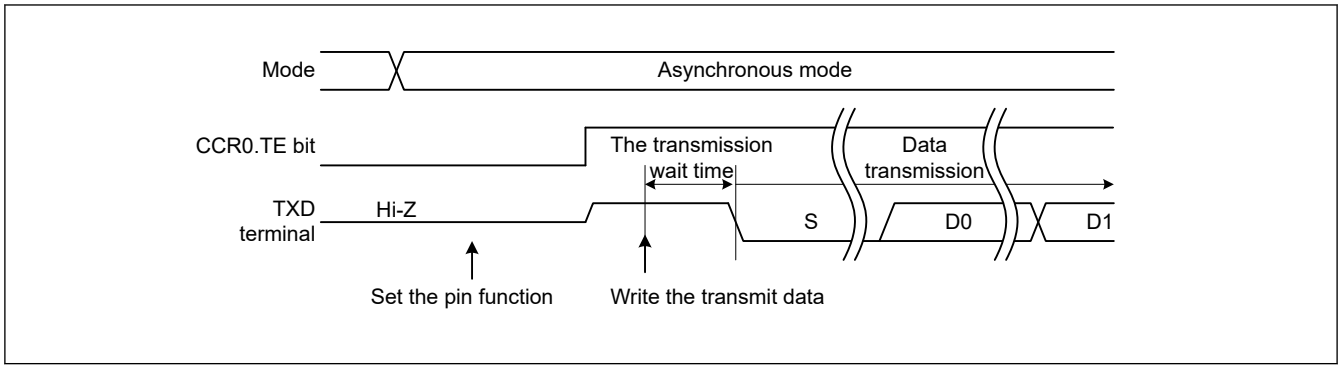


Figure 33.10 Data transmission timing example in asynchronous mode

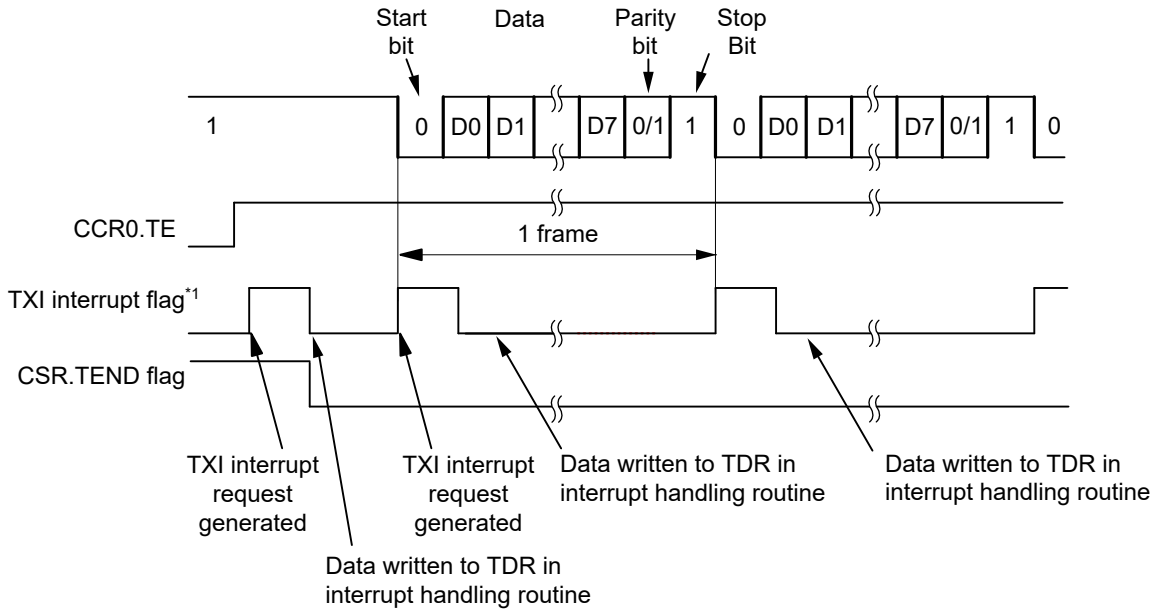
33.4.8 Serial Data Transmission (Asynchronous Mode)

(1) Non-FIFO selected

Figure 33.11, Figure 33.12, and Figure 33.13 show an example of the operation for serial transmission in asynchronous mode. In serial transmission, the SCI operates as described below.

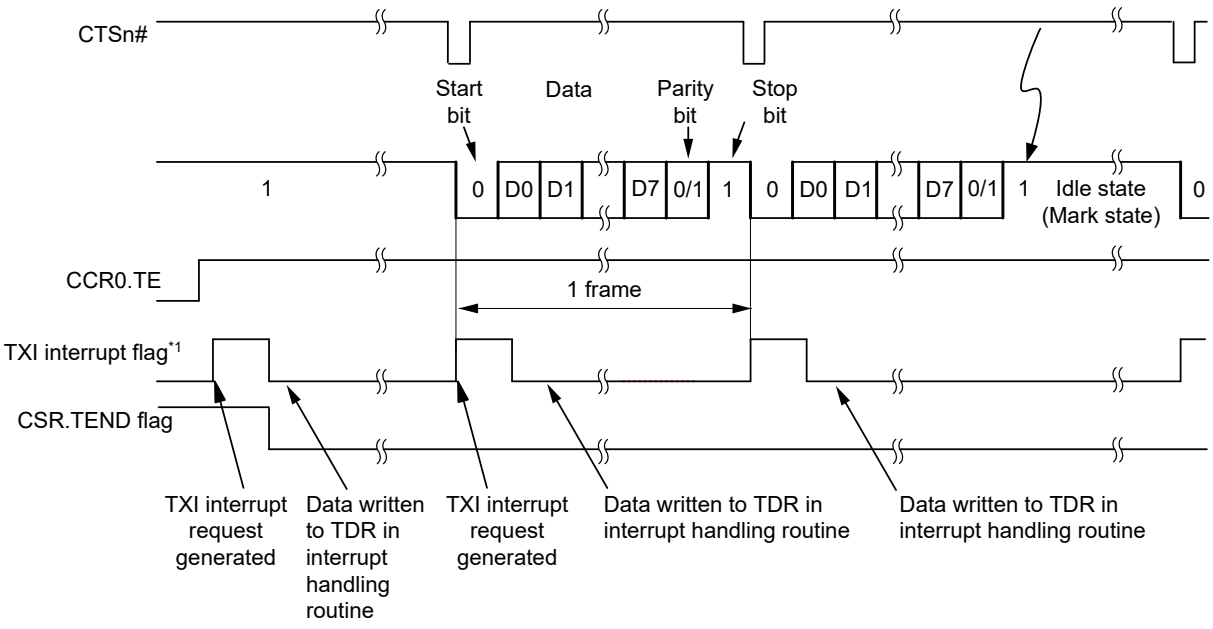
1. The SCI transfers data from TDR to TSR when data is written to TDR in the TXI interrupt handling routine. At the beginning of transmission, set 1 to CCR0.TE and CCR0.TIE simultaneously. Then the TXI interrupt request is generated.
2. Transmission starts at data transfer from TDR to TSR when CCR1.CTSE = 0 (CTS function is disabled) or when the CTS# pin level is low. If CCR0.TIE is 1 at this time, a TXI interrupt request is generated. Continuous transmission is obtainable by writing the next transmit data to TDR in the TXI interrupt handling routine before transmission of the current transmit data is completed. Write the last transmission data, then the last data transmit start, and TXI is generated. When TEI interrupt requests are in use, before the last data transmit end, set the CCR0.TIE bit to 0 (a TXI interrupt request is disabled) and the CCR0.TEIE bit to 1 (a TEI interrupt request is enabled) using the TXI handling routine.
3. Data is sent from the TXDn pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The SCI checks for updating of (writing to) TDR at the time of stop bit output.
5. When TDR is updated, setting of CCR1.CTSE to 0 (CTS function is disabled) or a low level input on the CTSn# pin cause the next transfer of the next transmit data from TDR to TSR and sending of the stop bit, after which serial transmission of the next frame starts.
6. If TDR is not updated, CSR.TEND is set to 1, the stop bit is sent, and then the mark state is entered in which 1 is output. If the CCR0.TEIE is 1 at this time, a TEI interrupt request is generated.

Figure 33.15 shows the example of Serial Transmission Flowchart.



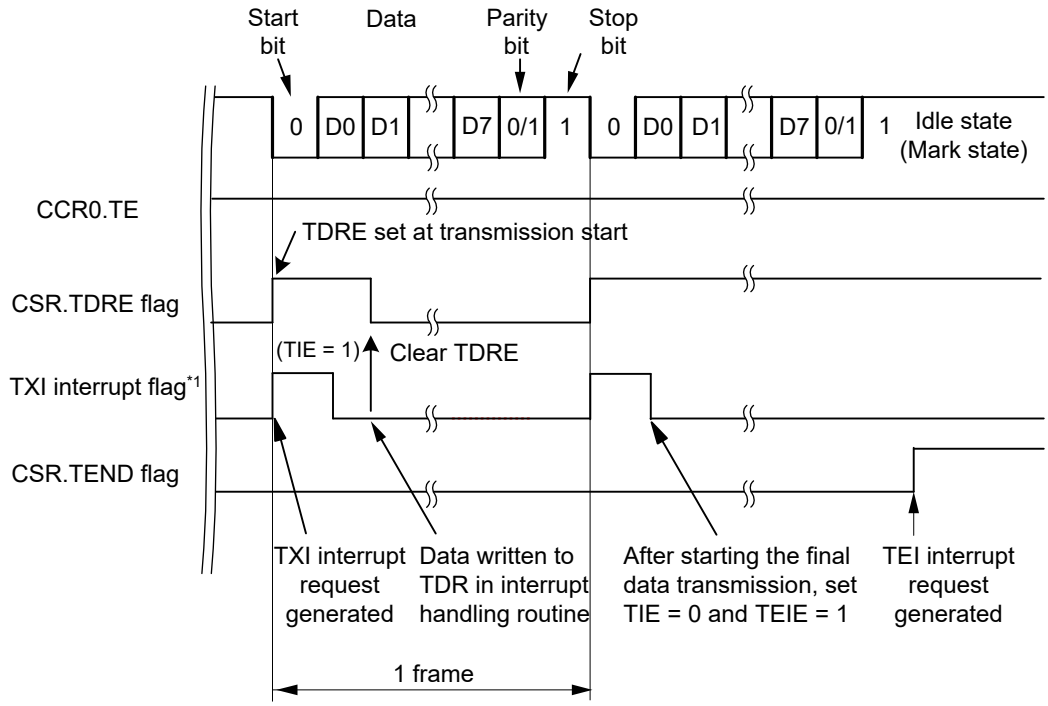
Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.11 Example of operation for serial transmission in asynchronous mode (1) (with 8-bit data, parity, 1 stop bit, CTS function not used, at the beginning of transmission)



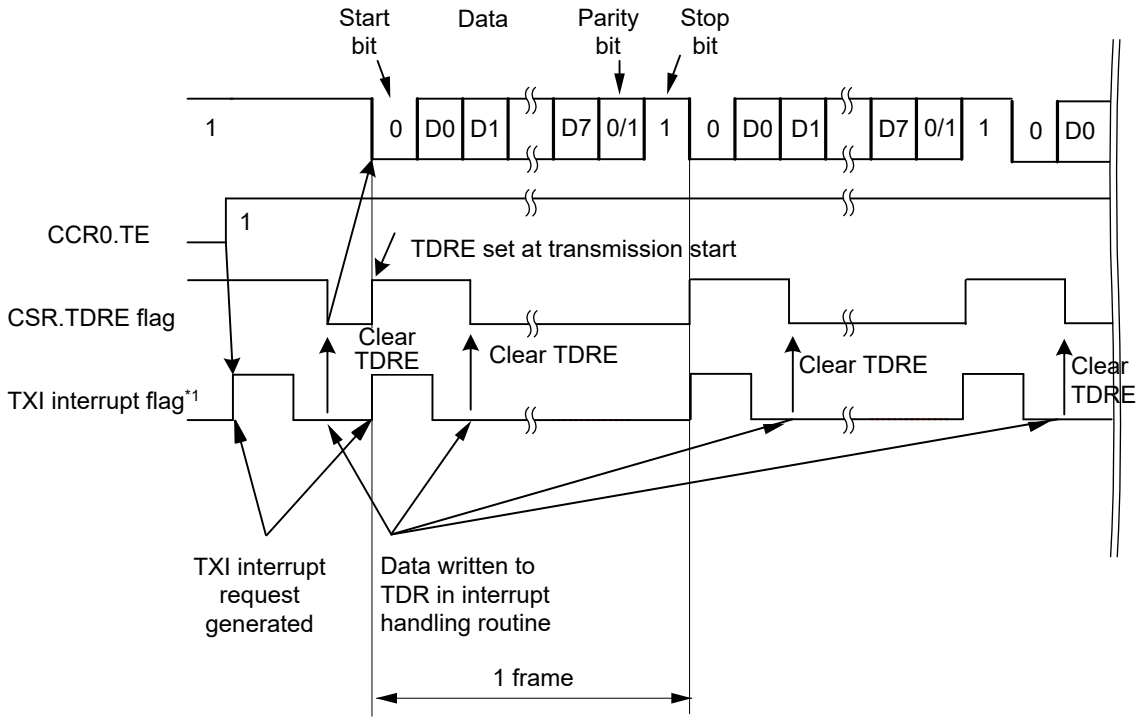
Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.12 Example of operation for serial transmission in asynchronous mode (2) (with 8-bit data, parity, 1 stop bit, CTS function used, at the beginning of transmission)



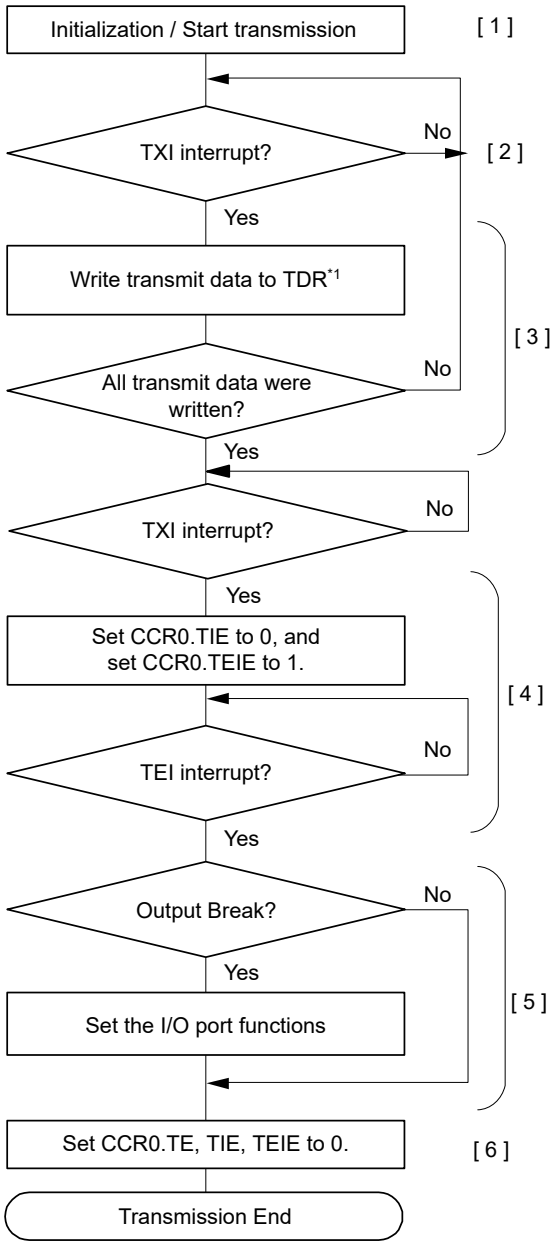
Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.13 Example of operation for serial transmission in asynchronous mode (3) (with 8-bit data, parity, 1 stop bit, CTS function not used, from the middle of transmission until transmission completion)



Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.14 Example of operation for serial transmission in asynchronous mode (4) (with 8-bit data, parity, 1 stop bit, CTS function not used, in the middle of transmission)



[1] Initialize SCI:
To enable TXI interrupt at the start of transmission, set TE and TIE to 1 with one instruction at the same time.

[2] TXI interrupt request:
The transmit-data-empty-interrupt (TXI) is generated at following conditions.
When set TE and TIE to 1 at same time.
When transmission-data forwards to TSR from TDR.

[3] Serial transmission continuation procedure:
To continue serial transmission write transmit data to TDR*1 once by using a TXI.
Transmit data can also be written by activating the DMAC.

[4] If you use TEI, set TIE = 0 and TEIE = 1 after writing the last-transmit-data to TDR*1 and transmission is started.

[5] Break output at the end of serial transmission:
To output a break, it is necessary to set SPB2IO and SPB2DT, for output status setting when TE is 0.
(If you set these bits at initialization, you can skip this step.)

[6] Set CCR0.TE, TIE, TEIE to 0.

Note 1. In case of byte access with data length 9 bits, write transmit data in order of TDR[15:8] and TDR[7:0].

Figure 33.15 Example of serial transmission flowchart in asynchronous mode (non-FIFO selected)

(2) FIFO selected

Figure 33.16 shows an example of data format that is written to transmit FIFO (TDR) in asynchronous mode with FIFO selected. MPBT write to transmit FIFO (TDR) bit 9. Data is set to TDR.TDAT[8:0] corresponded to data length. It should write to 0 for unused bits. It should write it in order of the TDR[15:8] register and the TDR[7:0] register at byte-access.

Data Length	Register setting		Transmit data in TDR[15:0]															
	CCR3. CHR[1:0]		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	1	–	–	–	–	–	–	MPBT	–	–	TDAT[6:0]						
8 bits	1	0	–	–	–	–	–	–	MPBT	–	TDAT[7:0]							
9 bits	0	x	–	–	–	–	–	–	MPBT	TDAT[8:0]								

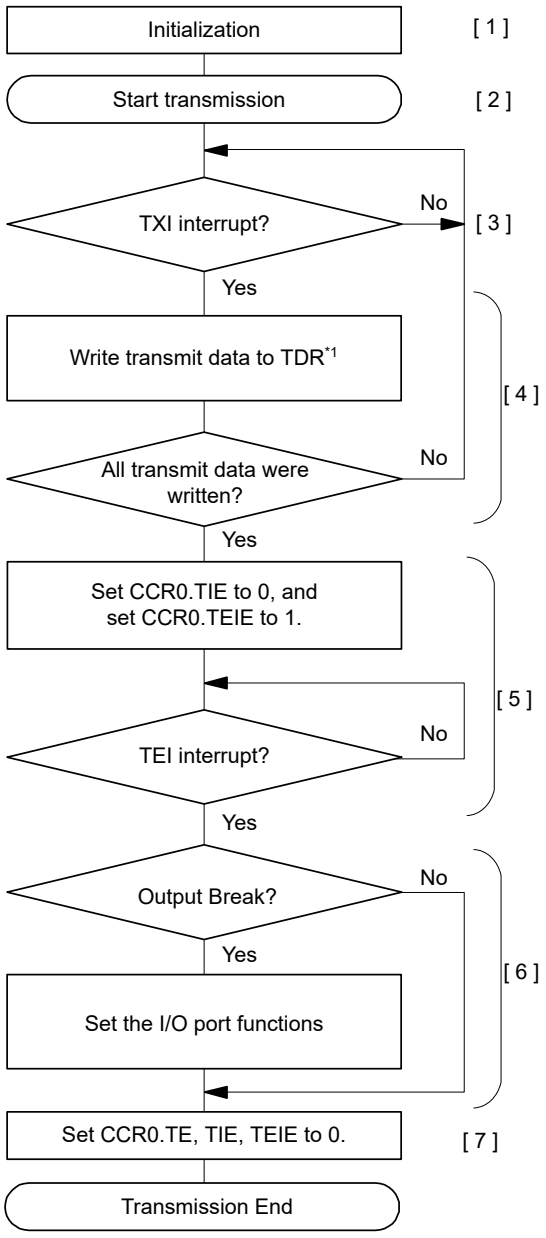
Note: –: Do not used. It should write to 0

Figure 33.16 Data format that is written to transmit FIFO (TDR) (FIFO selected)

In serial transmission, the SCI operates as described below.

1. The SCI transfers data from TDR to TSR when data is written to TDR in the TXI interrupt handling routine. The writable transmit data number is until (N_{FIFO} (= 16) - FTSR.T) bytes. At the beginning of transmission, set 1 to CCR0.TE and CCR0.TIE simultaneously. Then the TXI interrupt request is generated.
2. Transmission starts at data transfer from TDR to TSR when CCR1.CTSE = 0 (CTS function is disabled) or when the CTS# pin level is low. When the quantity of transmit data written in transmit FIFO (TDR) is equal to or less than the specified transmit triggering number, CSR.TDRE is set to 1. If CCR0.TIE is 1 at this time, a TXI interrupt request is generated. Continuous transmission is obtainable by writing the next transmit data to TDR in the TXI interrupt handling routine before transmission of the current transmit data is completed. Write the last transmission data, then the last data transmit start, and TXI is generated. When TEI interrupt requests are in use, before the last data transmit end, set the CCR0.TIE bit to 0 (a TXI interrupt request is disabled) and the CCR0.TEIE bit to 1 (a TEI interrupt request is enabled) using the TXI handling routine.
3. Data is sent from the TXDn pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The SCI checks whether non-transmitted data in transmit FIFO (TDR) or not at the time of stop bit output.
5. When data is set to transmit FIFO (TDR), setting of CCR1.CTSE to 0 (CTS function is disabled) or a low level input on the CTSn# pin cause the next transfer of the next transmit data from transmit FIFO (TDR) to TSR and sending of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set to transmit FIFO (TDR), CSR.TEND is set to 1, the stop bit is sent, and then the mark state is entered in which 1 is output. If CCR0.TEIE is 1 at this time, a TEI interrupt request is generated.

Figure 33.17 shows a sample flowchart for serial transmission in asynchronous mode at FIFO selected.



[1] Initialize SCI:
To enable TXI interrupt, set TE and TIE to 1 with one instruction at the same time.

[2] Set transmit-data to the transmit FIFO (TDR):
The number of transmittable data that can be set is 16.

[3] TXI interrupt request:
The transmit-data-empty-interrupt (TXI) is generated when transmission-data forwards to TSR from the transmit FIFO (TDR) and the number of transmit-data written in the transmit FIFO is equal to or less than the transmit FIFO threshold.

[4] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data to the transmit FIFO (TDR) by using a TXI interrupt and clear TDRE flag to 0. (Transmit data can also be written to the transmit FIFO (TDR) by activating the DMAC. In this case, the TDRE flag is cleared automatically, so please do not operate the TDRE flag.)
The number of transmission data it's possible to write in is N_{FIFO} (= 16) - (the number of stored transmit FIFO data).

[5] If you use TEI, set TIE = 0 and TEIE = 1 after writing the last-transmit-data to TDR.*1

[6] Break output at the end of serial transmission:
To output a break, it is necessary to set SPB2IO and SPB2DT, for output status setting when TE is 0.
(If you set these bits at initialization, you can skip this step.)

[7] Set CCR0.TE, TIE, TEIE to 0.

Note 1. In case of byte access with data length 9 bits, write transmit data in order of TDR[15:8] and TDR[7:0].

Figure 33.17 Example of serial transmission flowchart in asynchronous mode (FIFO selected)

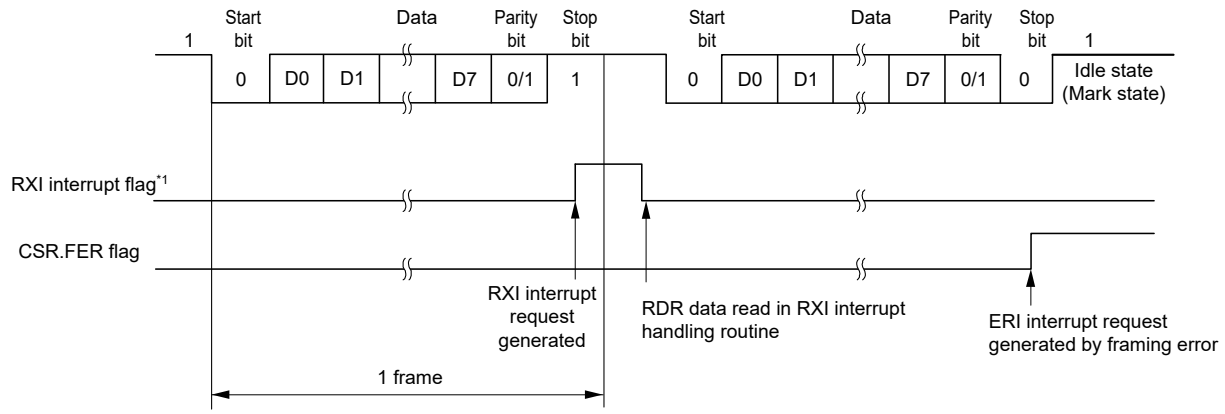
33.4.9 Serial Data Reception (Asynchronous Mode)

(1) Non-FIFO selected

Figure 33.18 and Figure 33.19 show an example of the operation for serial data reception in asynchronous mode. In serial data reception, the SCI operates as described below.

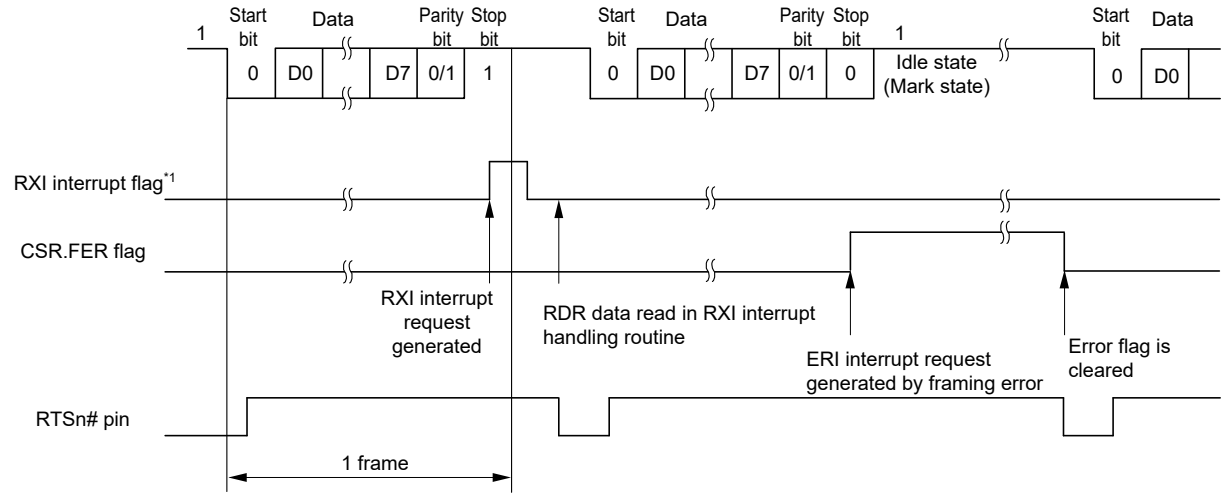
1. When the value of CCR0.RE becomes 1, the output signal on the RTSn# pin goes to the low level in the case of RTS function use.
2. When the SCI monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in RSR, and checks the parity bit and stop bit.
3. If an overrun error occurs, CSR.ORER is set to 1. If CCR0.RIE is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR.

4. If a parity error is detected, CSR.PER is set to 1 and receive data is transferred to RDR. If the CCR0.RIE is 1 at this time, an ERI interrupt request is generated.
5. If a framing error (when the stop bit is 0) is detected, CSR.FER is set to 1 and receive data is transferred to RDR. If CCR0.RIE is 1 at this time, an ERI interrupt request is generated.
6. When reception finishes successfully, receive data is transferred to RDR. If CCR0.RIE is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to RDR in this RXI interrupt handling routine before reception of the next receive data is completed. Reading the received data that have been transferred to RDR causes the RTSn# pin to output the low level in the case of RTS function use. If you do not want to turn the RTSn# pin output low after receiving the last data, set CCR0.RE bit to 0, before reading the RDR.



Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.18 Example of SCI operation for serial reception in asynchronous mode (1) (example with 8-bit data, parity, 1 stop bit, RTS function is not used)



Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

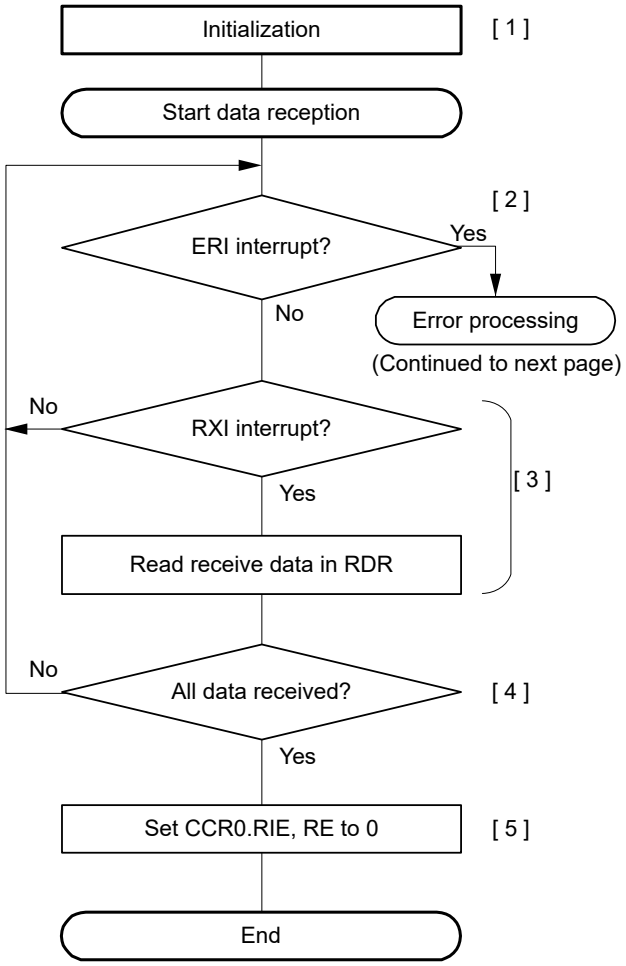
Figure 33.19 Example of SCI operation for serial reception in asynchronous mode (2) (example with 8-bit data, parity, 1 stop bit, RTS function is used)

Table 33.25 lists the states of the flags in CSR status register and receive data handling when a receive error is detected. If a receive error is detected, an ERI interrupt request is generated but an RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER bits to 0 before resuming reception. Moreover, be sure to read the RDR during overrun error processing. When a reception is forcibly terminated by

setting CCR0.RE bit to 0 during operation, read the RDR register because received data which has not yet been read may be left in RDR. Figure 33.20 and Figure 33.21 show samples of flowcharts for serial data reception.

Table 33.25 Flags in the CSR status register and receive data handling

Flags in the CSR status register			Receive data	Receive error type
ORER	FER	PER		
1	0	0	Lost	Overrun error
0	1	0	Transferred RDR	Framing error
0	0	1	Transferred RDR	Parity error
1	1	0	Lost	Overrun error + Framing error
1	0	1	Lost	Overrun error + Parity error
0	1	1	Transferred RDR	Framing error + Parity error
1	1	1	Lost	Overrun error + Framing error + Parity error



[1] Initialize SCI.
(Set CCR0.RE, RIE to 1.)

[2] Receive error processing and break detection:
If a receive error occurs, an ERI interrupt is generated. After performing the appropriate error processing, be sure to set the ORER, PER, and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. In the case of a framing error, a break can be detected by reading the value of the input port corresponding to the RXDn pin.

[3] Read the receive data in RDR once in the RXI interrupt handling routine.

[4] Serial reception continuation procedure:
To continue serial reception, before the stop bit of the current frame is received, read data from RDR in the RXI interrupt handling routine. The RDR data can also be read by activating the DMAC.

[5] Set CCR0.RIE, RE to 0.

Figure 33.20 Example flowchart of serial reception in asynchronous mode (non-FIFO selected) (1)

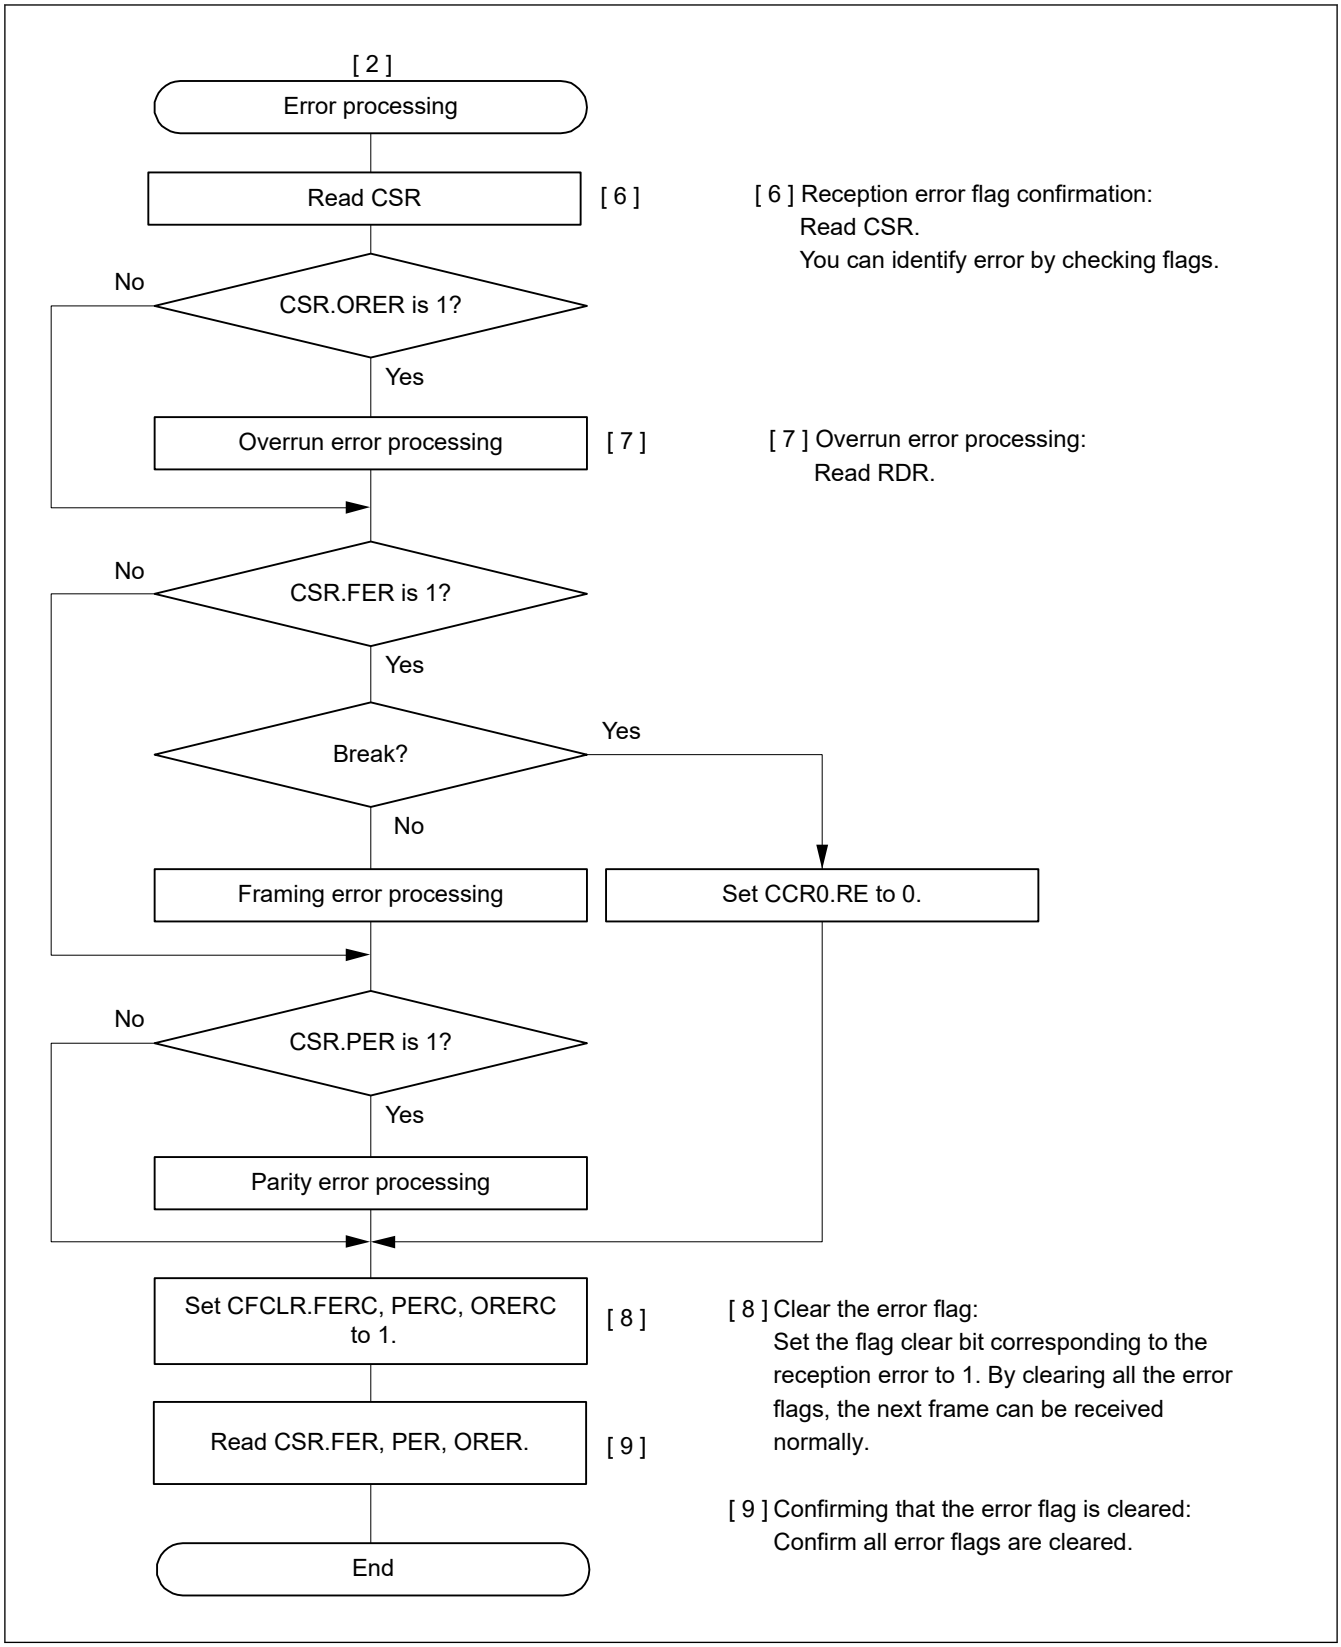


Figure 33.21 Example flowchart of serial reception in asynchronous mode (non-FIFO selected) (2)

(2) FIFO selected

Figure 33.22 shows an example of data format that is stored to receive FIFO (RDR) in asynchronous mode.

MPB (Receive FIFO (RDR) bit 9) is stored 0. Data is stored to receive FIFO (RDR) corresponded to data length. It is stored 0 for unused bits. If reading receive FIFO (RDR), SCI updates to next data which are FER, PER and receive data

(RDAT[8:0]) in receive FIFO. The flags which are BRK, RDRF, ORER and DR in receive FIFO, are always indicated to the flags corresponded to CSR register.

Data Length	Register Setting		Receive flag in RDR[31:0], MPB, RDAT[8:0]															
	CCR3.CHR[1:0]		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	1	–	–	–	FFER	FPER	DR	MPB	0	0	RDAT[6:0]						
8 bits	1	0	–	–	–	FFER	FPER	DR	MPB	0	RDAT[7:0]							
9 bits	0	x	–	–	–	FFER	FPER	DR	MPB	RDAT[8:0]								
	CCR3.CHR[1:0]		b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
7 bits	1	1	–	–	–	FER	PER	–	–	ORER	–	–	–	–	–	–	–	–
8 bits	1	0	–	–	–	FER	PER	–	–	ORER	–	–	–	–	–	–	–	–
9 bits	0	x	–	–	–	FER	PER	–	–	ORER	–	–	–	–	–	–	–	–

Note: The MPB flag, the RDR[9] bit, is always read as 0.
When a 7-bit data length is selected, the RDAT[8:7] bits are read as 00b.
When an 8-bit data length is selected, the RDAT[8] bit is read as 0.

Figure 33.22 Data format that is stored to receive FIFO (RDR) (FIFO selected)

Table 33.26 lists the states of the flags in CSR status register and receive data handling when a receive error is detected with FIFO selected. Figure 33.23 and Figure 33.24 show samples of flowcharts for serial data reception with FIFO selected.

In serial data reception, the SCI operates as described below.

1. When the value of CCR0.RE becomes 1, the output signal on the RTSn# pin goes to the low level in the case of RTS function use.
2. When the SCI monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in RSR, and checks the parity bit and stop bit.
3. If there is no space in RDR, CSR.ORER is set to 1. If CCR0.RIE is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to receive FIFO (RDR).
4. If a parity error is detected, CSR.PER is set to 1 and receive data is transferred to receive FIFO (RDR). If the CCR0.RIE is 1 at this time, an ERI interrupt request is generated.
5. If a framing error (when the stop bit is 0) is detected, CSR.FER is set to 1 and receive data is transferred to RDR. If CCR0.RIE is 1 at this time, an ERI interrupt request is generated.
6. After framing error is detected, when SCI detects that continuous receive data is 0 for 1 frame, reception stops.
7. When quantity of data stored in the receive FIFO data register (RDR) falls the specified receive triggering number, and that no next data has been received yet after the elapse of 15 etu from the last stop bit in asynchronous mode, FRSR.DR is set to 1. If RIE bit is set to 1, SCI occurs RXI interrupt request when FCR.DRES bit is 0 and SCI occurs ERI interrupt request when FCR.DRES = 1.
8. When reception finishes successfully, receive data is transferred to receive FIFO (RDR). RDRF is set to 1 when the quantity of receive data which is equal to or greater than the specified receive triggering number are stored in receive FIFO (RDR). If CCR0.RIE is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to receive FIFO (RDR) in this RXI interrupt handling routine before overrun error is occurred. Reading the received data that have been transferred to receive FIFO (RDR), and if it is less than RTS trigger number, causes the RTSn# pin to output the low level in the case of RTS function use.

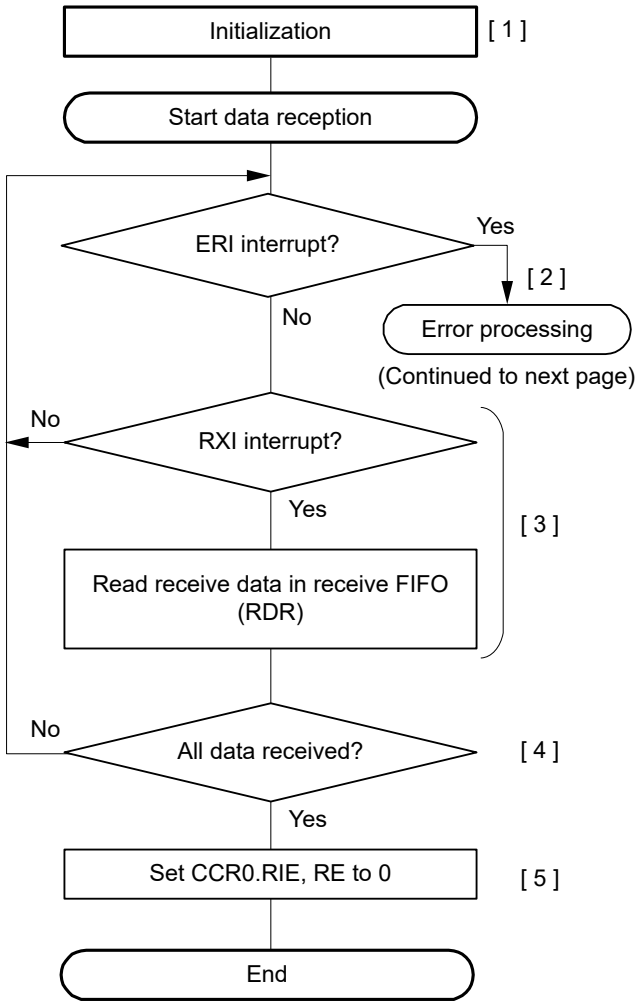
Table 33.26 Flags in the CSR status register and receive data handling (FIFO selected) (1 of 2)

CSR value			Receive FIFO (RDR)	
ORER	FER*1	PER*1	RDAT[8:0]	Receive Error Type
1	0	0	Lost	Overrun error
0	1	0	Transferred RDR	Framing error
0	0	1	Transferred RDR	Parity error

Table 33.26 Flags in the CSR status register and receive data handling (FIFO selected) (2 of 2)

CSR value			Receive FIFO (RDR)	
ORER	FER*1	PER*1	RDAT[8:0]	Receive Error Type
1	1	0	Lost	Overrun error + Framing error
1	0	1	Lost	Overrun error + Parity error
0	1	1	Transferred RDR	Framing error + Parity error
1	1	1	Lost	Overrun error + Framing error + Parity error

Note 1. This flag indicates whether there is an error in received data when reception is completed.



[1] Initialize SCI.
(Set CCR0.RE, RIE to 1.)

[2] Receive error processing and break detection:
If a receive error occurs, an ERI interrupt is generated. After performing the appropriate error processing, be sure to set the ORER, flags to 0. Reception cannot be resumed if ORER is set to 1. Reception can continue even if PER, FER, DR flags are 1.

[3] Read the receive data in the receive FIFO (RDR) in the RXI interrupt handling routine. The reception data stored in the receive FIFO (RDR) is read until the number of stored data will be below the FCR.RTRG value at least. You can confirm the number of the reception data in the FIFO by FRSR.R[5:0].

[4] Serial reception continuation procedure:
To continue serial reception, before an overrun error occurs, please read data from the receive FIFO (RDR) in the RXI interrupt handling routine and clear CSR.RDRF flag and FRSR.DR flag to 0. The receive FIFO data can also be read by activating the DMA. The RDRF flag is cleared automatically in this case, so please do not operate the RDRF flag.

[5] Set CCR0.RIE, RE to 0.

Figure 33.23 Example flowchart of serial reception in asynchronous mode (FIFO selected) (1)

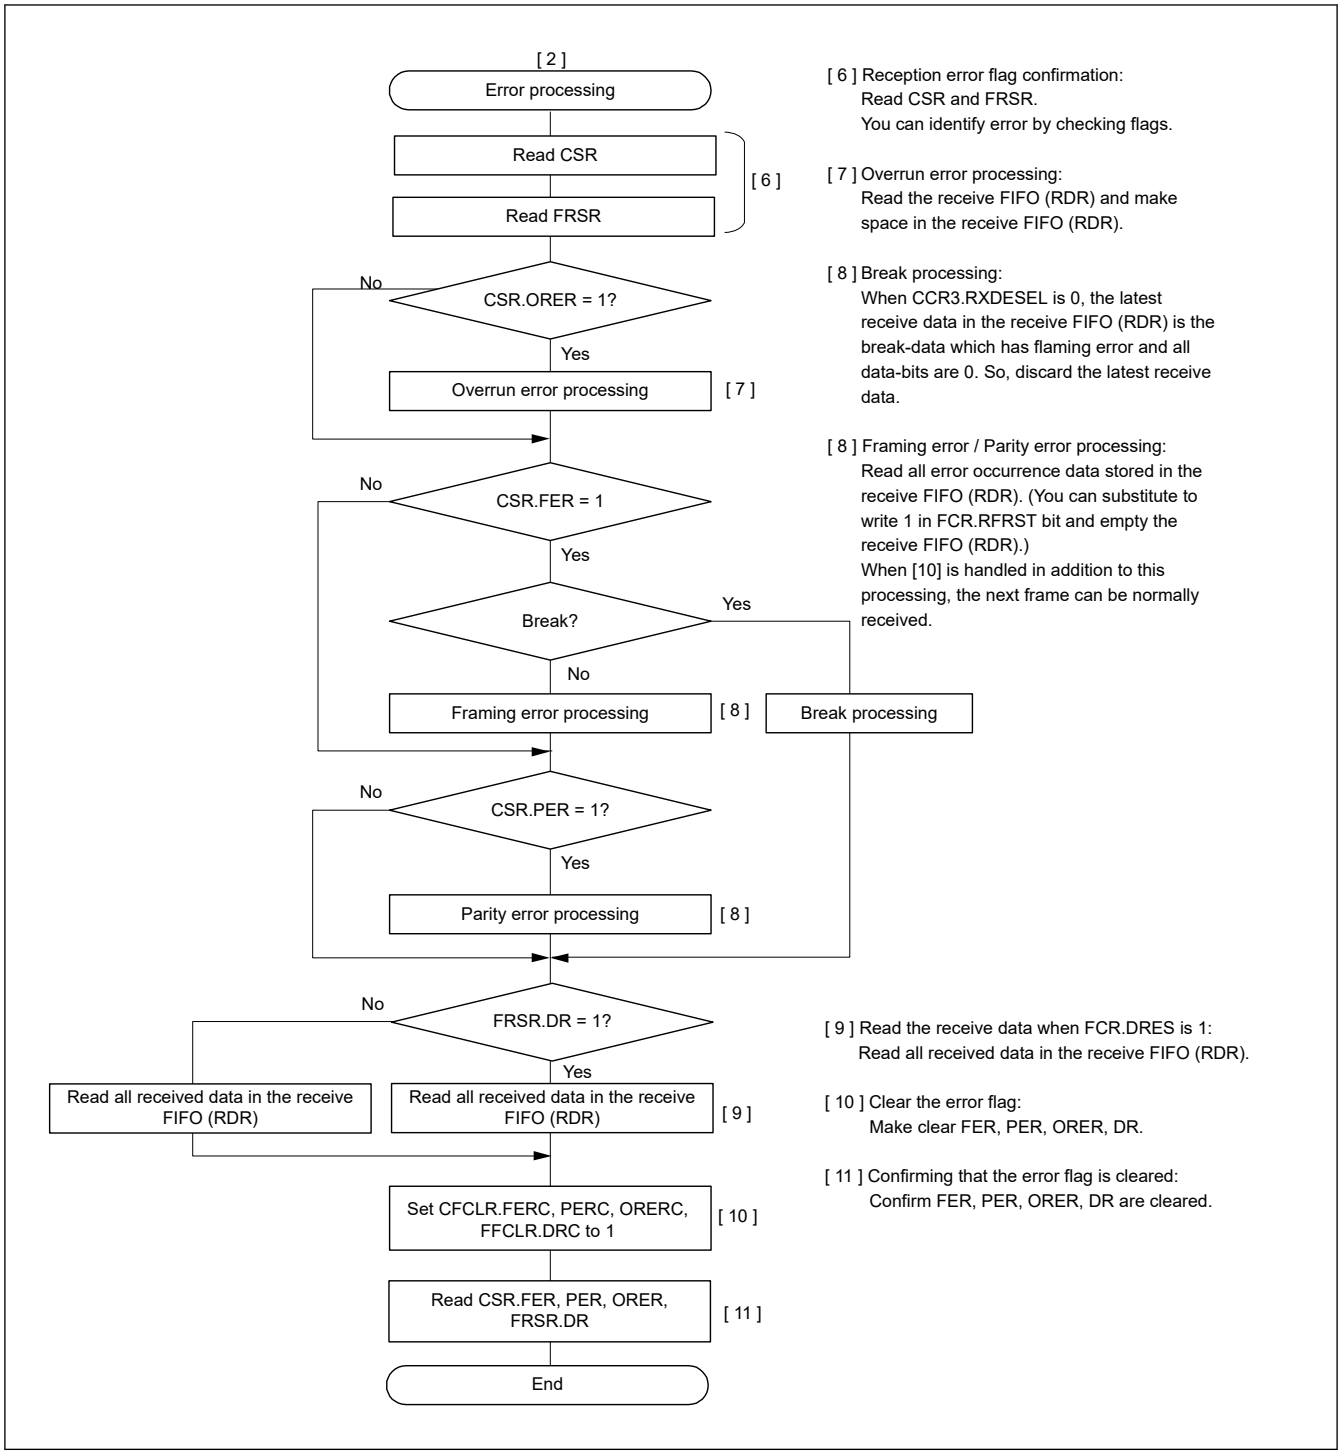


Figure 33.24 Example flowchart of serial reception in asynchronous mode (FIFO selected) (2)

33.4.10 The function of adjust receive sampling timing (Asynchronous Mode)

When there is the difference between the rising transfer time and the falling transfer time through a photo coupler, the receive sampling timing at middle of bit affects the reception margin. In this case, the receive sampling timing can adjust from the middle of bit to the optimum timing by using this function.

The receive sampling timing is adjusted from the middle of bit by following formula. And the adjustable direction is set by CCR4.AJD. You can select forward or backward from the middle of bit. When adjusting backward (CCR4.AJD = 0), substitute AJD = +1 and substitute AJD = -1 when adjusting forward (CCR4.AJD = 1).

Adjusted sampling timing = the middle of bit + AJD × (base clock × the setting value of CCR4.AST[2:0])

The setting timing is limited by base clock cycles per 1 bit. Please see Table 33.27 in detail.

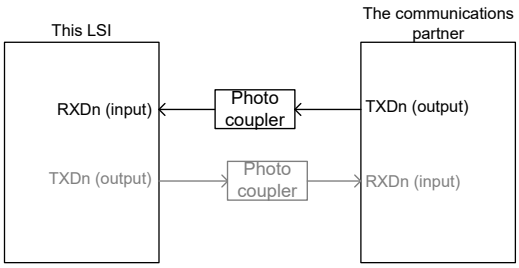
A reception movement image figure of the communication through a photo coupler with this function is shown in Figure 33.25 and Figure 33.26, the movement explanation of this function is shown in Figure 33.27.

Do not use this function when there is no difference between the rising transfer time and the falling transfer time, because there is a possibility of deteriorating the reception margin.

Table 33.27 The acceptable value of setting register (asynchronous mode using internal clock)

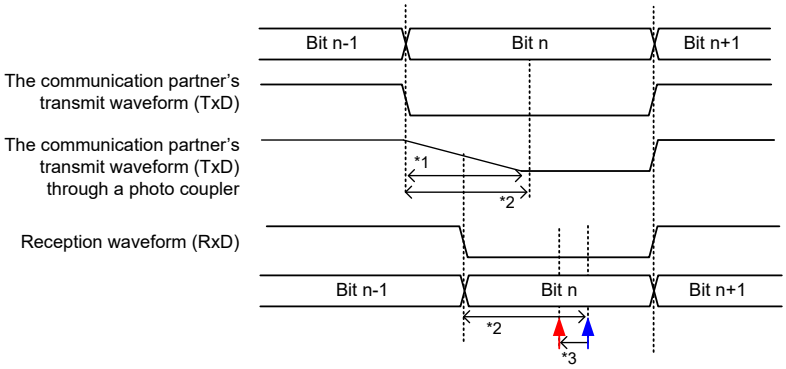
CCR2.ABCSE	CCR2.ABCS	The number of base cycles / 1 bit	The acceptable value	
			CCR4.AJD	CCR4.AST
1	x	6	0	000b to 010b*1
			1	
0	1	8	0	000b to 011b*1
			1	
0	0	16	0	000b to 111b
			1	

Note 1. When the value of CCR4.AST is over the acceptable value, sampling is done at default timing. (Adjustment of sampling is not done.)



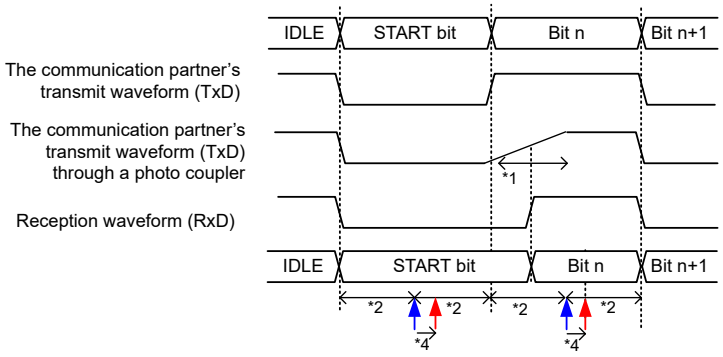
(a) In the case of the falling transfer time >> rising transfer time

The falling edge of reception waveform is made dull like following chart.
In this case, you can sampling at the middle of bit if you adjust the receive sampling timing to forward (AJD = 1b).



(b) In the case of the falling transfer time << rising transfer time

The rising edge of reception waveform is made dull like following chart.
So, the reception margin of communications partner will be bad. In this case, you can improve the reception margin if you adjust the receive sampling timing to back.



The receive sampling timing when unadjusted (middle of bit)

The adjusted receive sampling timing

Note 1. The dull period by a photo coupler

Note 2. Bit center timing at set communication rate

Note 3. When CCR4.AJD is 1, the receive sampling timing is shifted to forward by the setting value of CCR4.AST[2:0].

Note 4. When CCR4.AJD is 0, the Receive sampling timing is shifted to backward by the setting value of CCR4.AST[2:0].

Note: This waveform shows the operation image of adjustment receive sampling timing.

Figure 33.25 The reception movement image figure of the communication through a photo coupler

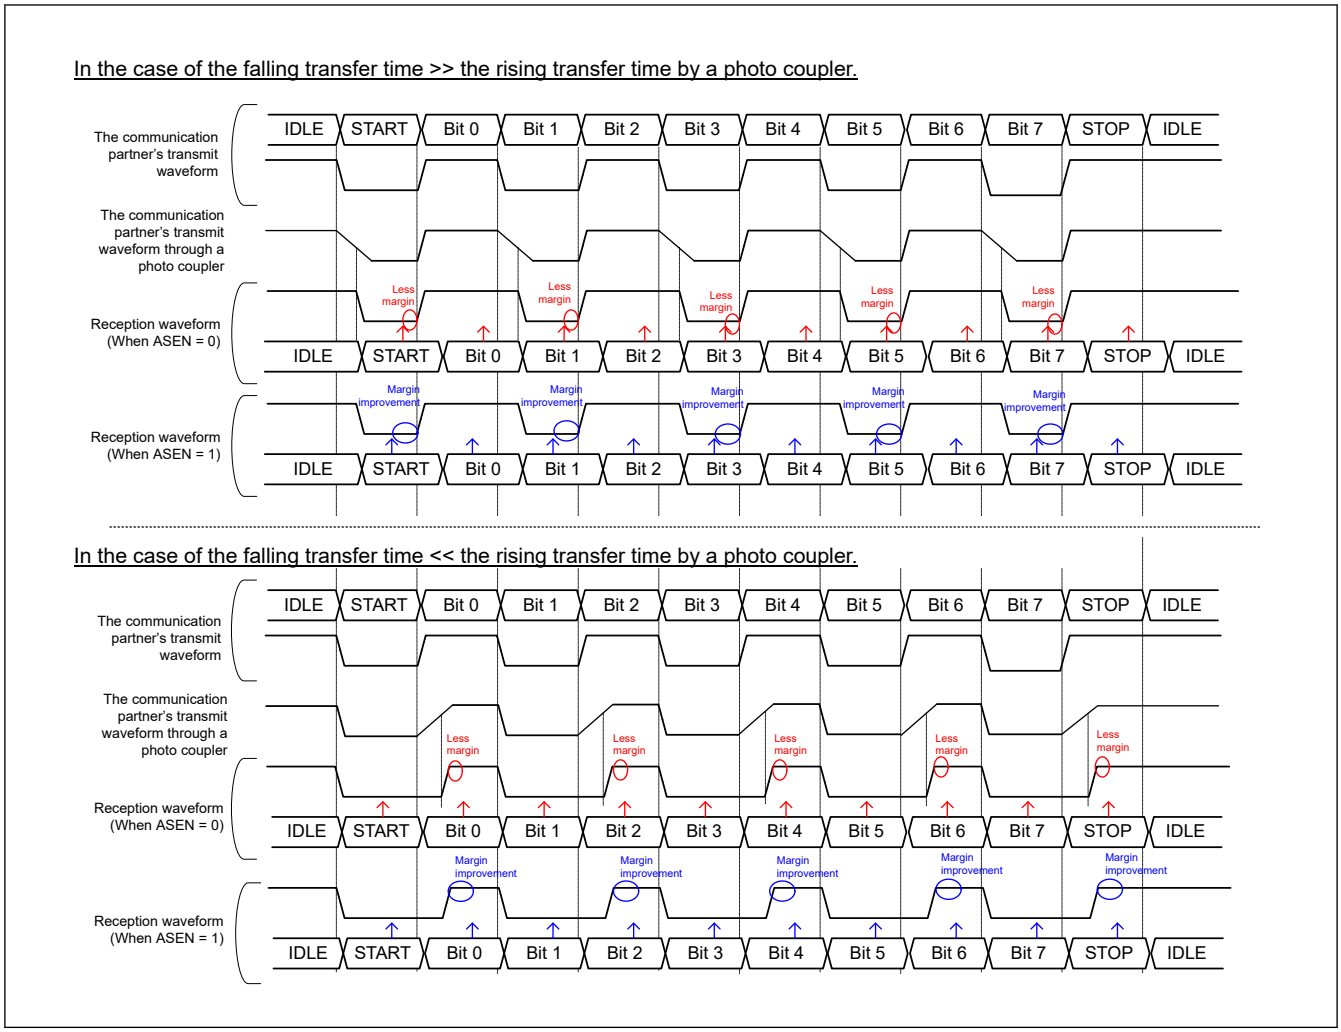


Figure 33.26 Improvement of reception margin when receive sampling timing adjustment function Image

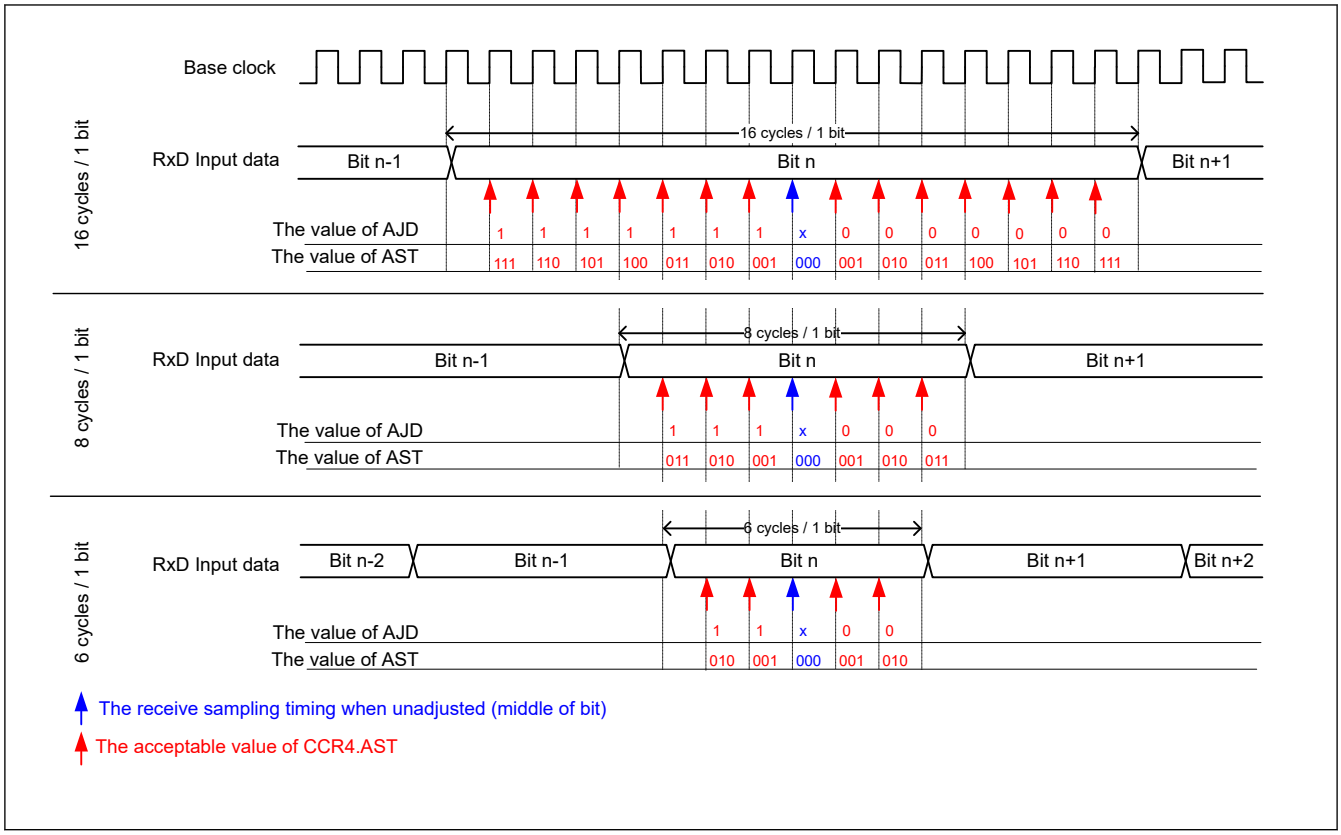

Figure 33.27 The adjustment operation explanation for the receive sampling timing (asynchronous mode using internal clock)

33.4.11 The function of adjust transmit timing (Asynchronous Mode)

In communication via a photo coupler or the like, when either the rising or falling transition time of the TxD output signal is long, then a communication partner receive dulled waveform. In this case, the reception margin may be affected.

In these cases, make a communication partner to be sampling at middle of bit using the function of adjust transmit timing. When CCR4.ATEN is 1, this function can adjust the edge timing at the timing calculated by the following formula for the edge set with CCR4.AET.

The adjustment edge timing = base clock × CCR4.ATT[2:0]

In addition, the upper limit of the adjustment edge timing is limited by setting the base clock cycles. For details, see Table 33.28.

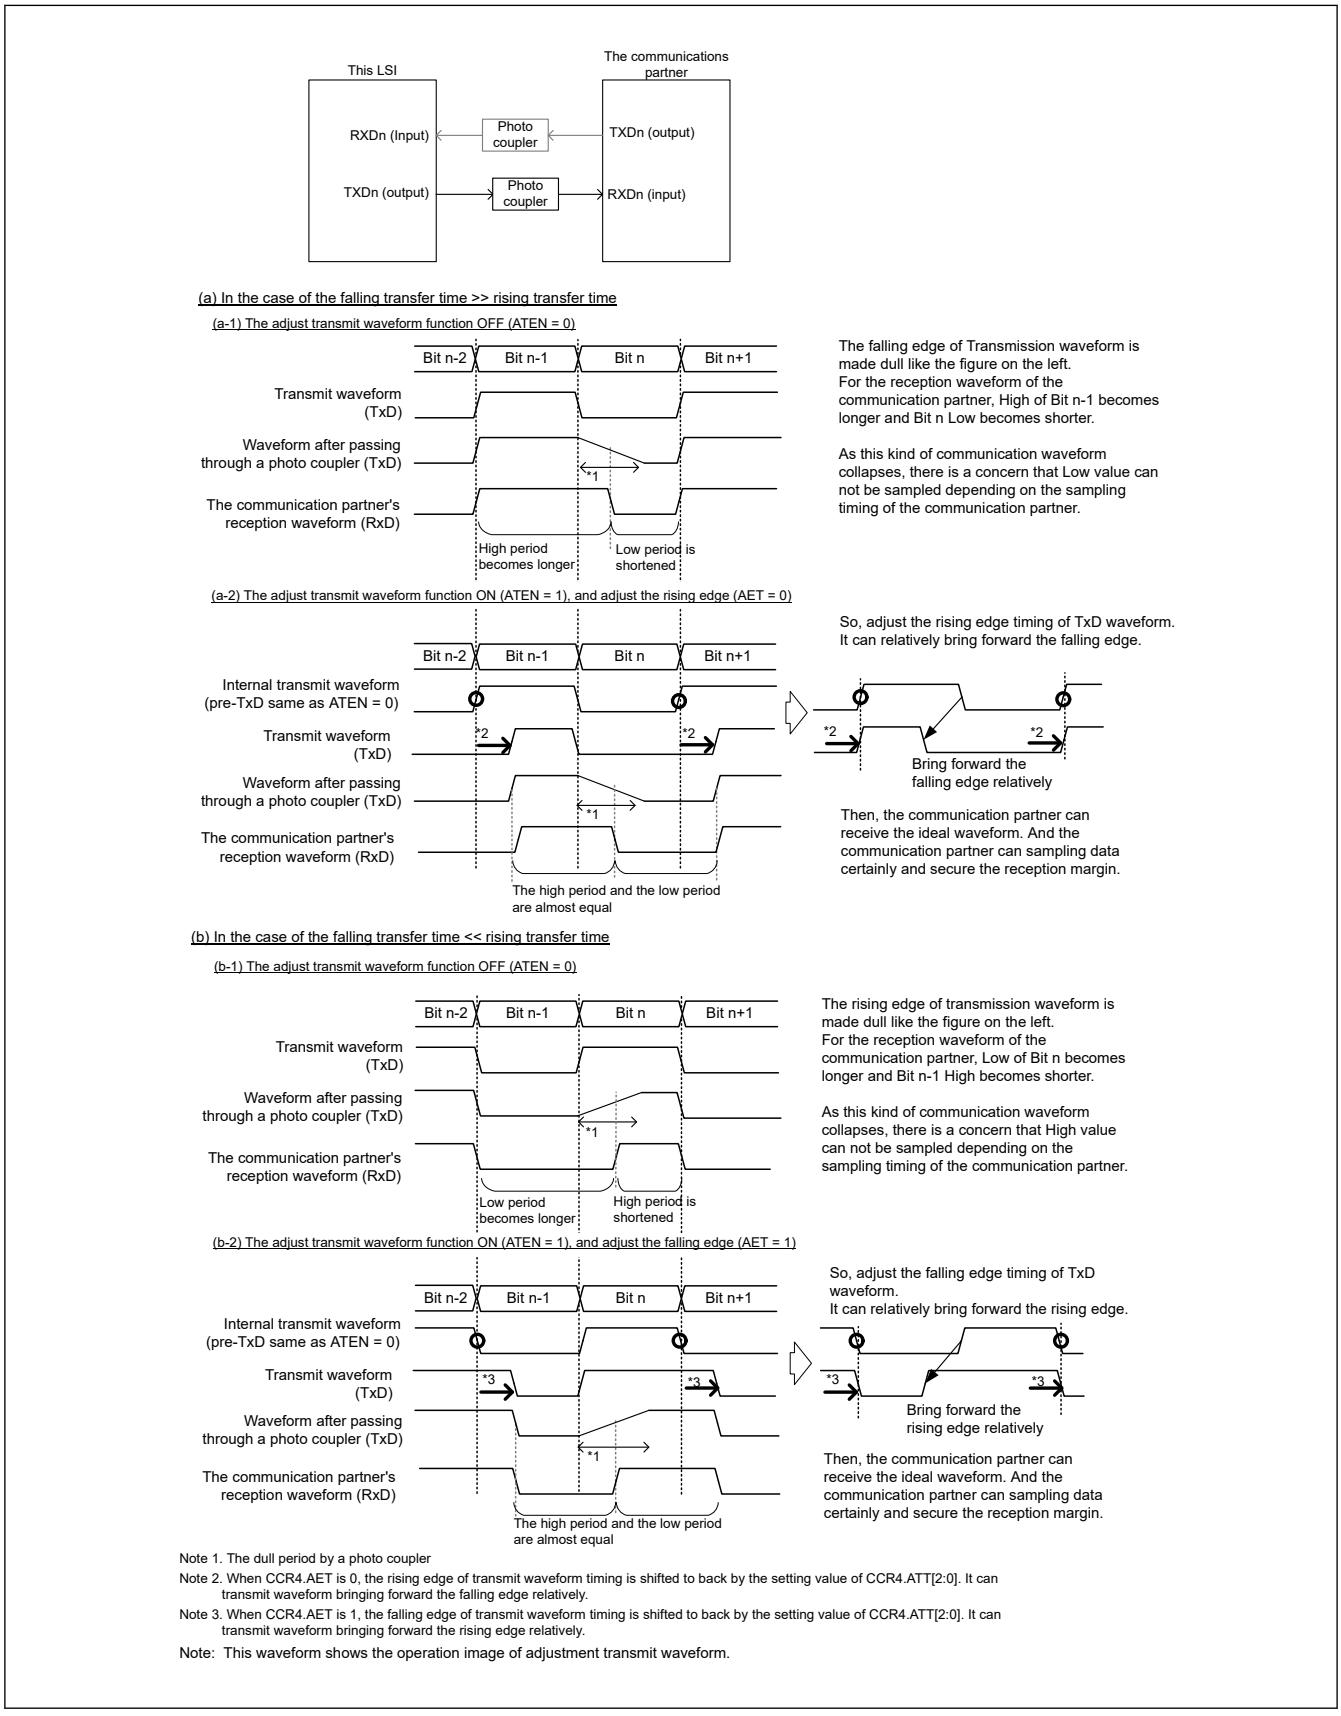
A transmission movement image figure of the communication through a photo coupler with this function is shown in Figure 33.28 and Figure 33.29, the movement explanation of this function is shown in Figure 33.30 and Figure 33.31.

Do not use this function when there is not the difference between the rising transfer time and the falling transfer time, there is a possibility of deteriorating the reception margin of a communication partner.

Table 33.28 The acceptable value of CCR4.AET and CCR4.ATT (asynchronous mode using internal clock)

ABCSE	ABCS	The number of base clock cycles / 1 bit	The acceptable value	
			AET	ATT[2:0]
1	x	6	0	000b to 101b
			1	
0	1	8	0	000b to 111b
			1	
0	0	16	0	000b to 111b
			1	

Note: When the value of CCR4.AET/ATT is out of the acceptable value, this module does not adjust transmit timing.



Note 1. The dull period by a photo coupler

Note 2. When CCR4.AET is 0, the rising edge of transmit waveform timing is shifted to back by the setting value of CCR4.ATT[2:0]. It can transmit waveform bringing forward the falling edge relatively.

Note 3. When CCR4.AET is 1, the falling edge of transmit waveform timing is shifted to back by the setting value of CCR4.ATT[2:0]. It can transmit waveform bringing forward the rising edge relatively.

Note: This waveform shows the operation image of adjustment transmit waveform.

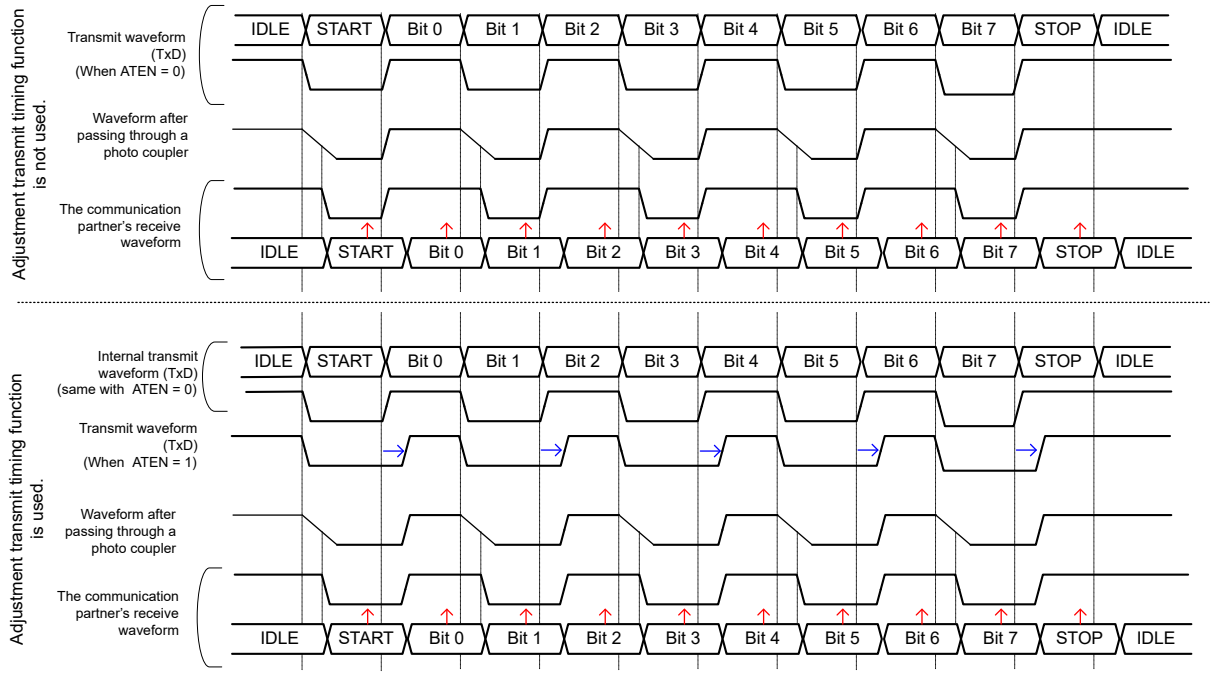
Figure 33.28 The transmission movement image figure of the communication through a photo coupler

The explanation of transmit waveforms of the communication through a photo coupler using adjust transmit timing function

When using the transmission timing adjustment function, adjust the edge timing of the transmission waveform and correct the reception waveform of the communication partner

The following example is 8 bit long data.

(a) In the case of the falling edge transfer time >> the rising transfer time



(b) In the case of the falling edge transfer time << the rising transfer time

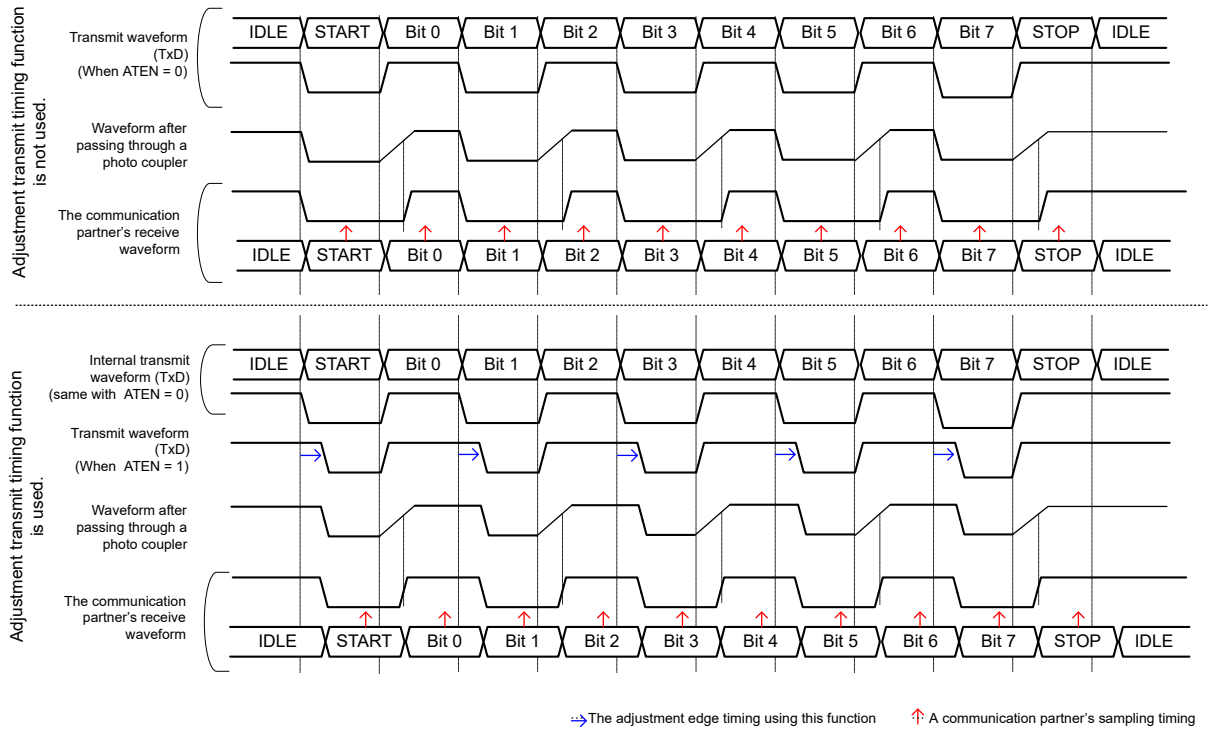


Figure 33.29 The explanation for the transmit waveform through a photo coupler

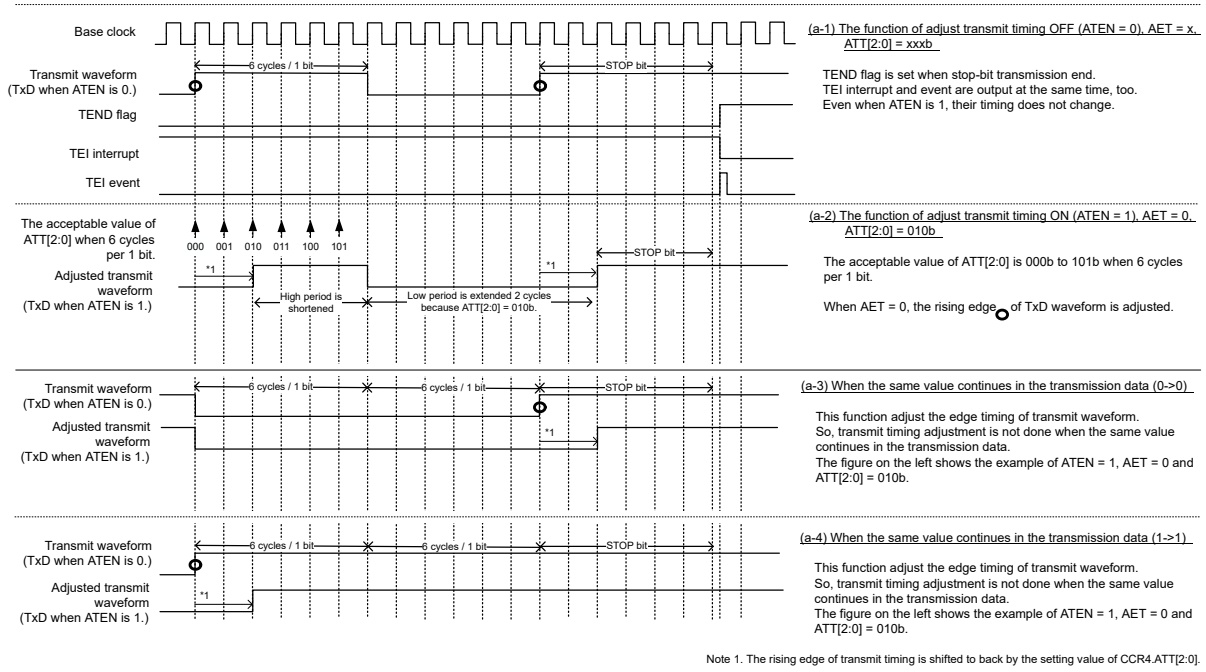
The operation explanation of adjustment the transmit timing

(a) In the case of the falling transfer time >> rising transfer time

In this case, the high period of a communication partner's reception waveform is made long, and the low period is made short.
Therefore, the LSI transmits the waveform with the falling edge relatively brought forward by adjusting the rising edge timing.
Then adjust value (ATT[2:0]) should be set to make equal the low-period/1 bit and high-period/1 bit for a communication partner.

This function's operation is explained as an example of 6 cycles/1 bit.



Note 1. The rising edge of transmit timing is shifted to back by the setting value of CCR4.ATT[2:0].

Figure 33.30 The adjustment operation explanation for the transmit timing when AET is 0

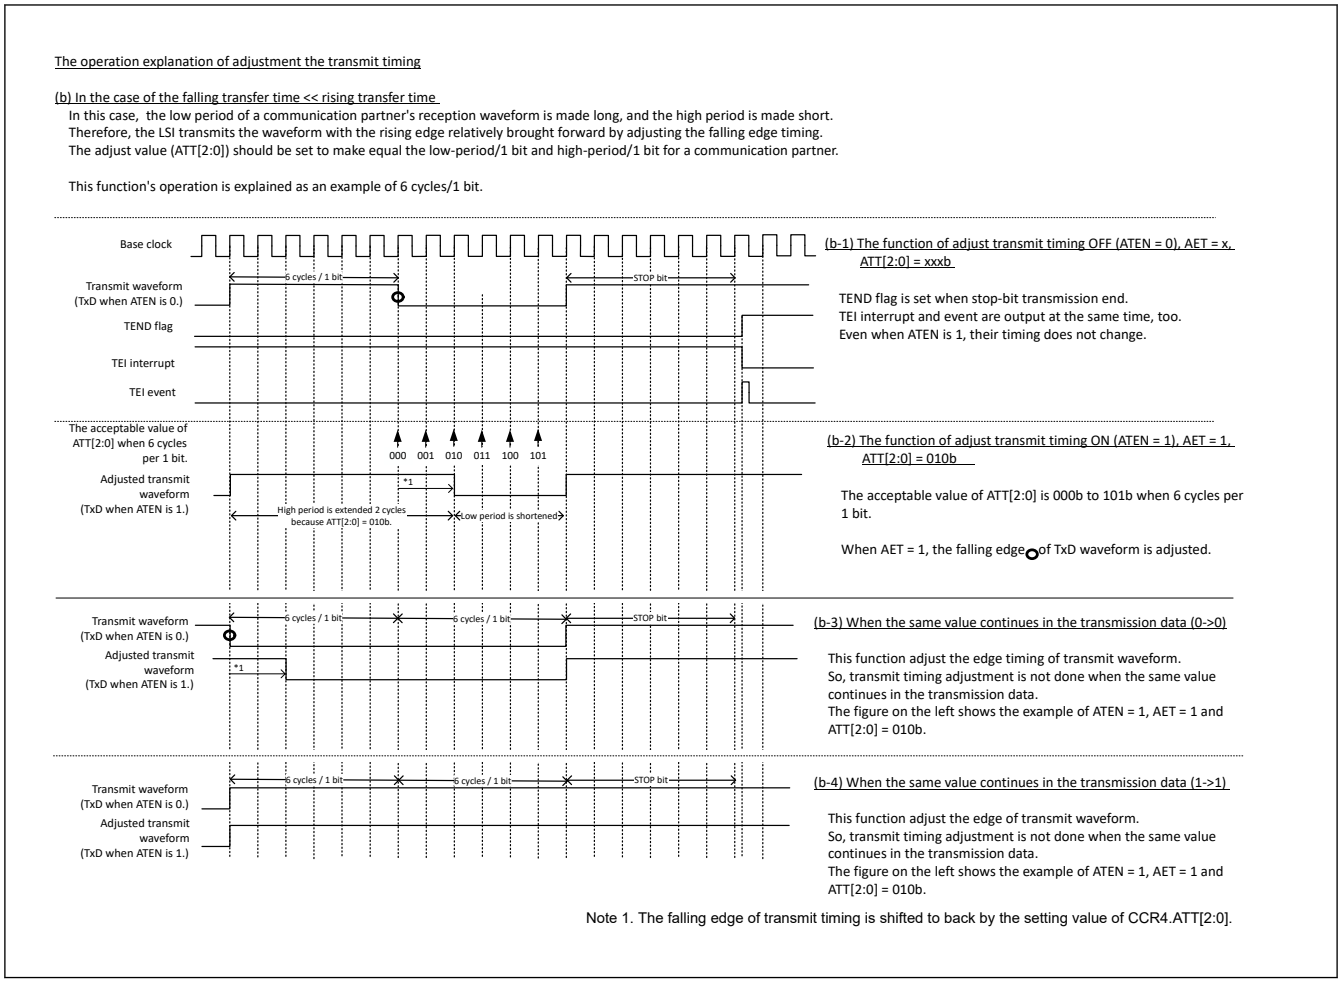


Figure 33.31 The adjustment operation explanation for the transmit timing when AET is 1

33.5 Multi-Processor Communication Function

Using the multi-processor communication functions enables to transmit and receive data by sharing a communication line between multiple processors by using asynchronous serial communication in which the multi-processor bit is added. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station. The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle. When the multi-processor bit is set to 1, it indicates the ID transmission cycle and when the multiprocessor bit is set to 0, it indicates the data transmission cycle. Figure 33.32 shows an example of communication between processors by using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits the communication data in which the multi-processor bit set to 0 is added to the transmit data. On receiving the communication data in which the multi-processor bit is set to 1, the receiving station compares the received ID with the ID of the receiving station itself and if the two matches, receives the communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until again receiving the communication data in which the multi-processor bit is set to 1.

RTS control cannot be used at the time of multi-processor communication function use, because this is a function corresponding to one-to-many communications.

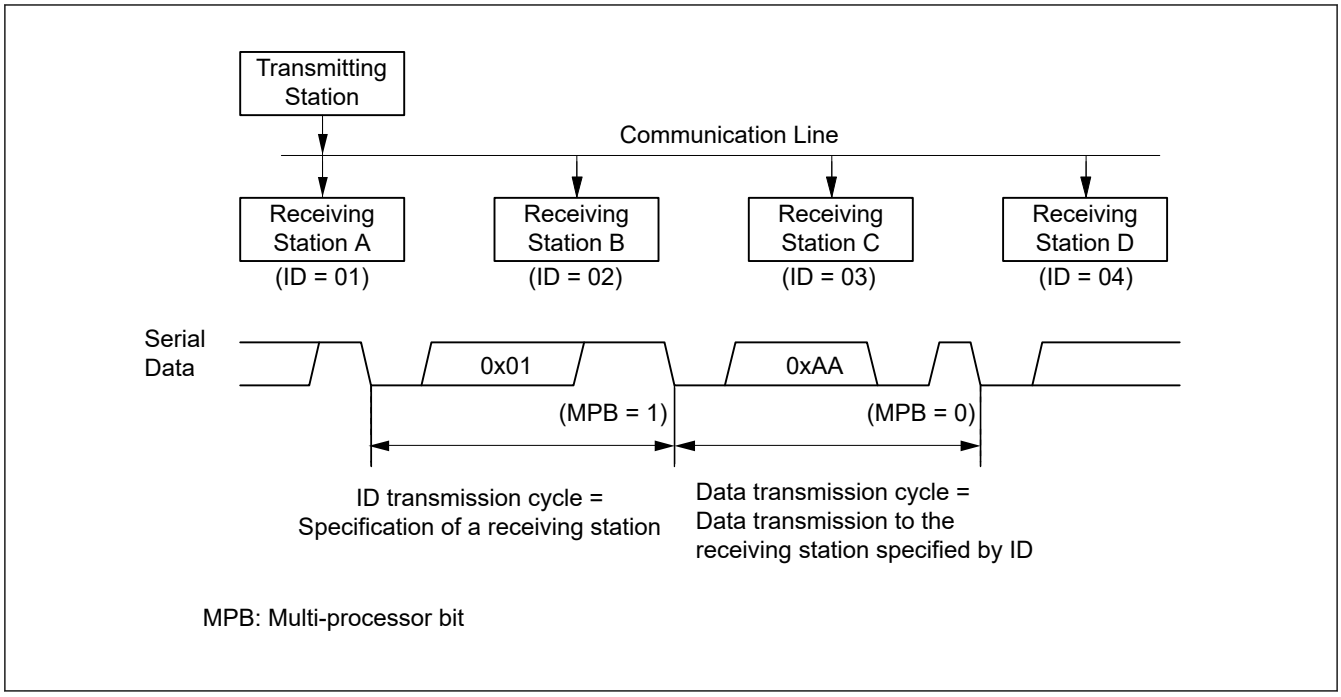

Figure 33.32 An example of communication using the multi-processor format (example of transmission of data 0xAA to receiving station A)

(1) Non-FIFO selected

For supporting this function, the SCI provides the MPIE bit in CCR0. When the MPIE bit is set to 1, transfer of receive data from the RSR to the RDR, detection of a receive error, and setting the respective status flags RDRF, ORER, and FER in CSR are disabled until reception of data in which the multi-processor bit is set to 1.

On receiving a reception character in which the multi-processor bit is set to 1, the MPB bit in RDR is set to 1 and the MPIE bit in CCR0 is automatically cleared, thus returning to a non-multi-processor reception operation. At this time, an RXI interrupt is generated if the RIE bit in CCR0 is set.

When the multi-processor format is specified, specification of the parity bit is disabled.

Apart from this, there is no difference from the operation in the non-multi-processor asynchronous mode. A clock which is used for the multi-processor communication is also the same as the clock used in the non-multi-processor asynchronous mode.

(2) FIFO selected

For transmission, it should write to TDR.MPBT (Multi-Processor Bit Transfer) which corresponds to transmit data in TDR.TDAT. For reception, Multi-processor bit that is a part of receive data, is stored to RDR.MPB, and receive data is stored to RDR.RDAT. When the MPIE bit is set to 1, transfer of receive data from the RSR to the RDR.RDAT, detection of a receive error, and detection of DR, and setting the respective status flags RDRF, ORER, and FER in CSR are disabled until reception of data in which the multi-processor bit is set to 1.

On receiving a reception character in which the multi-processor bit is set to 1, the MPB bit in RDR is set to 1, and receive data is stored to receive FIFO (RDR.RDAT), and the MPIE bit in CCR0 is automatically cleared, thus returning to a non-multi-processor reception operation. At this time, an RXI interrupt is generated if the RIE bit in CCR0 is set.

When the multi-processor format is specified, specification of the parity bit is disabled. Apart from this, there is no difference from the operation in the non-multi-processor asynchronous mode and non-FIFO selected.

33.5.1 Multi-Processor Serial Data Transmission

(1) Non-FIFO selected

Figure 33.33 shows a sample flowchart of multi-processor data transmission. In the ID transmission cycle, the ID should be transmitted with the MPBT bit in TDR set to 1. In the data transmission cycle, the data should be transmitted with the MPBT bit set to 0. The other operations are the same as the operations in asynchronous mode.

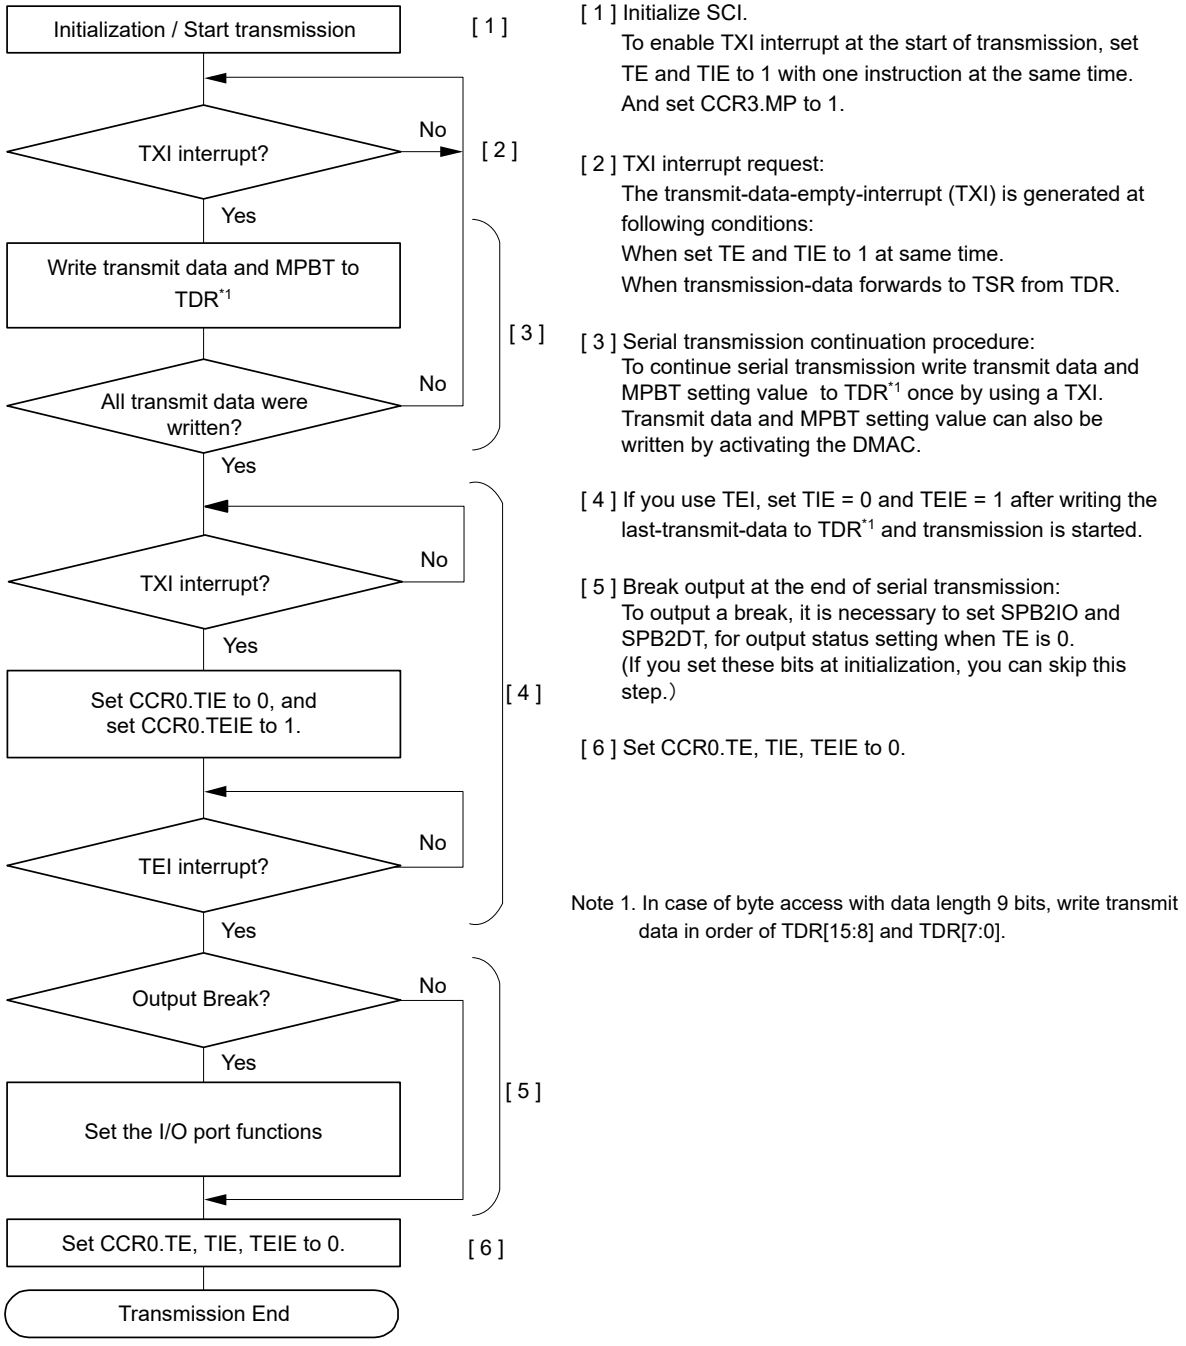

Figure 33.33 Example of multi-processor serial transmission flowchart (non-FIFO selected)

(2) FIFO selected

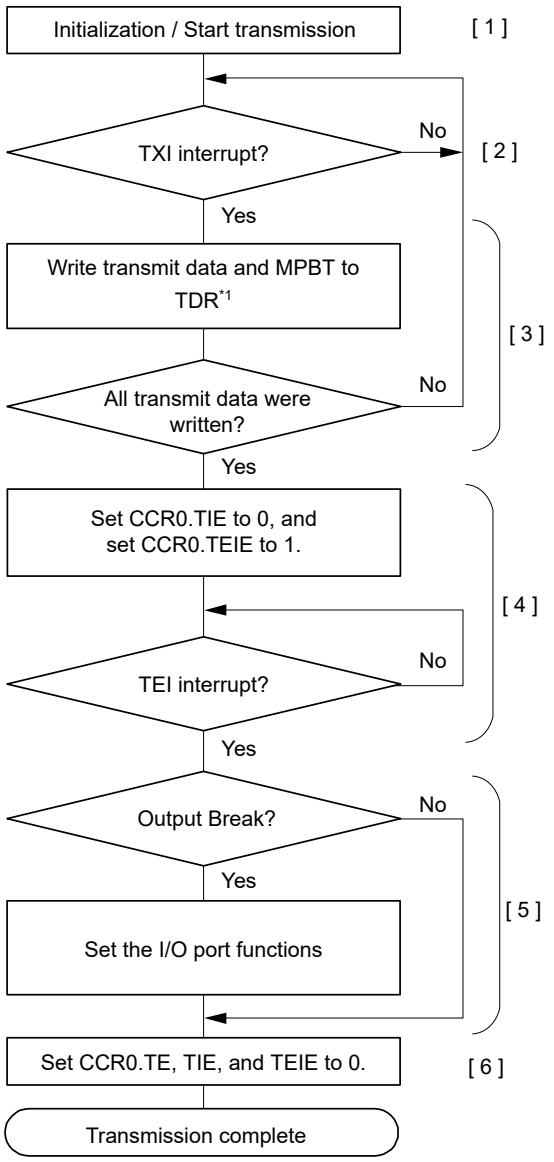
Figure 33.34 shows an example of data format that is written to transmit FIFO (TDR.TDAT) in multi-processor mode. Write MPBT in bit 9 of TDR. And write data to transmit FIFO (TDR.TDAT) corresponded to data length. It should write to 0 for unused bits.

Data Length	Register setting		Transmit data in TDR[15:0]															
	CCR3. CHR[1:0]		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	1	–	–	–	–	–	–	MPBT	–	–	TDAT[6:0]						
8 bits	1	0	–	–	–	–	–	–	MPBT	–	TDAT[7:0]							
9 bits	0	x	–	–	–	–	–	–	MPBT	TDAT[8:0]								

Note: The bits Indicated by "—" are not used. Therefore, those bits should be set to 0.

Figure 33.34 Data format in multi-processor mode that is written to transmit FIFO (TDR.TDAT)

Figure 33.35 shows a sample flowchart for multi-processor data transmission with FIFO selected. In the ID transmission cycle, the ID should be transmitted with the MPBT bit in TDR set to 1. In the data transmission cycle, the data should be transmitted with the MPBT bit set to 0. The other operations are the same as the operations in asynchronous mode with FIFO selected.



[1] Initialize SCI.
To enable TXI interrupt at he start of transmission, set TE and TIE to 1 with one instructions at the same time. And set CCR3.FM and MP to 1.

[2] TXI interrupt request:
The transmit-data-empty-interrupt (TXI) is generated when transmission-data forwards to TSR from the transmit FIFO (TDR) and the number of transmit-data written in the transmit FIFO is equal to or less than the transmit FIFO threshold.

[3] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data and MPBT setting value to the transmit FIFO (TDR) by using a TXI interrupt. Transmit data and MPBT setting value can also be written to the transmit FIFO (TDR) by activating the DMAC.

[4] If you use TEI, set TIE = 0 and TEIE = 1 after writing the last-transmit-data to TDR*1.

[5] Break output at the end of serial transmission:
To output a break, it is necessary to set SPB2IO and SPB2DT, for output status setting when TE is 0.
(If you set these bits at initialization, you can skip this step.)

[6] Set CCR0.TE, TIE, and TEIE to 0.

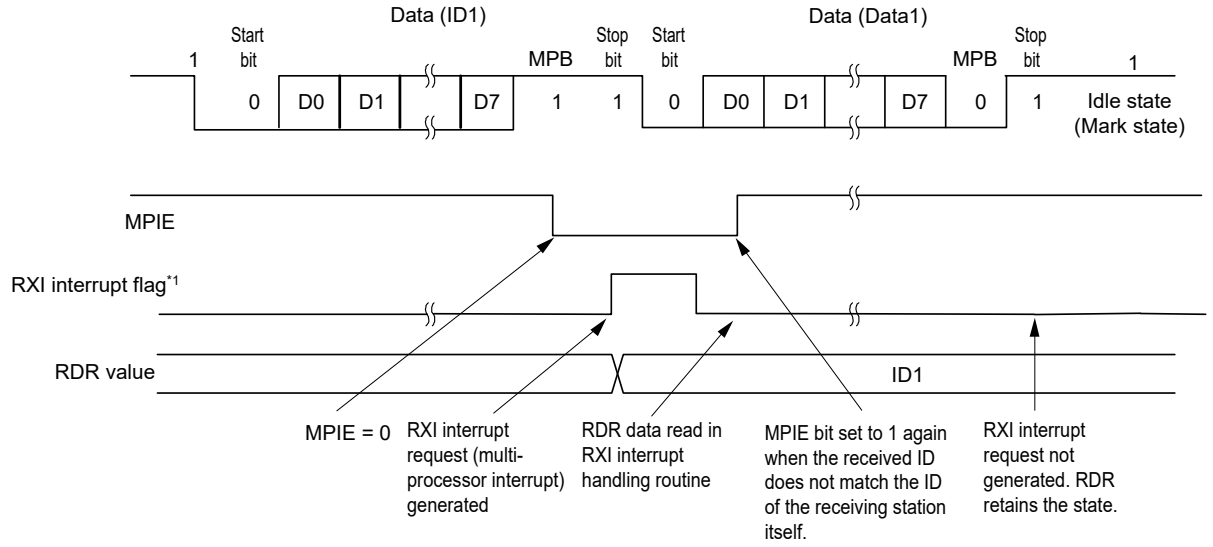
Note 1. In case of byte access with data length 9 bits, write transmit data in order of TDR[15:8] and TDR[7:0].

Figure 33.35 Example of serial transmission flowchart in multi-processor mode (FIFO selected)

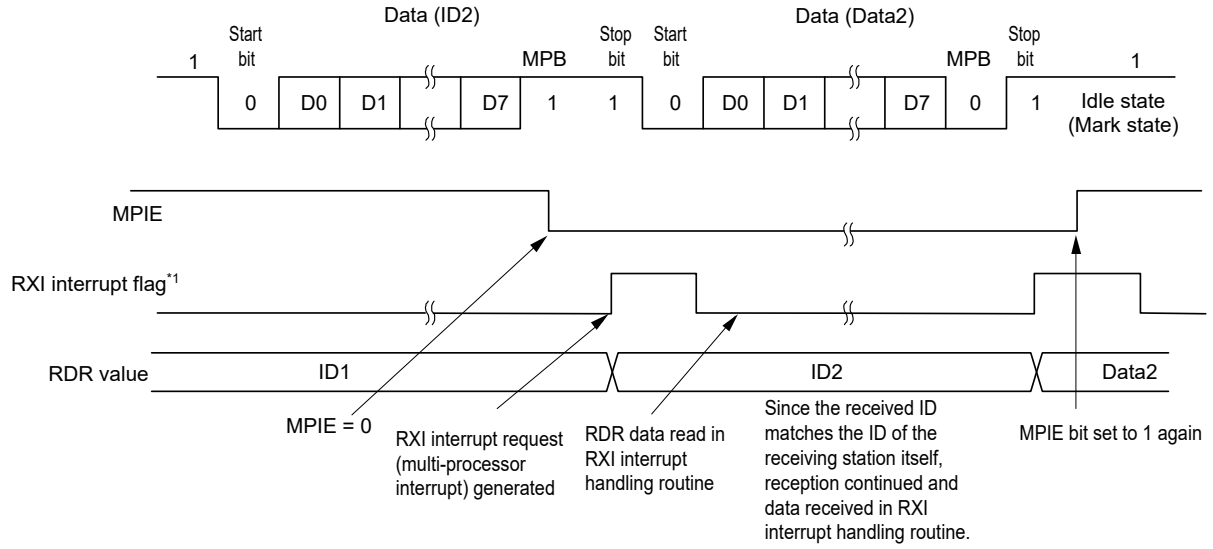
33.5.2 Multi-Processor Serial Data Reception

(1) Non-FIFO selected

Figure 33.37 and Figure 33.38 are sample flowcharts of multi-processor data reception. When the MPIE bit in CCR0 is set to 1, reading the communication data is skipped until reception of the communication data in which the multi-processor bit is set to 1. When the communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to RDR. At this time, the RXI interrupt request is generated. The other operations are the same as the operations in asynchronous mode. Figure 33.36 is the example of operation for reception.



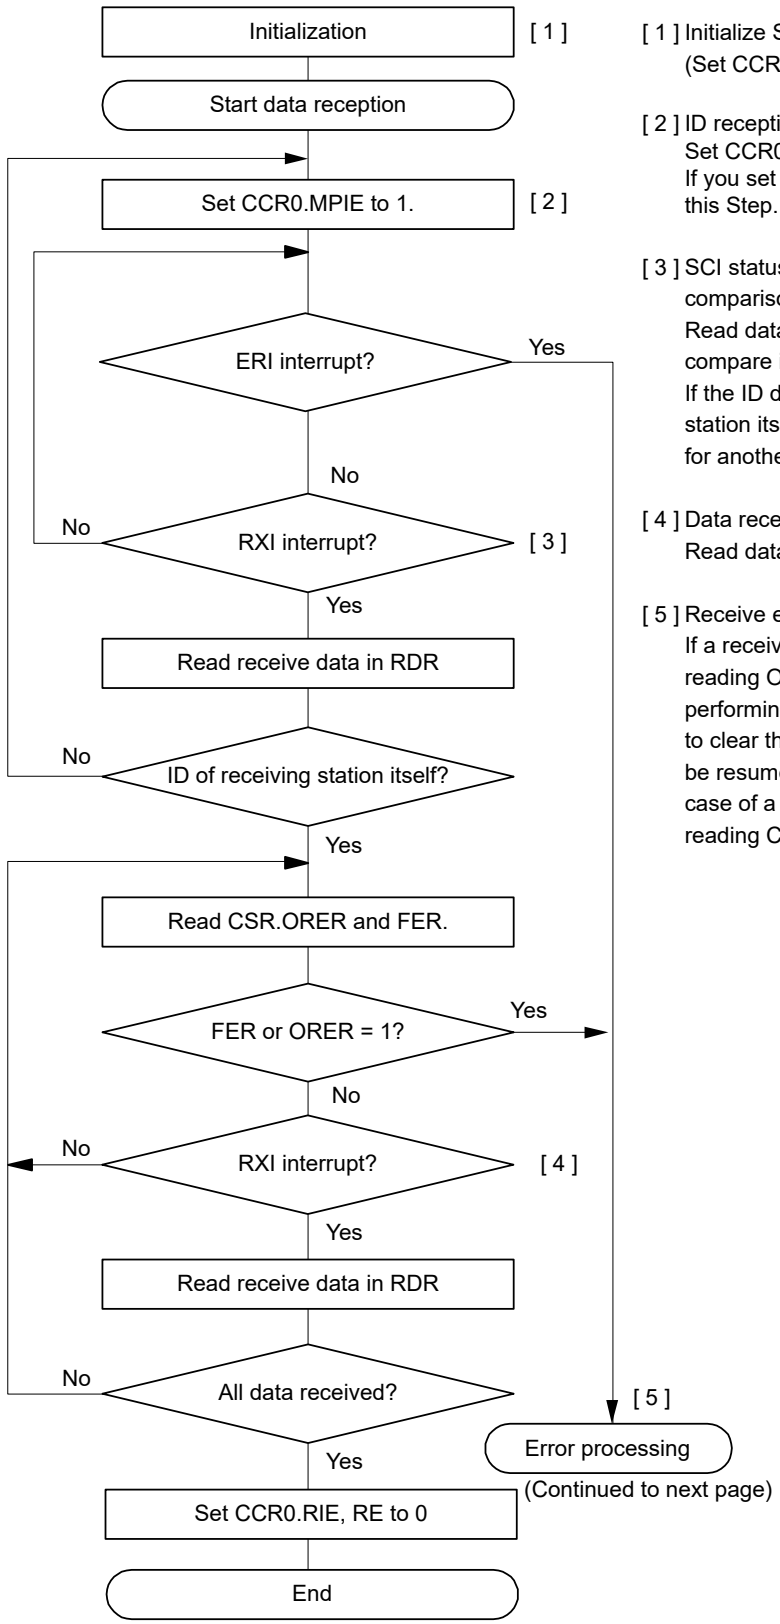
(a) When the received ID does not match the ID of the receiving station itself



(b) When the received ID matches the ID of the receiving station itself

Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.36 Example of SCI reception (8-bit data/multi-processor bit/1 stop bit)



[1] Initialize SCI.
(Set CCR0.RE, RIE to 1. And set CCR3.MP to 1.)

[2] ID reception cycle:
Set CCR0.MPIE to 1. and wait for ID reception.
If you set this bits at initialization ([1]), you can skip this Step.

[3] SCI status confirmation and reception and comparison of ID:
Read data in RDR at the first RXI interrupt and compare it with the ID of the receiving station itself.
If the ID does not match the ID of the receiving station itself, set the MPIE bit to 1 again, and wait for another RXI interrupt request.

[4] Data reception at an RXI interrupt:
Read data in RDR once in the RXI interrupt routine.

[5] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading ORER and FER flags in CSR. After performing the appropriate error processing be sure to clear the ORER and FER flags. Reception cannot be resumed if any of these flags is set to 1. In the case of a framing error, a break can be detected by reading CSR.RXDMON bit.

Figure 33.37 Example of multi-processor serial reception flowchart (1) (non-FIFO selected)

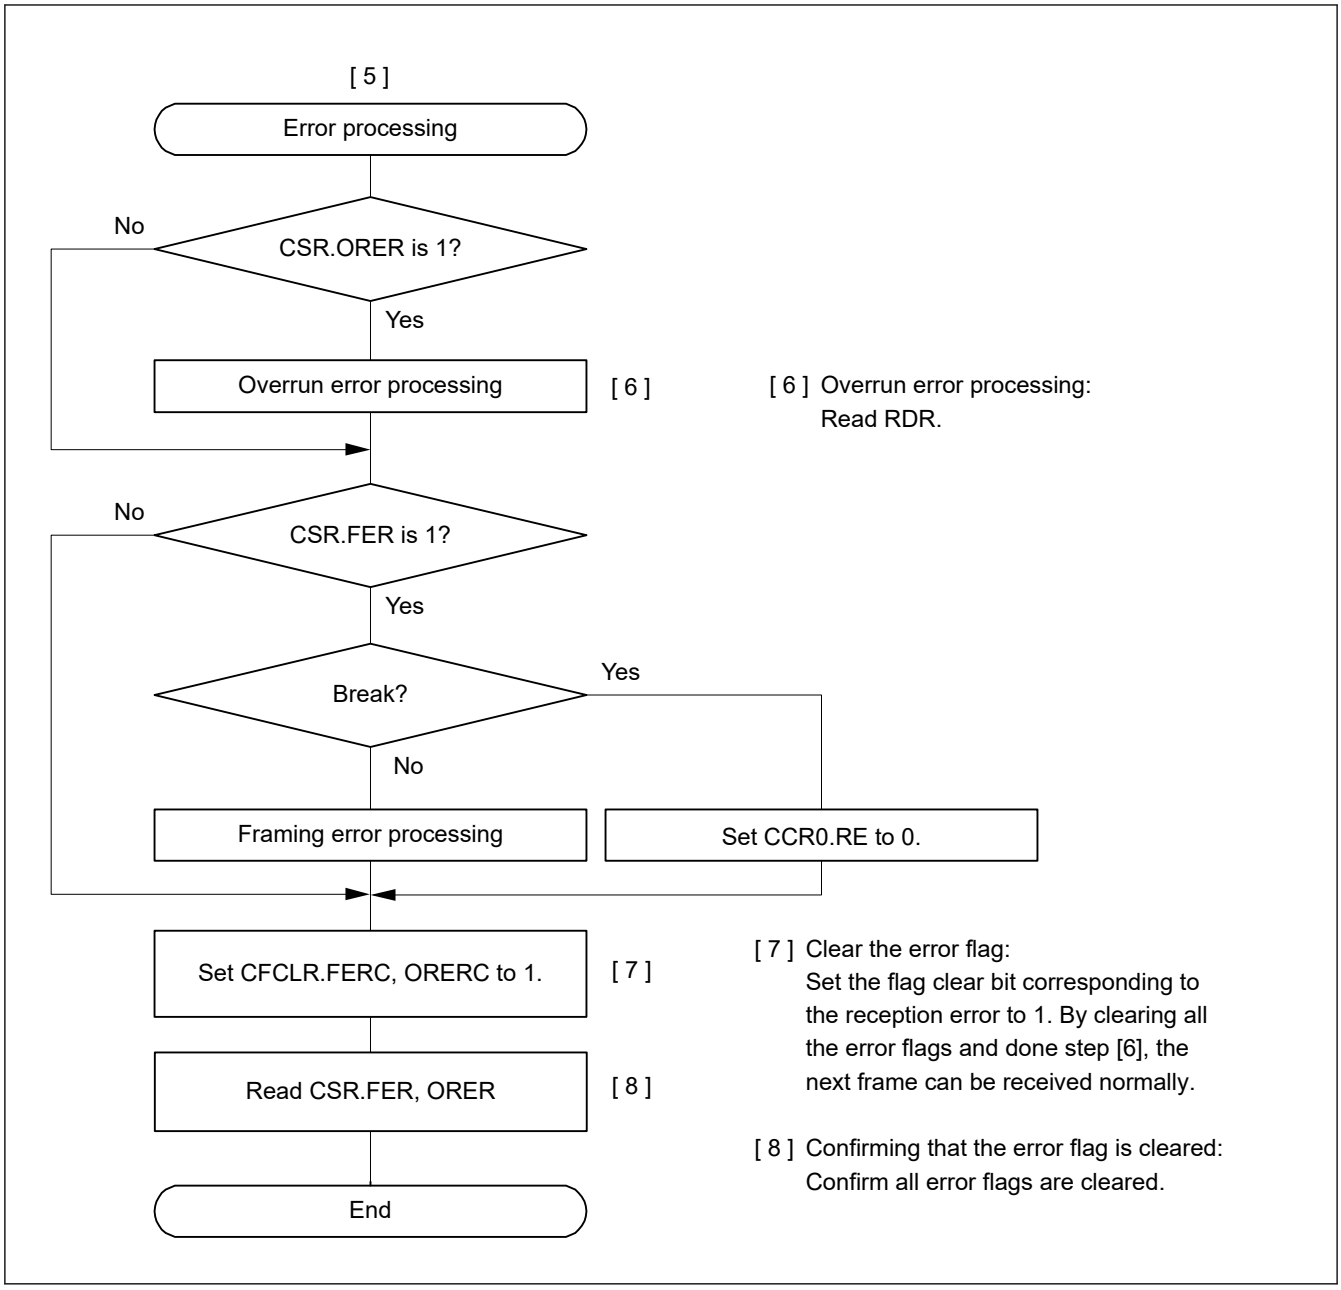


Figure 33.38 Example of multi-processor serial reception flowchart (2) (non-FIFO selected)

(2) FIFO selected

Figure 33.39 shows an example of data format that is stored to receive FIFO (RDR) in multi-processor mode. MPB is stored in bit 9 of RDR. 0 is stored to FPER and PER flag bit. Data is stored to receive FIFO (RDR) corresponded to data length. It is stored to 0 for unused bits. Reading the receive FIFO (RDR register) updates the FFER, FPER, MPB flags and receive data (RDAT[8:0]) in the receive FIFO (RDR register) with the next received data. The FER, PER, and ORER flags in the receive FIFO (RDR register) always reflect the status of the corresponding flags in the CSR and FRSR registers.

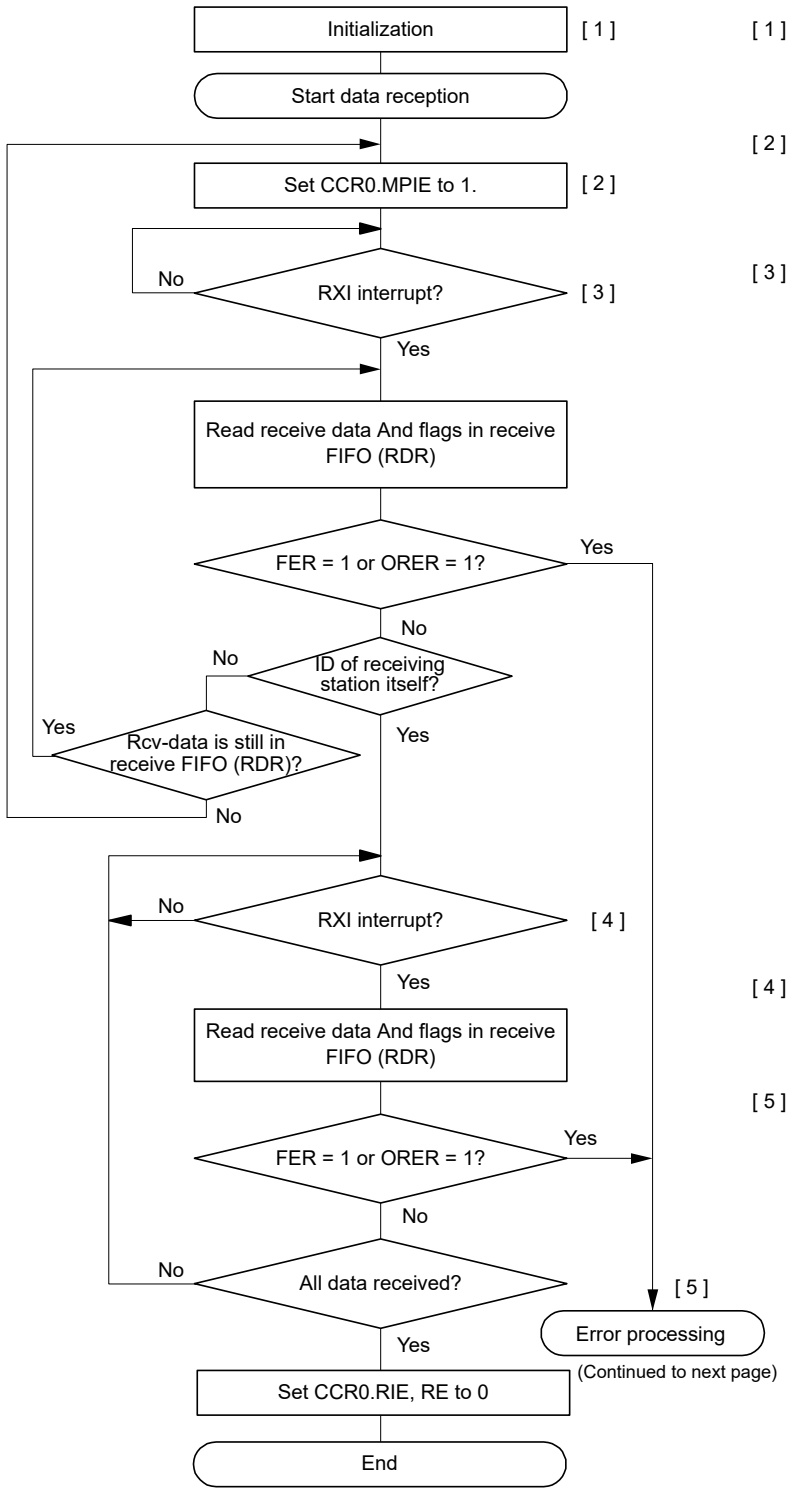
Data Length	Register Setting CCR3.CHR[1:0]		Receive data in RDR[31:0] b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	1	0	0	0	FFER	FPER	DR	MPB	0	0	RDAT[6:0]						
8 bits	1	0	0	0	0	FFER	FPER	DR	MPB	0	RDAT[7:0]							
9 bits	0	x	0	0	0	FFER	FPER	DR	MPB	RDAT[8:0]								
Data Length	CCR3.CHR[1:0]		b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
7 bits	1	1	0	0	0	FER	PER	0	0	ORER	0	0	0	0	0	0	0	0
8 bits	1	0	0	0	0	FER	PER	0	0	ORER	0	0	0	0	0	0	0	0
9 bits	0	x	0	0	0	FER	PER	0	0	ORER	0	0	0	0	0	0	0	0

Note: When a 7-bit data length is selected, the RDAT[8:7] bits are always read as 00b.
When an 8-bit data length is selected, the RDAT[8] bit is always read as 0.

Figure 33.39 Data format in multi-processor mode that is stored to receive FIFO (FIFO selected)

Figure 33.40 shows a sample flowchart for multi-processor data reception at FIFO selected. When the MPIE bit in CCR0 is set to 1, reading the communication data is skipped until reception of the communication data in which the multiprocessor bit is set to 1. When the communication data in which the multi-processor bit is set to 1 is received, the received data, MPB, and each errors are transferred to receive FIFO (RDR), and the MPIE bit in CCR0 is automatically cleared, thus returning to a normal reception operation. After a framing error occurred and CSR.FER flag is set to 1, but SCI continues data reception.

The other operations are the same as the operations in asynchronous mode at non-FIFO selected.



[1] Initialize SCI.
(Set CCR0.RE, RIE to 1.
And set CCR3.MP and FM to 1.)

[2] ID reception cycle:
Set CCR0.MPIE to 1. and wait for ID reception. If you set this bits at Initialization ([1]), you can skip this Step.

[3] SCI status confirmation and reception and comparison of ID:
The subsequent receive data including the data with MPB bit 1 is stored in receive FIFO (RDR). When the number of receive data stored in the receive FIFO (RDR register) reaches or exceeds the receive FIFO threshold, the CSR.RDRF flag is set to 1 and an RXI interrupt request is generated. When quantity of data stored in the receive FIFO data register (RDR) falls the specified receive triggering number and received data is equal to or greater than 1, and that no next data has been received yet after the elapse of 15 etus from the last stop bit, FRSR.DR is set to 1. Read data in receive FIFO (RDR) at the first RXI interrupt, and compare it with the ID of the receiving station itself. If the ID does not match the ID of the receiving station itself, it reads until the data with MPB = 1, and compares next ID. If it is not a data with MPB = 1 in receive FIFO (RDR), it is set the MPIE bit to 1 again, and wait for another RXI interrupt request.

[4] Data reception at an RXI interrupt:
Read data in the receive FIFO (RDR) once in the RXI interrupt routine.

[5] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading ORER and FER flags in CSR. After performing the appropriate error processing be sure to clear the ORER and FER flags. In the case of a framing error, a break can be detected by reading the CSR.RXDMON bit.

Figure 33.40 Example flowchart of serial reception in multi-processor mode (1) (FIFO selected)

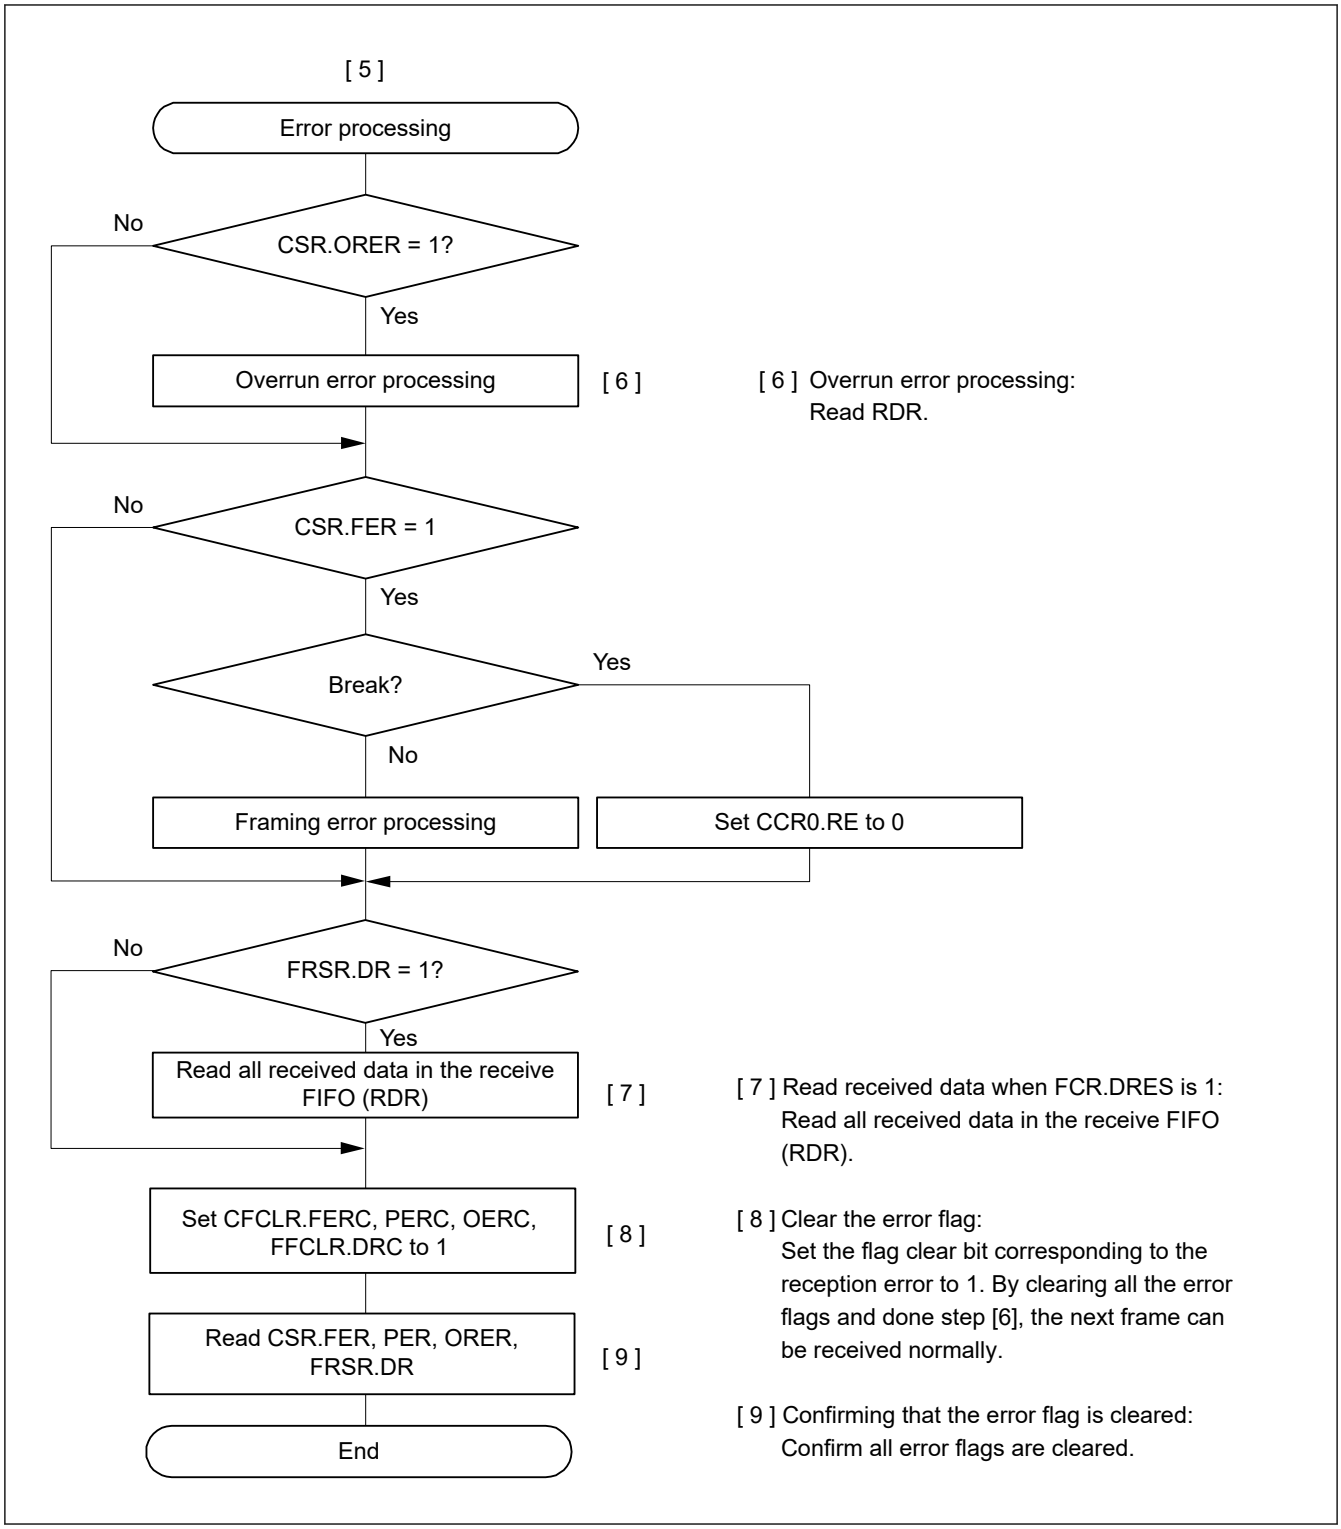


Figure 33.41 Example flowchart of serial reception in multi-processor mode (2) (FIFO selected)

33.6 Manchester Mode

In Manchester mode, the transmit or receive serial data is coded in Manchester encoding.

Figure 33.42 shows the conceptual image of Manchester encoding.

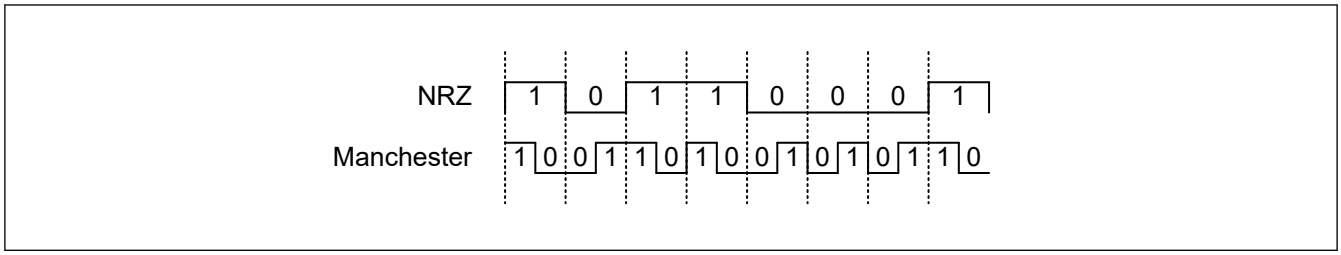

Figure 33.42 Example of Manchester encoding

In Manchester mode, a preface and a start bit area are added to the transmit data in the register to configure a transmit frame. For transmission, data is encoded in Manchester encoding. When data is received, frames having the same format as transmitted frames are detected and Manchester decoding is performed.

33.6.1 Frame Format

Figure 33.43 shows the frame format in Manchester mode. In the upper half of the figure, relevant setting registers are shown. The preface area and the data area are encoded in Manchester encoding.

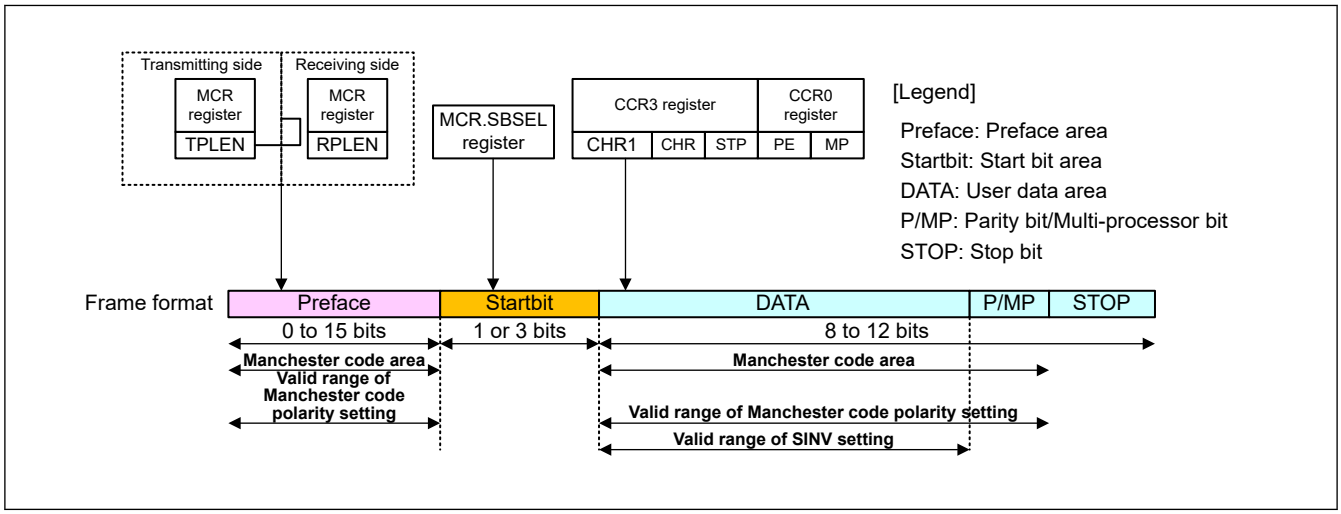

Figure 33.43 Frame format in Manchester mode

(1) Preface area

This is a fixed pattern area located at the beginning of each frame. Different registers are used to set the preface area for transmission and reception. The preface length is determined by setting MCR.TPLEN[3:0] for transmission. It is determined by setting MCR.RPLEN[3:0] for reception.

If it is set to 0, the transmit preface is disabled and is not added. If it is set to 1d to 15d, a preface whose length is determined by this setting is added. (For example, if it is set to 1d, a 1-bit preface is added. If it is set to 15d, a 15-bit preface is added.)

In addition, the preface pattern can be changed by setting, and it can be selected from four types of patterns by setting MCR.TPPAT[1:0] for transmission and MCR.RPPAT[1:0] for reception.

Figure 33.44 shows how the preface pattern is set. The preface area and the start bit area are added for each communication frame.

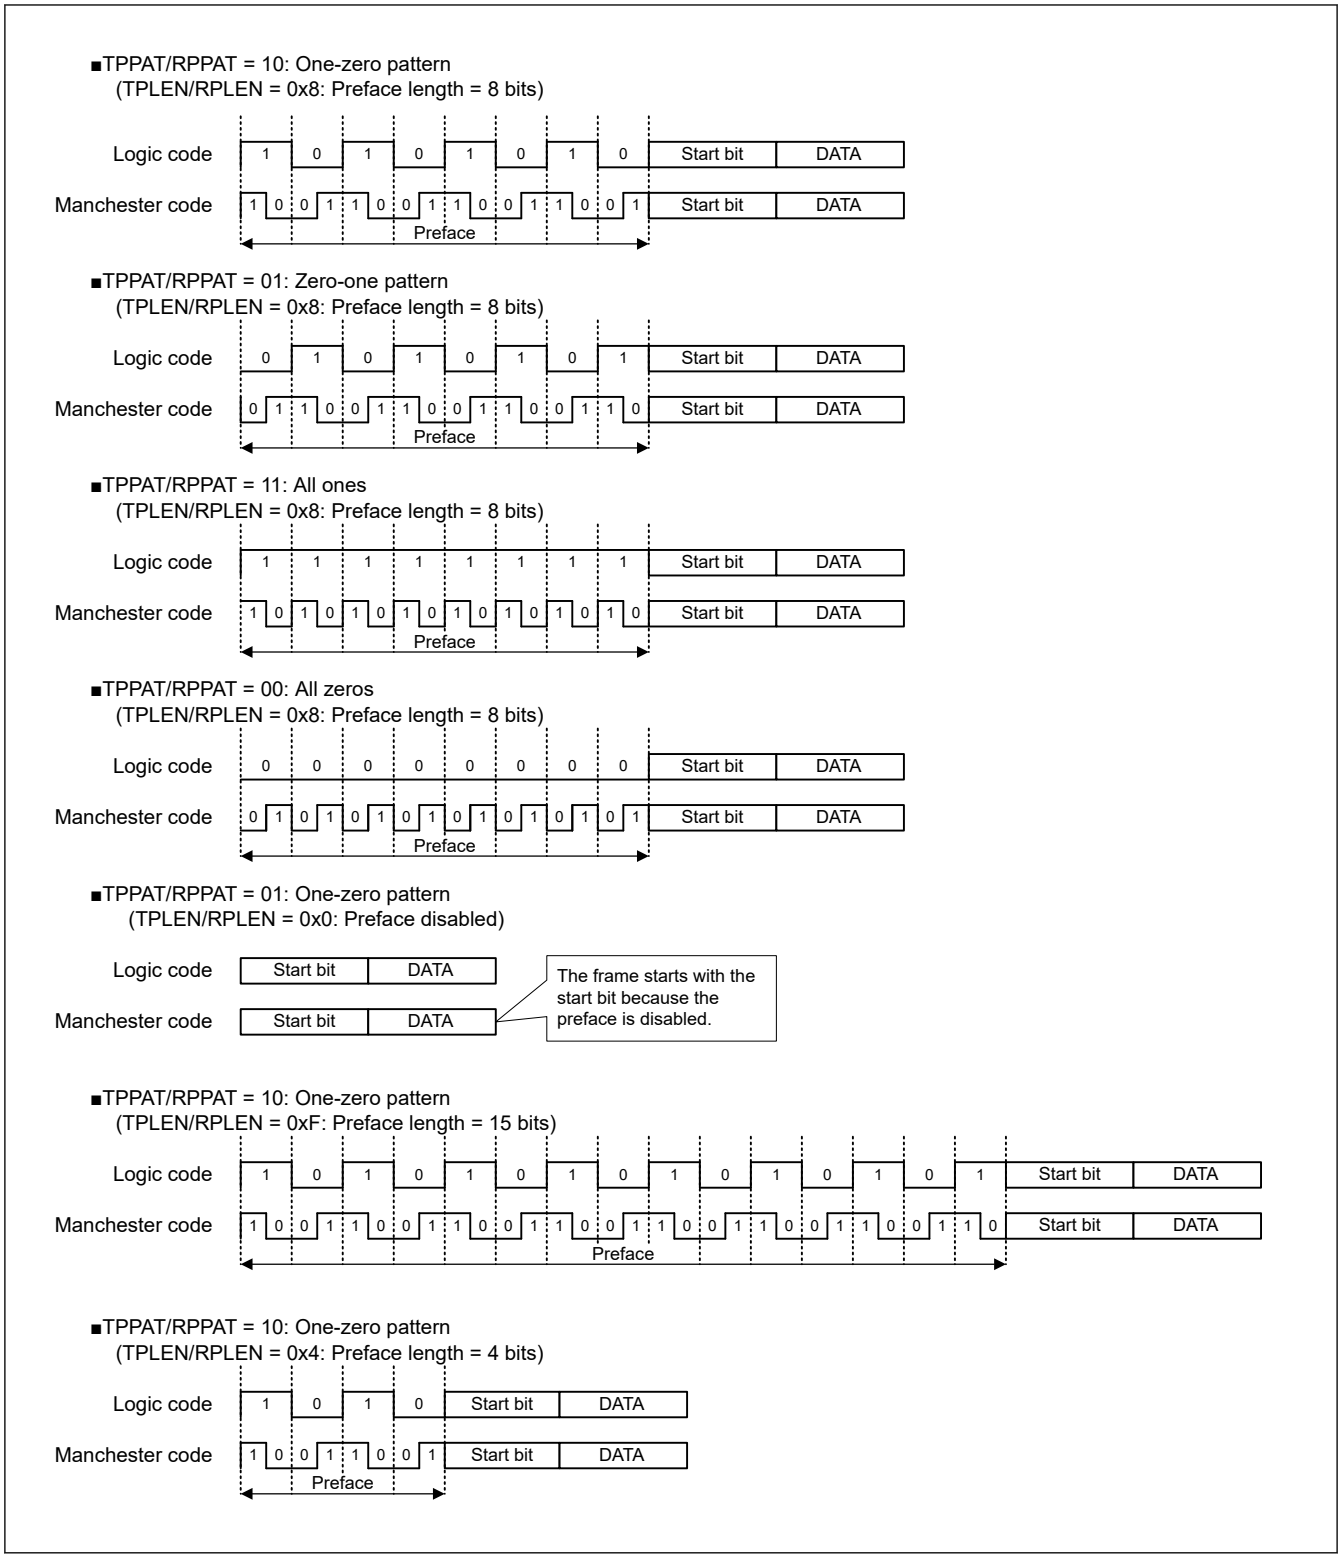

Figure 33.44 Preface pattern setting example

(2) Start bit area

This is an area indicating the start of valid data in a frame. It is added after the preface area. The start bit length is determined by MCR.SBSEL setting. When MCR.SBSEL = 0, the start bit length is 1 bit. When MCR.SBSEL = 1, the start bit length is 3 bits.

When MCR.SBSEL = 1, the SYNC type can be selected from command SYNC and data SYNC. Command SYNC means the three start bits are added as a one-to-zero transition. Data SYNC means the three start bits are added as a zero-to-one

transition. The SYNC type is determined by the MCR.SYNSEL, MCR.SYNVAL, and TDR.TSYNC settings. (When receiving, the received result is applied to MSR.RSYNC.)

When MCR.SBSEL = 0, the start bit is added as a zero-to-one or one-to-zero transition. The selection is determined by the MCR.SYNVAL setting.

The MCR.SYNSEL bit specifies the destination to be referred to when setting for transmission. When the MCR.SYNSEL bit is set to 1, the MCR.SYNVAL setting is referred to. When the MCR.SYNSEL bit is set to 0, the TDR.TSYNC setting is referred to.

Figure 33.45 shows the state of the start bit area according to the settings in the MCR.SYNSEL, MCR.SYNVAL, and TDR.TSYNC registers in the case of transmission. Figure 33.46 shows that in the case of reception. The start bit(s) is not affected by the MCR.TMPOL or MCR.RMPOL setting.

※ d.c. = don't care, Preface = preface area, START = start bit area, Data = user data area,
P = parity bit, MP = multi-processor bit, STOP = stop bit

Register setting				Output signal	Output Start bit
MCR			TDR	Output TxD waveform	
SBSEL	SYNSEL	SYNVAL	TSYNC		
0	d.c.	0	d.c.		1 bit 0 to 1 transition
0	d.c.	1	d.c.		1 bit 1 to 0 transition
1	0	0	d.c.		3 bit 0 to 1 transition (DATA SYNC)
1	0	1	d.c.		3 bit 1 to 0 transition (COMMAND SYNC)
1	1	d.c.	0		3 bit 0 to 1 transition (DATA SYNC)
1	1	d.c.	1		3 bit 1 to 0 transition (COMMAND SYNC)

Figure 33.45 Preface pattern setting example

d.c. = don't care, Preface = Preface area, START = Start bit area, Data = Data area
P = Parity bit, MP = Multi-processor bit, STOP = Stop bit

* Data other than the start bit is assumed to be normal.

					Start bit error	0
1	d.c.	d.c.	d.c.		Start bit error	0
					Start bit error	0
					Data SYNC	0
					Command SYNC	1

Figure 33.46 Settings related to and judgment of the start bit area at reception

(3) DATA

Since the format of the data area is the same as that of the asynchronous mode, see section 33.4.1. Serial Data Transfer Format. As shown in Figure 33.43, Frame Format in Manchester Mode, the stop bit is not included in the Manchester encoding range.

33.6.2 Clock

As the transfer clock in Manchester mode, the clock generated by the on-chip baud rate generator is used by setting the CCR2.CKS[1:0] bit.

Also it is possible to set the oversampling (transfer rate of one-bit period) by CCR2.ABCS bit. When the CCR2.ABCS bit is set to 0, oversampling x16 is selected with the one-bit period being 16 cycles of the base clock. When the CCR2.ABCS bit is set to 1, oversampling x8 is selected with the one-bit period being 8 cycles of the base clock.

33.6.3 SCI Initialization of (Manchester Mode)

Before transferring data, write 0 to CCR0.TE and CCR0.RE (or write the initial value to CCR0), and initialize the SCI following the example of flowchart shown in Figure 33.47.

Be sure to write 0 to CCR0.TE and CCR0.RE before changing the operation mode or communication format.

Note that setting the CCR0.RE bit to 0 initializes none of the ORER, FER, PER, MER, RDRF, RDF, SYER, PFER, and SBER flags and the RDR registers.

Note also that switching the value of CCR0.TE from 1 to 0 or 0 to 1 when CCR0.TIE is 1 generates a TXI interrupt request.

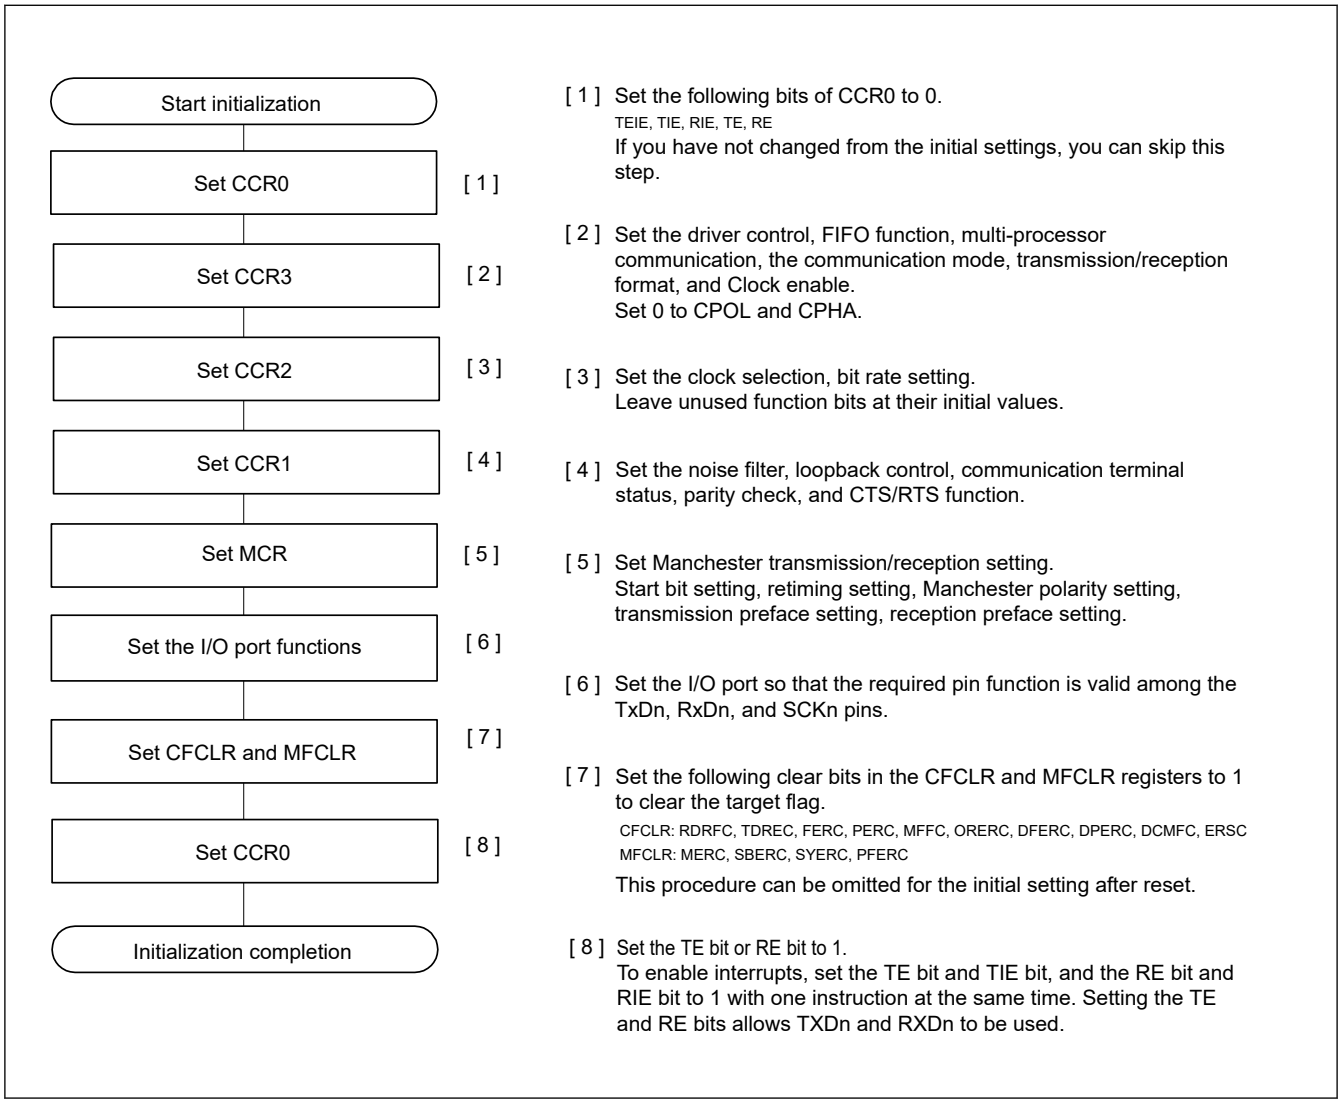

Figure 33.47 SCI initialization flow in Manchester mode

33.6.4 Double Speed Operation

When the ABCS bit in CCR2 is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the BGDM bit in CCR2 is set to 1, the cycle of the base clock is reduced to half and the SCI operates on the bit rate twice that of when BGDM is set to 0.

When the ABCS bit in CCR2 and the BGDM bit in CCR2 are set to 1, the SCI operates on the bit rate four times that of when the ABCS bit in CCR2 and the BGDM bit in CCR2 are set to 0.

33.6.5 CTS and RTS Functions

The CTS function controls transmission using the CTSn# pin input. Setting the CTSE bit in CCR1 to 1 enables the CTS function. The CTS/RTS pin can be set as a multiplexed pin which allows one pin to be used for either function, or as dedicated pins with each pin for a single function. Use the CTSPEN bit in CCR1 for this setting.

When the CTS function is enabled, reception starts only when the CTSn# pin is at the low level.

Even if the level of CTSn# pin goes High after transmission starts, does not affect transmission of the current frame, which continues.

The RTS function uses output on the CTSn# pin to request transmission. When SCI is ready to receive, it outputs a low level to the RTSn# pin, Conditions for output of the low level and high level are as follows:

[Conditions for low-level output]

When all conditions listed below are satisfied:

- The value of the CCR0.RE is 1.
- SCI is ready to receive.
- There is no received data yet to be read.
- All of the following flags are set to 0:
  CSR.ORER, FER, PER and MSR.MER, SBER (when SBEREN = 1), SYER (when SYEREN = 1), PFER (when PFEREN = 1)

[Conditions for high-level output]

When the conditions for low output are not satisfied.

33.6.6 Serial Data Transmission in Manchester Mode

The SCI encodes data in Manchester encoding and sends the resultant data in Manchester mode.

When the polarity setting (MCR.TMPOL) is set to 0, logic 0 is coded as a zero-to-one transition in Manchester code and logic 1 is coded as a one-to-zero transition in Manchester code.

When the polarity setting (MCR.TMPOL) is set to 1, logic 0 is coded as a one-to-zero transition in Manchester code and logic 1 is coded as a zero-to-one transition in Manchester code.

For this reason, a level transition occurs with the Manchester encoded data in the middle of individual logic data. (See Figure 33.42.)

The transmitter constructs transmit frames in a specific format by adding a preface area to data and setting the start bit(s) according to the polarity setting and sends resultant serial data.

For details on the frame format, see section 33.6.1. Frame Format.

Figure 33.48 shows the flowchart in transmission. At transmission starts, set the CCR0.TIE and CCR0.TE bits to 1 simultaneously with one instruction. Then, a TXI interrupt request is generated.

Figure 33.49, Figure 33.50, and Figure 33.51 show examples of the operation for serial transmission in Manchester mode.

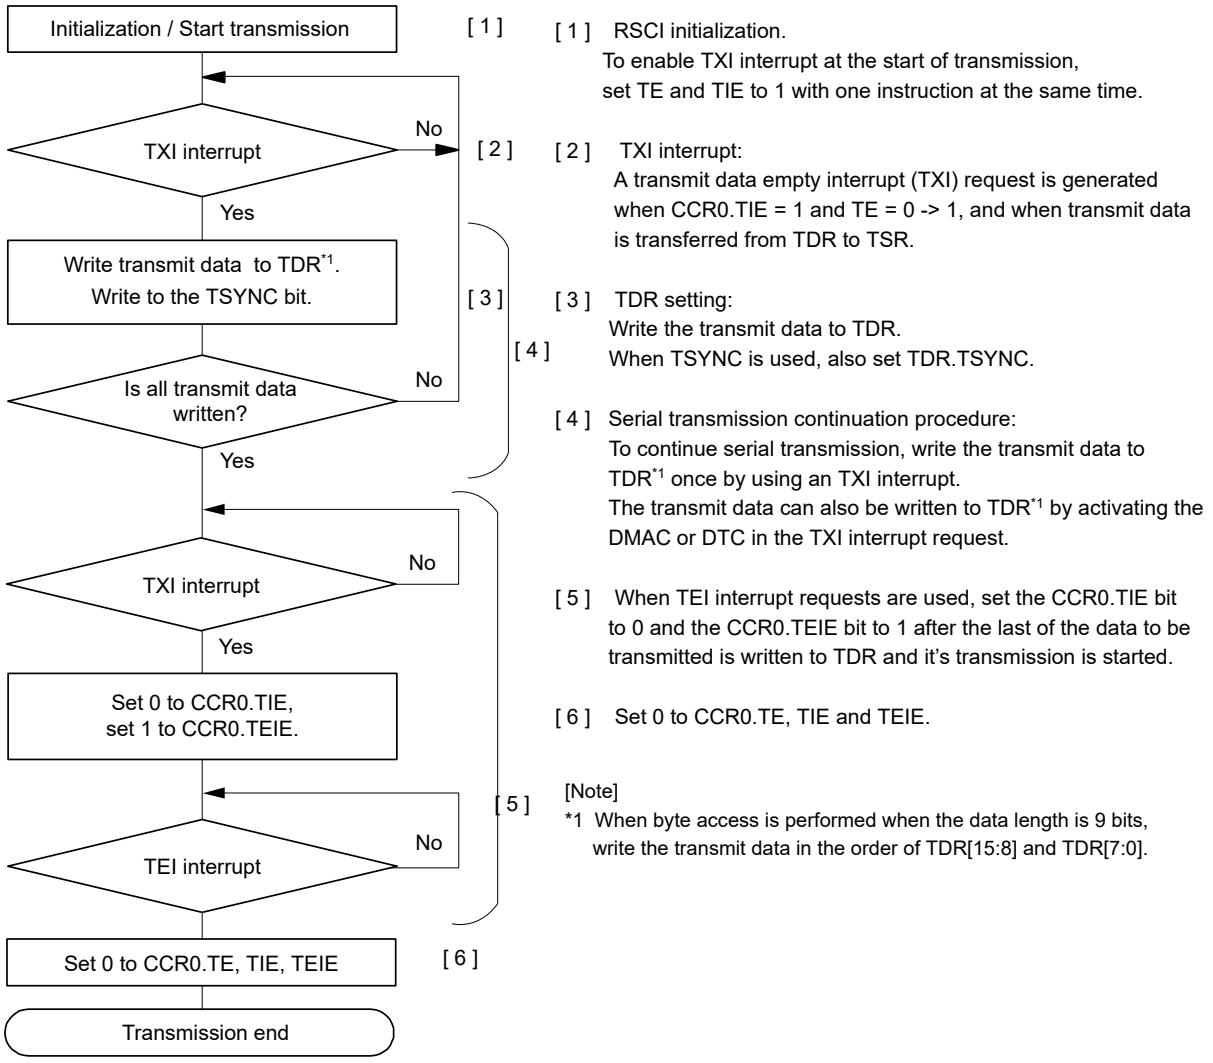

Figure 33.48 Example of serial transmission flowchart in Manchester mode

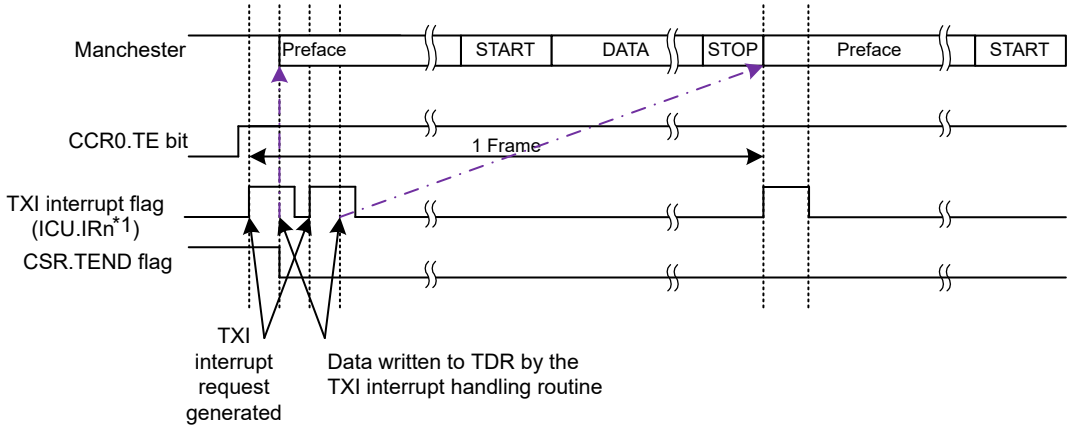

Figure 33.49 Example of Start-of-Transmission operation for serial transmission in Manchester mode (with Preface but without the CTS Function)

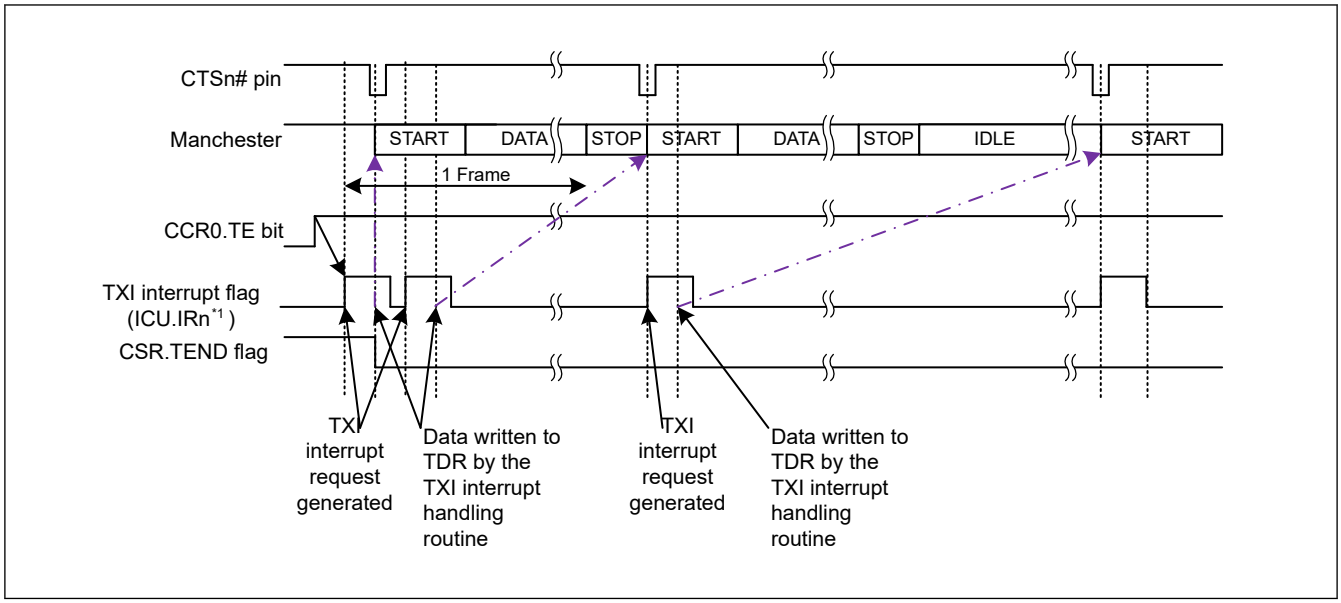

Figure 33.50 Example of Start-of-Transmission operation for serial transmission in Manchester mode (without Preface but with the CTS Function)

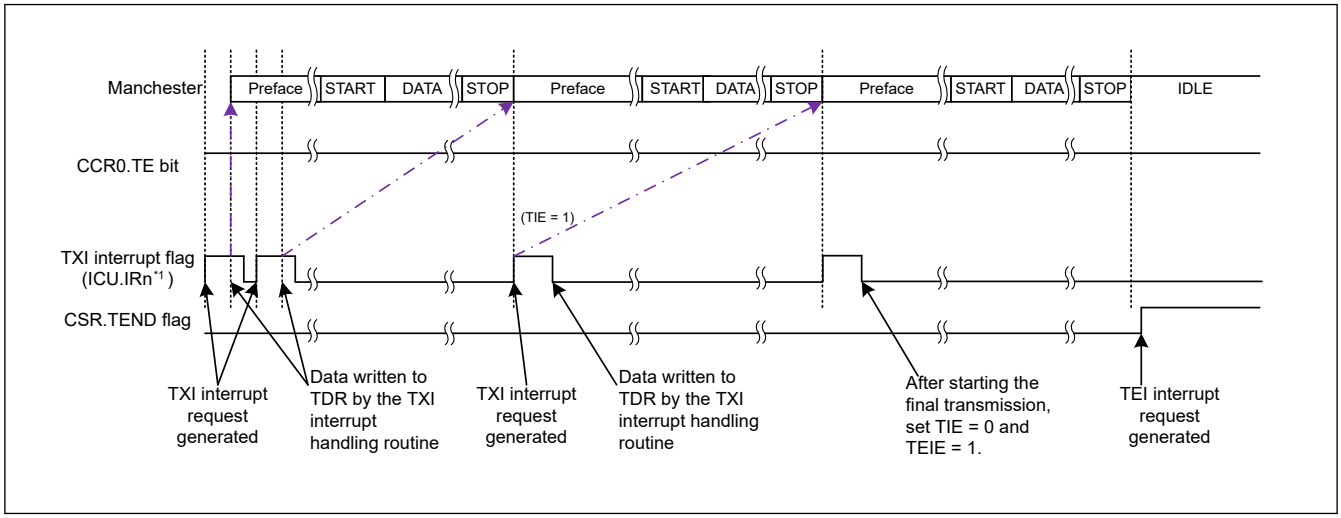

Figure 33.51 Example of End-of-Transmission operation for serial transmission in Manchester mode (with Preface but without the CTS Function)

33.6.7 Serial Data Reception in Manchester mode

In Manchester mode, the SCI operates on a base clock with a frequency of 16 times[*1] the bit rate. Reception starts by sampling the falling edges of received data at the base clock. As shown in Figure 33.52, reception starts at a falling edge of the received data and it continues if the received data keeps low for the duration of 1/4 bit. If the received data goes high within the duration of 1/4 bit, the SCI judges it as an error and waits for a falling edge again.

If a high level is expected in the first half of a bit in the received data, the SCI judges a low level that continues for one base clock cycle as an error and ignores the change to the low level.

Note 1. This is the case when CCR2.ABCS = 0. When CCR2.ABCS = 1, the SCI operates on a base clock with a frequency of 8 times the bit rate.

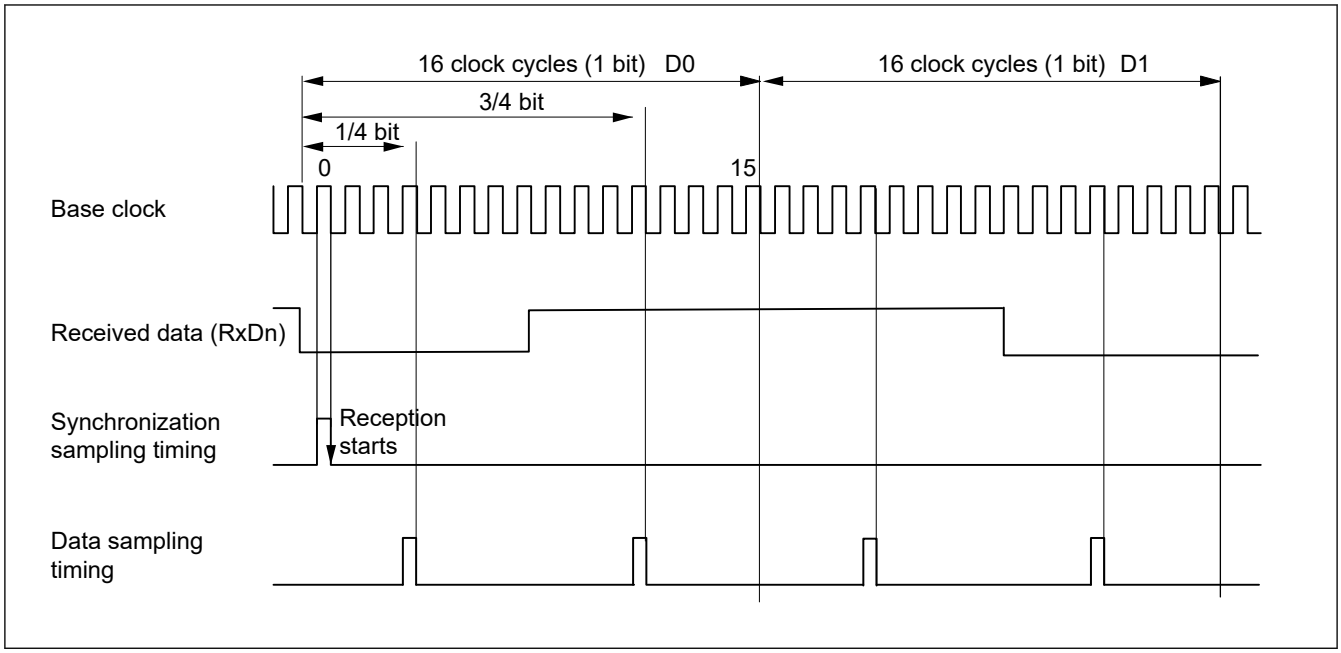

Figure 33.52 Data reception sampling timing in Manchester mode

In Manchester mode, data reception starts with detection of a preface and start bit area.

The SCI checks the input from the RxD pin to see whether a preface is added based on the value of MCR.RPLEN.

If the preface is disabled (MCR.RPLEN = 0), it moves on to the detection of a start bit area without detecting a preface.

When a preface is enabled, it identifies a preface pattern setting according to the set value in MCR.RPPAT, and compares it with the RxD input for a pattern match to detect a preface pattern.

Upon detection of a preface pattern match, it judges it as a normal preface and moves on to the detection of a start bit area.

If detecting a preface pattern mismatch or a Manchester code error in the preface area, it judges it as a preface error and asserts a preface error (PFER).

For start bit detection, the SCI selects an expected value based on the register settings (MCR.SBSEL and SYNVAL), compares it with the RxD input for a pattern match to detect a start bit area. Upon detection of a start bit pattern match, it judges it as a normal start bit area and moves on to the data processing.

Only when a preface and a start bit area are detected normally, it moves on to the next phase of data reception.

Upon detection of a start bit pattern mismatch, it asserts a start bit error flag (SBER).

In data processing, the SCI shifts the data by the expected received data length based on the register settings (CCR3.CHR[1:0]) through the RSR register. If two sampling points in a bit of the received data are identical, the SCI judges this as a Manchester code error. For details, see section 33.6.11. Errors in Manchester Mode (1) Manchester error.

When the parity function is disabled (CCR1.PE = 0), the SCI moves on to the next phase of stop bit detection. When the parity function is enabled (CCR1.PE = 1), the SCI performs parity checking. If detecting a parity error, it asserts a parity error flag (PER), and then moves on to stop-bit detection.

In stop bit detection, the SCI checks the following in the stop bit area of the received frame:

It has two sampling points in a bit. If both points are at the high level, the bit is recognized as a normal stop bit and the data is stored in the RDR register. At least one low-level point is judged as an abnormal stop bit, causing a framing error flag (FER) to be set. Even when an error is detected, the received data is stored in the RDR register as abnormal data.

Figure 33.53 shows an example of the operation for serial data reception in Manchester mode.

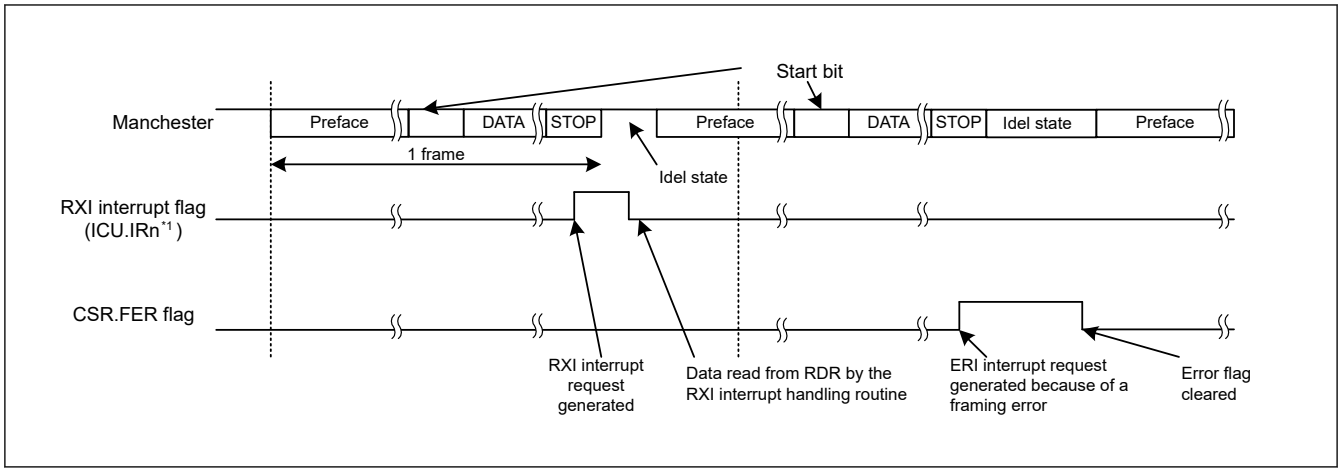

Figure 33.53 Example of operation for serial data reception in Manchester mode (with a Preface)

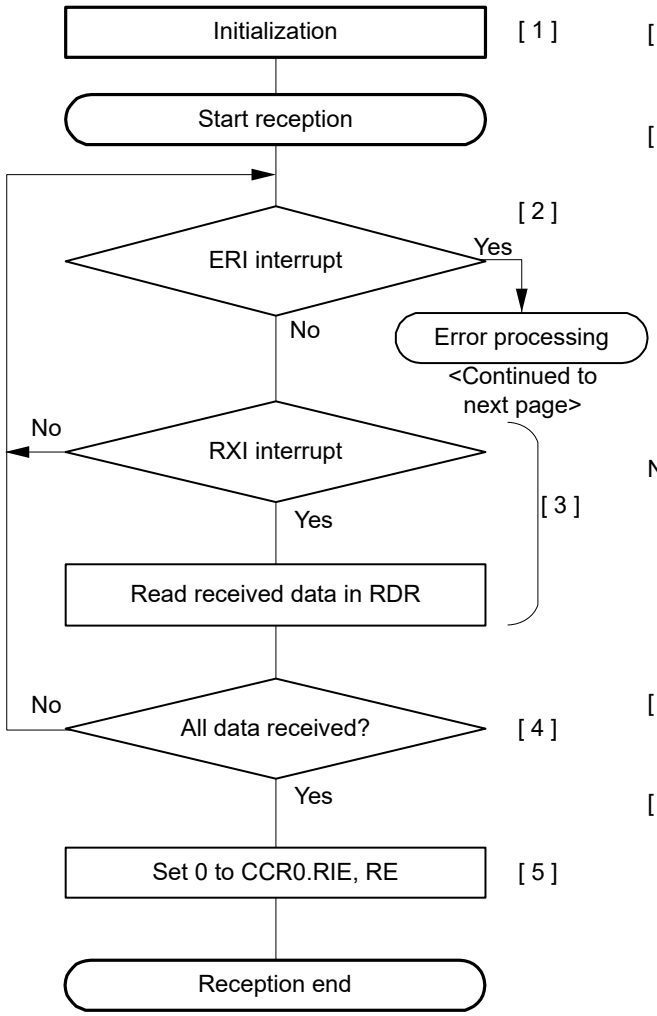
For the state of each status flag in the CSR register and RxD input processing when a receive error is detected, see section 33.6.11. Errors in Manchester Mode.

If a receive error is detected, an ERI interrupt request is generated but an RXI interrupt request is not generated.

Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, PER, MER, SYER*1, PFER*1, SBER*1 flags to 0 before resuming reception. Also, be sure to read the RDR register during overrun error processing. When a reception is forcibly terminated by setting the CCR0.RE bit to 0 during operation, read the RDR register because received data which has not yet been read may be left in the RDR register.

Figure 33.54 and Figure 33.55 show examples of serial data reception flowchart in Manchester mode.

Note 1. Effective when the corresponding bit is enabled.



[1] RSCI initialization.
(Set CCR0.RE = 1 and RIE = 1)

[2] Receive error processing:
When a receive error occurs, RSCI generates an ERI interrupt. An error is identified by reading the ORER, PER, FER in CSR and MER, SBER, SYER, PFER in MSR. After performing the appropriate error processing, always set the ORER, PER, FER, MER, SBER, SYER, PFER flags to 0. Reception cannot be resumed if any of these flags is set to 1.

Note: Each of the PFER, SYER, SBER bits in MSR has an enable bit (PFEREN, SYEREN, and SBEREN in MECR). If the corresponding enable bit is set to 0 (disable), the flag value does not affect the communication. Perform error processing as required.

[3] Read the received data in RDR once in the RXI interrupt handling routine.

[4] Serial reception continuation procedure:
To continue serial reception, before the stop bit of a frame is received, read data from RDR in the RXI interrupt handling routine. The RDR data can also be read by activating the DMAC or DTC.

[5] Write 0 to CCR0.RIE and RE.

Figure 33.54 Example of serial data reception flowchart in Manchester mode (Normal reception)

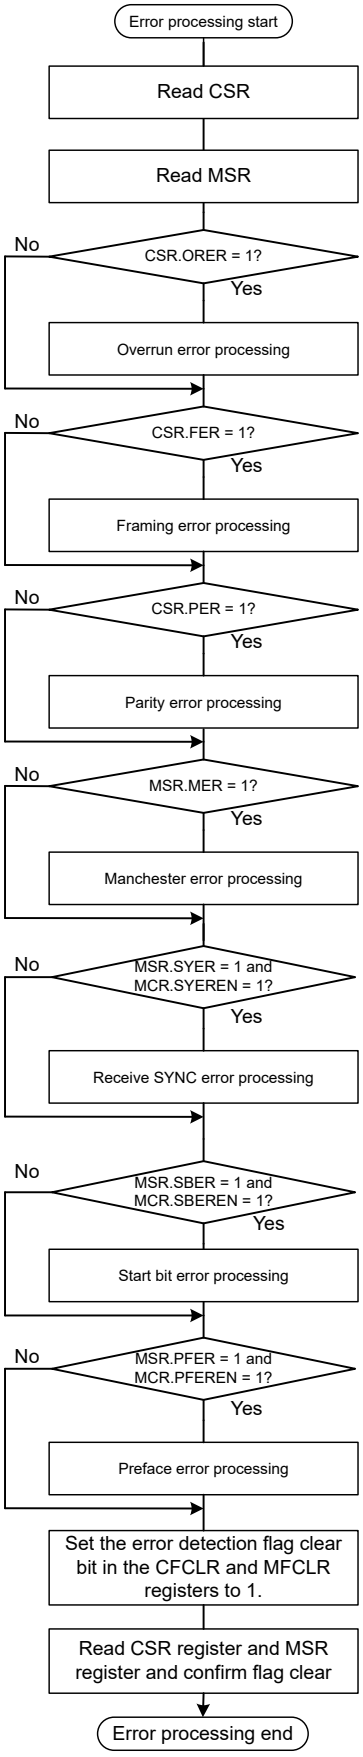


Figure 33.55 Example of serial reception flowchart in Manchester mode (Error processing)

33.6.8 Operation when Multi-processor bit is used

See section 33.5. Multi-Processor Communication Function (1) Non-FIFO selected for the operation in Manchester mode when using multi-processor mode because the operation is the same.

A preface and a start bit area are added to the frame format in Manchester mode.

See Figure 33.55 for error processing in Manchester mode for the reception flowchart. Refer to Table 33.31 for the operation status when detecting various errors.

33.6.9 Receive Retiming

This function corrects the timing for each central edge of the bit, taking advantage of the fact that each bit has an edge in the center in Manchester code.

The receive retiming function can be turned on or off by setting the ERTEN bit in the MCR register.

When the receive retiming function is turned off (MCR.ERTEN = 0), retiming is not performed, causing misalignment between the internal clock and the RxD input to be accumulated and the receive margin to be reduced.

When the receive retiming function is turned on (MCR.ERTEN = 1), retiming is performed for the preface area, the start bit area*1, and the data area (excluding the stop bit).

Note 1. Retiming is not performed for the start bit area if the preface length is 0 and the start bit length is 3.

As an example, the receive retiming when oversampling x16 is selected is shown below.

When detecting an RxD input edge two to four cycles before the expected receive cycle, the receive processing is shortened by one sampling CLK cycle.

When detecting a RxD input edge two to three cycles after the expected receive cycle, the receive processing is extended by one sampling CLK cycle.

(Even if the clock is misaligned with the data by more than two cycles, one cycle is corrected for each bit.)

Figure 33.56 shows the conceptual image of receive retiming range.

When detecting an edge in the tolerance area in the figure, data is received as is without making correction.

When detecting an edge in the SyncJump area in the figure, data is corrected for reception.

When detecting an edge in the SyncError area in the figure, data is received as abnormal data with no correction made.

For a Manchester code error (data matches at the 1/4-phase and 3/4-phase sampling points), the SCI reports a code error.

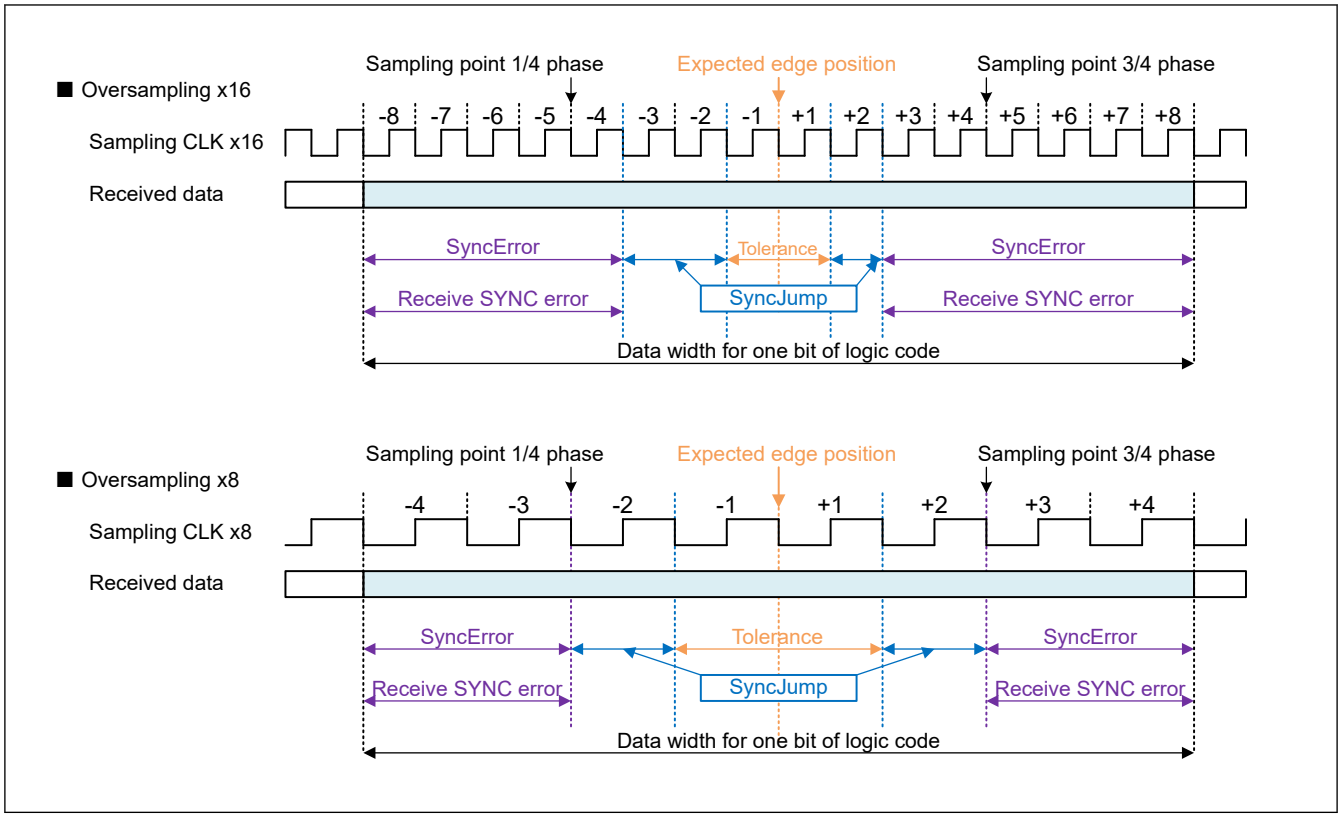

Figure 33.56 Conceptual image of reception retiming range

33.6.10 Polarity Setting for Manchester Code

The polarity of the Manchester code can be set with the Manchester Control Register (MCR).

It can be set separately for transmission and reception. Use the MCR.TMPOL bit to set the polarity for transmission and the MCR.RMPOL bit to set the polarity for reception.

The Manchester code polarity setting is valid for the preface area, the data area, and the parity or multi-processor area.

When the initial settings (TMPOL/RMPOL = 0) are used for the polarity of Manchester code, logic 0 is encoded as a zero-to-one transition in Manchester code and logic 1 is encoded as a one-to-zero transition in Manchester code.

If the settings are changed to TMPOL/RMPOL = 1, logic 0 is encoded as a one-to-zero transition in Manchester code and logic 1 is encoded as a zero-to-one transition in Manchester code. Figure 33.57 shows the conceptual image of the settings and operation.

Separately from the function above, the transmitted and received data in the data area can be inverted by the transmitted/received data inversion function (CCR3.SINV). Since the polarity of Manchester code (MCR.TMPOL/RMPOL) can be set separately from the transmitted/received data invert function (CCR3.SINV), if both are set to inversion (MCR.TMPOL/RMPOL = 1 and CCR3.SINV = 1), the transmitted and received data are set to initial state (inversion + inversion = normal).

The polarity of the start bit area can be set by a register different from the ones mentioned above.

Since a different register is used, the polarity of the start bit area is not affected by the polarity setting for Manchester code mentioned above.

For details on the setting for the start bit area, see section 33.6.1. Frame Format (2) Start bit area.

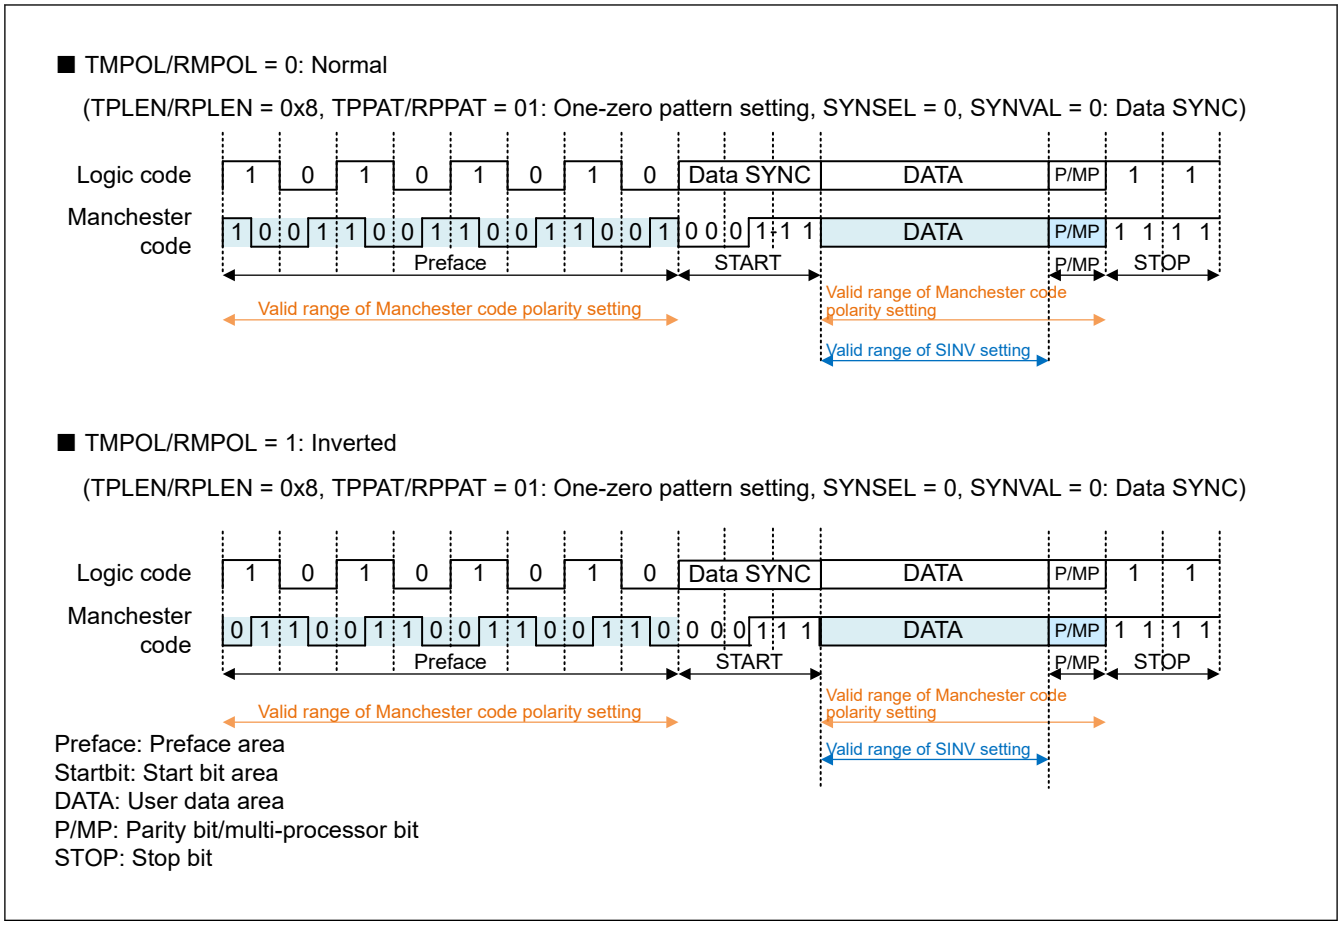

Figure 33.57 Valid range of the Manchester code polarity setting

33.6.11 Errors in Manchester Mode

There are the following errors in Manchester mode:

1. Parity error
2. Over run error
3. Framing error
4. Manchester error
5. Preface error
6. Start Bit error
7. Receive SYNC error

For errors 1 to 3, see section 33.4.9. Serial Data Reception (Asynchronous Mode) (1) Non-FIFO selected because they are the same as in asynchronous mode.

Each error is judged in each area, but they are reflected on flags and operations at the timing of 3/4-bit sampling of the STOP bit area. If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the previous information.

Table 33.29 lists the states of the serial status register when detecting errors and judgment about whether to store data in the RDR.

Table 33.30 lists the errors that can be detected in each area of a Manchester frame. If a Preface error or Start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the result of the previous frame reception. Also, if an error is detected in the previous frame, data will not be received, but errors in the preface area and start bit area will update that flag. Table 33.31 shows the flags and actions in this case.

(1) Manchester error

A Manchester error is generated when a Manchester code error is detected.

In Manchester code, there must be an edge (transition) in the center of the bit.

In the data area of a received frame (including the parity/multi-processor bit), the values of the 1/4-bit and 3/4-bit sampling points are checked in each received 1-bit data, and a Manchester code error is determined if these two values match.

If a Manchester code error is detected, the Manchester error flag (MSR.MER) is asserted.

If a Manchester error occurs, it is handled as an interrupt source and event source. If a Manchester error is detected, the next reception is not performed until the corresponding error flag is cleared.

(2) Preface error

A preface error is generated when the preface pattern does not match, or a Manchester code error is detected in the preface area. If a preface error is detected, the preface error flag (MSR.PFER) is asserted.

It is possible to set whether to use this error flag as an interrupt source with the setting of the MCR register.

When MCR.PFEREN = 1, a preface error is handled as an interrupt source or event source. If a preface error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MCR.PFEREN = 0, a preface error is not handled as an interrupt source or event source, and the next reception is not halted. However, a preface error is notified to MSR.PFER.

(3) Start bit error

A start bit error is generated when a mismatch is detected between the start bit area in the received frame and the preset start bit pattern. Upon detection of a start bit error, a start bit error flag (MSR.SBER) is asserted.

It is possible to set whether to use the start bit error as an interrupt source with the setting of the MCR register.

When MCR.SBEREN = 1, a start bit error is handled as an interrupt source or event source. If a start bit error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MCR.SBEREN = 0, a start bit error is not handled as an interrupt source or event source, and the next reception is not halted. However, a start bit error is notified to MSR.SBER.

(4) Receive SYNC error (SyncError)

When the receive retiming function described in section 33.6.9. Receive Retiming is enabled, the receive retiming operation is performed.

If no edges are detected within the receive retiming range (SyncError area in Figure 33.56) when receive timing operation is being performed, a receive SYNC error is generated. Upon detection of a receive SYNC error, a receive SYNC error flag (MSR.SYER) is asserted. In areas not subject to retiming, receive SYNC errors are not detected.

The preface area*1, the start bit area*1 *2, and the data area (excluding the stop bit) for which receive retiming operation is performed are checked.

It is possible to set whether to use the receive SYNC error as an interrupt source with the setting of the MCR register.

When MCR.SYEREN = 1, a receive SYNC error is handled as an interrupt source or event source. If a receive SYNC error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MCR.SYEREN = 0, a receive SYNC error is not handled as an interrupt source or event source, and the next reception is not halted. However, a receive SYNC error is notified to MSR.SYER.

Note 1. In the case of a frame that starts with a pattern that expects the first half of the bit to be High, it is excluded from retiming.

Note 2. In the start bit area, when there is no preface length and 3 bit start bit is set, it is not subject to retiming. Also, the 1st bit and the 2nd bit in the start bit area when 3 bit start bit is set are not subject to retiming.

Table 33.29 Flags in the status register and receive data handling in Manchester (1 of 2)

Flags in the CSR register			Flags in the MSR register				Received data	Received error status (ERI interrupt/event generation)
ORER	FER	PER	MER	SBER*1	PFER*1	SYER		
0	0	0	0	0	0	0	transfer to RDR	No error

Table 33.29 Flags in the status register and receive data handling in Manchester (2 of 2)

Flags in the CSR register			Flags in the MSR register				Received data	Received error status (ERI interrupt/event generation)
ORER	FER	PER	MER	SBER*1	PFER*1	SYER		
0	1	0	0	0	0	0	transfer to RDR	Framing error
0	0	1	0	0	0	0	transfer to RDR	Parity error
0	1	1	0	0	0	0	transfer to RDR	Framing error + Parity error
0	0	0	1	0	0	0	transfer to RDR	Manchester error
0	1	0	1	0	0	0	transfer to RDR	Framing error + Manchester error
0	0	1	1	0	0	0	transfer to RDR	Parity error + Manchester error
0	1	1	1	0	0	0	transfer to RDR	Framing error + Parity error + Manchester error
1	0	0	0	0	0	0	Lost	Overrun error
1	1	0	0	0	0	0	Lost	Overrun error + Framing error
1	0	1	0	0	0	0	Lost	Overrun error + Parity error
1	1	1	0	0	0	0	Lost	Overrun error + Framing error + Parity error
1	0	0	1	0	0	0	Lost	Overrun error + Manchester error
1	1	0	1	0	0	0	Lost	Overrun error + Framing error + Manchester error
1	0	1	1	0	0	0	Lost	Overrun error + Parity error + Manchester error
1	1	1	1	0	0	0	Lost	Overrun error + Framing error + Parity error + Manchester error
0	Combination of above			0	0	1	transfer to RDR	Errors above + Receive SYNC error*2
1				0	0	1	Lost	Errors above + Receive SYNC error*2
hold	hold	hold	hold	0	1	0	Lost	Preface error*3
hold	hold	hold	hold	1	0	0	Lost	Start bit error*3
hold	hold	hold	hold	0	1	1	Lost	Preface error*3 + Receive SYNC error*2
hold	hold	hold	hold	1	0	1	Lost	Start bit error*3 + Receive SYNC error*2

Note 1. Start bit error and Preface error never become 1 at the same time.
Note 2. When MCR.SYEREN = 1, ERI interrupt/event is generated by SYER factor.
Note 3. If MCR.PFEREN = 1 or MCR.SBEREN = 1, an ERI interrupt/event is generated when the corresponding flag is set.

Table 33.30 Errors detectable in each area

	Preface error (PFER)	Start Bit error (SBER)	Manchester error (MER)	Receive SYNC error (SYER)	Parity error (PER)	Framing error (FER)
Preface area	✓	—	—*1	✓*2	—	—
Start Bit area	—	✓	—	✓*2	—	—
Data area	—	—	✓	✓	—	—
Parity area	—	—	✓	✓	✓	—
Multi-processor area	—	—	✓	✓	—	—
Stop Bit area	—	—	—	—	—	✓

Note: ✓: Detected, —: Not detected
Note 1. When an Manchester code error occurs in the preface area, it is defined as a preface error.
Note 2. It may not be subject to Receive SYNC error detection. For details, see (4) Receive SYNC error (SyncError).

Table 33.31 Operation status due to the presence/absence of error in the previous frame and operation status list when CCR0.MPIE = 0 in multi-processor mode (1 of 2)

Previous frame	Each area of the frame					PFEREN	SBEREN	SYEREN	Received data	Error flag	Interrupt request	Event signal

	There are some errors.				ORER	Don't Care	Don't Care	Don't Care	Lost	set some flags*2	output	output
	No Error	No Error	No Error	No Error	No Error ORER	Don't Care	Don't Care	Don't Care	Lost	set ORER	output	output

Table 33.31 Operation status due to the presence/absence of error in the previous frame and operation status list when CCR0.MPIE = 0 in multi-processor mode (2 of 2)

Previous frame	Each area of the frame					PFEREN	SBEREN	SYEREN	Received data	Error flag	Interrupt request	Event signal
	preface	start bit	data	parity	stop							
Some Error*3 *6	PFER No SYER*1	No Error	Don't Care	Don't Care	Don't Care	0	Don't Care	Don't Care	Lost	set PFER*1	Output*4	not output*5
						1						
	No Error	SBER No SYER*1	Don't Care	Don't Care	Don't Care	Don't Care	0	Don't Care		set SBER*1		
							1					
	SYER No PFER	No Error	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	0		set SYER		
								1				
	No Error	SYER No SBER	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	0		set SYER		
								1				
	No Error	No Error	SYER		No Error	Don't Care	Don't Care	0		set SYER		
								1				
	No Error	No Error	MER		No Error	Don't Care	Don't Care	Don't Care		don't set any flags		
	No Error	No Error	Don't Care	PER	No Error	Don't Care	Don't Care	Don't Care				
	No Error	No Error	Don't Care	Don't Care	FER	Don't Care	Don't Care	Don't Care				
	There are some errors. ORER					Don't Care	Don't Care	Don't Care				
	No Error	No Error	No Error	No Error	No Error ORER	Don't Care	Don't Care	Don't Care				

Note 1. If SYER is detected, the SYER flag is also set. Other operations are as shown in this table.
Note 2. Other detected error flags including ORER are also set.
Note 3. If all the error flags are cleared before the STOP bit is judged, the operation will be the same as the case where is no error in the previous frame of this table.
Note 4. Since the ERI interrupt request is level output, it remains active due to errors in the previous frame regardless of the presence or absence of errors in the relevant frame.
Note 5. Since the error cause is continuously detected, the ERI event is not newly output regardless of the presence or absence of errors in the relevant frame.
Note 6. For PFER, SBER and SYER, when each enable bit is set to disable, it is treated as no error.

Table 33.32 Operation when CCR0.MPIE = 1 in multi-processor mode

MPB*1	Each area of the frame					PFEREN	SBEREN	SYEREN	Received data	Error flag	Interrupt request	Event signal
	preface	start bit	data	parity	stop							
1	No Error No PFER SYER*3	No Error No SBER SYER*3	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	transfer to RDR	set some flags	output*2	output*2
			Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	0				
								1	Lost	don't set any flags	not output	not output
	PFER	No Error	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care				
	No Error	SBER	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care					

Note 1. If the received MPB bit is 0, it is not received the frame, and the operation is the same as lost of the reception data of this table.
Note 2. If no error is detected, RXI interrupt request or event is output, and if it is detected, ERI interrupt request or event is output.
Note 3. When SYER is detected in the preface area or the start bit area, the behavior of handling as an error depending on the SYEREN bit changes.

33.7 Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function.

Smart card interface mode can be selected using the appropriate register.

33.7.1 Sample Connection

Figure 33.58 shows a sample connection between a smart card (IC card) and this LSI.

As in the figure, since this LSI communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor. Setting the TE and RE bits in CCR0 to 1 with an IC card disconnected enables closed transmission/reception allowing self-diagnosis.

To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.

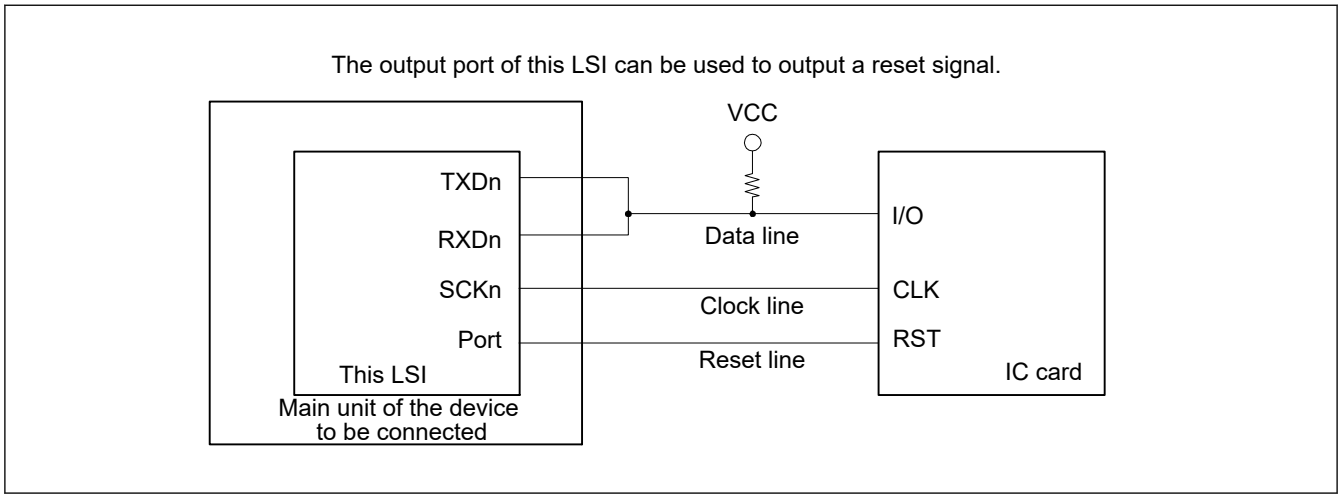

Figure 33.58 Sample connection with a smart card (IC card)

33.7.2 Data Format (Except in Block Transfer Mode)

Figure 33.59 shows the data transfer formats in smart card interface mode.

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etu (elementary time unit: time required for transferring 1 bit) is secured as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low-level error signal is output for 1 etu after 10.5 etu has passed from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etu.

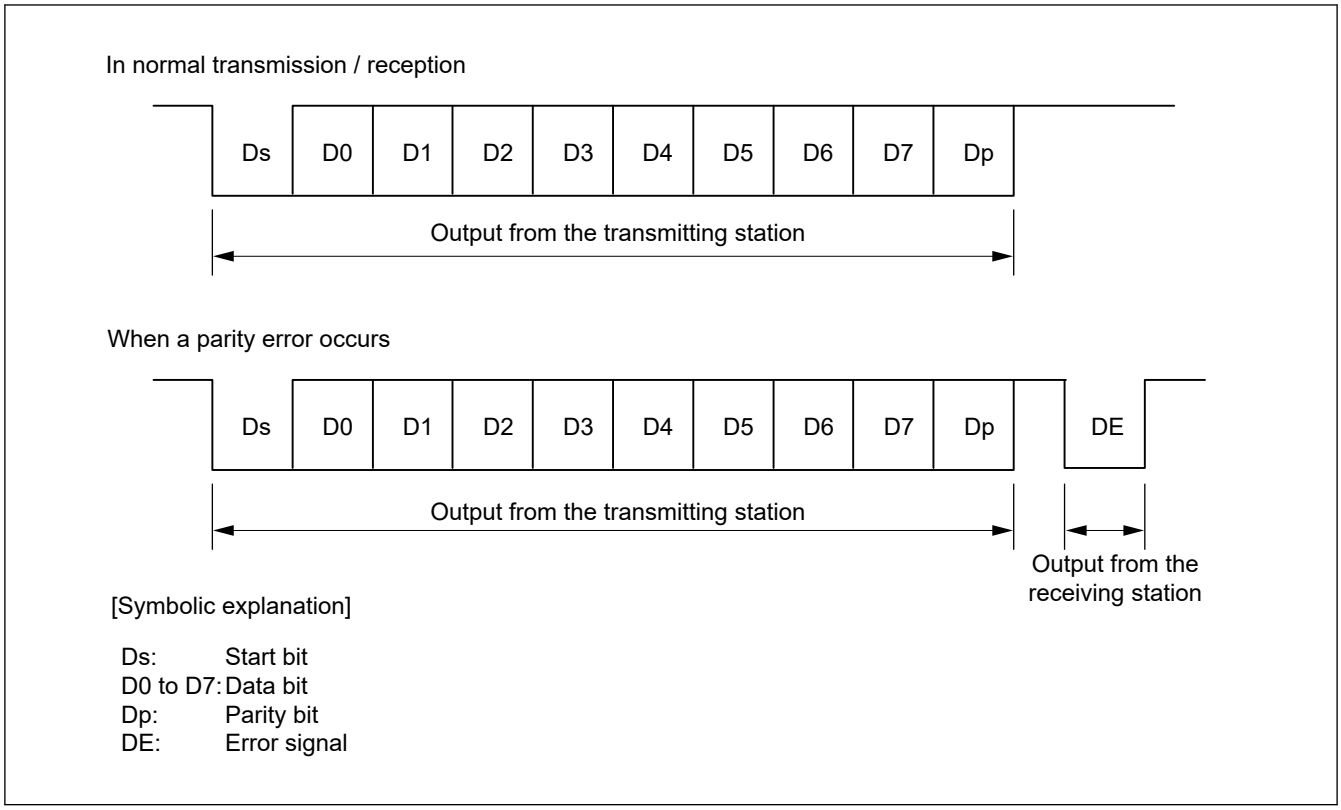

Figure 33.59 Data formats in smart card interface mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedure below.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 correspond to states Z and A, respectively, and data is transferred with LSB first as the start character, as shown in Figure 33.60. Therefore, data in the start character in the figure is 0x3B.

When using the direct convention type, write 0 to the CCR3.SINV bit and write 1 to the CCR3.LSBF bit. Write 0 to CCR1.PM in order to use even parity, which is prescribed by the smart card standard.

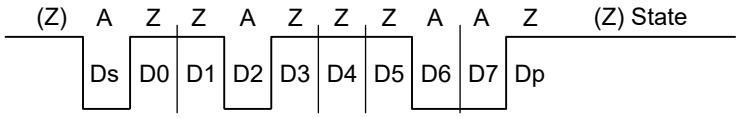

Figure 33.60 Direct convention type (CCR3.LSBF=1, CCR3.SINV=0, CCR1.PM=0)

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 correspond to states A and Z, respectively and data is transferred with MSB first as the start character, as shown in Figure 33.61. Therefore, data in the start character in the figure is 0x3F.

When using the inverse convention type, write 1 to the CCR3.SINV bit and write 0 to the CCR3.LSBF bit. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to state Z. Since the SINV bit of this LSI only inverts data bits D7 to D0, write 1 to CCR1.PM to invert the parity bit for both transmission and reception.

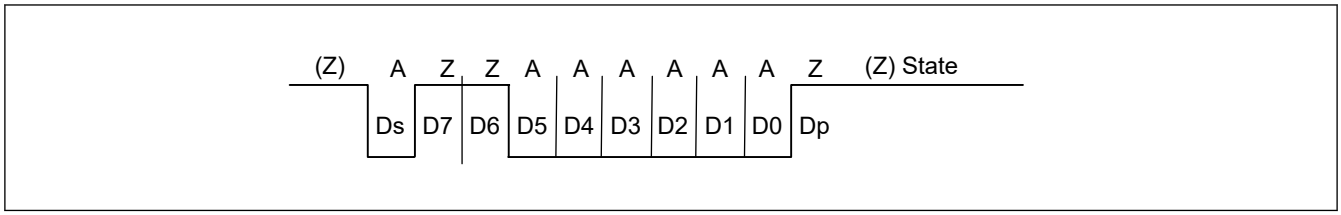

Figure 33.61 Inverse convention type (CCR3.LSBF=0, CCR3.SINV=1, CCR1.PM=1)

33.7.3 Block Transfer Mode

Block transfer mode is different from non-block-transfer-mode of smart card interface mode in the following respects.

- Even if a parity error is detected during reception, no error signal is output. Since CSR.PER is set by error detection, clear the PER bit before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is secured as a guard time from the end of the parity bit until the start of the next frame.
- Since the same data is not retransmitted during transmission, CSR.TEND is set 11.5 etu after transmission start.
- In block transfer mode, CSR.ERS flag indicates the error signal status as in non-block-transfer-mode of smart card interface mode, but the flag is always read as 0 because no error signal is transferred.

33.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the baud rate generator can be used as a transfer clock in smart card interface mode. In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate according to the settings of CCR2.BCP[2:0]. For data reception, the falling edge of the start bit is sampled with the base clock to perform synchronization. Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 33.62. The reception margin here is determined by the following formula.

$$M = \left|(0.5 - \frac{1}{2N}) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\%$$

M: Reception margin (%)

N: Ratio of bit rate to clock (N = 32, 64, 372, 256)

D: Duty cycle of clock (D = 0 to 1.0)

L: Frame length (L = 10)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the above formula, the reception margin is determined by the formula below.

$$M = \{0.5 - 1/(2 \times 372)\} \times 100\% = 49.866\%$$

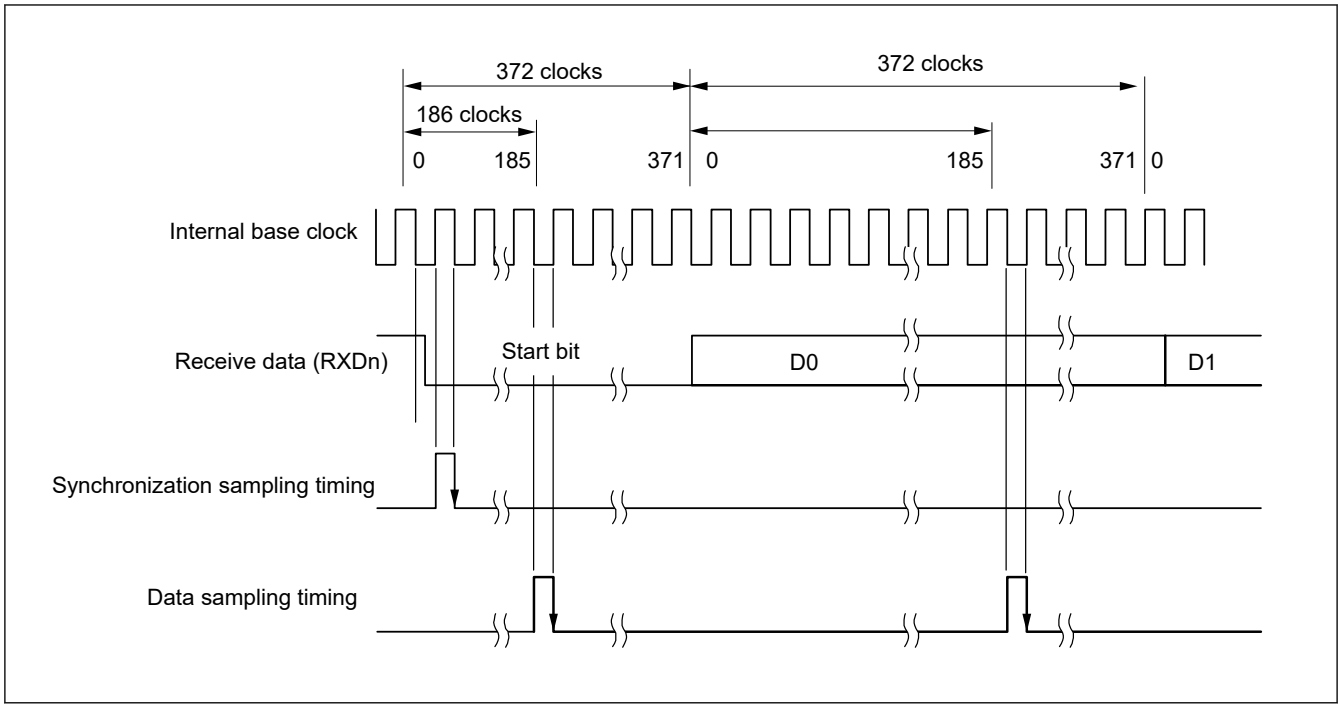

Figure 33.62 Receive data sampling timing in smart card interface mode (when clock frequency is 372 times the bit rate)

33.7.5 Initialization of SCI (Smart Card Interface Mode)

Before transmitting and receiving data, write 0 to CCR0.TE and CCR0.RE (Or write the initial value to CCR0). And initialize SCI following example flowchart in Figure 33.63.

Be sure to set the initial value in the TIE, RIE, TE, RE, and TEIE bits in CCR0 register before switching from transmission mode to reception mode and vice versa. Even if the RE bit is set to 0, the RDR register is not initialized. In transmission mode, set 1 to the TE bit and TIE bit simultaneously, then the TXI interrupt request is generated. To change reception mode to transmission mode, first check that reception has completed, and then initialize SCI. At the end of initialization, set TE = 1 and RE = 0. Reception completion can be verified by RXI request, CSR.ORER, or CSR.PER. To change transmission mode to reception mode, first check that transmission has completed, and then initialize SCI. At the end of initialization, set TE = 0 and RE = 1. Transmission completion can be verified by reading CSR.TEND.

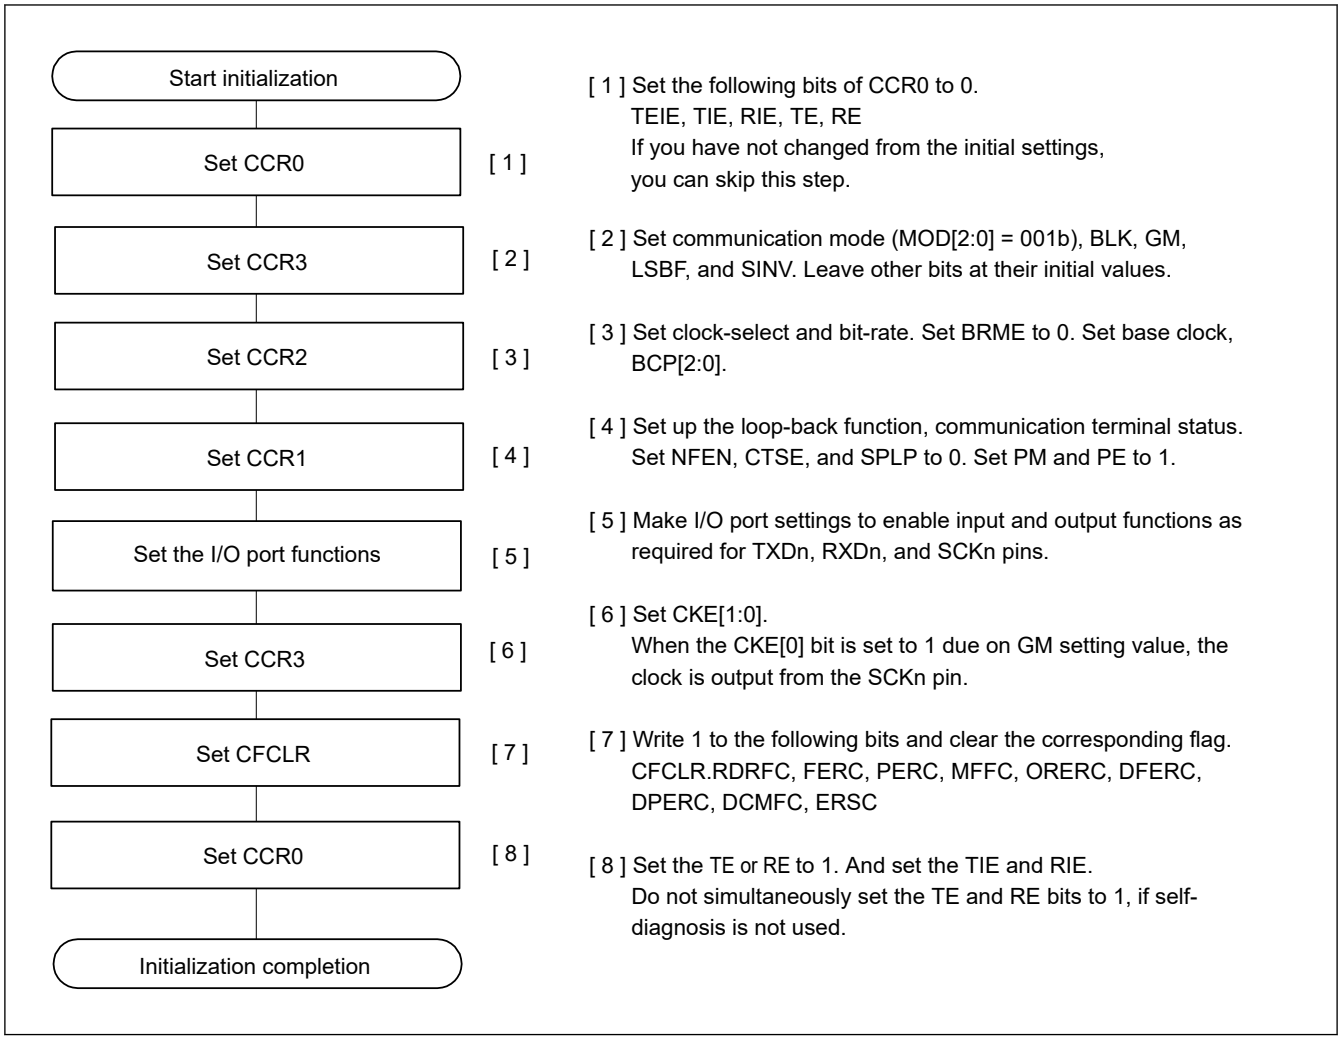

Figure 33.63 Example of SCI initialization flowchart (smart card interface mode)

Figure 33.64 is a timing chart when data transmission is performed by making transition to the Smart Card Interface mode according to the above flow chart. The figure shows the case when CCR3.GM bit is 0. As shown in the figure, when the pin function is set to the SCK pin, the SCK pin is high impedance because the CCR3.CKE[0] bit is 0. When the TXD pin is set, the TXD pin is high impedance because the CCR0.TE bit is 0. Start clock output to the SCK pin with the clock output setting CCR3.CKE[0] to 1, start data transmission by writing transmit data after setting CCR0.TE to 1.

In the smart card interface mode, even if not communicating at CCR0.TE = 0 and CCR0.RE = 0, the clock is continuously output if the clock output setting is used.

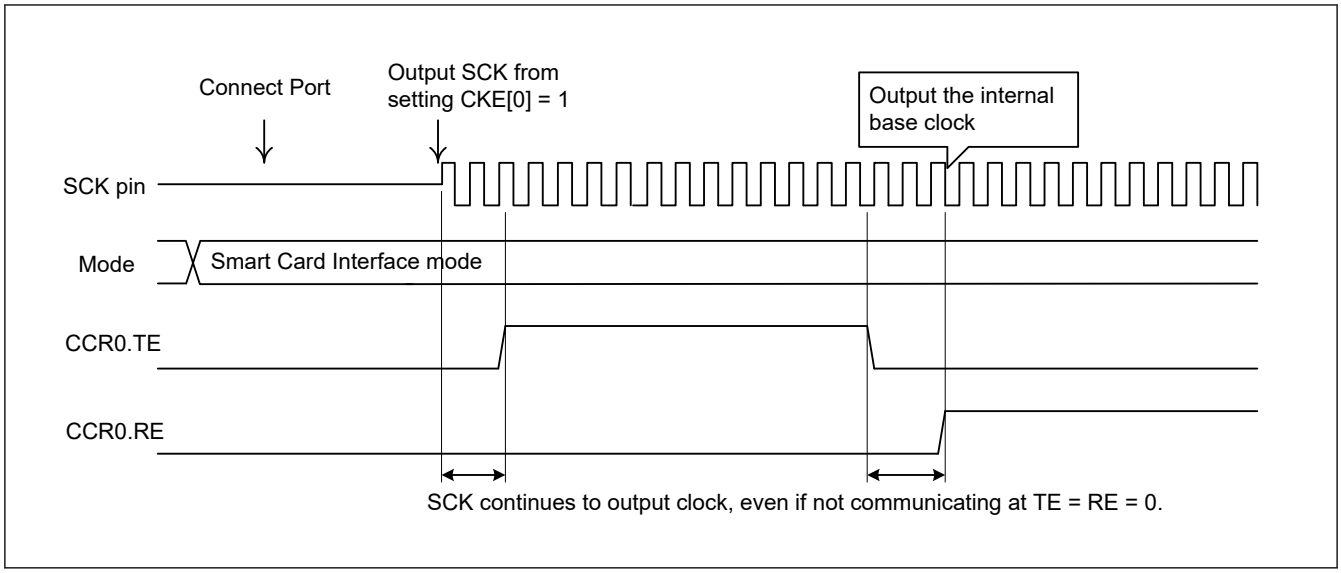

Figure 33.64 Example of timing chart of data transmission (smart card interface mode)

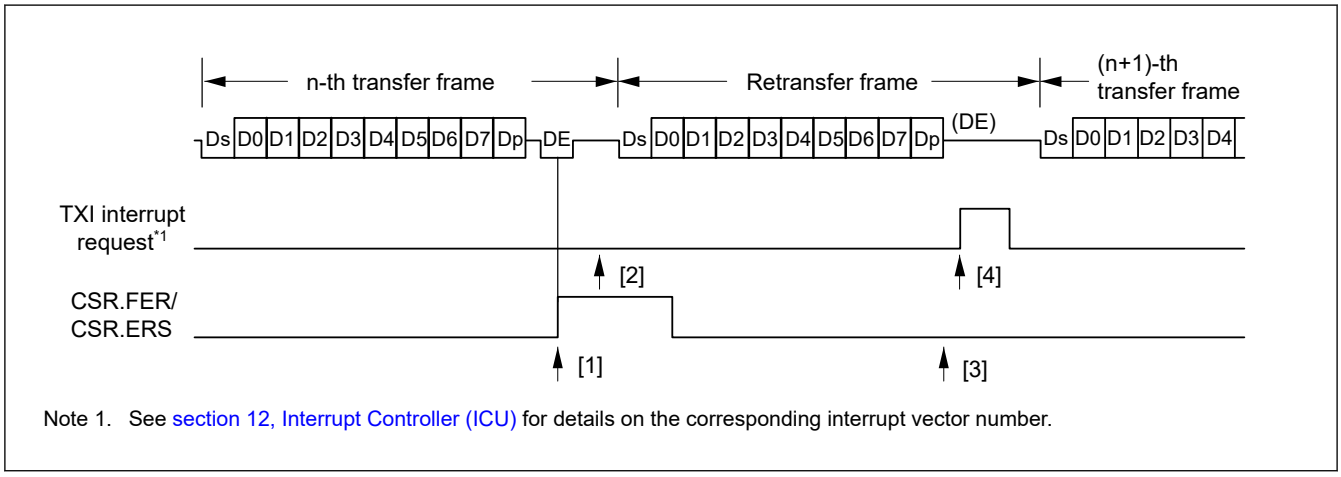
33.7.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode), in that an error signal is sampled and data can be retransmitted, is different from that in non-smart card interface mode. Figure 33.65 shows the data retransfer operation during transmission.

1. When an error signal from the receiver end is sampled after one-frame data has been transmitted, CSR.ERS is set to 1. If CCR0.RIE is 1 at this time, an ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
2. For a frame in which an error signal is received, CSR.TEND is not set. Data is retransferred from TDR to TSR allowing data retransmission automatically.
3. If no error signal is returned from the receiver, the ERS flag is not set to 1.
4. In this case, the SCI judges that transmission of one-frame data (including retransfer) has been completed, and the TEND flag is set. If CCR0.TIE is 1 at this time, a TXI interrupt request is generated. Writing transmit data to TDR starts transmission of the next data.



Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.65 Data retransfer operation in SCI transmission mode

Figure 33.67 shows a sample flowchart of serial transmission. All the processing steps are automatically performed by using a TXI interrupt request to activate the DMAC. When CSR.TEND is set to 1 in transmission, if the CCR0.TIE is 1, a TXI interrupt request is generated. The DMAC is activated by a TXI interrupt request if the TXI interrupt request is specified as a source of DMAC activation beforehand, allowing transfer of transmit data. The TEND flag is automatically set to 0 when the DMAC transfers the data. If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept to 0 and the DMAC is not activated. Therefore, the SCI and DMAC automatically

transmit the specified number of bytes, including retransmission in the case of error occurrence. However, since the ERS flag is not automatically cleared, set the RIE bit to 1 beforehand to enable an ERI interrupt request to be generated at error occurrence, and clear the ERS flag to 0.

When transmitting/receiving data using the DMAC, be sure to make settings to enable the DMAC before making SCI settings. For DMAC settings, see section 15, DMA Controller (DMAC).

Note that CSR.TEND flag is set in different timings depending on the CCR3.GM bit setting. Figure 33.66 shows the TEND flag generation timing.

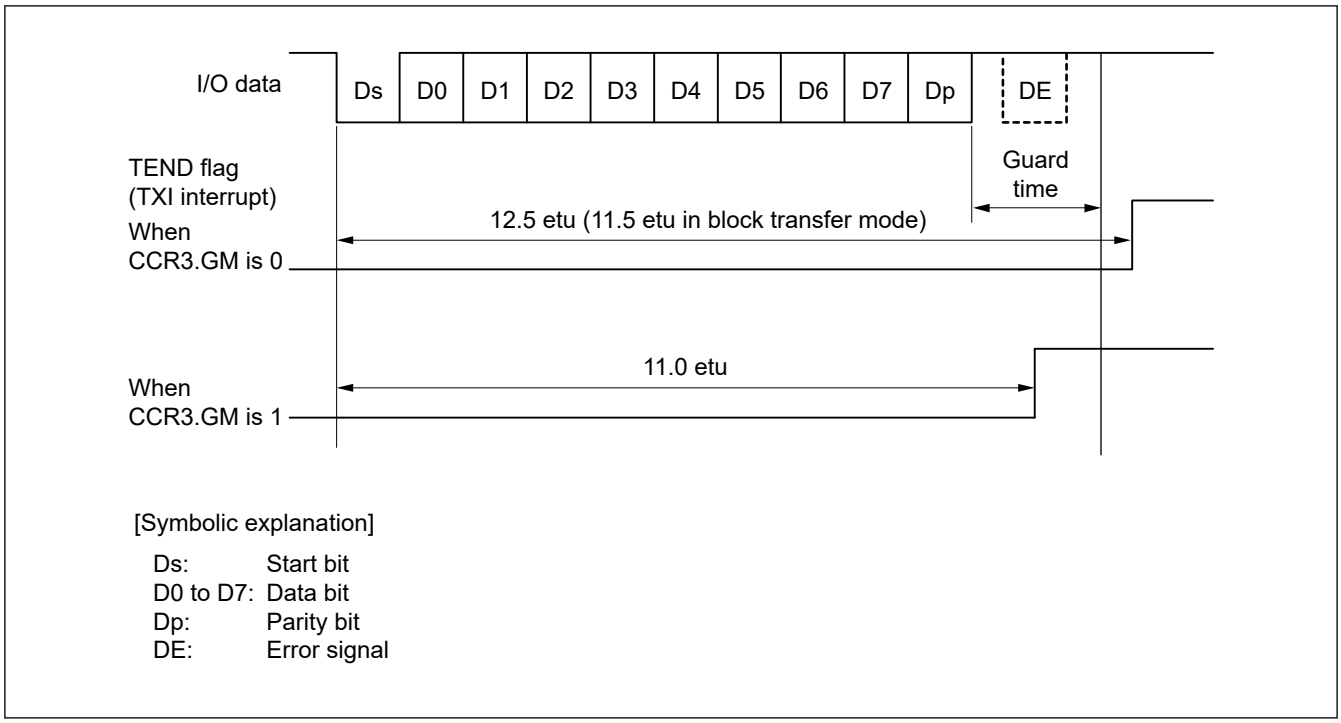


Figure 33.66 CSR.TEND flag generation timing during transmission

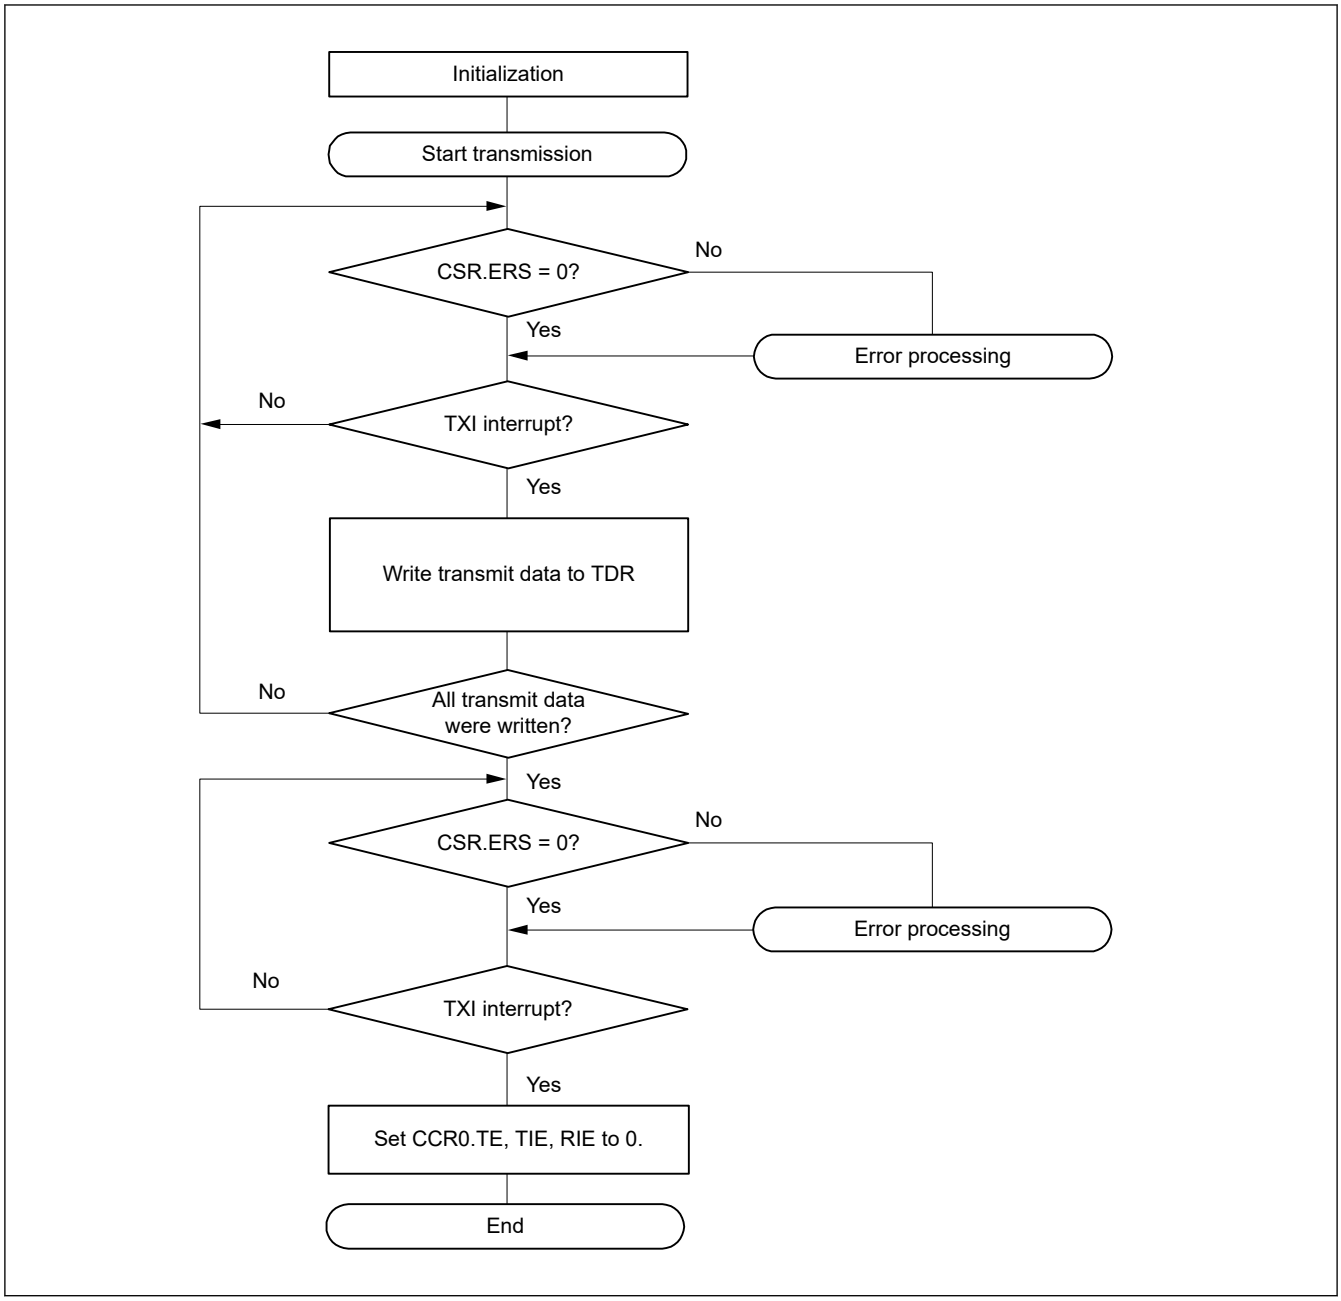

Figure 33.67 Sample smart card interface transmission flowchart

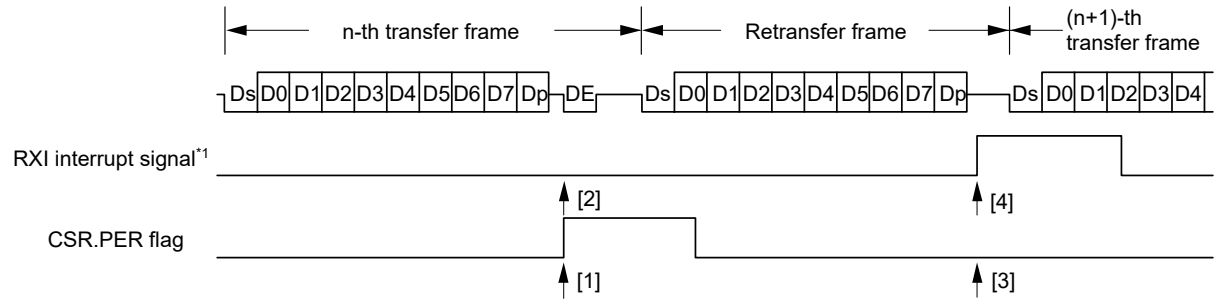
33.7.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is like that in non-smart card interface mode. Figure 33.68 shows the data retransfer operation in reception mode.

1. If a parity error is detected in receive data, the CSR.PER flag is set to 1. When the CCR0.RIE is 1 at this time, an ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no RXI interrupt is generated.
3. When no parity error is detected, the CSR.PER flag is not set to 1.
4. In this case, data is determined to have been received successfully. When the CCR0.RIE is 1, an RXI interrupt request is generated.



Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.68 Data retransfer operation in SCI reception mode (data retransfer operation during reception)

Figure 33.69 shows a sample flowchart for serial data reception. All the processing steps are automatically performed using an RXI interrupt request to activate the DMAC. In reception, setting the RIE bit to 1 allows an RXI interrupt request to be generated. The DMAC is activated by an RXI interrupt request if the RXI interrupt request is specified as a source of DMAC activation beforehand, allowing transfer of receive data. If an error occurs during reception and either the CSR.ORER or PER flag is set to 1, a receive error interrupt (ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DMAC is transferred.

Even if a parity error occurs and the PER flag is set to 1 during reception, receive data is transferred to RDR, thus allowing the data to be read. When a reception is forcibly terminated by setting the CCR0.RE to 0 during operation, read the RDR register because the received data which has not yet been read may be left in RDR.

Note: For operations in block transfer mode, see section 33.4. Asynchronous Mode.

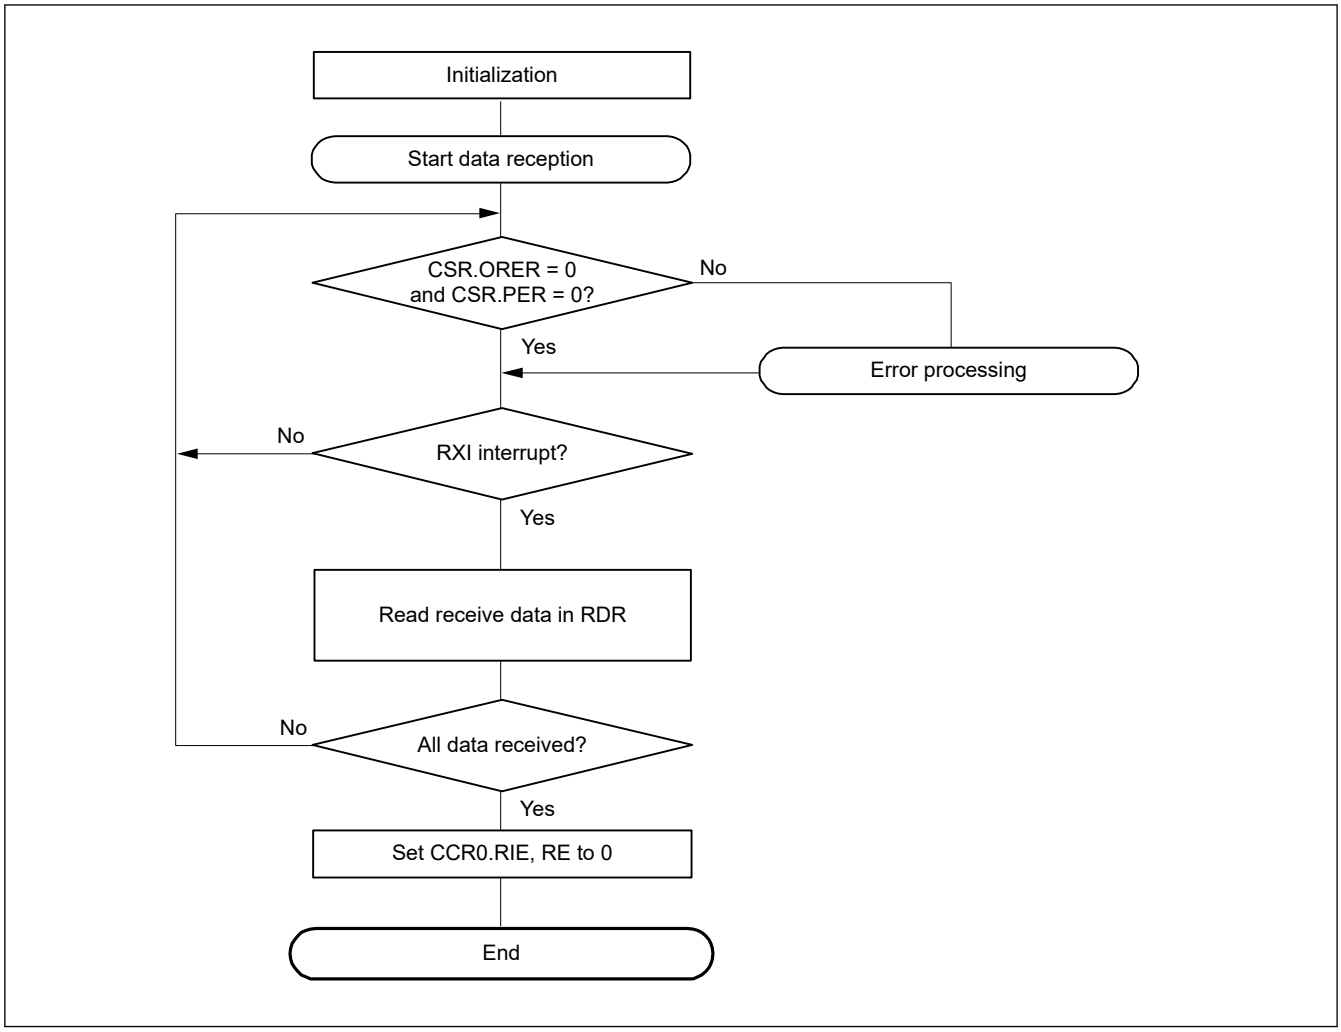


Figure 33.69 Sample smart card interface reception flowchart

33.7.8 Clock Output Control

When the CCR3.GM is set to 1, the clock output can be controlled by the CCR3.CKE[1:0]. Refer to the description of the CKE in section 33.3.8. CCR3 : Common Control Register 3. When setting the clock output, the base clock described in section 33.4.3. Clock is output, so the width of the clock pulse can be kept to the width specified by setting the bit rate. It is described in section 33.3.7. CCR2 : Common Control Register 2, the bit rate is set by CCR2.CKS[1:0], CCR2.BCP[2:0], and BRR[7:0].

Figure 33.70 shows the timing chart for explaining clock output control. This is an example when the CCR3.CKE[1] is set to 0 and the CCR3.CKE[0] is controlled.

When the CCR3.GM is 0, output control by the CCR3.CKE[0] is immediately reflected on the SCK pin, so there is a possibility that pulses with an unintended width may be output from the SCK pin.

When the CCR3.GM is 1, the output pulse control by the CCR3.CKE[0] controls the pulse width set to be based on the state of the base clock.

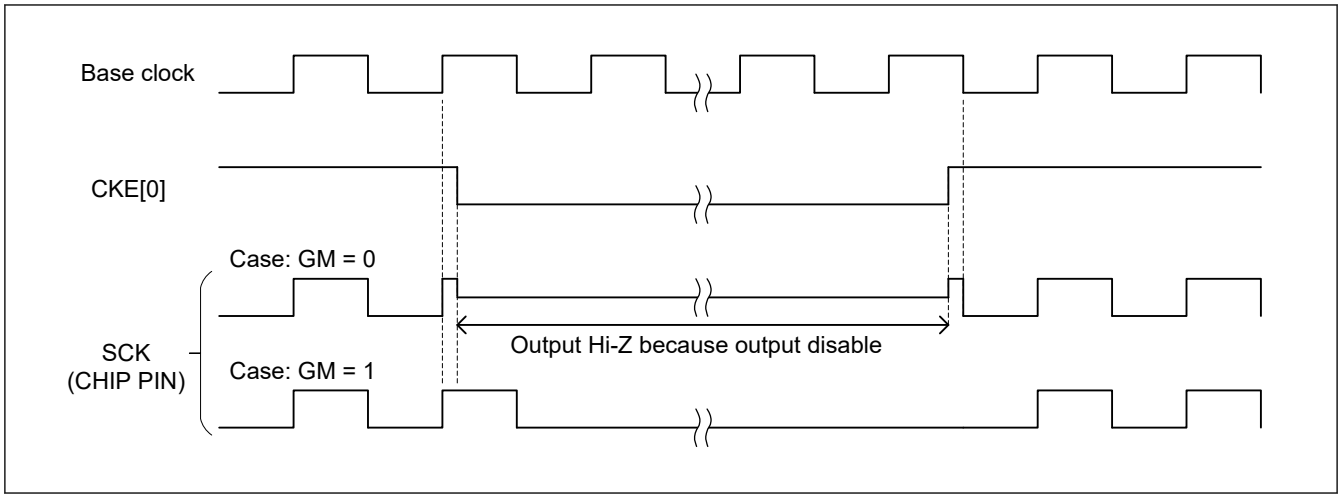

Figure 33.70 Clock control timing chart by CCR3.GM

33.8 Simple I2C mode

Simple I2C mode supports master operation only. Simple I2C bus format is composed of 8 data bits and an acknowledge bit. A slave-address frame follows start condition or restart condition. And the slave-address frame is used to specify a slave device as the partner by master device. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8-bit data of each frame is transmitted from MSB.

Figure 33.71 shows I2C bus format, and Figure 33.72 shows the timing of I2C.

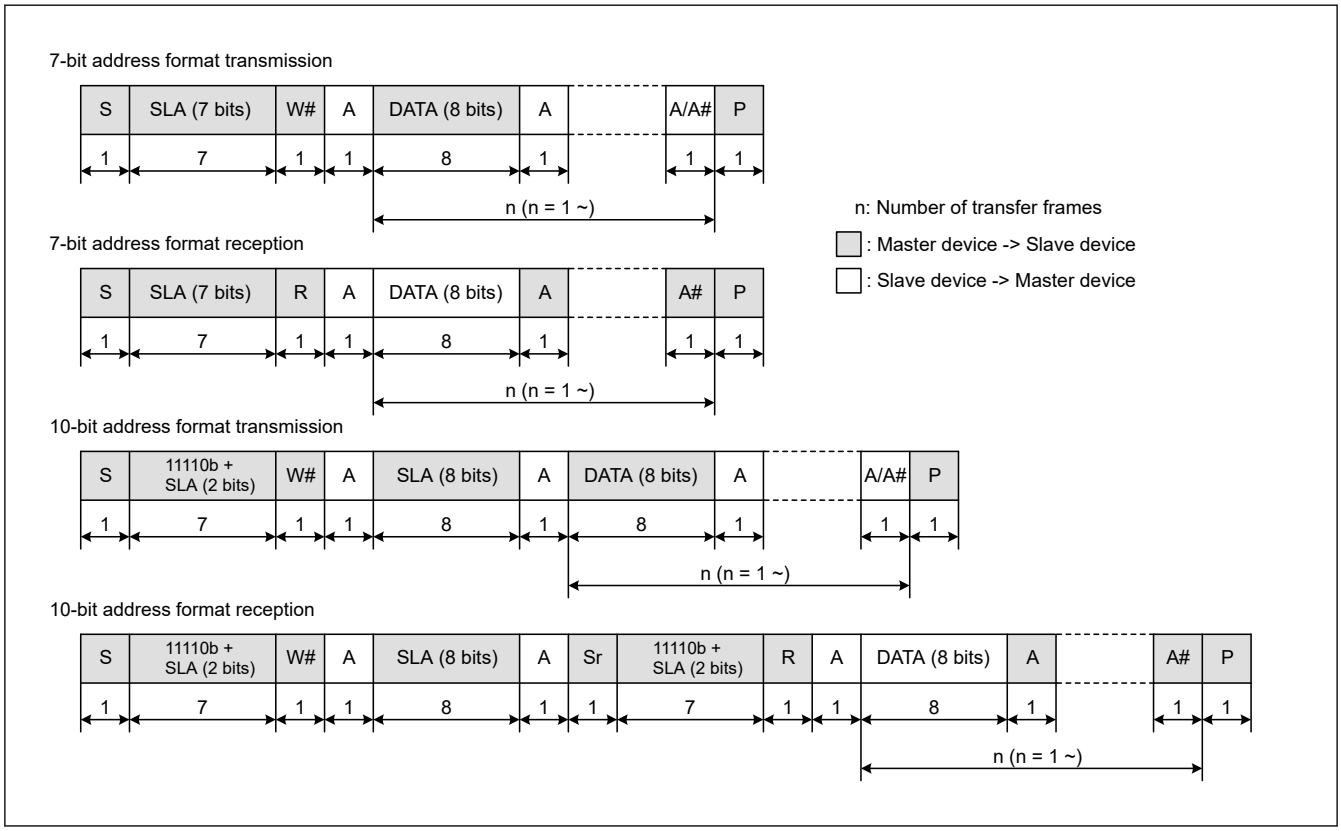

Figure 33.71 I2C bus format

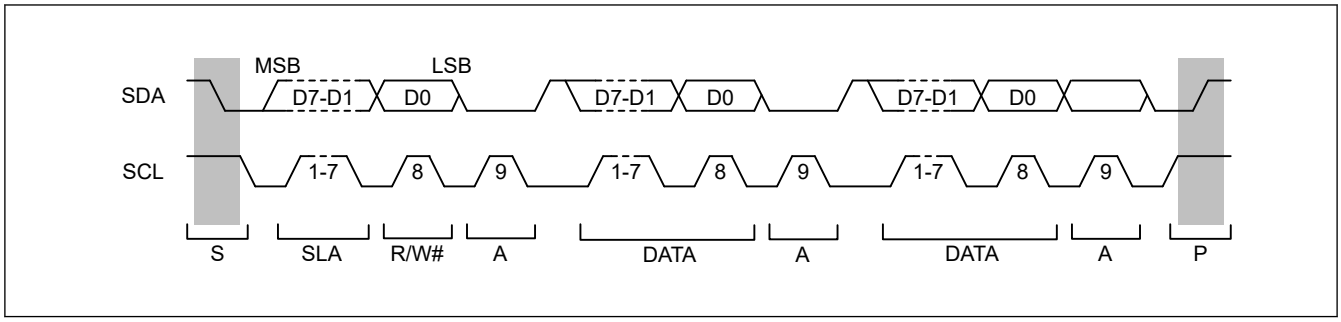

Figure 33.72 I2C bus timing (SLA = 7 bit)

[Symbol explanation]

S: Indicates a start condition. The master device changing the level on the SDAn line from the high to the low level when the SCLn line is at the high level.

SLA: Indicates a slave address. The master device selects a slave device.

R/W#: Indicates the direction of transfer (reception or transmission). When R/W# is high, the transfer direction is from the slave device to the master device. When R/W# is low, the transfer direction is from the master device to the slave device.

A/A#: Indicates an acknowledge. This is returned by the slave device for master transmission and by the master device for master reception. The low level indicates ACK and the high level indicates NACK.

Sr: Indicates a restart condition. The master device changing the level on the SDAn line from the high to the low level when the SCLn line is at the high level.

DATA: Indicates the received or transmitted data.

P: Indicates a stop condition. The master device changing the level on the SDAn line from the low to the high level when the SCLn line is at the high level.

33.8.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to ICR.IICSTAREQ causes the generation of a start condition. The following operations are done at the generation of a start condition.

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept in the released state.
- The hold time for the start condition is secured as half of a bit period at the bit rate determined by the setting of the CCR2.BRR.
- The level on the SCLn line falls (from the high level to the low level), the ICR.IICSTAREQ is set (to 0), and a start condition generated STI interrupt (SCIn_TEI) is output.

Writing 1 to ICR.IICRSTAREQ causes the generation of a restart condition. The following operations are done at the generation of a restart condition.

- The SDAn line is released and the SCLn line is kept at the low level.
- The period at low level for the SCLn line is secured as half of a bit period at the bit rate determined by the setting of the CCR2.BRR.
- The SCLn line is released (transition from the low to the high level).
- Once the high level on the SCLn line is detected, the setup time for the restart condition is secured as half of a bit period at the bit rate determined by the setting of the CCR2.BRR.
- The level on the SDAn line falls (from the high level to the low level).
- The hold time for the restart condition is secured as half of a bit period at the bit rate determined by the setting of the CCR2.BRR.
- The level on the SCLn line falls (from the high level to the low level), the ICR.IICRSTAREQ is set (to 0), and a restart condition generated STI interrupt (SCIn_TEI) is output.

Writing 1 to ICR.IICSTPREQ causes the generation of a stop condition. The following operations are done at the generation of a stop condition.

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept at the low level.
- The period at low level for the SCLn line is secured as half of a bit period at the bit rate determined by the setting of the CCR2.BRR.
- The SCLn line is released (transition from the low to the high level).
- Once the high level on the SCLn line is detected, the setup time for the stop condition is secured as half of a bit period at the bit rate determined by the setting of the CCR2.BRR.
- The SDAn is released (transition from the low to the high level), the ICR.IICSTPREQ is set (to 0), and a stop condition generated STI interrupt (SCIn_TEI) is output.

Figure 33.73 shows the timing of operations in the generation of start, restart and stop conditions.

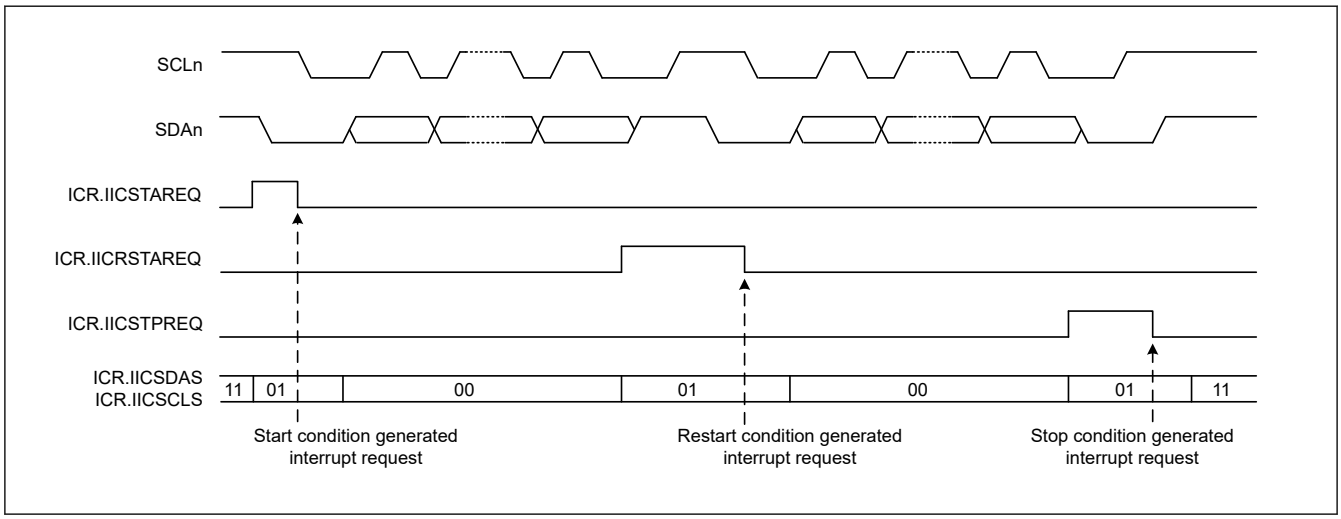

Figure 33.73 The timing of operations in the generation of start, restart and stop conditions

33.8.2 Clock Synchronization

The slave device of the communication partner may make SCLn line Low-level with a view to insert a wait. Setting the ICR.IICCSC to 1, applies control to obtain synchronization when the levels of the internal SCLn clock signal and the level being input on the SCLn pin differ.

When the ICR.IICCSC is set to 1, the level of the internal SCLn clock signal changes from low to high, counting to determine the period at high level is stopped while the low level is being input on the SCLn pin, and counting to determine the period at high level starts after the transition of the input on the SCLn pin to the high level. The interval until counting to determine the period at high level starts on the transition of the SCLn pin to the high level is the total time which contains the SCLn input delay, the noise filtering delay of the SCLn pin (2 or 3 cycles of the filtering clock), and the internal processing delay (1 or 2 cycles of PCLKSCIn). The period at high level of the internal SCLn clock is extended even if other devices are not placing the low level on the SCLn line.

If the ICR.IICCSC is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SCLn pin and the internal SCLn clock. If the ICR.IICCSC is 0, synchronization with the internal SCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a period of waiting into the interval until the transition of the internal SCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a period of waiting after the transition of the internal SCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the period of waiting, generation of the condition itself is not guaranteed.

Figure 33.74 shows an example of operations to synchronize the clocks.

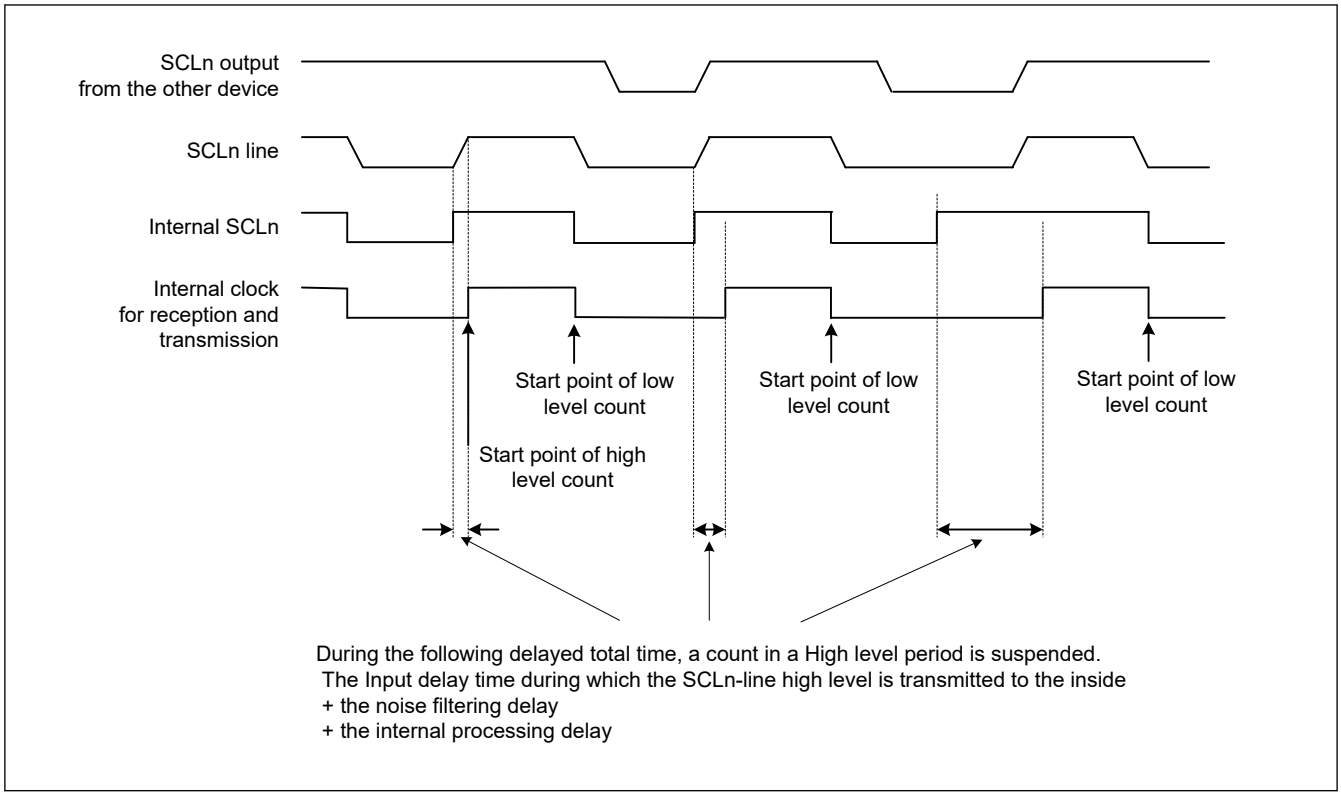

Figure 33.74 Example of operations for clock synchronization

33.8.3 SDA Output Delay

The ICR.IICDL[4:0] can be used to set a delay for output on the SDAn pin relative to falling edges of output on the SCLn pin. The delay-time settings are selectable from 0 to 31 cycles of the clock signal from the baud rate generator (The base is PCLKSCIn and selected the divided clock by the CCR2.CKS[1:0]). About Start/Restart/Stop conditions, 8-bit transmission data and acknowledge, the SDAn pin output can be delayed.

If the SDA output delay is shorter than the falling time of the SCLn output pin, the change of the SDAn output pin will start while the SCLn output pin level is falling, then there is a possibility of erroneous operation for slave devices. Ensure setting the SDA output delay greater than the SCLn maximum falling time (300 ns for I2C normal/fast mode).

Figure 33.75 shows the timing of SDA output delay.

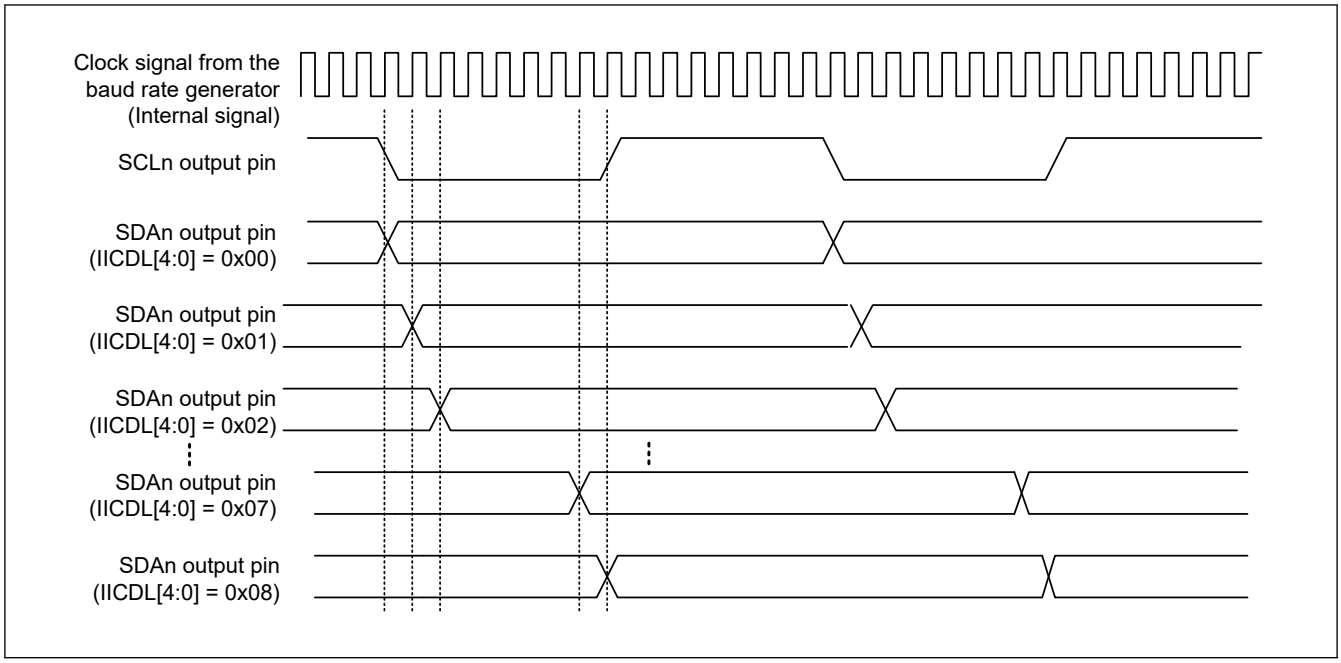

Figure 33.75 Timing of SDA output delay

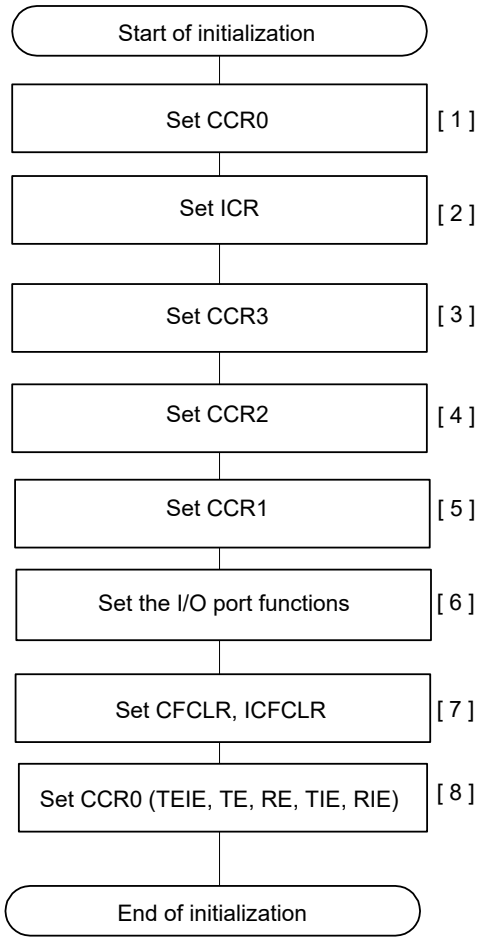
33.8.4 SCI Initialization (Simple I2C mode)

Write initial value (all 0) to CCR0, then initialize SCI according to Figure 33.76.

When changing the operating mode, transfer format, and so on, be sure to set 0 to CCR0.TE and CCR0.RE before proceeding with the changes. (Or write initial value to CCR0 again.)



Note 1. If you do not use the bit rate modulation function, you do not need to set it.

Note: Set the CCR0.TE and RE bits to 0 or 1 at the same time.

[1] Set the following bits of CCR0 to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set the IICSDAS[1:0] and IICSCLS[1:0] to 11b.
Set the IICDL[4:0] and IICINTM as required.
Set the IICACKT and the IICCSC bits to 1.

[3] Set the transmission/reception format as the communication mode (MOD[2:0] = 100b) and CCR3.LSBF = 0.

[4] Set the bit rate modulation function*1, the clock selection, and the bit rate.

[5] Set up the Noise-filter function.

[6] Set I/O port settings that allow use of the SCLn and SDAn pin functions.

[7] Write 1 to the following bits and clear the corresponding flag.
CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
ICFCLR.IICSTIFC

[8] Set the TE and RE to 1.
To enable interrupts, set the TE bit, TIE bit, TEIE bit, RE bit, and RIE bit to 1 with one instruction at the same time.
(for transmission and when the IICINTM bit is 1, clear the RIE bit.)
Setting the TE and RE bits to 1 makes the SCLn and SDAn pin functions available.

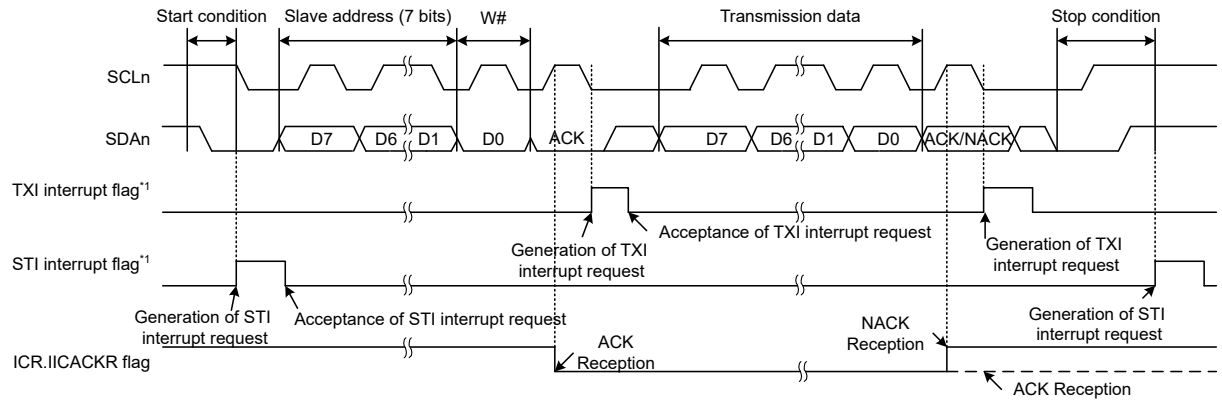
Figure 33.76 Example of the flow of SCI initialization (for simple I2C mode)

33.8.5 Operation in Master Transmission (Simple I2C mode)

Figure 33.77 and Figure 33.78 show examples of operations in master transmission, Figure 33.79, Figure 33.80, and Figure 33.81 show the example flowcharts. See Table 33.39 about the STI interrupt.

Figure 33.77 shows the operation example when ICR.IICINTM is 1 (Reception/Transmission interrupts are in use). In this case, you can start DMAC by TXI interrupt. However, if use DMAC, ACK/NACK can not be confirmed. So, if you want to confirm ACK/NACK, prepare transmit data by CPU. In simple I2C mode, TXI interrupt is generated when communication of one frame is completed. And it is not used RXI interrupt in master transmission, so the CCR0.RIE set to 0.

Figure 33.79 shows a flow chart in the case of ICR.IICINTM is 1 and address transmission by CPU and data transmission by DMAC. Figure 33.80 shows a flow chart of address and data transmission by CPU. When 10-bit slave addresses are in use, steps [3] and [4] are repeated twice.



Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

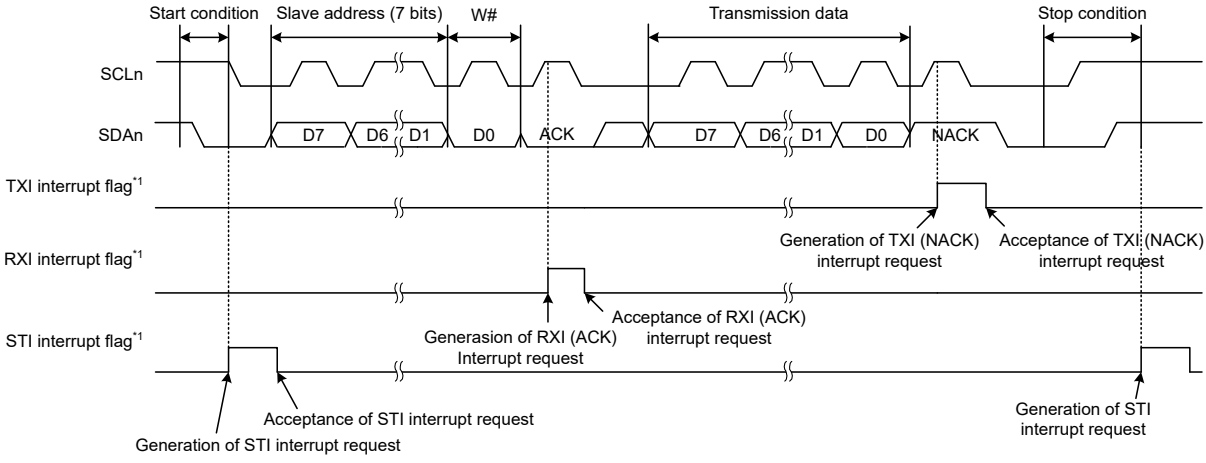
Figure 33.77 Example 1 of operations for master transmission in simple I2C bus mode (7-bit slave address, transmission and reception interrupt in use (ICR.IICINTM = 1))

Figure 33.78 shows an example of operations when ICR.IICINTM is 0 (ACK and NACK interrupt in use). In this case, DMAC is activated by the ACK (RXI) interrupt, and necessary number of data bytes are transmitted. When the NACK is received, error processing, such as transmission stop and retransmission, is performed by the NACK (TXI) interrupt as the trigger.

Figure 33.81 shows a flow chart of ICR.IICINTM is 0.

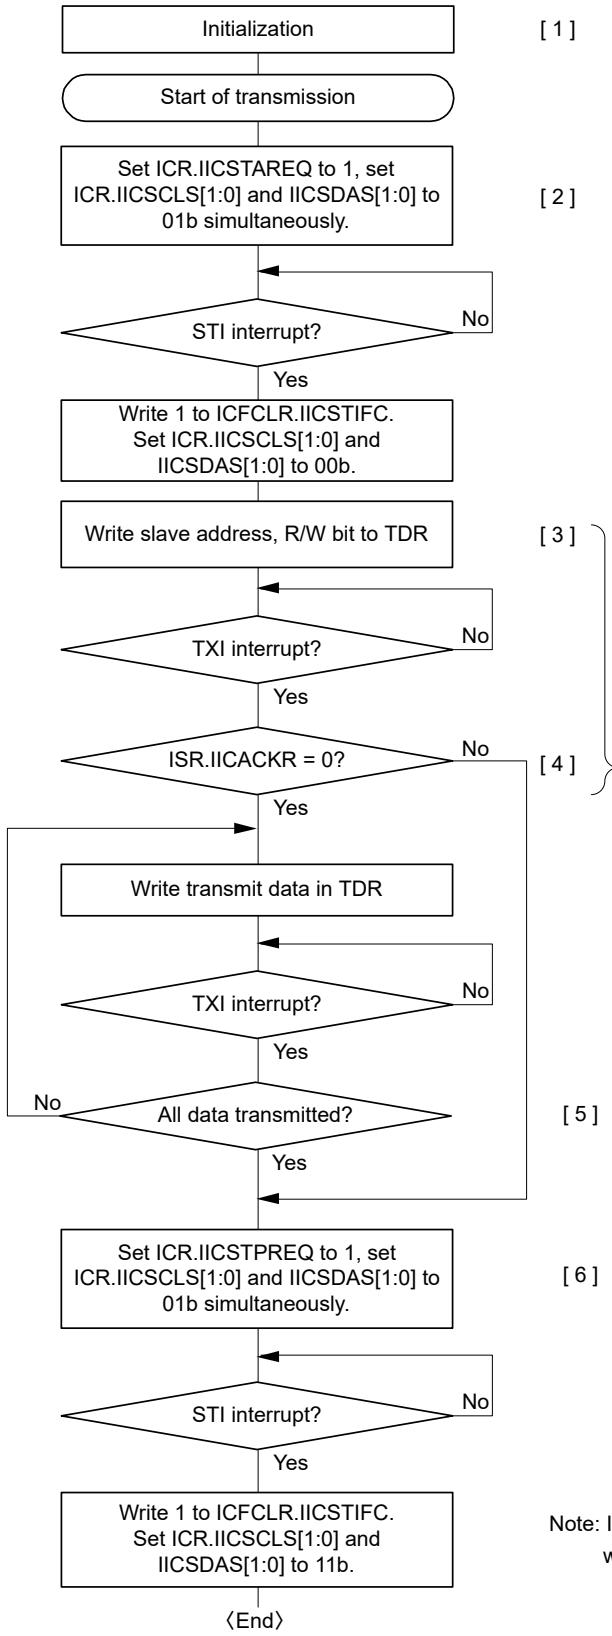
To resume communication after interrupting communication for some reason after writing transmit data to TDR, follow the procedure below.

1. Set the CCR0.TE and CCR0.RE bits to 0 to stop communication.
2. Set ICR.IICSCLS[1:0] and ICR.IICSDAS[1:0] to 11b, release the I2C bus, and clear various condition generation requests.
3. When CSR.RDRF = 1, the RDR register is read by dummy and the RDRF bit is set to 0.
4. Set the CCR0.TE and CCR0.RE bits to 1 and restart communication.



Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.78 Example 2 of operations for master transmission in simple I2C bus mode (7-bit slave address, ACK and NACK interrupt in use (ICR.IICINTM = 0))



[1] Initialization for simple I2C mode
For transmission, set the CCR0.RIE to 0.
(RXI and ERI interrupts requests are disabled)

[2] Generate a start condition.

[3] Writing to TDR:
Writing the slave address and value for the R/W bit to TDR.

[4] Confirm ACK response from the slave device:
Check the ISR.IICACKR bit. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device so the next transition is to generation of the stop condition.

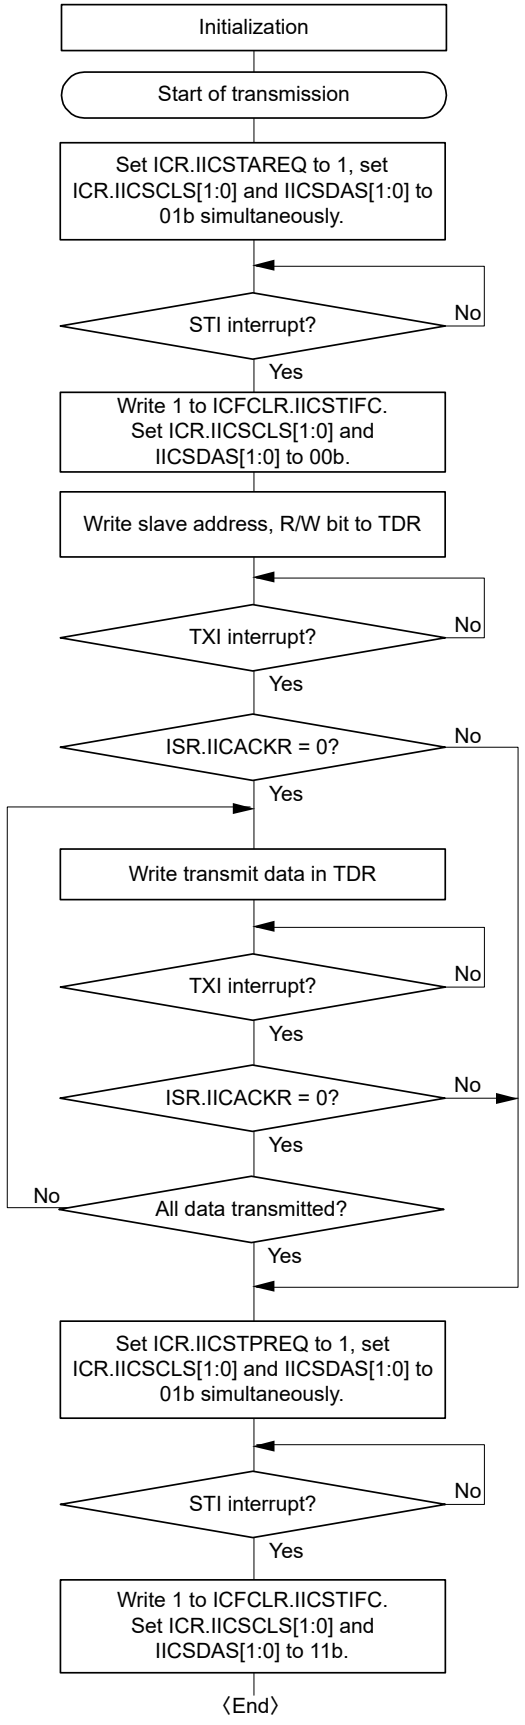
[5] Steps for continuing with serial transmission:
When transmission is to continue, write further transmit data to TDR. Except for the first data to be transmitted, a TXI interrupt request can activate the DMAC to handle writing of data to TDR.
But it cannot be confirmed status of ACK or NACK in this case.

[6] Generation of a stop condition.

If 10-bits slave address are in use, processing from [3] to [4] is repeated twice.

Note: In simple I2C mode, the TXI interrupt request is generated when communication is completed.

Figure 33.79 Example of the procedure for master transmission operations in simple I2C mode (when ICR.IICINTM is 1, and when confirming ACK / NACK by address transmission only.)



[1] [1] Initialization for simple I2C mode
For transmission, set the CCR0.RIE to 0.
(RXI and ERI interrupts requests are disabled)

[2] Generate a start condition.

[2] [3] Writing to TDR:
Writing the slave address and value for the R/W bit to TDR.

[4] Confirm ACK response from the slave device:
Check the ISR.IICACKR bit. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device so the next transition is to generation of the stop condition.

[3] [5] Steps for continuing with serial transmission:
When transmission is to continue, write further transmit data to TDR. If ACK or NACK is checked in every transmission, DMAC cannot be used.

[6] Generation of a stop condition.

[4] If 10-bits slave address are in use, processing from [3] to [4] is repeated twice.

[5]

[6]

Note: In simple I2C mode, the TXI interrupt request is generated when communication is completed.

Figure 33.80 Example of the procedure for master transmission operations in simple I2C mode (when ICR.IICINTM is 1, and when confirming ACK / NACK in all transmissions.)

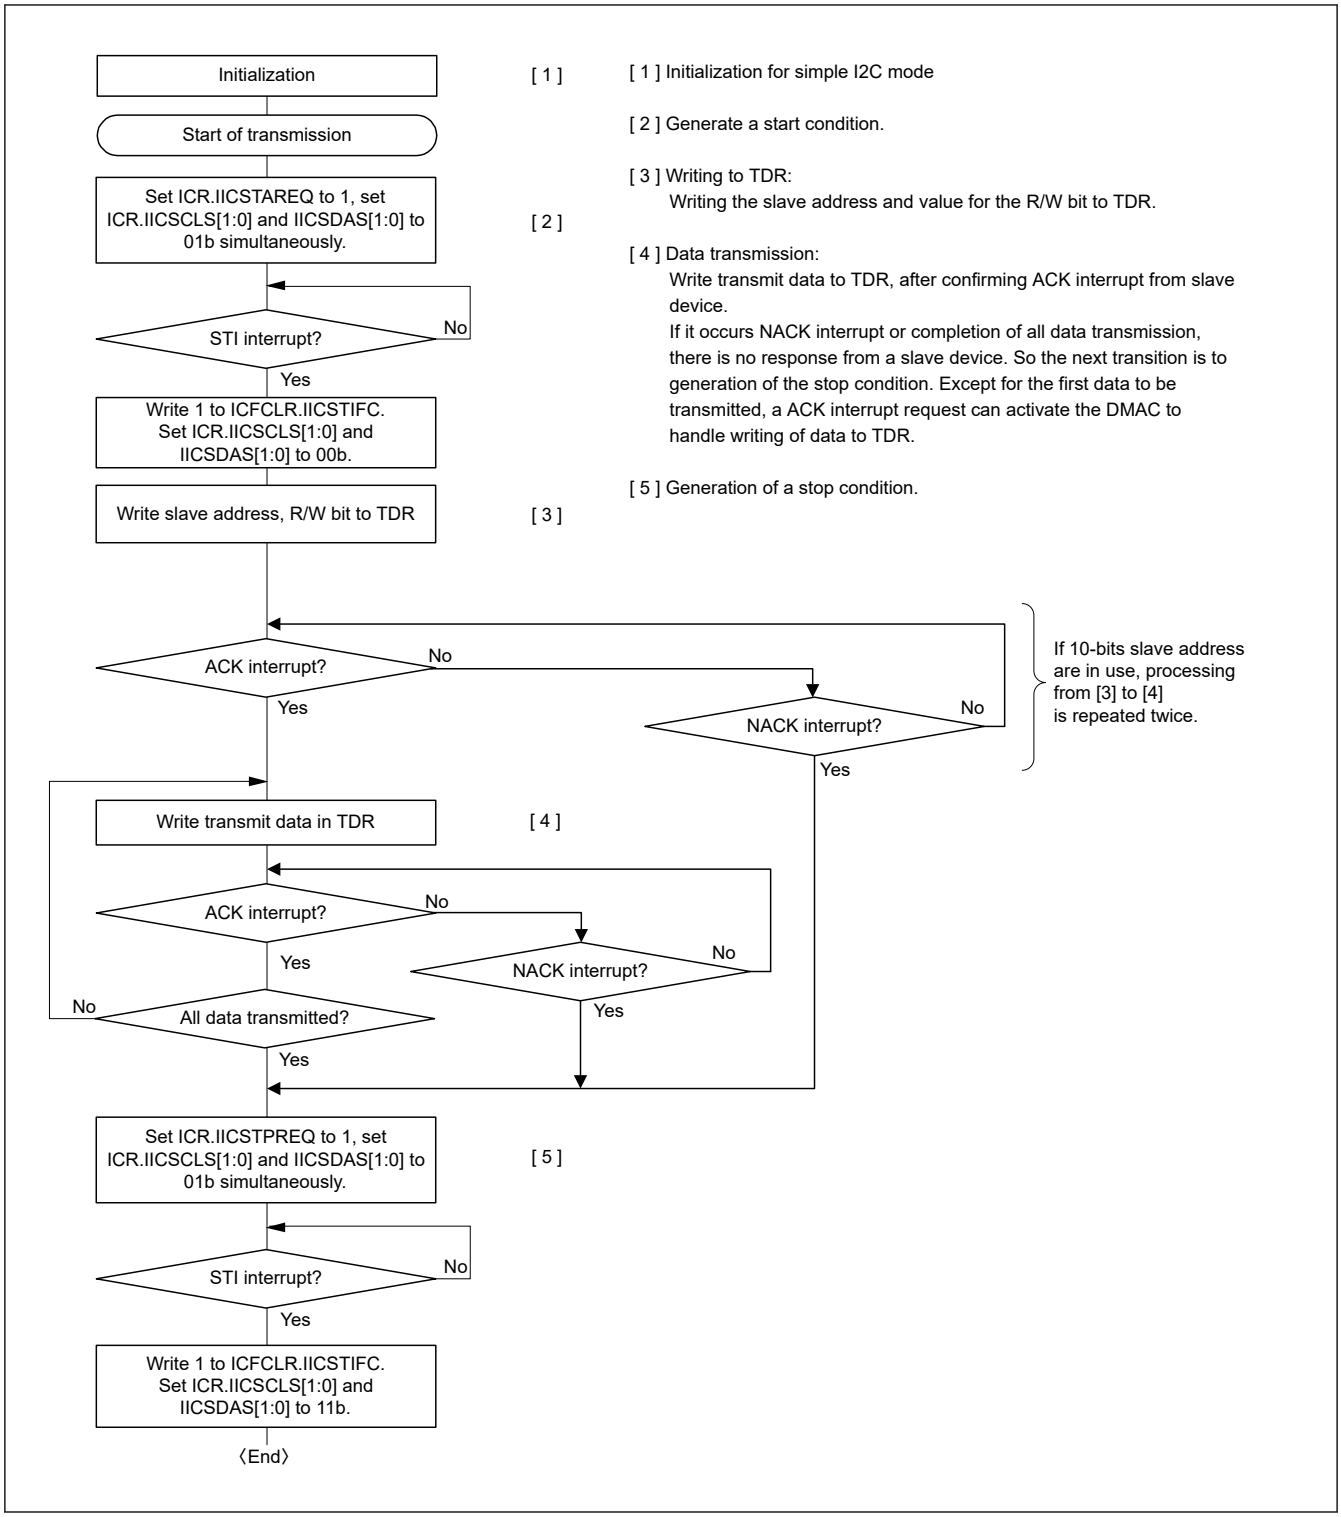


Figure 33.81 Example of the procedure for master transmission operations in simple I2C mode (when ICR.IICINTM is 0.)

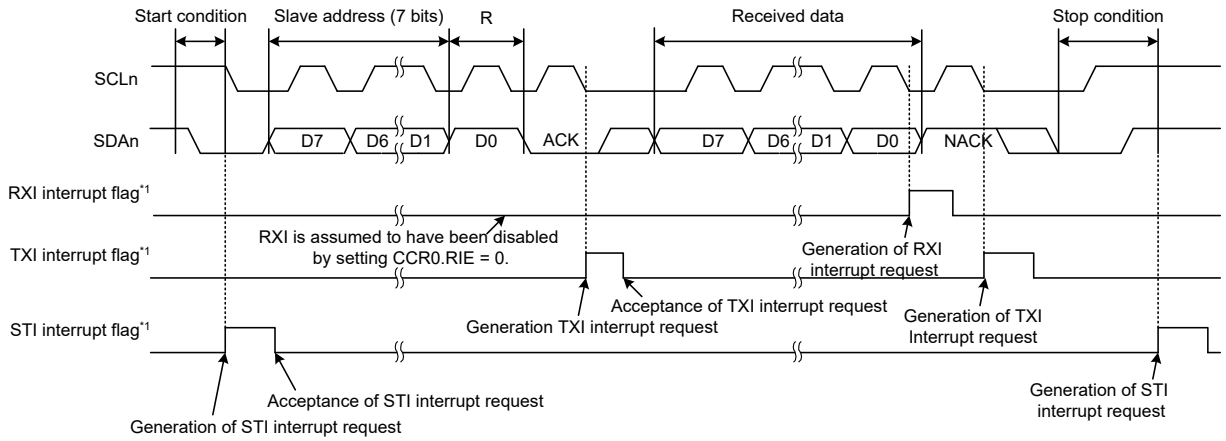
33.8.6 Master Reception (Simple I2C mode)

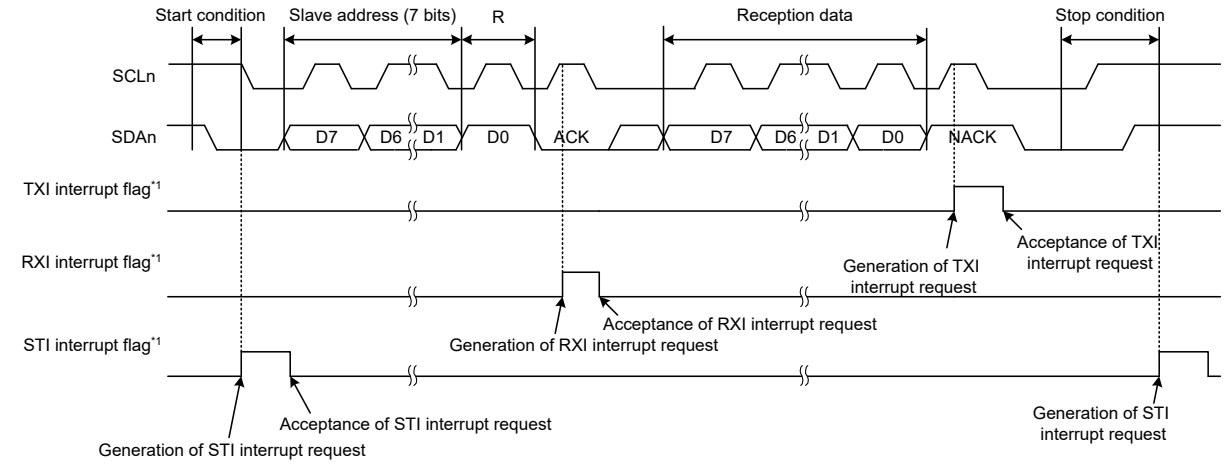
Figure 33.82 and Figure 33.83 show example of operations in simple I2C mode master reception. Figure 33.84 and Figure 33.85 show flowchart of the master reception. The value of the ICR.IICINTM bit is assumed to be 1 (use reception and transmission interrupts) and 0 (use ACK and NACK interrupts).

In simple I2C mode, the transmit data empty interrupt (TXI) is generated when communication of one frame is completed.



Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.82 Example of operations for master reception in simple I2C bus mode (7-bit slave address, transmission and reception interrupt in use (ICR.IICINTM = 1))



Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.83 Example of operations for master reception in simple I2C bus mode (7-bit slave address, ACK and NACK interrupt in use (ICR.IICINTM = 0))

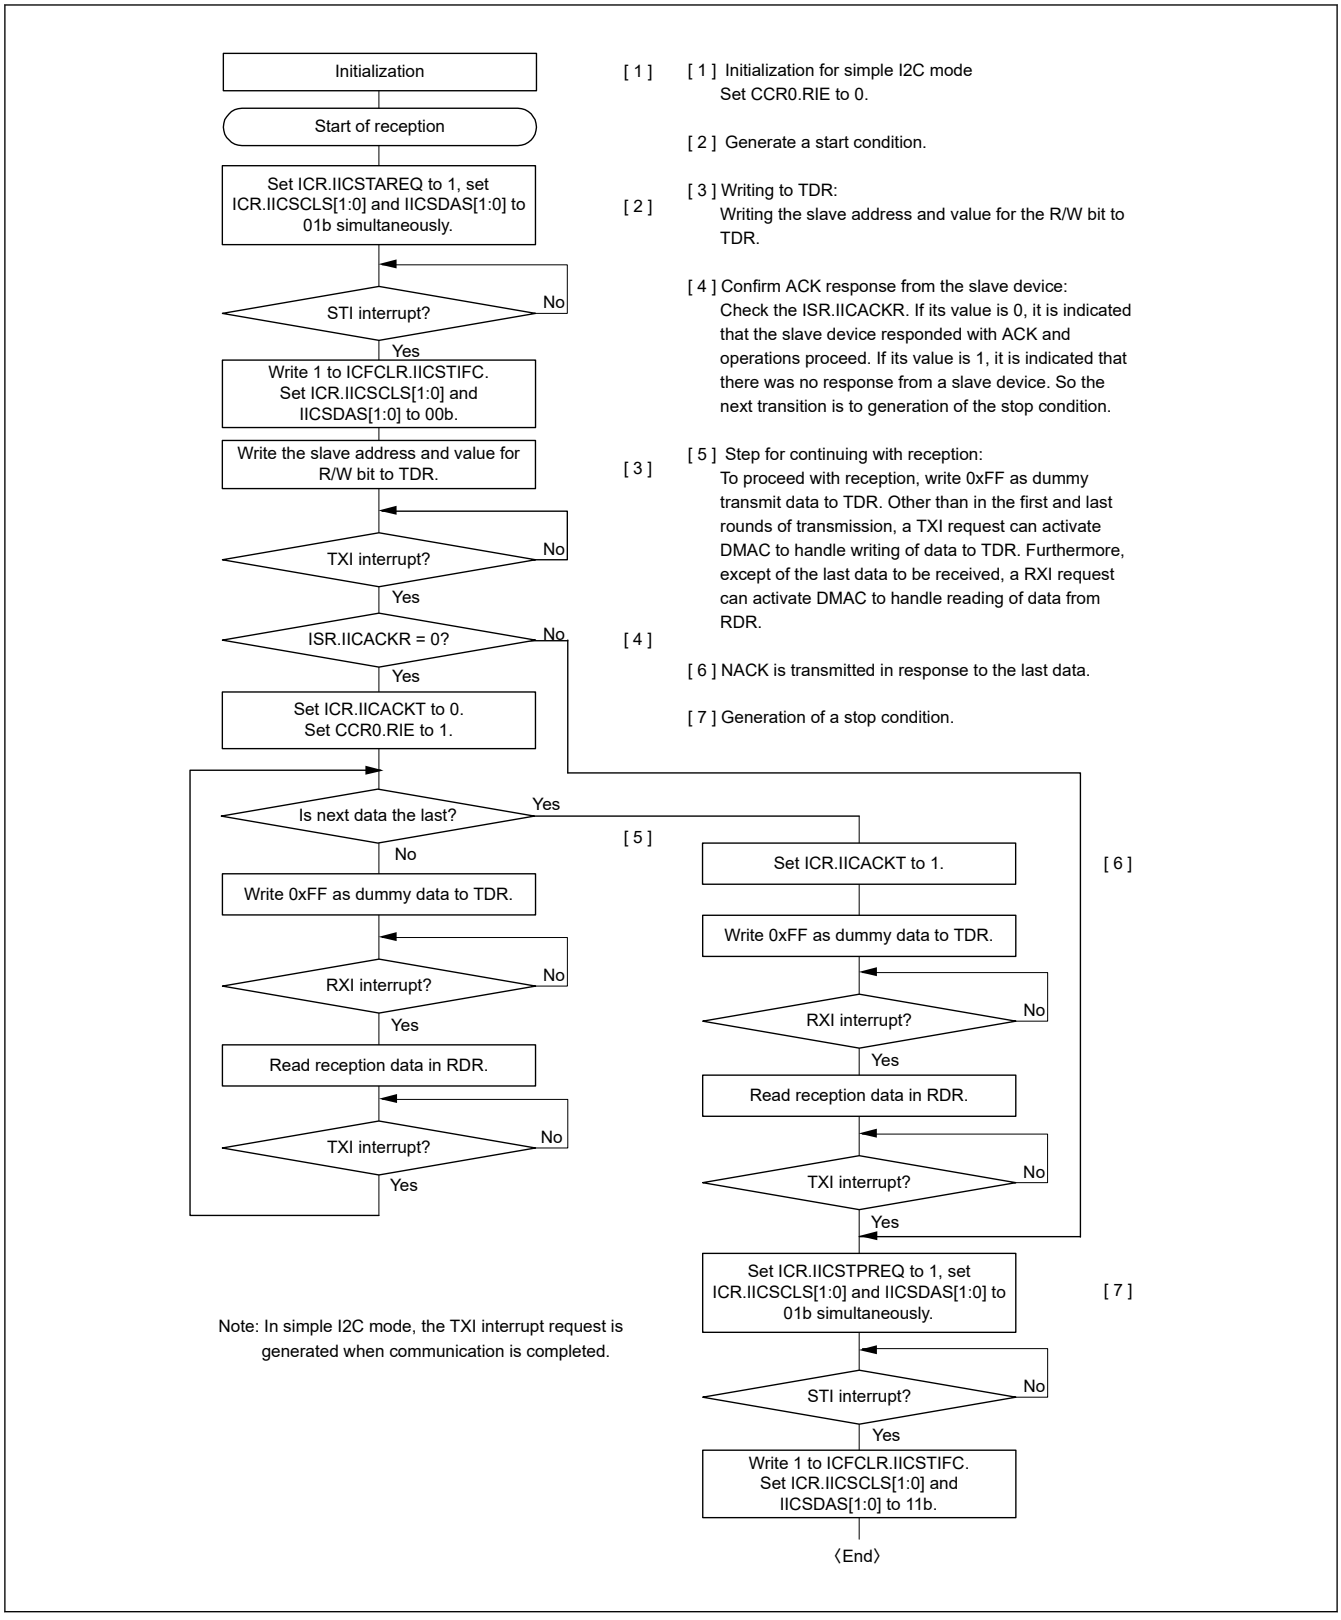


Figure 33.84 Example of the procedure for master reception operations in simple I2C mode (when ICR.IICINTM is 1, and transmission interrupts and reception interrupts are in use.)

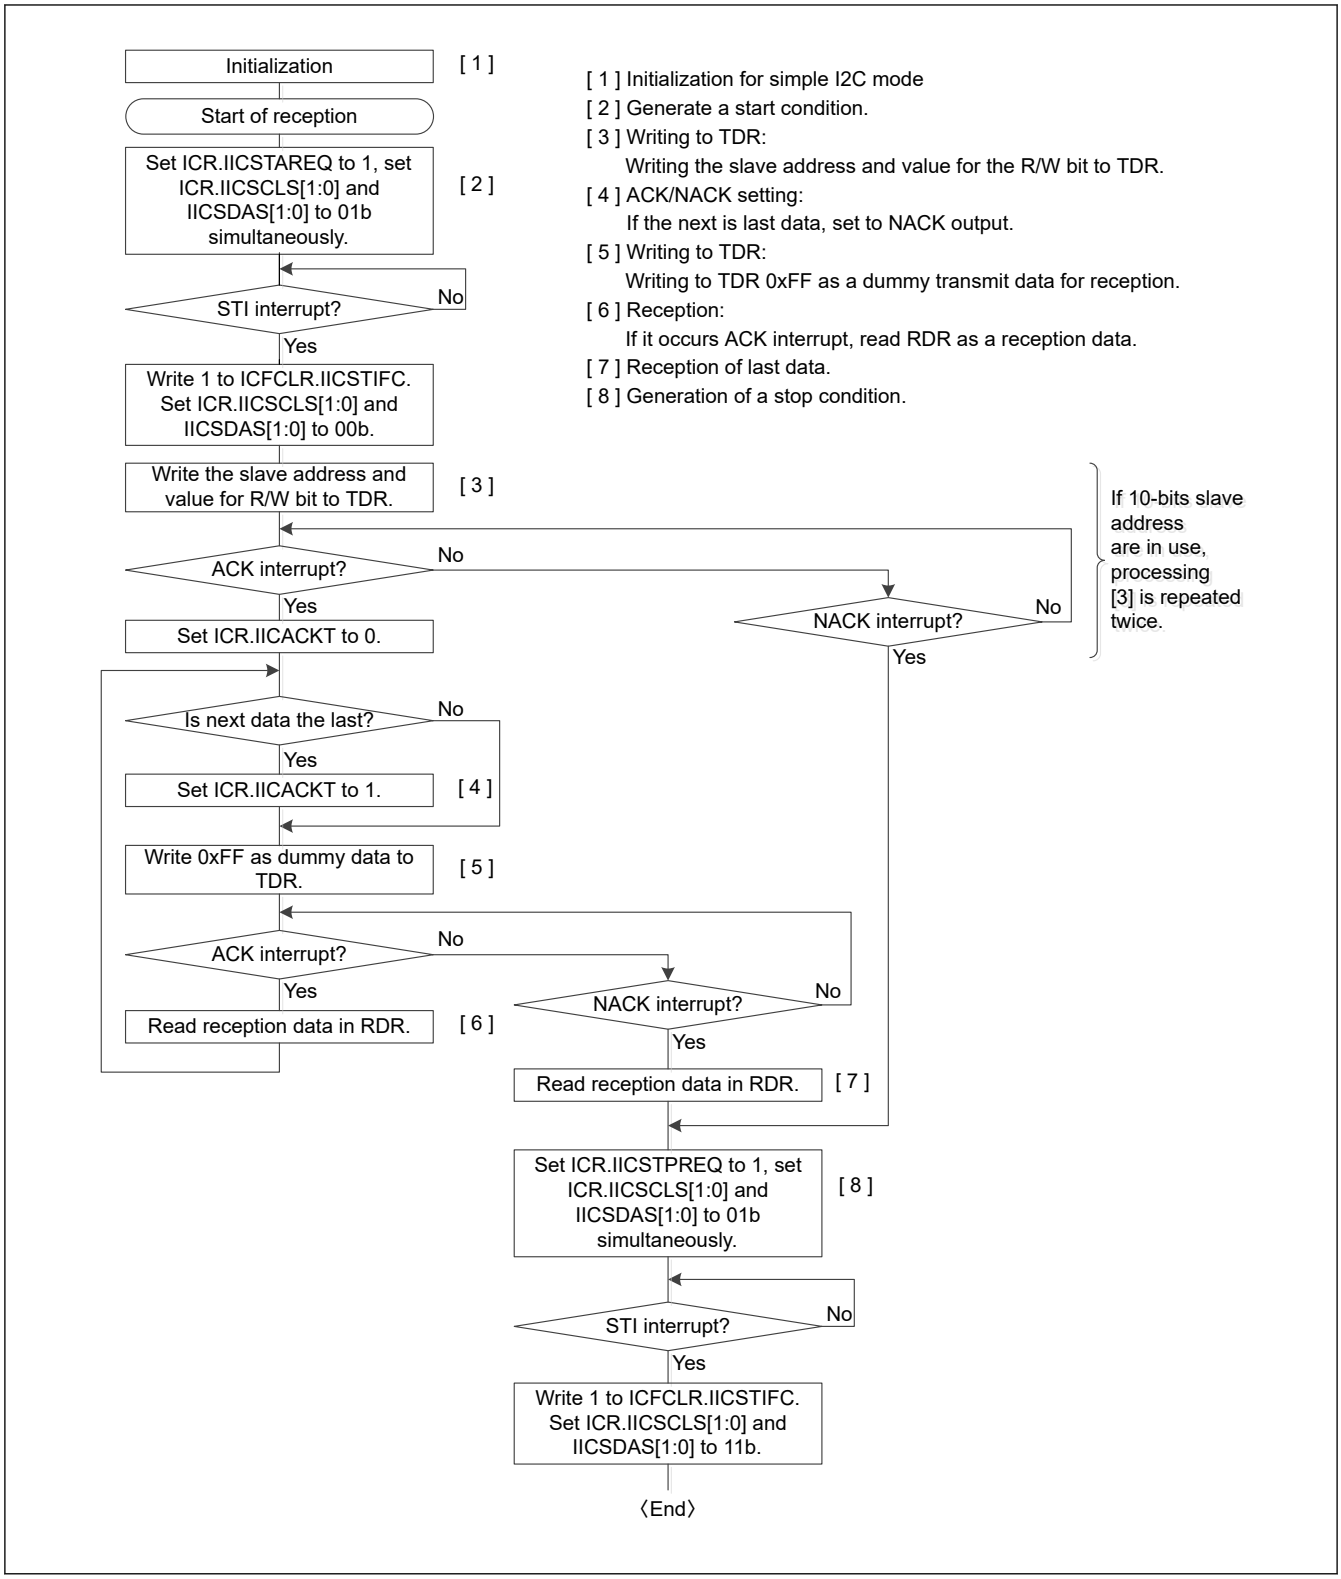

Figure 33.85 Example of the procedure for master reception operations in simple I2C mode (when ICR.IICINTM is 0, and ACK interrupts and NACK interrupts are in use.)

33.9 Clock Synchronous Mode

Figure 33.86 shows the communication data format of clock synchronous serial communication.

In clock synchronous mode, data is transmitted and received in synchronization with clock pulses. A communication data character consists of 8-bit data. In clock synchronous mode, no parity bit can be added. In data transmission when CPHA = 1 and CPOL = 1, the SCI outputs data from the falling edge of the sync clock until the next falling edge. In data reception,

data is read at the rising edges of the sync clock. After 8-bit data is output, the communication line holds the final-bit output state. In slave communication when CPHA = 1, however, the communication line holds the first-bit output state.

Because the SCI has an internal transmitter and a receiver independently, SCI enable full-duplex communication by sharing a communication clock of the transmitter and the receiver. Furthermore, because both the transmitter and the receiver have a double- buffer structure, continuous transmission and reception are possible by writing the next transmit data during transmission and reading the previous receive data during reception.

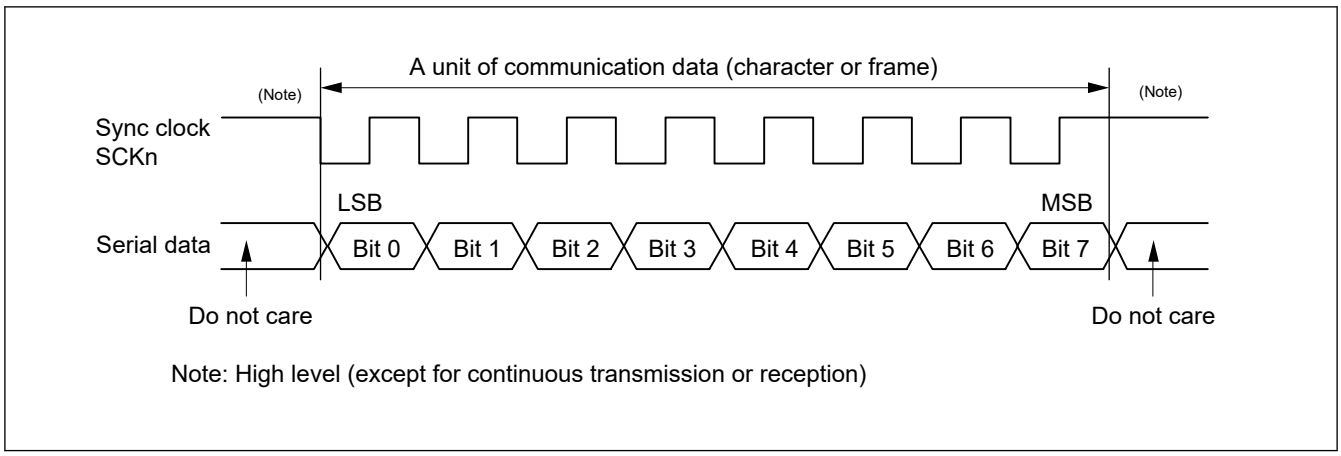

Figure 33.86 Data format of clock synchronous serial communication (LSB first, CPHA = 1, CPOL = 1)

33.9.1 Clock

(1) When the internal clock is selected

When the CCR3.CKE[1:0] bits are set to 00b or 01b (master mode), the internal clock generated by the baud rate generator can be selected and the sync clock is output from the SCKn pin. Eight pulses of the sync clock are output during single-character transmission/reception. The sync clock remains at a high level[*1] while no transmission or reception is performed. In transmission-only or transmission/reception, the sync clock is not output unless transmit data is prepared.

When the internal clock is selected, the clock with a delay from the SCKn signal is used for the master reception sampling clock. This ensures the data setup time and hold time for high-speed communication.

Note 1. When CCR3.CPOL = 1, the sync clock stops at a high level. When CCR3.CPOL = 0, the sync clock stops at a low level.

(2) When the external clock is selected

When the CCR3.CKE[1:0] bits are set to 10b or 11b (slave mode), data is transmitted and received using the external clock that is input from the SCKn pin.

33.9.2 CTS and RTS Functions

The CTS function performs transmission/reception and controls transmission start using the CTSn# pin input when the internal clock is selected. Setting the CCR1.CTSE bit to 1 enables the CTS function. Two settings are possible for the CTS/RTS pin: dual setting for using either function with a single pin, and dedicated setting for using each function simultaneously with two pins. The CCR1.CTSPEN register is used for these settings.

When the CTS function is enabled, transmission/reception and transmission start only when the CTSn# pin input level is low. Even if the CTSn# pin input becomes high level during transmission/reception or transmission operation, frames that are being transmitted/received or being transmitted are not affected and transmission/reception or transmission operation continues.

The RTS function makes a serial communication start request using the RTSn# pin output when the external sync clock is selected. When serial communication is enabled, the RTSn# pin outputs a low level. A low level and a high level are output under the following conditions.

[Conditions for low level]

(1) When a non-FIFO buffer is selected, all the following conditions are met.

- CCR0.RE bit or TE bit = 1
- Serial communication is enabled.
- No receive data is present before reading. (when CCR0.RE bit = 1)
- Data before transmission start is remaining in the TSR register. (when CCR0.TE bit = 1)
- CSR.ORER flag = 0

(2) When a FIFO buffer is selected, all the following conditions are met.

- CCR0.RE bit or TE bit = 1
- Serial communication is enabled
- The number of receive data stored in the receive FIFO (RDR register) is less than the value set in FCR.RSTRG[4:0]. (when CCR0.RE bit = 1)
- Unsent data is remaining in the transmit FIFO (TDR register). (when CCR0.TE bit = 1 and CCR3.CKE[1] bit = 0)
- Data before transmission start is remaining in the TSR register. (when CCR0.TE bit = 1 and CCR3.CKE[1] bit = 1)
- ORER (RDR.ORER) flag = 0

[Conditions for high level]

(1) When a non-FIFO buffer is selected

If conditions for low level are not met:

When CCR0.RE is set to 0 without reading the RDR register to terminate reception after reception is complete, the RTSn# pin output level remains high. At this time, write 0 to CCR0.RE.

(2) When a FIFO buffer is selected

If conditions for low level are not met:

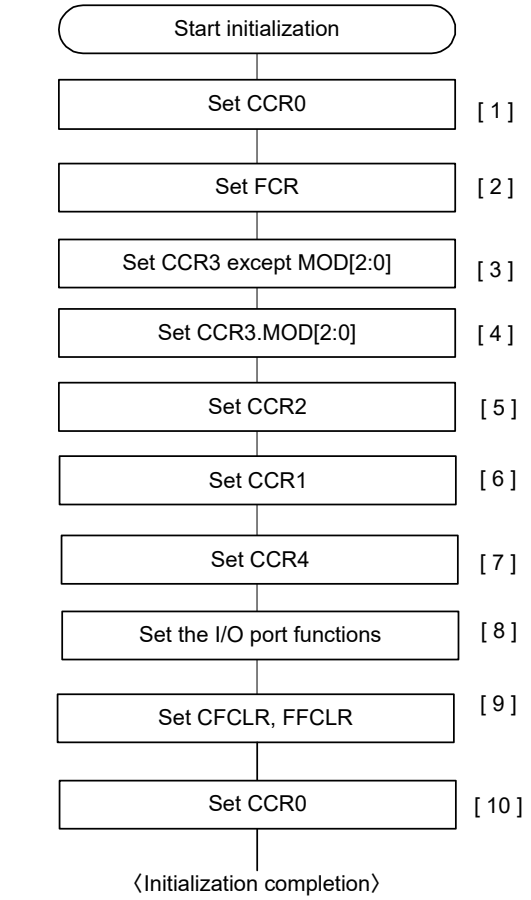
33.9.3 Initializing the SCI (Clock Synchronous Mode)

Before starting data transmission/reception, write 0 to CCR0.TE and CCR0.RE (or write initial values to the CCR0 register) and initialize the SCI according to the flowchart example in Figure 33.87.

Before changing operating mode or communication format, also be sure to write 0 to CCR0.TE and CCR0.RE.

Note that writing 0 to the RE bit does not initialize the ORER, FER, PER, and RDRF flags in CSR and the RDR register. Also note that writing 0 to the TE bit does not initialize the TEND flag when a FIFO buffer is selected. Attention is also needed for changing operating mode.

When CCR0.TIE = 1, note that setting the TE bit to 1 from 0 generates a TXI interrupt.



Note 1. In simultaneous transmit and receive operations, the TE and RE bits in CCR0 should both be to 0 or set to 1 simultaneously.

Note 2. Set CPOL and CPHA before setting the Communication mode.

Note 3. If you do not use the bit rate modulation function, you do not need to set it.

Note 4. If you use an external clock, you do not need to set it.

Note 5. When using the internal clock (master), the setting of reception only is prohibited.

[1] Set the following bits of CCR0 to 0[*1].
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set the TFRST and RFRST to 1 to empty FIFO.
Set the TTRG[4:0], RTRG[4:0], and RSTRG[4:0] bits.

[3] Set CCR3 except of communication mode.
FIFO use / no-use
Transmission / reception format
Clock setting
Leave unused bits (CHR[1:0], STP, RXDESEL, MP, DE, ACS0,GM,BLK) at their initial values.

[4] Set communication mode (MOD[2:0] = 010b)[*2].

[5] Set up the bit-rate-modulation function[*3 *4], select clock, set bit rate[*4]. Leave unused bits (BCP[2:0], ABCS, ABCSE) at their initial values.

[6] Set up the Noise-filter function, the loop-back function, communication terminal status, the parity check function, and the CTS/RTS function.

[7] Set up the adjust sampling timing function.
Leave unused bits (CMPD[8:0], ATEN, ATT[2:0], AET) at their initial values.

[8] Make I/O port settings to enable input and output functions as required for TXDn, RXDn, SCKn, CTS#, and RTSn# pins.

[9] Write 1 to the following bits and clear the corresponding flag.
CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
FFCLR.DRC

[10] Set the TE or RE bit to 1.[*1 *5] To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time.
Setting the TE and RE bits allows TXDn and RXDn to be used.

Figure 33.87 SCI initialization flowchart example (clock synchronous mode)

33.9.4 Serial Data Transmission (Clock Synchronous Mode)

(1) Non-FIFO selected

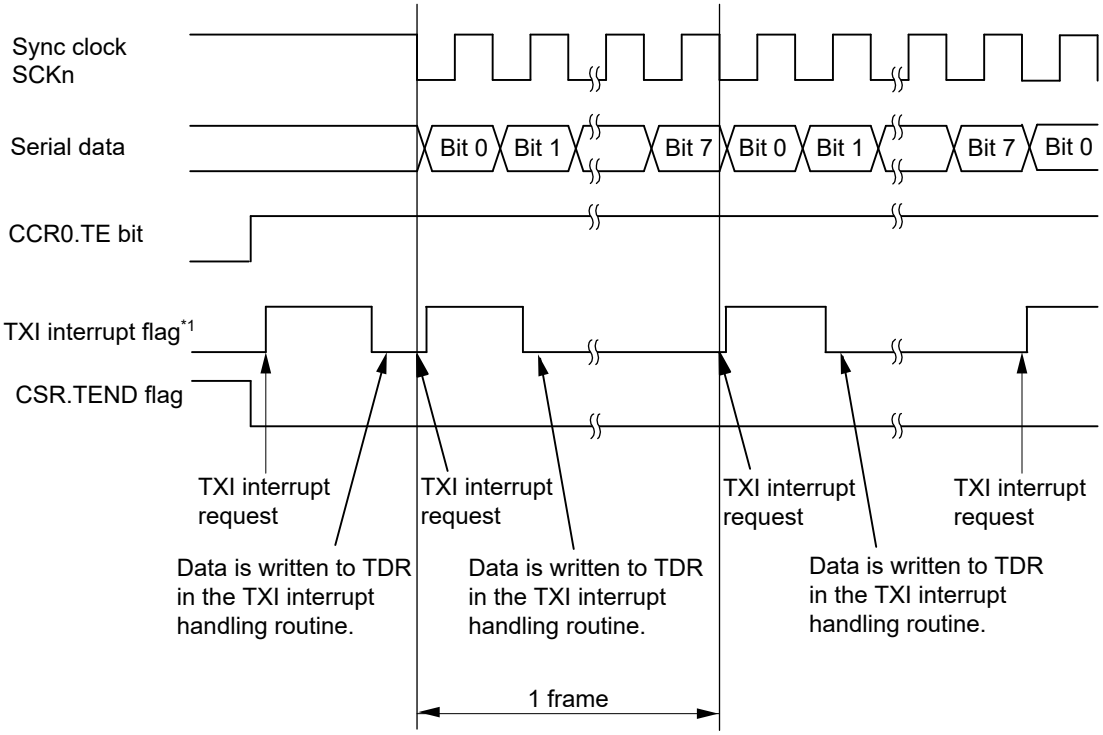
Figure 33.88, Figure 33.89, and Figure 33.90 show operation examples of serial transmission in clock synchronous mode. The SCI operates as follows during serial data transmission.

1. When data is written to the TDR register in the TXI interrupt routine, the SCI transfers the data from the TDR register to the TSR register. When starting data transmission, set the CCR0.TIE bit and the CCR0.TE bit to 1 simultaneously by a single instruction. Then a TXI interrupt request is generated.
2. The written data is transferred from the TDR register to the TSR register, which starts transmission. When the CCR0.TIE bit is set to 1 at this time, a TXI interrupt request is generated. Writing the next transmit data to the TDR register before transmission of data transferred previously in the TXI interrupt routine is complete enables continuous transmission. When a TEI interrupt request is used, after the final transmit data is written to the TDR register in the TXI

interrupt request processing routine and the final data's transmission is started, set 0 to the CCR0.TIE bit and set 1 to the TEIE bit.

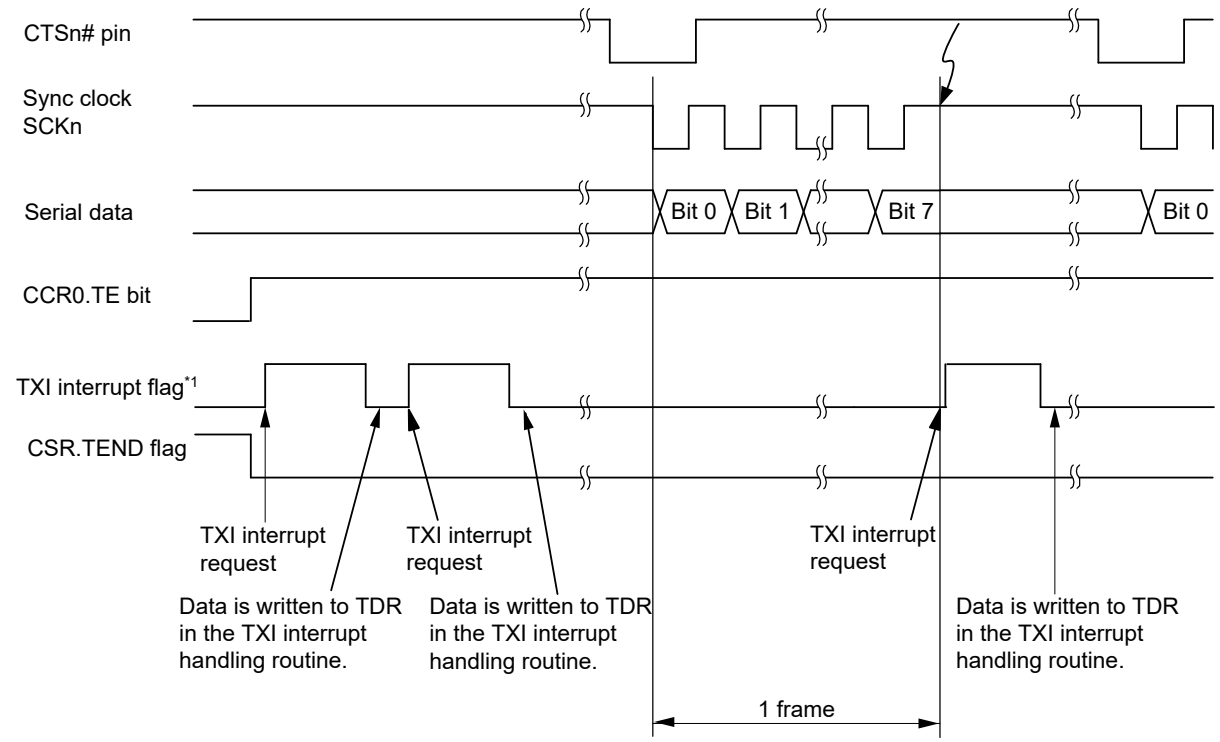
3. The TXDn pin outputs 8-bit data in synchronization with the output clock (in clock output mode) or with the input clock (when external clock is selected). When the CCR1.CTSE bit = 1 (CTS function enabled), the output clock starts after the CTS signal input becomes low level.
4. Update (data write) of the TDR register is checked at the final-bit transmission timing.
5. When the TDR register has been updated, data is transferred from the TDR register to the TSR register to start sending the next frame.
6. If the TDR register has not been updated, the CSR.TEND flag is set to 1 and the final-bit output state is retained. When the CCR0.TEIE bit is set to 1 at this time, a TEI interrupt request is generated. The SCKn pin is held high.

Figure 33.91 shows an example of data transmission flowchart.



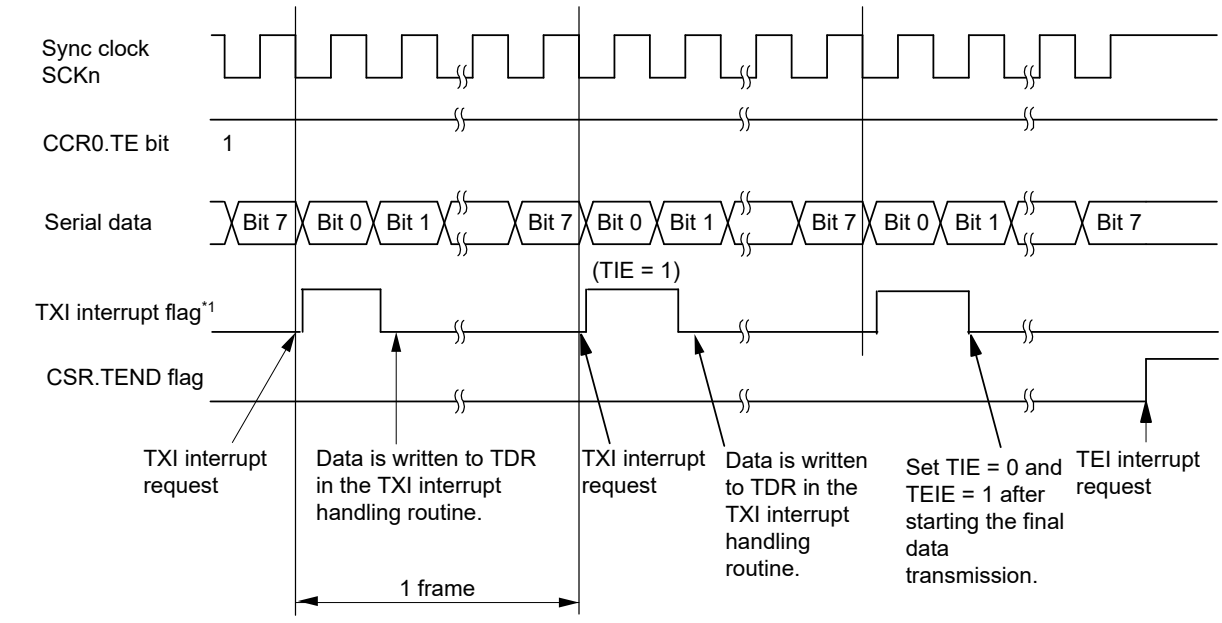
Note 1. For corresponding interrupt source numbers, see section 12, Interrupt Controller (ICU).

Figure 33.88 Serial transmission example in clock synchronous mode (1) (CTS function not used / transmission start / CPHA = 1, CPOL = 1)



Note 1. For corresponding interrupt source numbers, see section 12, Interrupt Controller (ICU).

Figure 33.89 Serial transmission example in clock synchronous mode (2) (CTS function used / transmission start / CPHA = 1, CPOL = 1)



Note 1. For corresponding interrupt source numbers, see section 12, Interrupt Controller (ICU).

Figure 33.90 Serial transmission example in clock synchronous mode (3) (during transmission to transmission end / CPHA = 1, CPOL = 1)

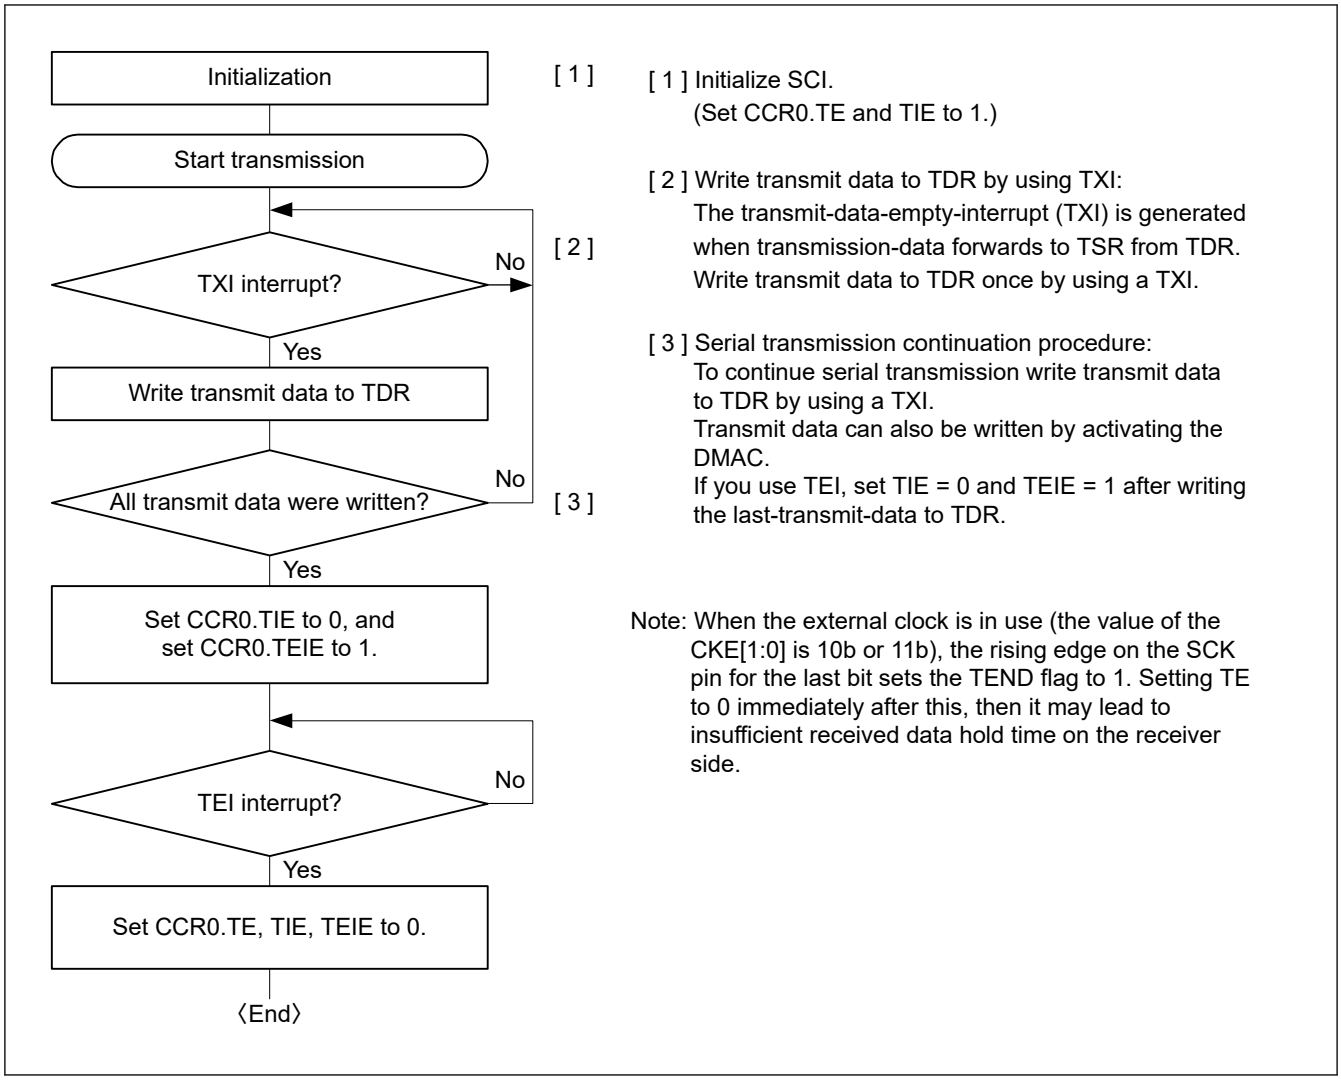


Figure 33.91 Serial transmission flowchart example in clock synchronous mode (non-FIFO selected)

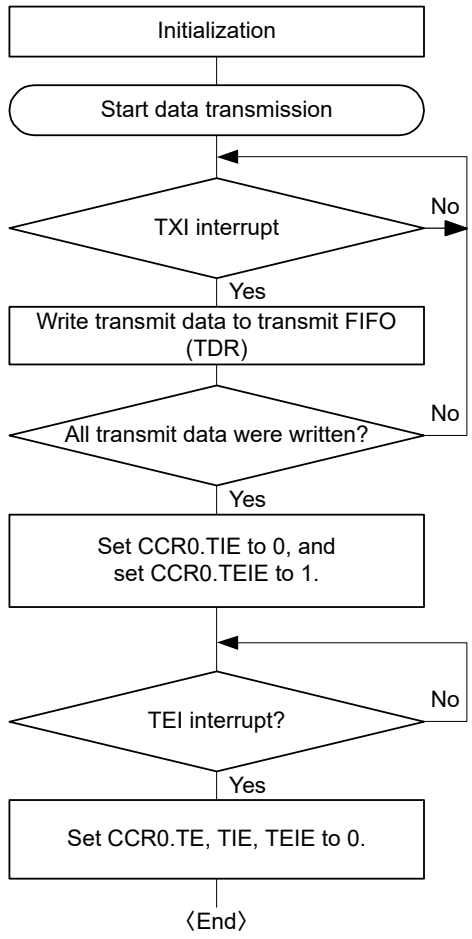
(2) FIFO selected

Figure 33.92 shows an example of flowchart of serial transmission (a FIFO buffer selected) in clock synchronous mode. The SCI operates as follows when serial data transmission.

1. When data is written to the transmit FIFO (TDR register) in the TXI interrupt routine, the SCI transfers the data from the transmit FIFO (TDR register) to the TSR register. The number of writable transmit data is [N_{FIFO} (= 16) - number of unsent transmit data stored in the transmit FIFO (TDR register)]. In addition, when starting data transmission, set the CCR0.TIE bit and the CCR0.TE bit to 1 simultaneously by a single instruction. Then a TXI interrupt request is generated.
2. Data is transferred from the transmit FIFO (TDR register) to the TSR register and transmission starts. When the number of data stored in the transmit FIFO (TDR register) is equal to or less than the threshold value of the transmit FIFO, the CSR.TDRE flag is set to 1. When the CCR0.TIE bit is set to 1 at this time, a TXI interrupt request is generated. Writing the next transmit data to the transmit FIFO (TDR register) in the TXI interrupt routine before transmission of data written to the transmit FIFO (TDR register) is complete enables continuous transmission. When a TEI interrupt request is used, after the final transmit data is written to the transmit FIFO (TDR register) in the TXI interrupt request processing routine, set 0 to the CCR0.TIE bit and set 1 to the TEIE bit.
3. The TXDn pin outputs 8-bit data in synchronization with the output clock (in clock output mode) or with the input clock (when external clock is selected). When CCR1.CTSE = 1 (CTS function enabled), the output clock starts after the CTS signal input becomes low level.
4. The SCI checks whether unsent transmit data is remaining in the transmit FIFO (TDR register)[*1] at the final-bit transmission timing.

5. When data is remaining in the transmit FIFO (TDR register), the data is transferred from the transmit FIFO (TDR register) to the TSR register to start sending the next frame.
6. If no data is remaining in the transmit FIFO (TDR register), the CSR.TEND flag is set to 1 and the final-bit output state is retained. When the CCR0.TEIE bit is set to 1 at this time, a TEI interrupt request is generated. The SCKn pin is held high.

Note 1. The number of unsent transmit data stored in the TDR register (transmit FIFO) can be monitored by reading the FTSR.T[5:0] bits.



[1] [1] Initialize SCI.
(Set CCR0.TE and TIE to 1.)

[2] [2] Write transmit data to transmit FIFO (TDR) by using TXI:
The transmit-data-empty-interrupt (TXI) is generated when transmission-data forwards to TSR from the transmit FIFO (TDR) and the number of transmit-data written in the transmit FIFO is equal to or less than the transmit FIFO threshold.

[3] [3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to the transmit FIFO (TDR) by using a TXI interrupt and clear TDRE flag to 0.
The number of transmission data it's possible to write in is N_{FIFO} (= 16) - (the number of stored transmit FIFO data).
Transmit data can also be written to the transmit FIFO (TDR) by activating the DMAC. In this case, the TDRE flag is cleared automatically, so please do not operate the TDRE flag.
If you use TEI, set TIE = 0 and TEIE = 1 after writing the last-transmit-data to TDR.

Note: When the external clock is in use (the value of the CKE[1:0] is 10b or 11b), the rising edge on the SCK pin for the last bit sets the TEND flag to 1. Setting TE to 0 immediately after this, then it may lead to insufficient received data hold time on the receiver side.

Figure 33.92 Serial transmission flowchart example in clock synchronous mode (FIFO buffer selected)

33.9.5 Serial Data Reception (Clock Synchronous Mode)

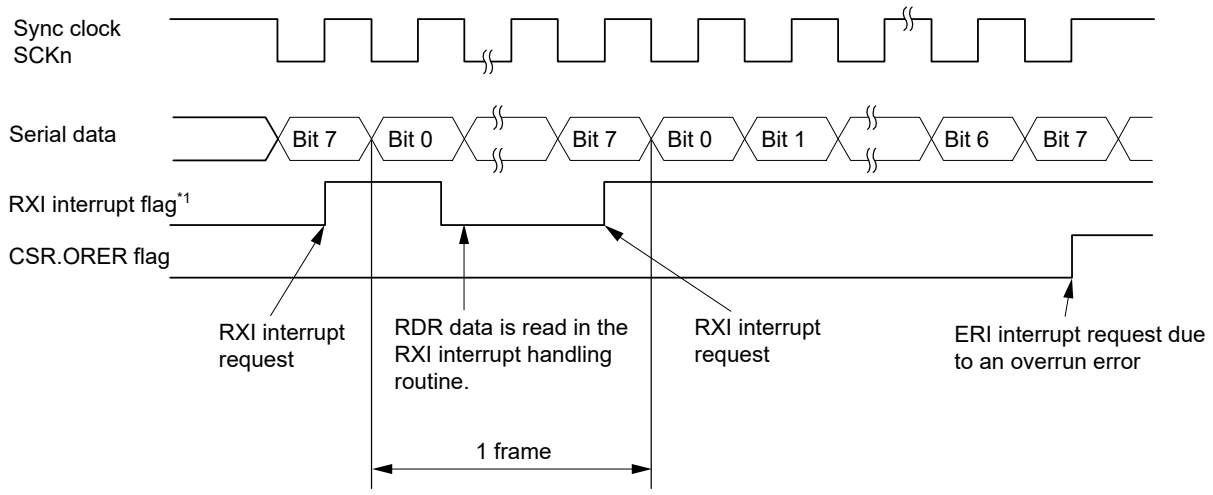
(1) Non-FIFO selected

Figure 33.93 and Figure 33.94 show operation examples of serial data reception in clock synchronous mode.

The SCI operates as follows during serial data reception. Reception-only operation is possible only in slave mode. (In master mode, reception-only operation is prohibited.)

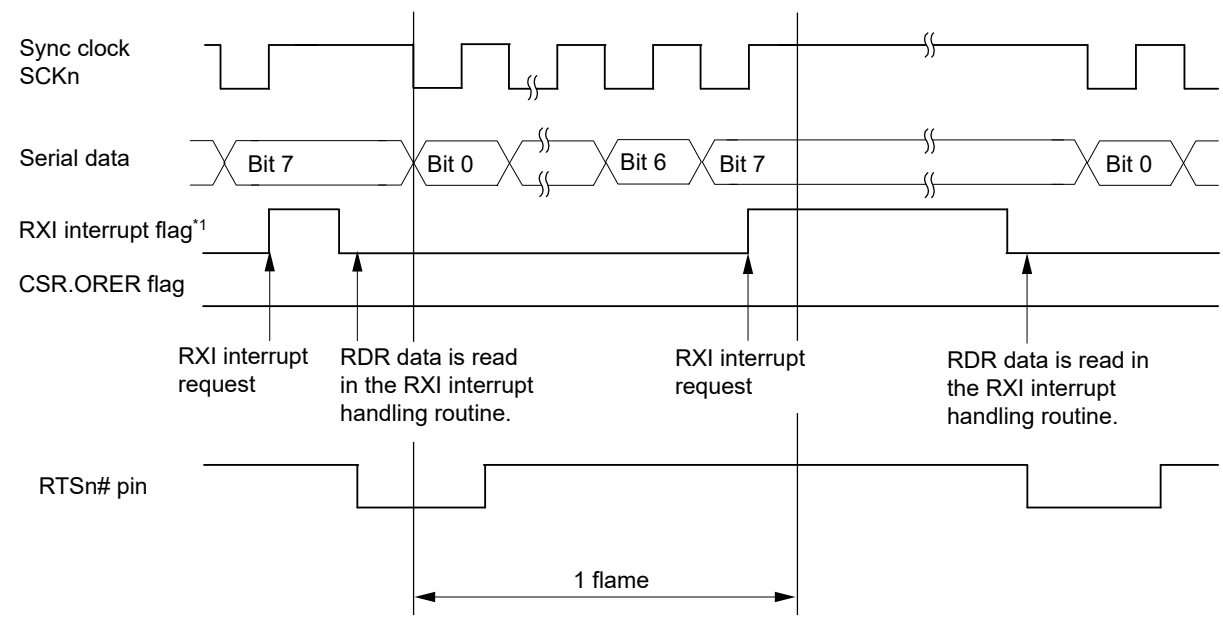
1. When the CCR0.RE bit is set to 1, the RTSn# pin output becomes low level (when the RTS function is used).
2. The SCI starts data reception in synchronization with input or output of the sync clock, and transfers receive data to the RSR register.
3. When an overrun error occurs, the CSR.ORER flag is set to 1. When the CCR0.RIE bit = 1 at this time, an ERI interrupt request is generated and the received data is not transferred to the RDR register.

4. When data is normally received, the received data is transferred to the RDR register. When the RIE bit = 1 at this time, an RXI interrupt request is generated. Reading the received data transferred to the RDR register in the RXI interrupt handling routine before the next data is completely received enables continuous reception. When the received data transferred to the RDR register is read, the RTSn# pin output becomes low level (when the RTS function is used). If you want to prevent the RTSn# pin output from turning low level after the final data is received, clear the CCR0.RE bit to 0 and then read the RDR register.



Note 1. For corresponding interrupt source numbers, see section 12, Interrupt Controller (ICU).

Figure 33.93 Serial data reception example in clock synchronous mode (1) (RTS function not used / CPHA = 1, CPOL = 1)



Note 1. For corresponding interrupt source numbers, see section 12, Interrupt Controller (ICU).

Figure 33.94 Serial data reception example in clock synchronous mode (2) (RTS function used / CPHA = 1, CPOL = 1)

While the reception error flag is set to 1, subsequent reception is disabled. Therefore, before continuing reception, be sure to clear the ORER flag in CSR to 0. Also be sure to read the RDR register in the overrun error processing. If the CCR0.RE bit

is set to 0 during reception to forcibly terminate the reception operation, unread receive data may be remaining in the RDR register. In this case, read the RDR register.

Figure 33.95 shows an example of serial data reception flowchart.

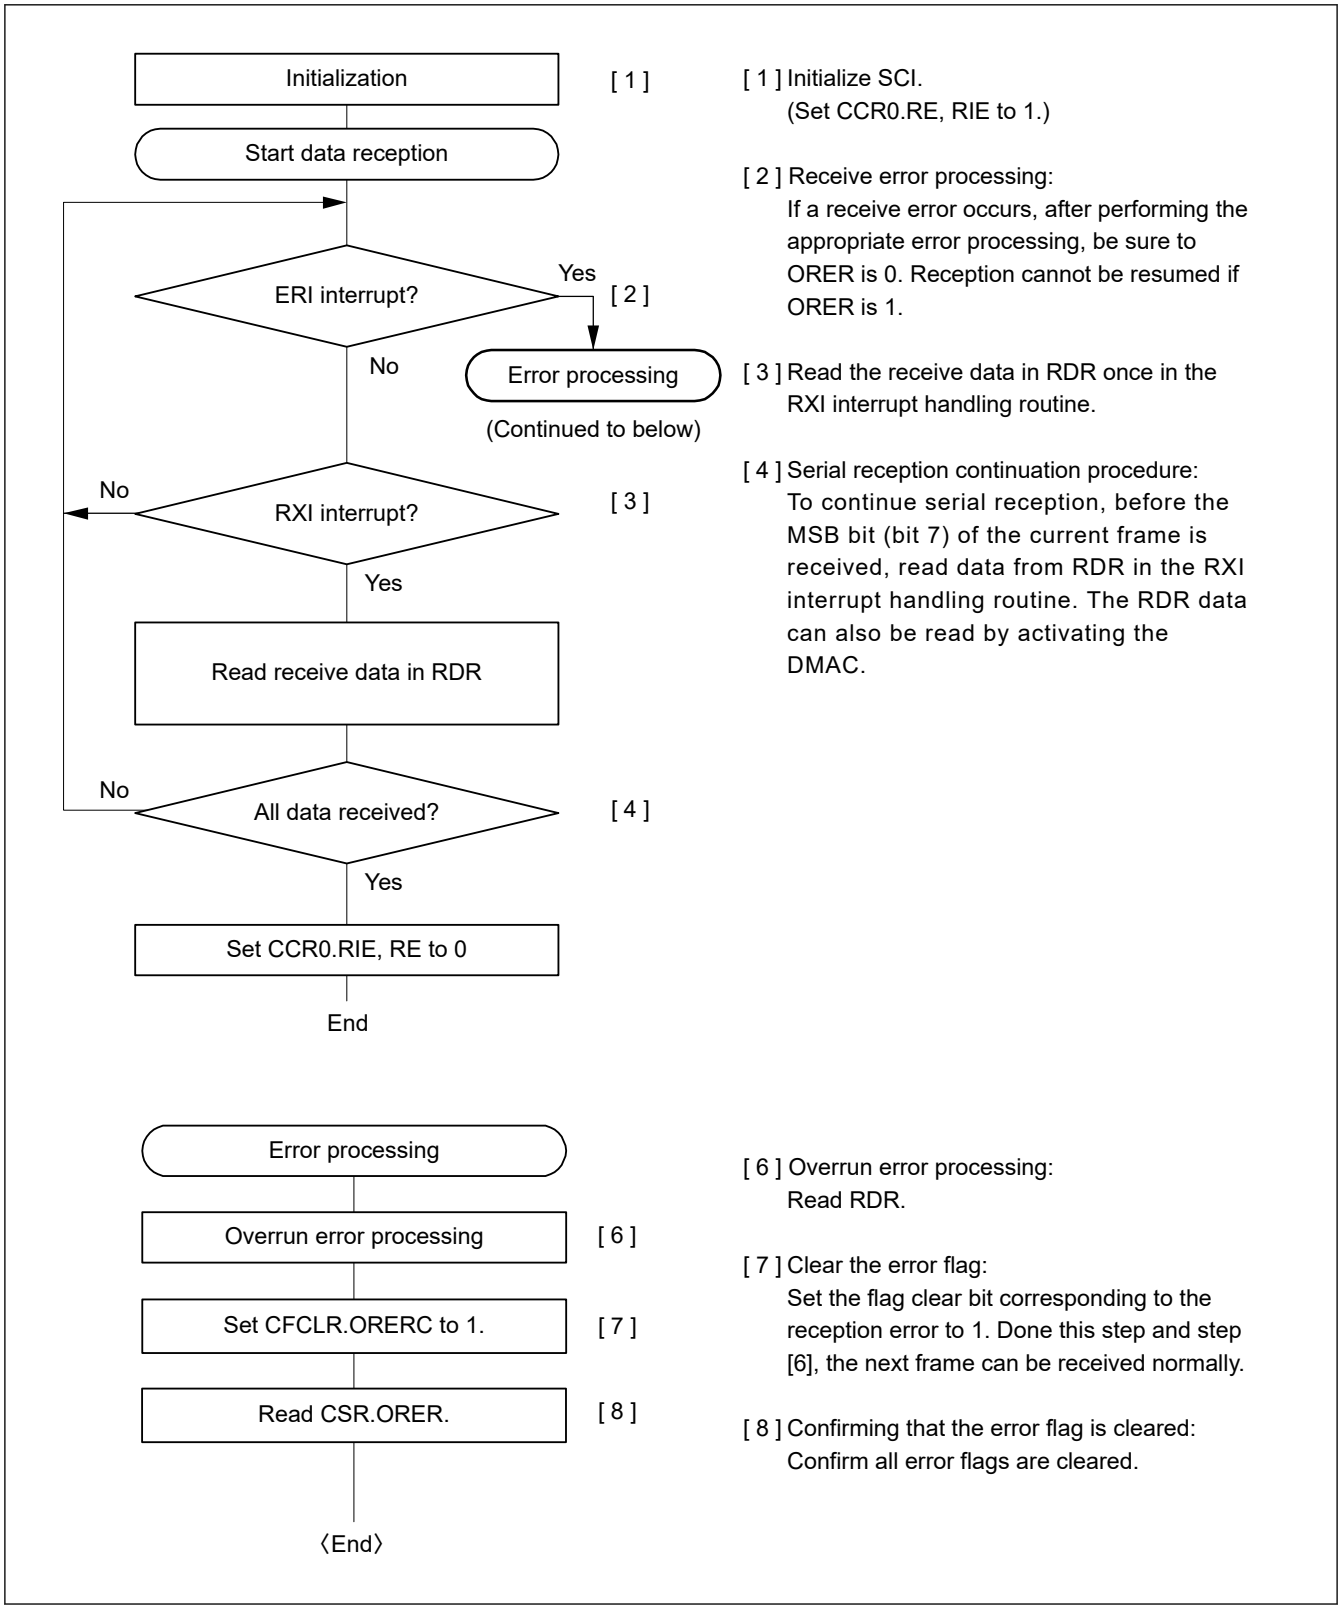


Figure 33.95 Sample flowchart for serial reception in clock synchronous mode (non-FIFO selected)

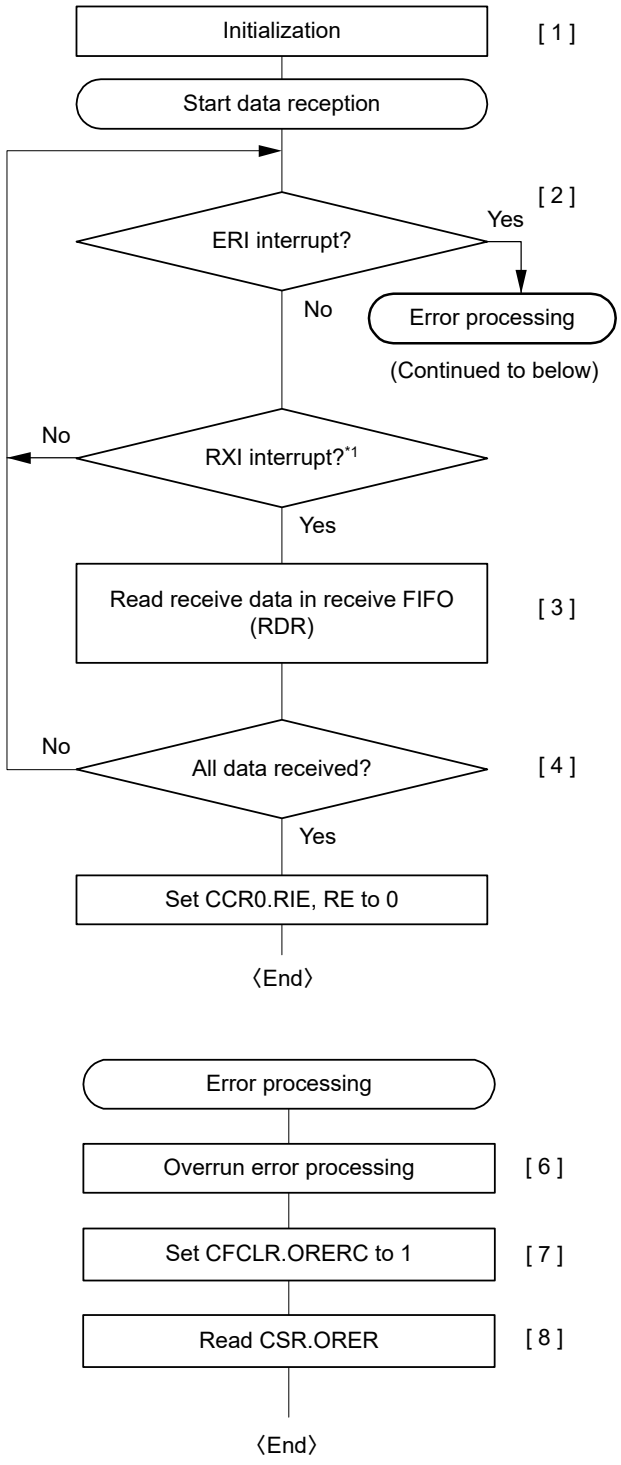
(2) FIFO selected

Figure 33.96 shows an example of serial data reception flowchart (a FIFO buffer selected) in clock synchronous mode. The SCI operates as follows during serial data reception. Reception-only operation is possible only in slave mode. (In master mode, reception-only operation is prohibited.)

1. When the CCR0.RE bit is set to 1, the RTSn# pin output turns low level (when the RTS function is used).
2. The SCI starts receiving data in synchronization with input or output of the sync clock and transfers the received data to the receive FIFO (RDR register).
3. When an overrun error occurs, the CSR.ORER flag is set to 1. When the CCR0.RIE bit = 1 at this time, an ERI interrupt request is generated and the received data is not transferred to the receive FIFO (RDR register)*1.
4. When data is normally received, the received data is transferred to the receive FIFO (RDR register)*1. When the number of receive data stored in the receive FIFO (RDR register) is equal to or more than the threshold value of the receive FIFO, the CSR.RDRF flag is set to 1. When the RIE bit = 1 at this time, an RXI interrupt request is generated. Reading the received data transferred to the receive FIFO (RDR register) in the RXI interrupt handling routine before an overrun error occurs enables continuous reception. When the received data transferred to the receive FIFO (RDR register) is read and the number of data becomes lower than the RTS# output threshold value, the RTSn# pin output becomes low level (when the RTS function is used).

Note 1. The RDR.RDAT[8] bit is not used.



[1] Initialize SCI.
(Set CCR0.RE, RIE to 1.)

[2] Receive error processing:
If a receive error occurs, after performing the appropriate error processing, be sure to ORER is 0. Reception cannot be resumed if ORER is 1.

[3] Read the receive data in the receive FIFO (RDR) in the RXI interrupt handling routine. The reception data stored in the receive FIFO (RDR) is read until the number of stored data will be below the FCR.RTRG value at least. You can confirm the number of the reception data in the FIFO by FRSR.R[5:0].

[4] Serial reception continuation procedure:
To continue serial reception, before the overrun error occurs, read data from RDR and clear RDRF flag to 0. The RDR data can also be read by activating the DMAC. In this case, the RDRF flag is cleared automatically, so please do not operate the RDRF flag.

Note 1. Set all received data to an integer multiple of the receive FIFO threshold. If it is not an integral multiple, return to step [2] and it will become an infinite loop, so set a timeout time separately using a timer etc.

[6] Overrun error processing:
Read RDR.

[7] Clear the error flag:
Set the flag clear bit corresponding to the reception error to 1. Done this step and step [6], the next frame can be received normally.

[8] Confirming that the error flag is cleared:
Confirm all error flags are cleared.

Figure 33.96 Example of serial reception in clock synchronous mode (FIFO selected)

33.9.6 Serial Data Transmission and Reception (Clock Synchronous Mode)

(1) Non-FIFO selected

Figure 33.97 shows an example of serial data concurrent transmission/reception flowchart in clock synchronous mode. After the SCI is initialized, perform the following procedure for serial data concurrent transmission/reception. When switching mode from transmission to concurrent transmission/reception, check that the CSR.TEND flag is set to 1 to ensure that the

SCI is in the transmission complete state. Then set CCR0.TE = 0 and RE = 0 and then set the TE, RE, TIE, and RIE bits in CCR0 to 1 simultaneously by a single instruction.

When switching mode from reception to concurrent transmission/reception, check that the SCI is in the reception complete state, and then set CCR0.TE = 0 and RE = 0. After that, check that the error flags (ORER, FER, and PER) in CSR are cleared to 0, and then set the TE, RE, TIE, and RIE bits in CCR0 to 1 simultaneously by a single instruction.

When the RTS function is used in the concurrent transmission/reception operation, if you want to prevent the RTSn# pin output from turning to low after the final data is received as in the reception operation, clear the RE and TE bits in CCR0 to 0 simultaneously, and then read the RDR register.

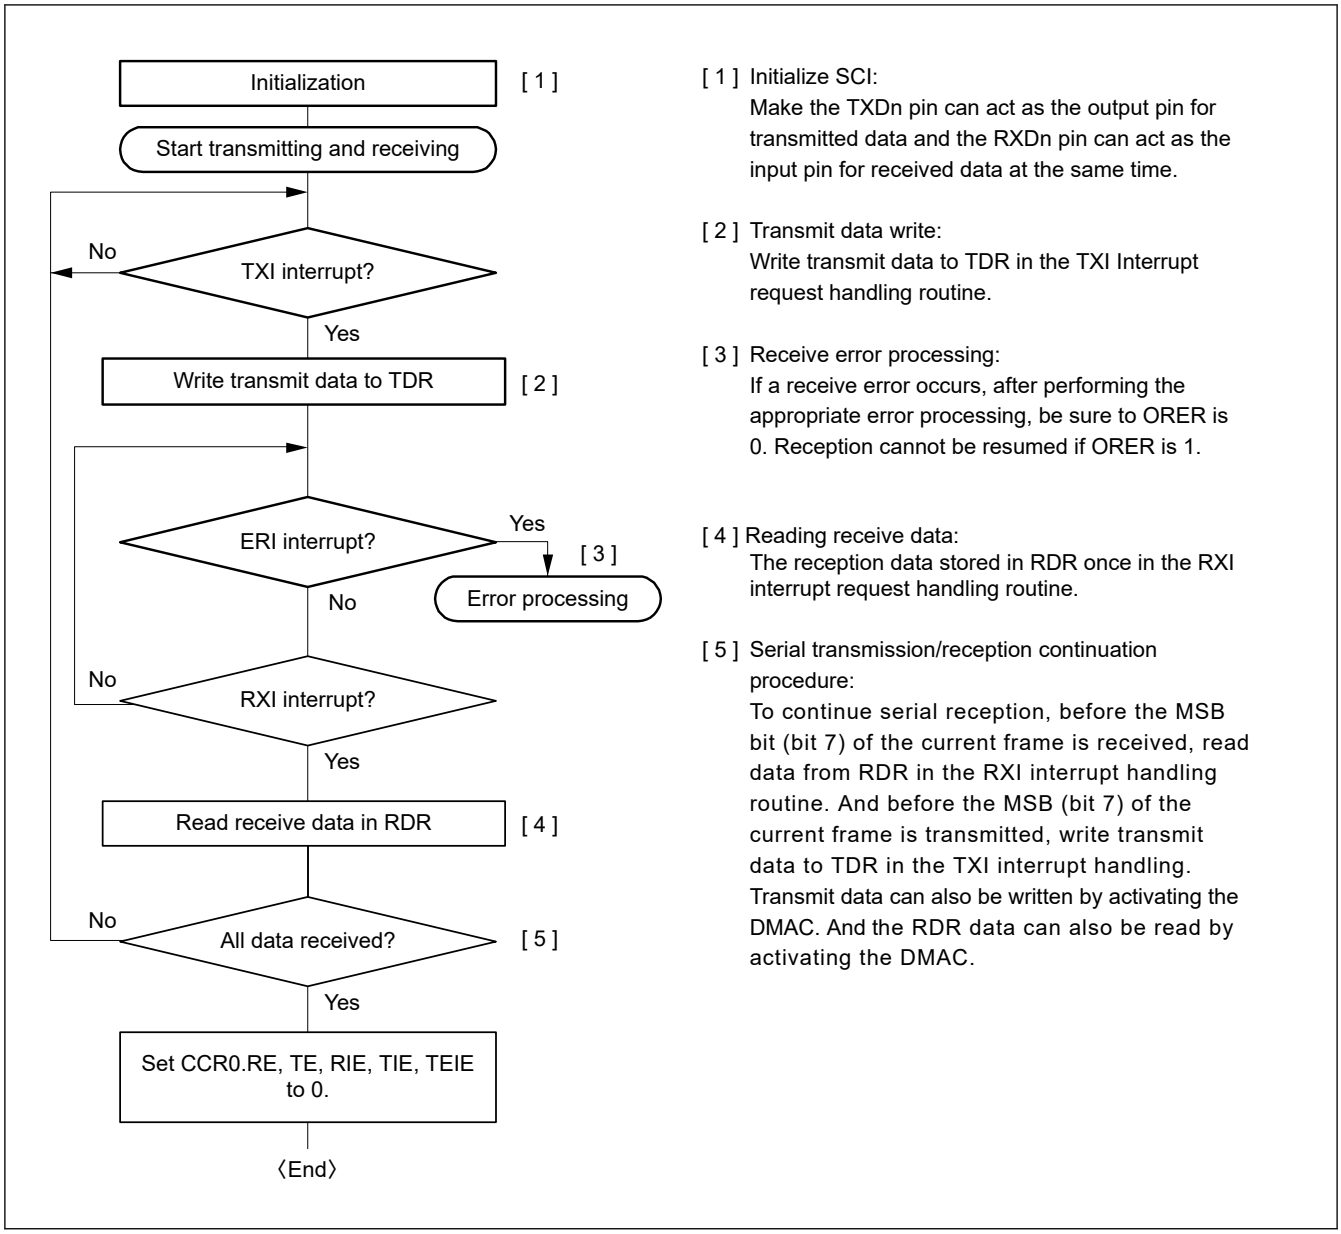


Figure 33.97 Serial data concurrent transmission/reception flowchart example in clock synchronous mode (non- FIFO selected)

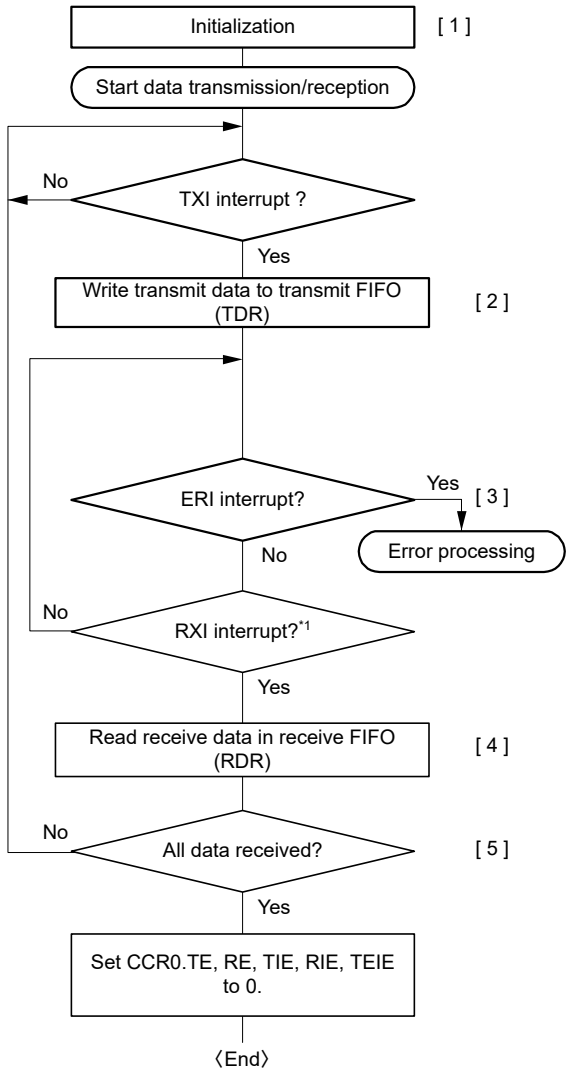
(2) FIFO selected

Figure 33.98 shows an example of serial data concurrent transmission/reception flowchart (a FIFO buffer selected) in clock synchronous mode.

After the SCI is initialized, perform the following procedure for serial data concurrent transmission/reception. When switching mode from transmission to concurrent transmission/reception, check that the CSR.TEND flag is set to 1 to ensure

that the SCI is in the transmission complete state. Then set CCR0.TE = 0 and RE = 0 and then set the TE, RE, TIE, and RIE bits in CCR0 to 1 simultaneously by a single instruction.

When switching mode from reception to concurrent transmission/reception, check that the SCI is in the reception complete state, and then set CCR0.TE = 0 and RE = 0. After that, check that the error flags (ORER, FER, and PER) in CSR are cleared to 0, and then set the TE, RE, TIE, and RIE bits in CCR0 to 1 simultaneously by a single instruction.



[1] Initialize SCI:
Make the TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[2] Transmit data write:
Write transmit data to transmit FIFO (TDR) in the TXI Interrupt request handling routine.
The number of transmission data it's possible to write in is N_{FIFO} (= 16) - (the number of stored transmit FIFO data).

[3] Receive error processing:
If a receive error occurs, after performing the appropriate error processing, be sure to ORER is 0. Reception cannot be resumed if ORER is 1.

[4] Read receive data:
Read the receive data in the receive FIFO (RDR) in the RXI interrupt handling routine. The reception data stored in the receive FIFO (RDR) is read until the number of stored data will be below the FCR.RTRG value at least. You can confirm the number of the reception data in the FIFO by FRSR.R[5:0].

[5] Serial transmission/reception continuation procedure:
To continue serial reception, before the overrun error occurs, read data from RDR and clear CSR.RDRF.
To continue serial transmission, write transmit data to the transmit FIFO (TDR) by using a TXI interrupt and clear TDRE flag to 0.
Transmit data can also be written to the transmit FIFO (TDR) by activating the DMAC. And The RDR data can also be read by activating the DMAC. In this case, the TDRE and RDRF are cleared automatically, so please do not operate the TDRE and RDRF.

Note 1. Set all received data to an integer multiple of the receive FIFO threshold. If it is not an integral multiple, return to step [2] and it will become an infinite loop, so set a timeout time separately using a timer etc.

Figure 33.98 Serial data concurrent transmission/reception flowchart example in clock synchronous mode (FIFO selected)

33.9.7 Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with Internal Clock Used

When the clock synchronous internal clock is used (master mode), MRCLK is used as a reception sampling clock.

This function adjusts the reception sampling timing by delaying MRCLK by 1 to 4 PCLKSCIn and adding a digital delay.

Setting the CCR4.ASEN bit to 1 enables this function. The delay value is set in CCR4.AST[1:0].

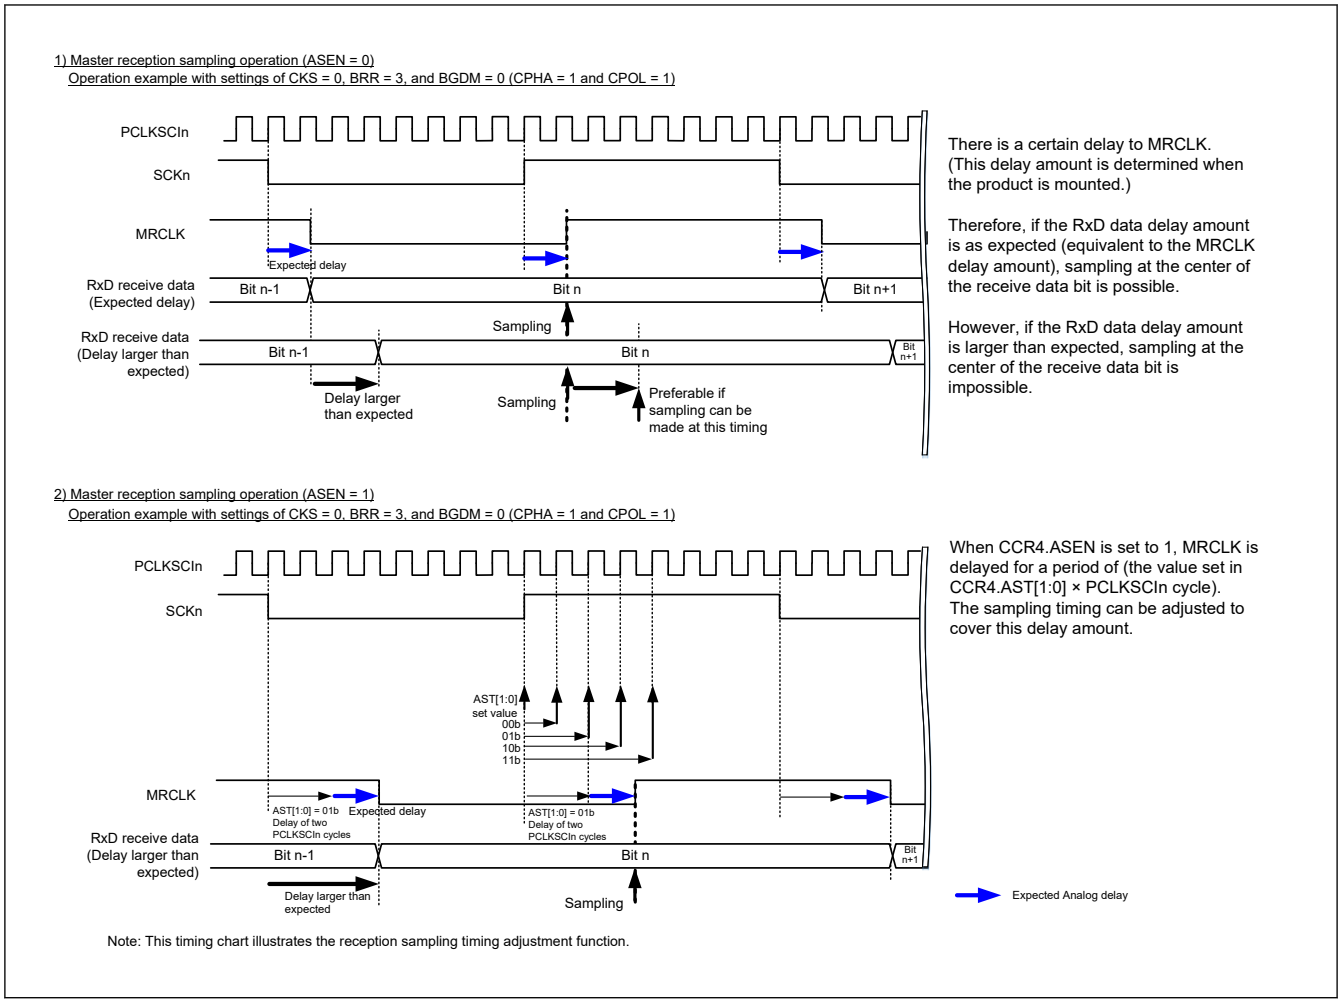


Figure 33.99 Reception sampling timing adjustment operation in clock synchronous mode (master)

33.10 Simple-SPI Mode

As an extended function of the SCI, the SCI supports Simple-SPI (4-wire serial bus) mode that allows communication from one or more master devices to multiple slave devices.

Simple-SPI mode is enabled by the Simple-SPI mode setting (CCR3.MOD[2:0] = 011b) and by setting the CCR0.SSE bit to 1. When using the 4-wire serial bus in master mode with a single master, the SS pin function on the master side is not required. Therefore, the CCR0.SSE bit is set to 0.

Figure 33.100 shows an example of Simple-SPI connection.

In simple-SPI mode, data is transmitted and received in synchronization with clock pulses in the same way as clock synchronous mode. A character of communication data consists of 8-bit data. No parity bit can be attached.

Because the SCI has an internal transmitter and a receiver independently, the transmitter and the receiver can share a clock to enable full-duplex communication. Furthermore, because both the transmitter and the receiver have a double-buffer structure, continuous transmission and reception are possible by writing the next transmit data during transmission and reading the previous receive data during reception.

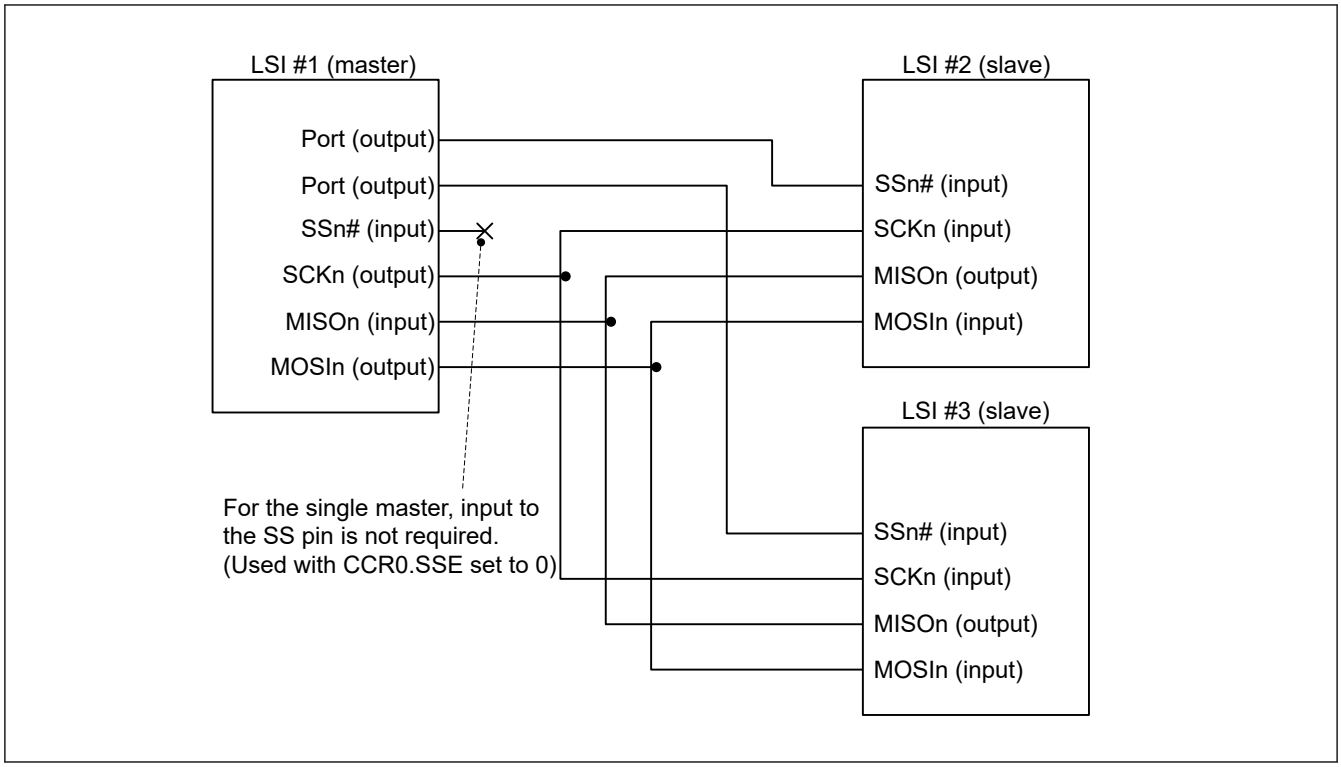

Figure 33.100 Simple-SPI connection example

33.10.1 Pin Status in Master and Slave Mode

In simple-SPI mode, input and output directions of each pin vary depending on master mode (CCR3.CKE[1:0] = 00b or 01b) and slave mode (CCR3.CKE[1:0] = 10b or 11b).

Table 33.33 shows the relationship among mode, SSn# pin input, and each pin state.

Table 33.33 Relationship among mode, SSn# pin input, and each pin state

Mode	SSn# pin input	TXDn (MOSIn) pin state	RXDn (MISOn) pin state	SCKn pin state
Master mode*1	High level (Communication enabled)	Transmit data output*2	Receive data input	Clock output*3
	Low level (Communication disabled)	High impedance	Receive data input (disabled)	High impedance
Slave mode	High level (Communication disabled)	Receive data input (disabled)	High impedance	Clock input (disabled)
	Low level (Communication enabled)	Receive data input	Transmit data output*2	Clock input

Note 1. When single master is selected (SSE bit = 0), communication is enabled (equivalent to the state when the SSn# pin input is high level) regardless of the SSn# pin input level. The SSn# pin is not used and is available for other purposes.
Note 2. High impedance when transmission is disabled (CCR0.TE bit = 0)
Note 3. High impedance when multi-master (SSE bit = 1) is selected and transmission/reception is disabled (CCR0.TE, RE bits = 00b)

33.10.2 SS Function in Master Mode

Setting the CCR3.CKE[1:0] bits to 00b or 01b enables master mode.

In single master mode (SSE bit = 0), the SSn# pin is not used and data transmission and reception are enabled regardless of the SSn# pin input level. The SSn# pin is available for other purposes.

When in multi-master mode (SSE bit = 1) and the SSn# pin input is high, the master outputs a clock from the SCKn pin and performs transmission and reception operations. And outputting clock indicates "There are no other masters" or "Another master is not performing reception or transmission". When the SSn# pin input level is low in multi-master mode (SSE bit = 1), this means that another master exists and it is performing data transmission/reception. At this time, the SCI makes the TXDn pin output and the SCKn pin output high impedance and does not start data transmission/reception. In

addition, the CSR.MFF bit is set to 1 as a mode fault error. In multi-master mode, read this flag bit to perform the error processing. If a mode fault error occurs during the transmission/reception operation, the SCKn pin and the TXDn pin output are made high impedance while the SSn# pin input level is low. When the SSn# pin input becomes high level, the SCKn pin outputs a clock signal and the TXDn pin outputs data. Even if the SCKn pin and the TXDn pin are in the high impedance state, internal transmission/reception operation continues, but it stops after transmission/reception of a single character is complete. In this case, any of TXI, RXI, and TEI interrupts occurs.

Control the SSn# pin output in master mode with a general-purpose port.

33.10.3 SS Function in Slave Mode

Setting the CCR3.CKE[1:0] bits to 10 or 11 enables slave mode.

When the SSn# pin input level is high, the RXDn pin output becomes high impedance and the clock input from the SCKn pin is ignored. When the SSn# pin input level is low, the clock input from the SCKn pin becomes effective, enabling data transmission and reception.

When the SSn# pin input changes from low to high level during the transmission/reception operation, the RXDn pin output is made high impedance and the transmission/reception operation is immediately suspended. If the transmission is in progress, the CSR.TEND flag will not be set, a transmit end interrupt will not be output, and an abnormal stop status will occur. So, do not negate the SSn# pin during slave transmission/reception. If an abnormal stop occurs, set CCR0.RE and CCR0.TE to 0 to stop transmission / reception. To resume transmission/reception, set CCR0.RE and CCR0.TE to 1 after at least PCLKSCIn × 3 cycles + PCLKM × 3 cycles.

33.10.4 Relationship between Clock and Transmit/Receive Data

The clock to be used for data transmission/reception is selectable from four types using the CCR3.CPOL and CPHA bits. Figure 33.101 shows the relationship between clock and transmit data/receive data. The same relationship applies to master mode and slave mode.

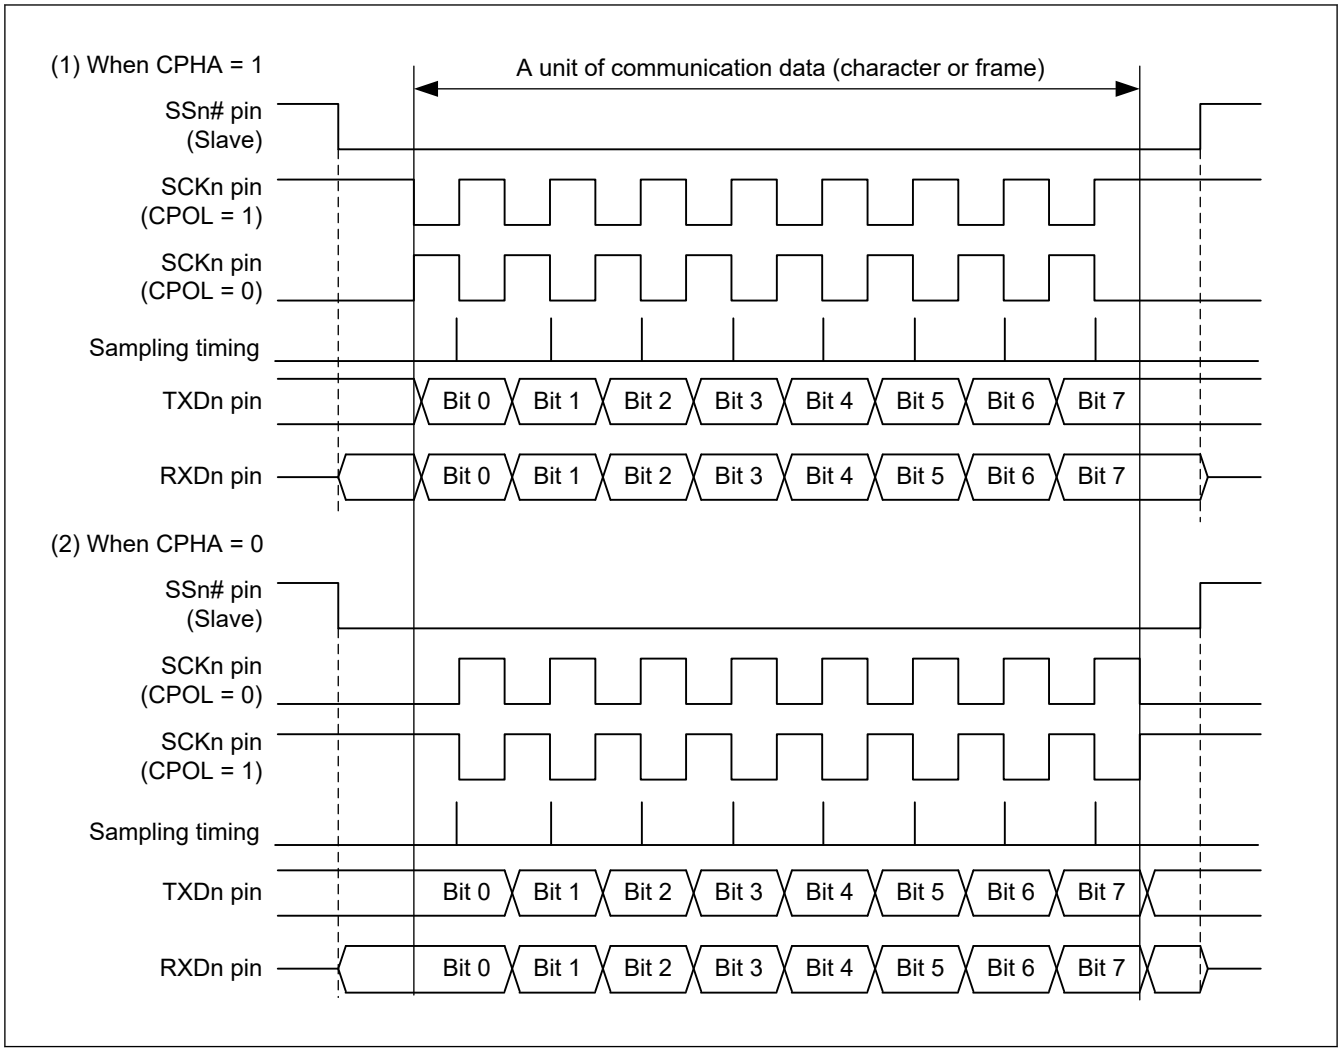

Figure 33.101 Relationship between clock and transmit data/receive data in simple-SPI mode

33.10.5 SCI Initialization in Simple-SPI Mode

The SCI can be initialized using the same initialization procedure as for clock synchronous mode (Figure 33.87). The master devices and slave devices use the same clock type selected by the CCR3.CPOL and CPHA bits.

Before performing initialization or changing operating mode or communication format, be sure to stop communication (CCR0.RE = 0 and CCR0.TE = 0).

Note that setting the RE bit to 0 does not initialize the ORER, FER, and PER flags in CSR and the RDR register.

Note that, when CCR0.TIE = 1, setting the TE bit to 1 from 0 generates a TXI interrupt.

33.10.6 Serial Data Transmission and Reception in Simple-SPI Mode

In master mode, set the SSn# pin of the destination slave device to low level before starting data transmission/reception and set to high level after the end of data transmission/reception. In multiple master operation with CCR0.SSE = 1 even in master mode, a mode fault error will occur if the SSn# pin goes low. Therefore, make sure that no mode fault error has occurred before starting communication, and start communication, and make sure that no mode fault error has occurred even after communication ends. If a mode fault error has occurred, communication may be incomplete, so measures such as retransmission are required. The other procedures are the same as in clock synchronous mode.

In slave mode, it operates according to the SSn# pin input level. Other steps are the same as those of clock synchronous mode.

33.10.7 Reception Sampling Timing Adjustment Function in Simple-SPI Mode with Internal Clock Used

The reception sampling timing adjustment function in simple SPI mode is the same as the reception sampling timing adjustment function in clock synchronous mode. For the description of operation, see section 33.9.7. Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with Internal Clock Used.

33.11 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be corrected by evenly enabling the clocks of the number specified in the CCR2.MDDR[7:0] bits among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in CCR2.

Figure 33.102 shows an example where the PCLKSCIn is selected by the CKS[1:0] bits in CCR2 and the BRR and MDDR are set to 0 and 160 respectively in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256). The enable of internal clock has non-balanced. So, notice the pulse width of the internal base clock is caused bias.

Do not use this function in Clock Synchronous mode, Simple-SPI mode, Smart Card Interface mode, and Manchester mode.

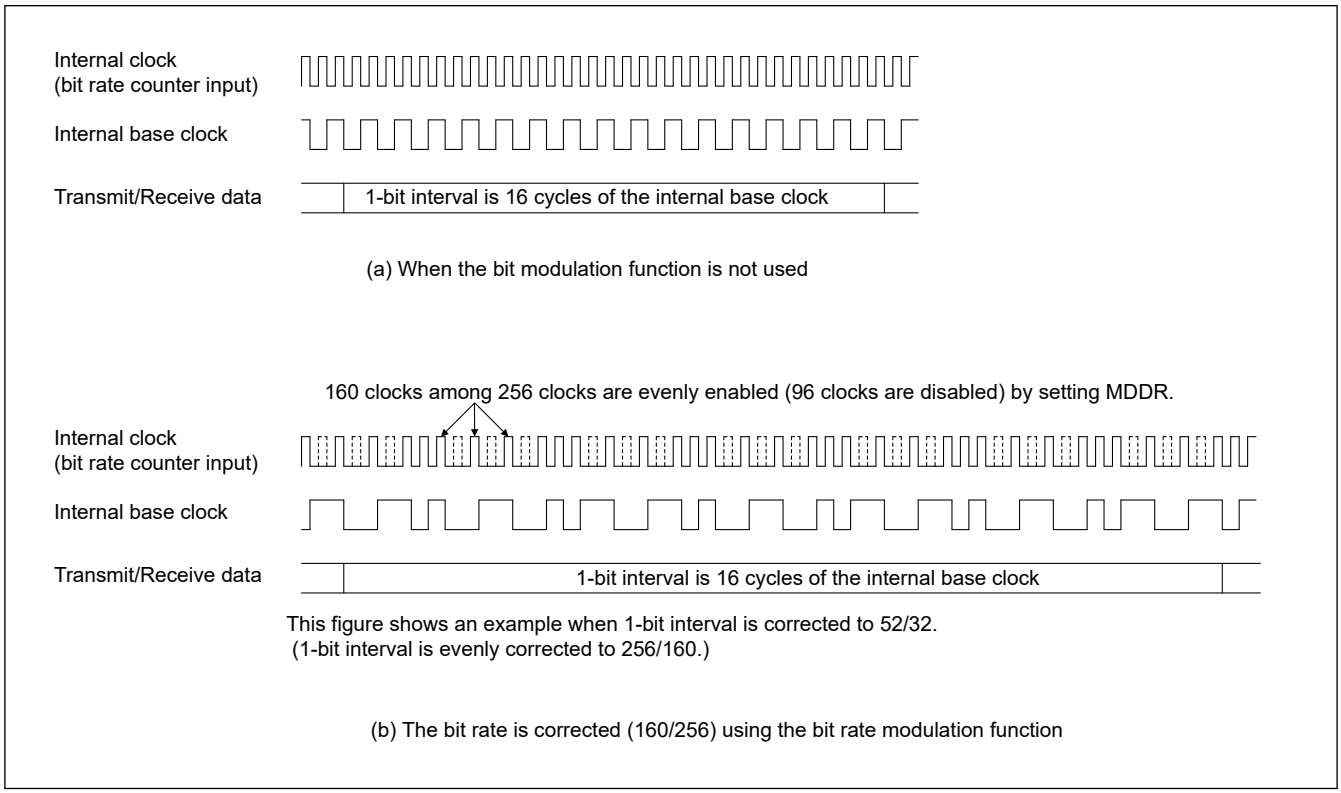

Figure 33.102 Example of internal base clock when bit rate modulation function is used

33.12 Noise Cancellation Function

Figure 33.103 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a two-stage flip-flop circuits and a match detection circuit. When the input signals of the noise filter and the output signals of the two-stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. (When the same level is retained for three cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for three cycles or shorter is considered as a noise, not as a receive signal.)

In asynchronous mode and Manchester mode, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The sampling period of the noise filter can be selected from the base clock period and the divided clock of the baud rate generator clock source by CCR1.NFCS[2:0].

(When CCR1.NFCS[2:0] = 000b, CCR2.ABCS = 0 and CCR2.ABCSE = 0, the cycle is 1/16 of a period 1 transfer bit.

When CCR1.NFCS[2:0] = 000b, CCR2.ABCS = 1 and CCR2.ABCSE = 0, the cycle is 1/8 of a period 1 transfer bit.

When CCR1.NFCS[2:0] = 000b, CCR2.ABCSE = 1, the cycle is 1/6 of a period 1 transfer bit.)

In simple I2C mode, the noise elimination function can be used for the input pins of SDAn and SCLn. The sampling period of the noise filter can be selected from the divided clock of the baud rate generator clock source by CCR1.NFCS[2:0].

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When CCR0.TE and CCR0.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, it is determined that a level match is detected and is conveyed as an internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles.

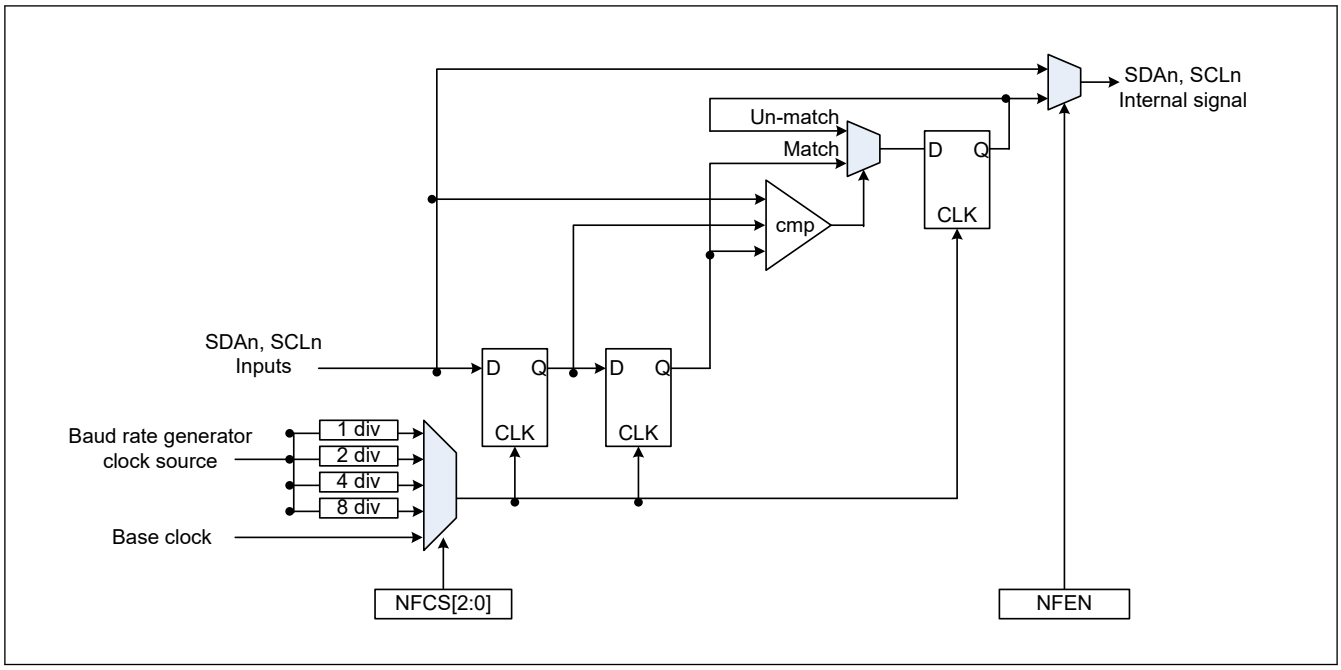

Figure 33.103 Block diagram of digital noise filter circuit

33.13 RS-485 Driver Control Function

Setting the DEN bit in the SCI Common Control Register 3 (CCR3) to 1 enables the RS-485 driver control function and generates a DE (Driver Enable) signal that enables the external transceiver transmission mode. The DE signal outputs a valid level for the period with assertion time and negation time added before and after data transmission. The DE signal valid level is set by the DEPOL bit in the driver control register (DCR).

The Assert time is the time from when the DE signal is valid until the start bit starts. Set by DEAST[4:0] of driver control register (DCR).

The Negate time is the time from the end of the last stop bit of the transmitted message to the invalidation of the DE signal. Set with DENGT[4:0] of the driver control register (DCR).

DEAST and DENGT are expressed in base clock units. For details, see section 33.3.13. DCR : Driver Control Register.

When this function is used (DEN = 1), the TEND set timing and TEI interrupt output timing are at the end of the driver negation time.

When transmission is completed and the next transmission data is not written before the DE signal is negated, the DE signal is negated once. If the timing for writing the next transmit data is not in time, assert the DE signal after negating it again, insert the set assert time, and transmit the next data. If you want to perform the next transmission with the DE signal asserted, write the next transmission data to the TDR quickly enough in consideration of the synchronization delay time of the register.

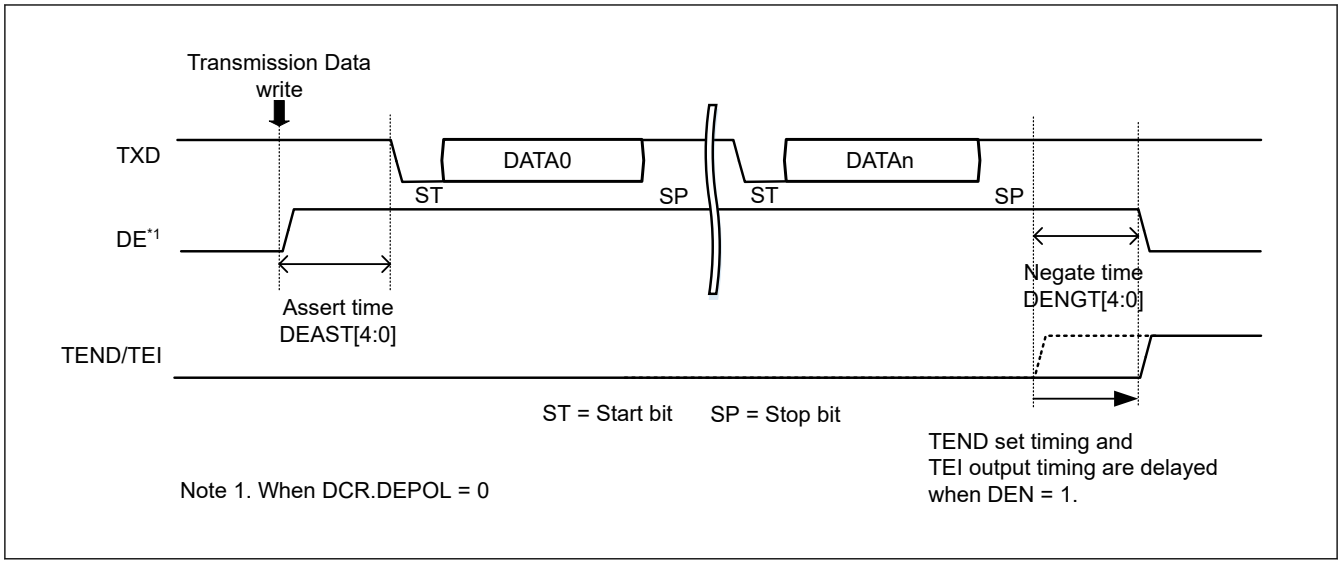

Figure 33.104 The image waveform for RS-485 driver control DE signal output

33.14 Loopback Function

The loopback function can be used in asynchronous mode with the internal clock, Manchester mode with the internal clock, and clock synchronous mode with the internal clock.

When 1 is written to the SPLP bit in the CCR1 register, SCI blocks the external input (RXD) path and connects the output path of the transmit data register and the input path of the receive data register.

When this function is used with TINV = 1, inversion of transmission data becomes reception data. However, this function can be used with TINV = 1 only when operating in clock synchronous mode internal clock.

Table 33.34 shows the relationship between the TINV and SPLP bit settings and the received data.

Table 33.34 TINV and SPLP bit settings and received data

TINV	SPLP	Receive data	Communication mode		
			Async internal clock	Manchester internal clock	Clock sync internal clock
x	0	Receive Data from RXD pin	Possible	Possible	Possible
0	1	Transmit Data	Possible	Possible	Possible
1	1	Inverted transmit data	Impossible	Impossible	Possible

Figure 33.105 shows the configuration of the shift register input/output path in loopback mode.

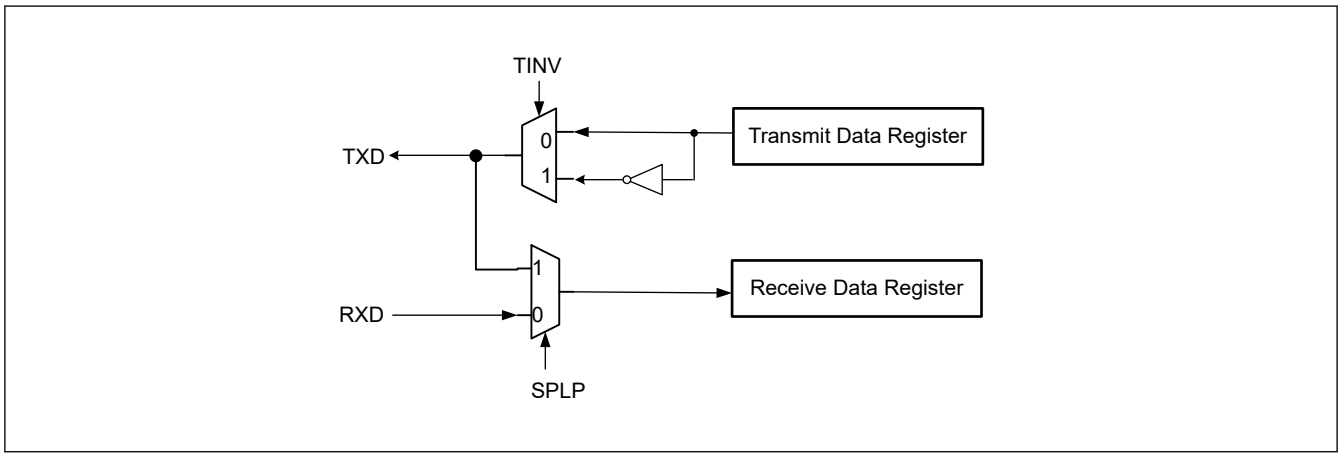

Figure 33.105 Shift register input/output configuration image in loopback mode

33.15 Half-Duplex communication Function

Do not use the half-duplex communication function in Simple-I2C mode, Simple-SPI mode, and Smart Card Interface mode.

In other communication modes, if the CCR1.SHARPS bit is set to 1, half-duplex communication using the TXD pin is possible. When half-duplex communication is used, transmission and reception must be performed exclusively. Transmission and reception settings (CCR0.TE = 1 and CCR0.RE = 1) is prohibited.

However, if half-duplex communication is performed as the master in clock synchronous mode, perform transmission/reception settings (CCR0.TE = 1 and CCR0.RE = 1) and perform dummy transmission. By dummy transmission (arbitrary transmission data is written to TDR), SCKn is output and reception is enabled. The dummy transmission data is discarded inside the module and is not actually transmitted.

During half-duplex communication, the only communication port terminal used is the TXD pin. Output when CCR0.TE = 1, input when CCR0.TE = 0.

33.16 Synchronizer Bypass Function

This module has a bus clock and the operation clock (PCLKSCIn). And these have each operating circuit. Therefore, there is a synchronization circuit for signal transfer between different clocks, and synchronization delay time is required for signal propagation between different clocks.

However, the synchronization circuit can be bypassed by the CCR3.BPEN bit only when the same clock is input to the bus clock and the operation clock. In this case, eliminates synchronization delay time and improves responsiveness. Figure 33.106 shows the image waveform of the bypass function.

This module also has a synchronization circuit between the communication clock (SCK) and the operation clock (PCLKSCIn), but this synchronization circuit can not be bypassed.

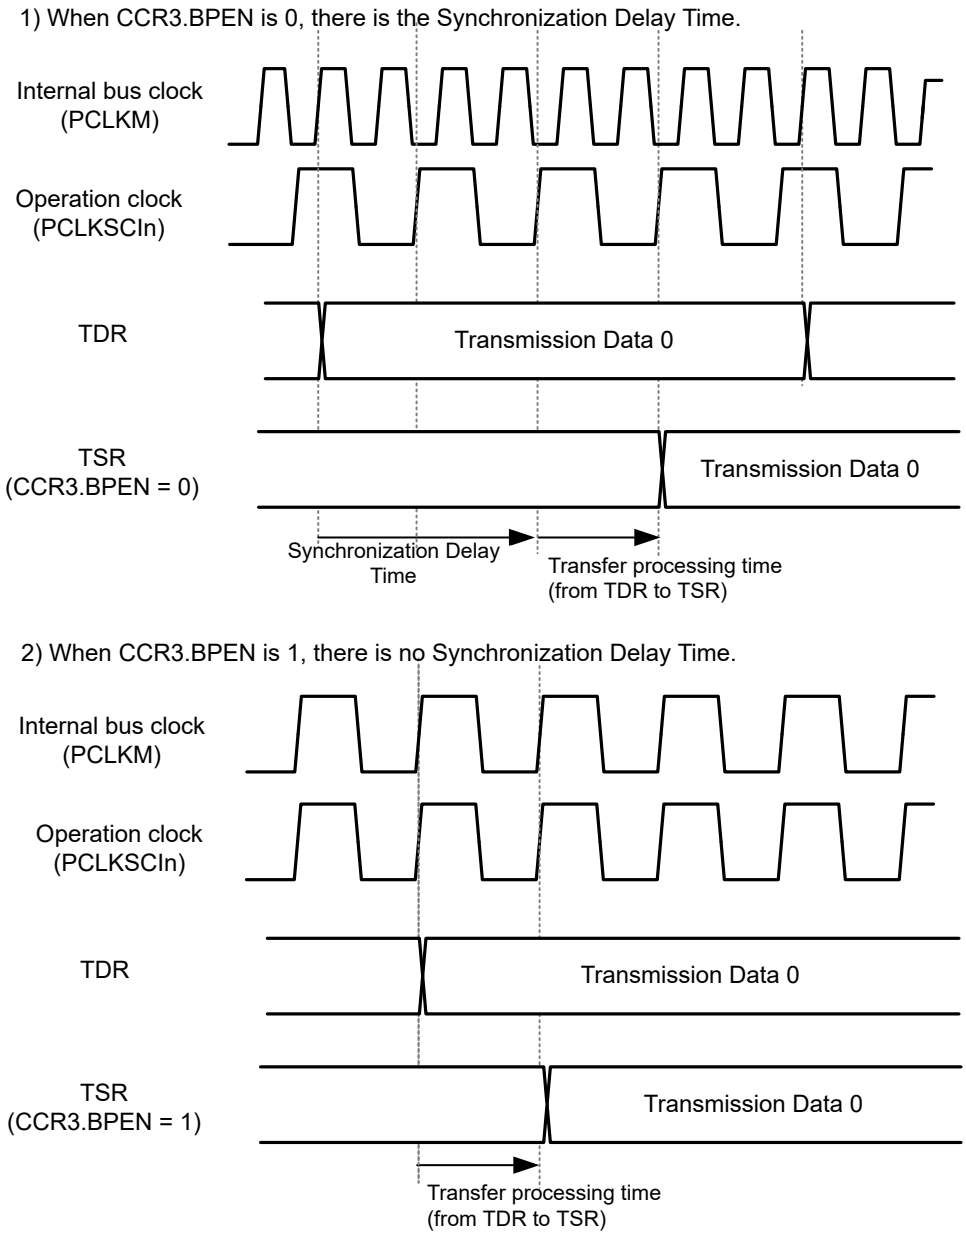

Figure 33.106 Image waveform of Synchronizer bypass function

33.17 Interrupt signal

Table 33.35 lists SCI interrupt signals.

When performing transmission and reception using DMAC, be sure to set DMAC first, and then set SCI. See section 15, DMA Controller (DMAC) for how to set DMAC.

Table 33.35 SCI interrupt sources (1 of 2)

Name	Interrupt sources	CPU0 GIC request	CPU1 GIC request	DMAC activation
SCIn_ERI	Error interrupt	Possible	Possible	Not possible
SCIn_RXI	Simple-I2C: Reception end interrupt Other mode: Receive data full interrupt	Possible	Possible	Possible*1

Table 33.35 SCI interrupt sources (2 of 2)

Name	Interrupt sources	CPU0 GIC request	CPU1 GIC request	DMAC activation
SCIn_TXI	Simple-I2C and Smart Card Interface: Transmit end interrupt Other mode: Transmit data empty interrupt	Possible	Possible	Possible*1
SCIn_TEI	Simple-I2C: Completion of generation of a start, restart, or stop condition (STI) Other mode: Transmit end interrupt	Possible	Possible	Not possible

Note: n = 0 to 5
Available interrupt sources change dependent on operation mode.
Note 1. DMAC activation is not available for n = 5.

33.17.1 Buffer Operations for TXI and RXI interrupts

The TXI and RXI interrupts have an interrupt buffer function. When the first interrupt request is generated during interrupt handling and the next interrupt request is generated (when the status flag of the Interrupt Controller Unit (ICU) is 1), the module does not output the interrupt request, and the SCI holds it internally. The interrupt that can be held is up to one.

33.17.2 Interrupt in Asynchronous Mode, Clock Synchronous Mode, and Simple-SPI Mode

A different interrupt vector is assigned to each interrupt source, and individual interrupt sources can be enabled or disabled with the enable bits in CCR0 register.

(1) Non-FIFO selected

Table 33.36 lists interrupt sources in Asynchronous Mode, Clock Synchronous Mode, and Simple-SPI Mode with Non-FIFO selected.

If the CCR0.TIE bit is 1, a TXI interrupt request is generated when transmit data is transferred from the TDR to the TSR. At the start of transmission, a TXI interrupt request can also be generated by using a single instruction to set the CCR0.TE and CCR0.TIE bit to 1 at the same time. A TXI interrupt request can activate the DMAC to handle data transfer.

A TXI interrupt request is not generated by setting the CCR0.TIE bit to 1 while the setting of the CCR0.TE bit is 1.*1

When the CCR0.TEIE bit is 1, the CSR.TEND flag becomes 1 and the TEI interrupt request is generated if the next data is not written to the TDR register by the timing to transmit the last bit of transmission data. In addition, the TEND flag holds 1 during the period from setting the CCR0.TE bit to 1 until writing transmit data to the TDR register, and if the TEIE bit is set to 1, a TEI interrupt request is generated.

Writing data to the TDR register clears the TEND flag and cancels the TEI interrupt request, but it takes time to cancel it.

If the CCR0.RIE bit is 1, an RXI interrupt request is generated when received data is stored in the RDR. An RXI interrupt request can activate the DMAC to handle data transfer.

Setting of any from among the ORER, FER, PER flags in the CSR to 1 while the CCR0.RIE bit is 1 leads to the generation of an ERI interrupt request.

An RXI interrupt request is not generated at this time. Clearing all three flags (ORER, FER, PER) leads to discarding of the ERI interrupt request.

Note 1. To temporarily prohibit TXI interrupts at the time of transmission of the last of the data and so on when you wish a new round of transmission to start after handling of the transmit end interrupt, control prohibiting and permitting of the interrupt by using the interrupt request enable bit in the interrupt controller rather than using the TIE bit. This can prevent the suppression of TXI interrupt requests in the transfer of new data.

Table 33.36 SCI interrupt sources with Non-FIFO selected

Name	Interrupt source	Interrupt flag	Level/pulse output	Interrupt enable	DMAC activation	Priority
ERI	Receive error	ORER, FER, PER, DFER, DPER, MER, SYER (SYEREN = 1), PFER (PFEREN = 1), SBER (SBEREN = 1)	Level	RIE	Not possible	High
RXI	Receive data full	RDRF	Pulse	RIE	Possible	↑
	Address match	DCMF				
TXI	Transmit data empty	TDRE	Pulse	TIE	Possible	↑
	TE = 0 -> 1 detection					
TEI	Transmit end	TEND	Level	TEIE	Not possible	Low

(2) FIFO selected

Table 33.37 lists interrupt sources in Asynchronous Mode, Clock Synchronous Mode, and Simple-SPI Mode with FIFO selected.

If the CCR0.TIE bit is 1, a TXI interrupt request is generated when the stored number of data in transmit FIFO becomes the threshold value indicated in FCR.TTRG or below. A TXI interrupt request can also be generated by using a single instruction to set the CCR0.TE and CCR0.TIE bit to 1 at the same time. A TXI interrupt request is not generated by setting the CCR0.TIE bit to 1 while the setting of the CCR0.TE bit is 1. If CCR0.TEIE bit is 1, when the next data is not being written in transmit FIFO by the timing to which the last bit of the transmission data is sent, CSR.TEND flag will be 1 and TEI interrupt request is generated.

If the CCR0.RIE bit is 1, RXI interrupt request is generated when the stored number of data in receive FIFO becomes the threshold value indicated in FCR.RTRG or above. When FCR.RTRG is set to 0, RXI interrupt request is occurred if the quantity of data in receive FIFO is greater than or equal to 1.

If the CCR0.RIE bit is 1, when CSR.ORER flag is set to 1 or the data a framing error or a parity error generated is stored in receive FIFO, ERI interrupt request is generated.

When the number of data stored in a receive FIFO at this time is a threshold value or above, RXI interrupt request is also generated. The ERI interrupt request can be canceled by clearing all flags (CSR.ORER, FER, and PER).

Table 33.37 SCI interrupt sources with FIFO selected

Name	Interrupt source	Interrupt flag	Level/pulse output	Interrupt enable	DMAC activation	Priority
ERI	Receive error	ORER, FER, PER, DFER, DPER	Level	RIE	Not possible	High
		DR (FCR.DRES = 1)				
RXI	Receive FIFO data full	RDRF	Pulse	RIE	Possible	↑
	Receive data ready	DR (FCR.DRES = 0)				
	Address match	DCMF				
TXI	Transmit FIFO data empty	TDRE	Pulse	TIE	Possible	↑
	TE = 0 -> 1 detection					
TEI	Transmit end	TEND	Level	TEIE	Not possible	Low

33.17.3 Interrupt in Smart Card Interface Mode

Table 33.38 lists interrupt sources in smart card interface mode. A transmit end interrupt (TEI) request cannot be used in this mode.

Table 33.38 SCI interrupt sources in smart card interface mode

Name	Interrupt source	Interrupt flag	Level/pulse output	Interrupt enable	DMAC activation	Priority
ERI	Receive error or error signal detection	ORER, PER, ERS	Level	RIE	Not possible	High
RXI	Receive data full	RDRF	Pulse	RIE	Possible	↑
TXI	Transmit end	TEND	Pulse	TIE	Possible	Low
	When set TE = 0 -> 1					

Data transmission/reception using the DMAC is also possible in smart card interface mode. In transmission operation, when the TEND flag in CSR is set to 1, a TXI interrupt request is generated. This TXI interrupt request activates the DMAC allowing transfer of transmit data if the TXI request is specified beforehand as a source of DMAC activation. The TEND flag is automatically set to 0 when the DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept to 0 and the DMAC is not activated. Therefore, the SCI and DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, the ERS flag in CSR is not automatically cleared to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the RIE bit in CCR0 to 1 to enable an ERI interrupt request to be generated at error occurrence.

In reception operation, an RXI interrupt request is generated when receive data is set to RDR. This RXI interrupt request activates the DMAC allowing transfer of receive data if the RXI request is specified beforehand as a source of DMAC activation. If an error occurs, the error flag is set. Therefore, the DMAC is not activated and an ERI interrupt request is issued to the CPU instead; the error flag must be cleared.

When transmitting/receiving data using the DMAC, be sure to make settings to enable the DMAC before making SCI settings. For DMAC settings, see section 15, DMA Controller (DMAC).

33.17.4 Interrupts in Simple-I2C Mode

Table 33.39 lists SCI interrupts in simple-I2C mode.

The STI interrupt is allocated to the transmit end interrupt (TEI) request. The receive error interrupt (ERI) request cannot be used.

The DMAC can also be used to handle transfer in simple I2C mode.

When the value of the IICINTM bit in ICR is 1, a RXI request will be generated on the falling edge of the SCLn signal for the eighth bit. If the RXI has been set up as an activating request for the DMAC beforehand, the RXI request will activate the DMAC to handle transfer of the received data. Furthermore, a TXI request is generated on the falling edge of the SCLn signal for the ninth bit (acknowledge bit). If the TXI has been set up as an activating request for the DMAC beforehand, the TXI request will activate the DMAC to handle transfer of the transmit data. (In this case, ACK/NACK judging are impossible.)

When the value of the IICINTM bit in ICR is 0, SCI operates as follows.

RXI request (ACK detection) is generated if the input on the SDAn pin is at the low level on the rising edge of the SCLn signal for the ninth bit (acknowledge bit).

TXI request (NACK detection) is generated if the input on the SDAn pin is at the high level on the rising edge of the SCLn signal for the ninth bit (acknowledge bit).

If the RXI has been set up as an activating request for the DMAC beforehand, the RXI request will activate the DMAC to handle transfer of the received data. Also, if the DMAC is used for data transfer in reception or transmission, be sure to set up and enable the DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in ICR are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Table 33.39 SCI interrupt sources in Simple-I2C mode

Name	Interrupt source		Interrupt flag	Level/ pulse output	Interrupt enable	DMAC activation	Priority
	IICINTM = 1	IICINTM = 0					
RXI	Reception end	—	—	Pulse	RIE	Possible*1	High
	—	ACK detection	—			Possible	↑
TXI	Transmit end	—	—	Pulse	TIE	Possible*1	↑
	—	NACK detection	—			Possible	↑
STI	Completion of generation of a start, restart, or stop condition		IICSTIF	Level	TEIE	Not Possible	Low

Note 1. If the DMAC is being used, you can not confirm whether ACK or NACK.

33.18 Usage Notes

33.18.1 SCI Operations during Low Power Consumption State

(1) Transmission

Before using the power consumption reduction function to reduce SCI's power consumption, please do the following to confirming transmission end (CSR.TEND = 1):

- Set the output pin state after transmission operation is stopped by CCR1.SPB2DT, SPB2IO.
- Stop the transmission (CCR0.TIE = 0, TE = 0, TEIE = 0).

When transitions to these states are made during transmission, the data being transmitted become indeterminate.

To transmit data in the same transmission mode after cancellation of the low power consumption state, set the TE bit to 1, read CSR, and write data to TDR sequentially to start data transmission. To transmit data with a different transmission mode, initialize the SCI first.

To start transmission using the DMAC after cancellation of the low power consumption state, set the TE and TIE bit to 1. The TXI interrupt flag is set to 1 and transmission starts using the DMAC.

Figure 33.107 shows a sample flowchart for transition to the low power consumption state during transmission. Figure 33.108 and Figure 33.109 show the port pin states during transition to the low power consumption state.

(2) Reception

(a) When Address match function is non used as condition of resumption (wake-up)

Before specifying the module stop state or making a transition to the low power consumption state, stop the receive operations (CCR0.RE = 0). If transition is made during data reception, the data being received will be invalid.

Figure 33.110 shows a sample flowchart for reception to software standby mode during reception.

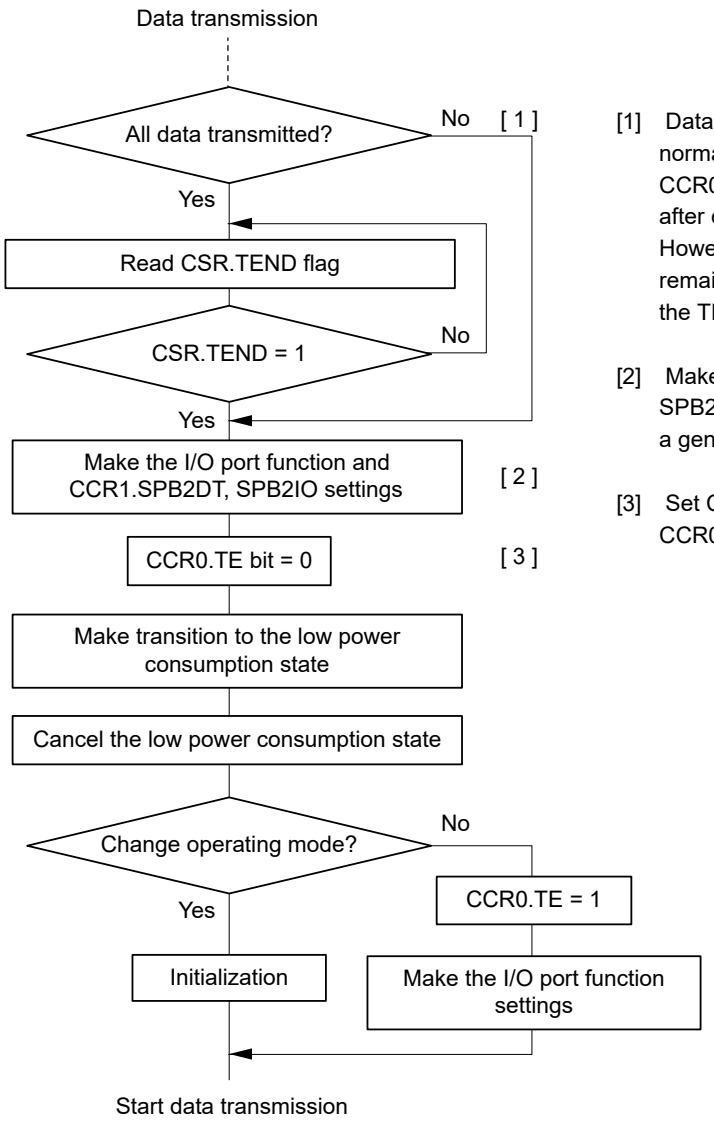
(b) When Address match function is used as condition of resumption (wake-up)

When using the power consumption reduction function to reduce SCI's power consumption, please do the following:

- Set the operation mode of after released.
- Set the compare data to CCR4.CMPD and set 1 to CCR0.DCME.
- Set the receive operation (CCR0.RE = 1).

When SCI transfers to the low power consumption mode if the reception data pin (RXD) is Low level, set CCR3.RXDESEL = 0. When setting it as CCR3.RXDESEL = 1, there is a possibility that a start bit (fall edge of RXDn pin) can not be detected at the time of low power consumption mode release.

Figure 33.111 shows a sample flowchart for reception to the low power consumption state during reception.



[1] Data being transmitted is lost halfway. Data can be normally transmitted from the CPU by setting the CCR0.TE to 1, reading CSR, and writing data to TDR after canceling the low power consumption state. However, if the DMAC has been activated, the data remaining in the DMAC will be transmitted when both the TE and TIE bits in CCR0 are set to 1.

[2] Make the I/O port function and CCR1.SPB2DT, SPB2IO settings to switch the TXDn pin to operate as a general I/O port.

[3] Set CCR0.TE bit to 0. Set also 0 to CCR0.TIE and CCR0.TEIE if you set these bits were 1.

Figure 33.107 Example of flowchart for transition to the low power consumption state during transmission

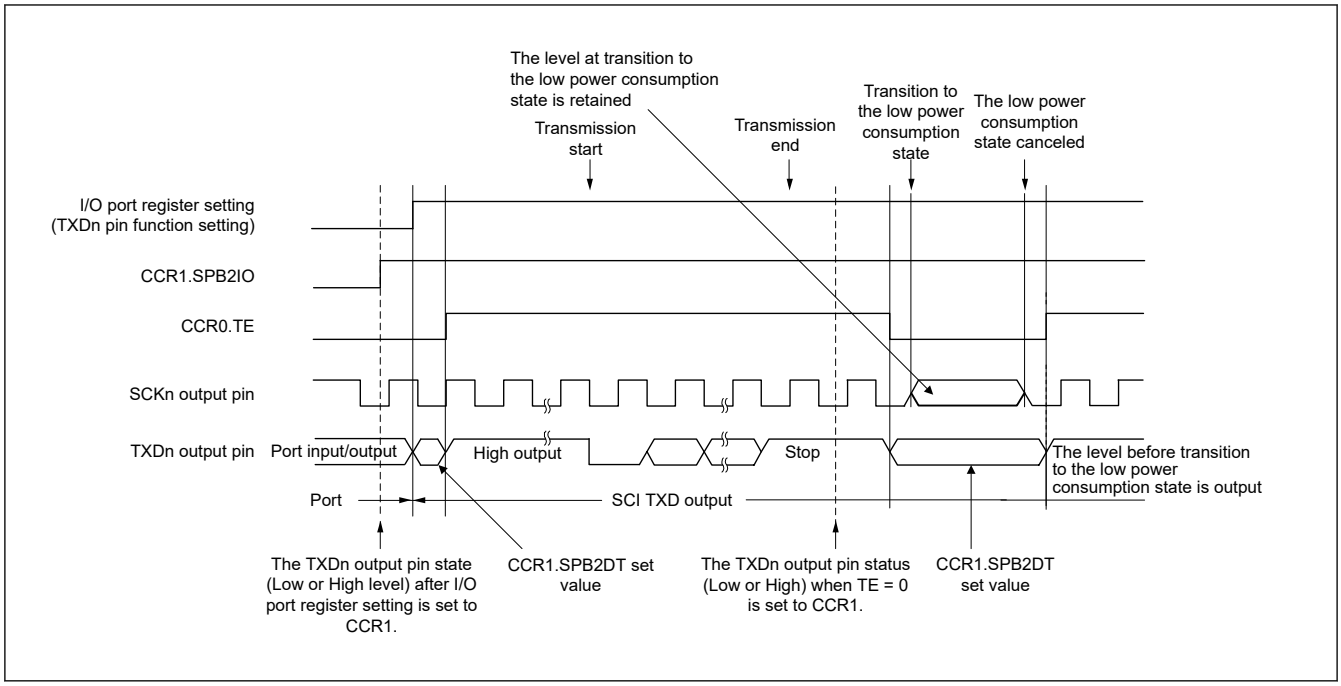


Figure 33.108 Port pin states during transition to the low power consumption state (internal clock, asynchronous transmission)

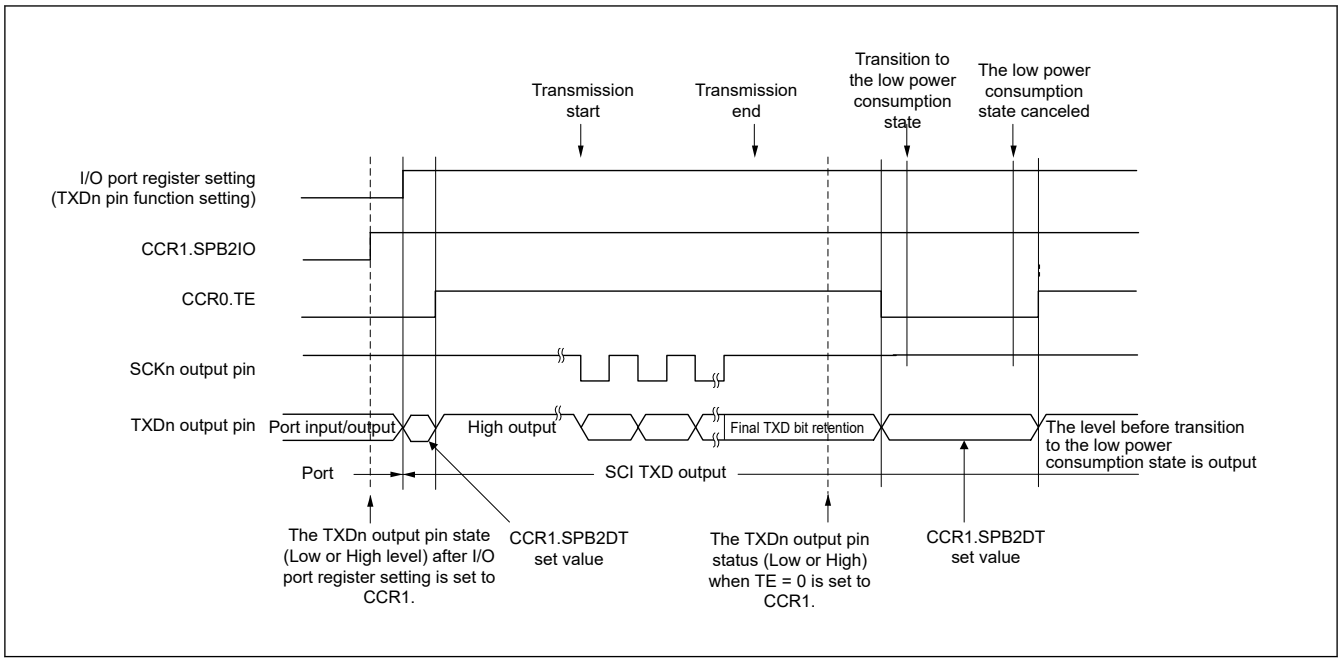

Figure 33.109 Port pin states during transition to the low power consumption state (internal clock, clock synchronous transmission)

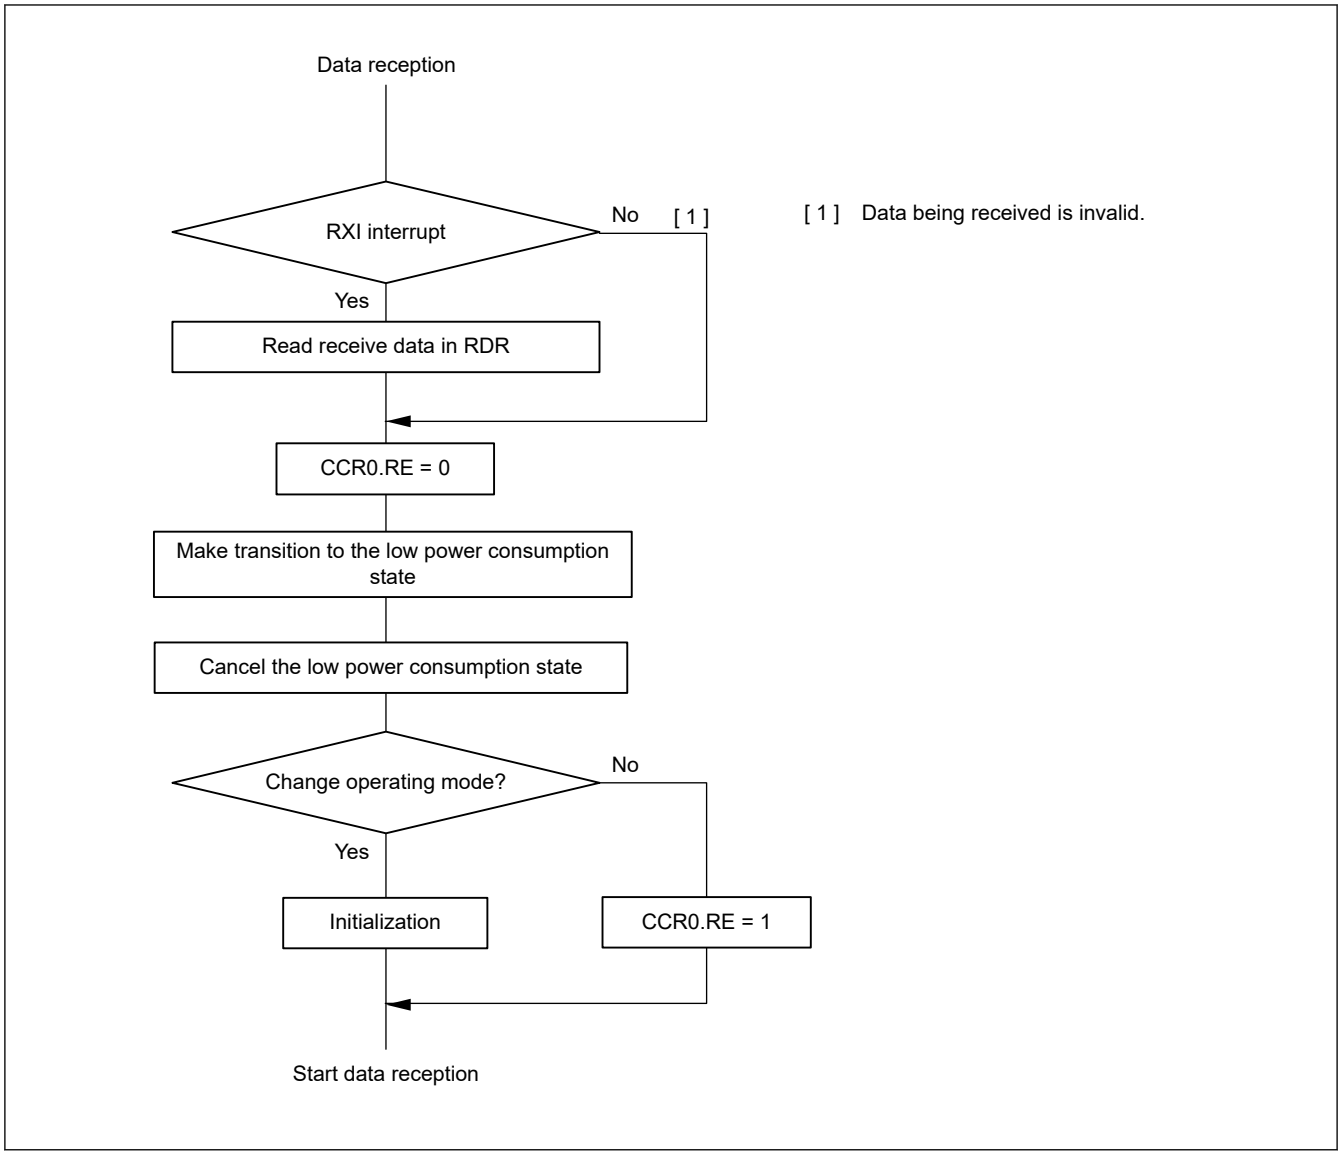

Figure 33.110 Example of flowchart for reception to the low power consumption state during reception

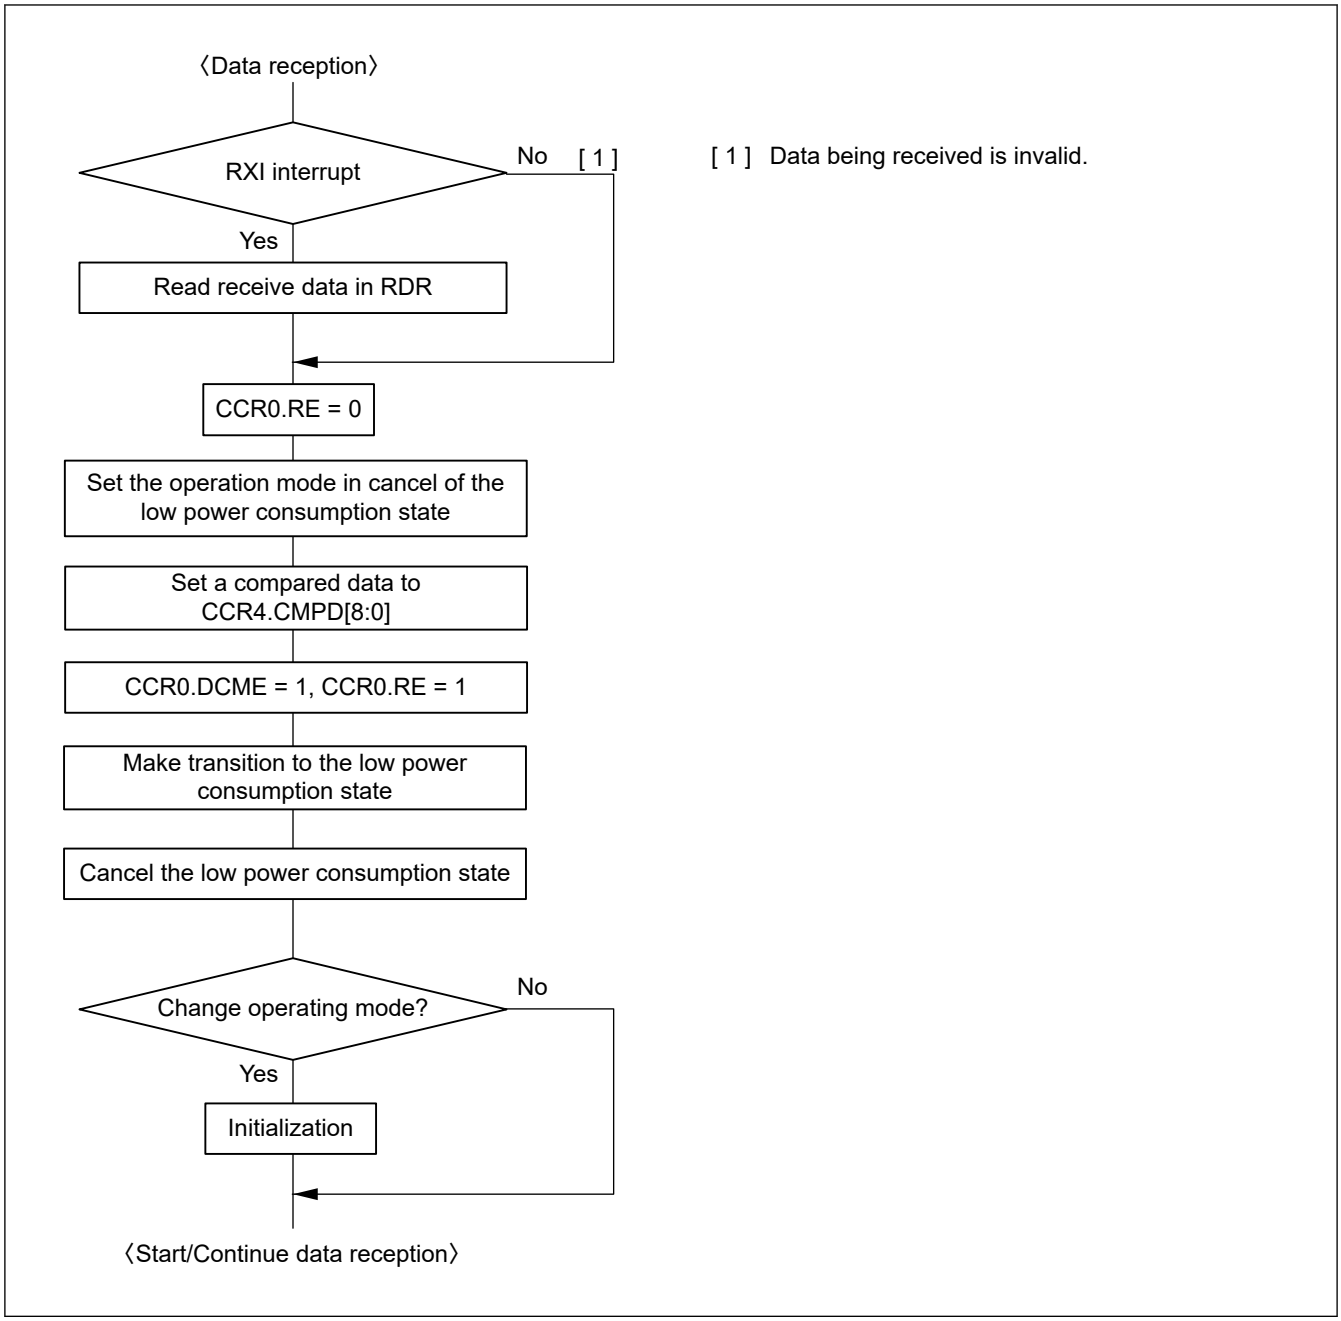

Figure 33.111 Example of flowchart for reception to the low power consumption state during reception with address match

33.18.2 Break Detection and Processing

(1) Non-FIFO selected

When a framing error is detected, a break can be detected by reading CSR.RXDMON bit value. In a break, the input from the RXDn pin becomes all 0s, and so the CSR.FER flag is set to 1 (framing error has occurred), and the CSR.PER flag may also be set to 1 (parity error has occurred). When the CCR3.RXDESEL bit is 0, the SCI continues the receive operation even after a break is received. Therefore, note that even if the FER flag is set to 0 (no framing error occurred), it will be set to 1 again. When the CCR3.RXDESEL bit is 1, the SCI sets the CSR.FER flag to 1 and stops receiving operation until a start bit of the next data frame is detected. If the CSR.FER flag is set to 0 at this time, the CSR.FER flag retains 0 during the break. When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit at the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

(2) FIFO selected

After a framing error is detected, when SCI detects that continuous receive data is 0 for 1 frame, the data stored into the receive FIFO (RDR) and reception stops. When a framing error is detected, a break can be detected by reading CSR.RXDMON bit value. After the RxD signal is in the mark state and it has finished the break, a stock of reception data to the receive FIFO (RDR) resumes.

33.18.3 Mark State and Production of Breaks

When CCR0.TE = 0 (serial transmission is disabled), the state of the TXDn pin can be set by CCR1.SPB2IO bit and CCR1.SPB2DT bit. Using this, it's possible to do a TXDn pin in the mark state and send a breakout. When you want to make a communication-line in the mark state (the state of 1) until the CCR0.TE bit is set to 1 (serial transmission is enabled), execute the following operations. First, set output level High by the CCR1.SPB2IO and CCR1.SPB2DT bits. Next, it's changed to a TXDn pin by I/O port function. On the other hand, if you want to send a break when sending data, set the CCR0.TE bit to 0 after setting the SPB2IO and SPB2DT bits in the CCR1 register to low level output. Setting the TE bit to 0 initializes the transmitter regardless of the current transmission status.

33.18.4 Receive Error Flags and Transmit Operations (Clock Synchronous Mode and Simple SPI Mode)

Transmission can be started by writing transmit-data to TDR even if CSR.ORER is 1. However, reception can not be started. Note also that the receive error flags cannot be set to 0 even if the CCR0.RE is set to 0 (serial reception is disabled).

33.18.5 Writing Data to TDR (Transmit FIFO)

(1) Non-FIFO selected

Data can be written to TDR anytime when CCR0.TE = 1. However, if new data is written to TDR when transmit data is remaining in TDR, the previous data in TDR is lost because it has not been transferred to TSR yet. If you use DMAC, be sure to write transmit data to TDR in the TXI interrupt request handling routine.

(2) FIFO selected

Data can be written to transmit FIFO (TDR) when TE is 1. Check the number of writable data with the FTSR.T[4:0] bits.

33.18.6 Restrictions on Clock Synchronous Transmission (Clock Synchronous Mode and Simple SPI Mode)

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

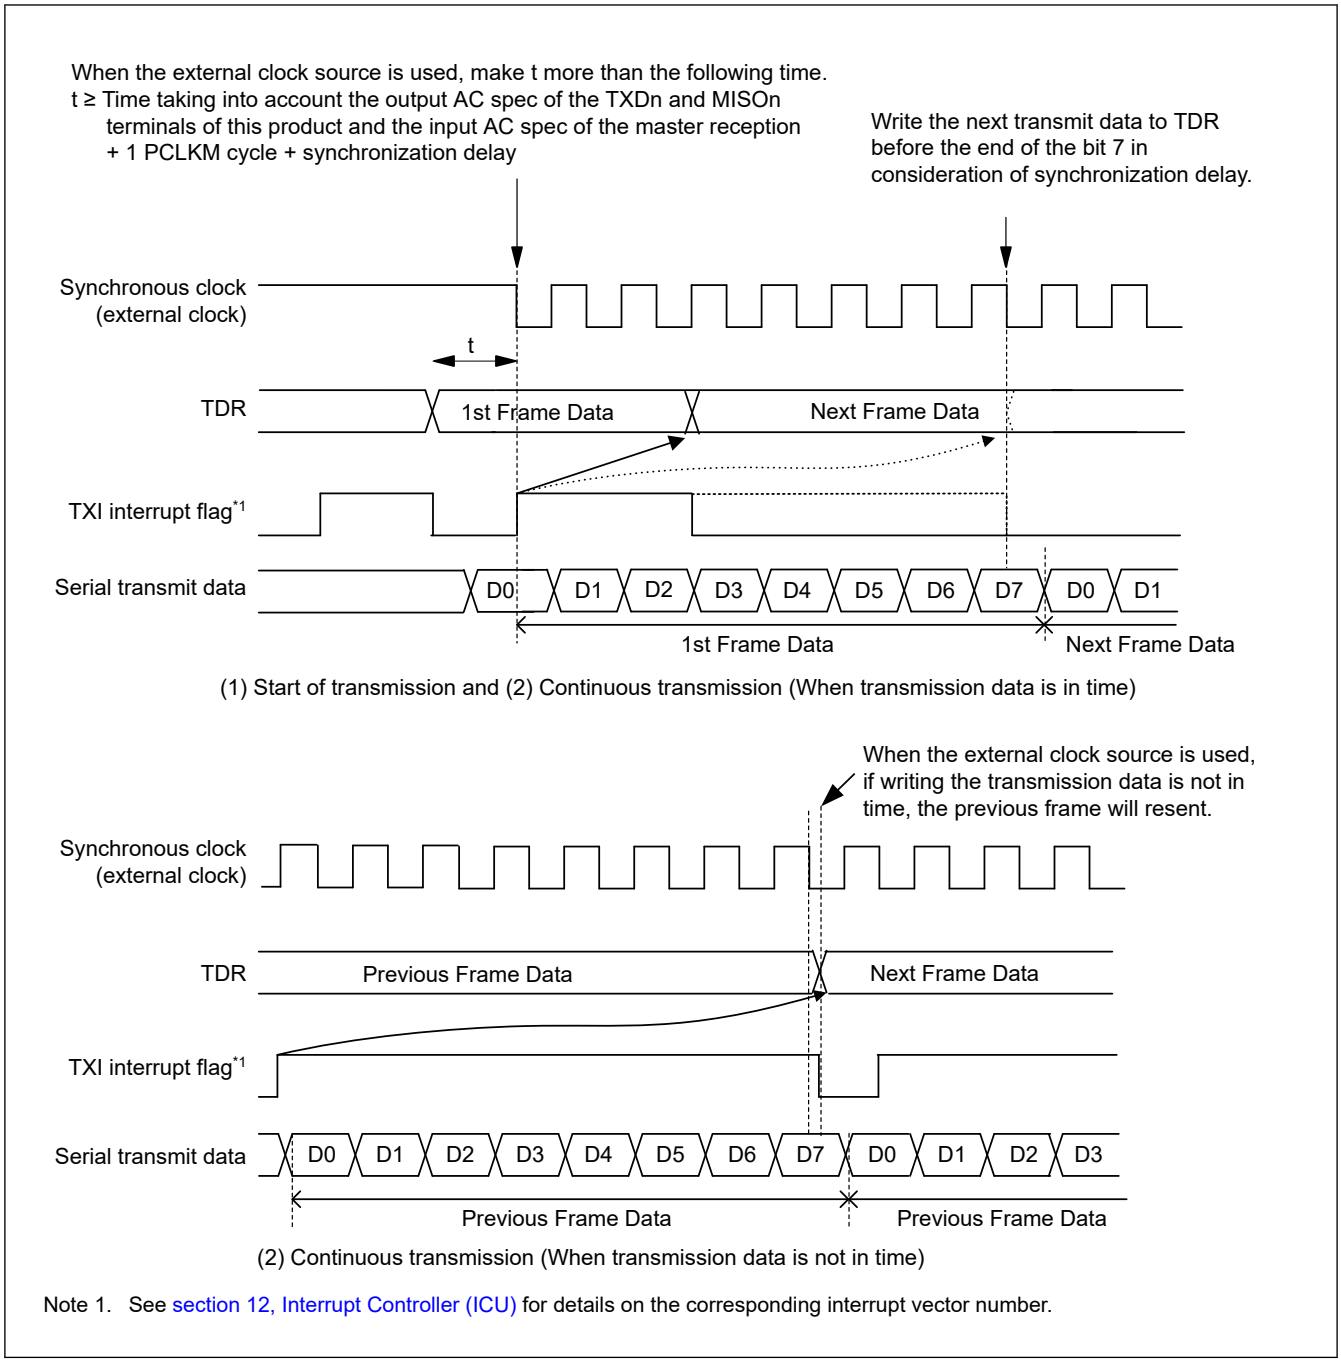
Update TDR by the CPU or DMAC and wait at least the following time until the start of the external clock input: (See Figure 33.112.)

Time taking into account the output AC specification of the TXDn and MISOn pins of this product and the input AC specification of the master reception + 1 PCLKM cycle + synchronization delay (2 to 3 PCLKSCIn).

(2) Continuous transmission

Write the next transmit data to TDR before the falling edge[*1] of the transmit clock for bit 7. Please write the transmit data to TDR in consideration of synchronization delay [2 to 3 PCLKSCIn]. If the transmit data can not be written in time, the previous frame data is resent. (See Figure 33.112.)

Note 1. When CCR3.CPOL = 1 and CCR3.CPHA = 0, or CCR3.CPOL = 0 and CCR3.CPHA = 1. In the case of CCR3.CPOL = 0 and CCR3.CPHA = 0, or CCR3.CPOL = 1 and CCR3.CPHA = 1, it is the rising edge.



Note 1. See section 12, Interrupt Controller (ICU) for details on the corresponding interrupt vector number.

Figure 33.112 Restrictions on use of external clock in clock synchronous transmission

33.18.7 Notes on Starting Transfer

At the point where transfer starts, when the interrupt status flag in the interrupt controller is 1, follow the procedure below to clear interrupt requests before permitting operations (by setting the CCR0.TE or CCR0.RE bit to 1).

For details on the interrupt status flag, see section 12, Interrupt Controller (ICU).

- Confirm that transfer has stopped (the setting of the CCR0.TE or CCR0.RE bits is 0).
- Set the corresponding interrupt enable bit (CCR0.TIE, CCR0.TEIE, or CCR0.RIE) to 0.
- Read the corresponding interrupt enable bit (CCR0.TIE, CCR0.TEIE, or CCR0.RIE bit) to check that it has actually become 0.
- Set the interrupt status flag in the interrupt controller to 0.

33.18.8 Limitations on Simple SPI Mode

(1) Master Mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set by the CCR3.CPHA and CPOL bits when CCR0.SSE = 1. This prevents the clock line from being placed in the high-impedance state when the CCR0.TE bit is set to 0 or unexpected edges from being generated on the clock line when the CCR0.TE bit is changed from 0 to 1.
  In a single-master mode, pull up or pull down the clock line is not necessary because the clock line does not become high-impedance state when CCR0.SSE = 0 and CCR0.TE = 0.
- In the case of the setting for clock delay (CCR3.CPHA = 0), the receive data full interrupt (RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 33.113. If the TE and RE bits become 0 at this time before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Furthermore, an RXI interrupt may lead to the input signal on the SSn# pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master mode, take care because the SCKn pin output becomes high-impedance while the input on the SSn# pin is at the low level if a mode fault error occurs as the current character is being transferred. And stopping supply of the clock signal to the connected slave. Remake the settings for the connected slave to avoid misaligned bits when transfer is restarted.

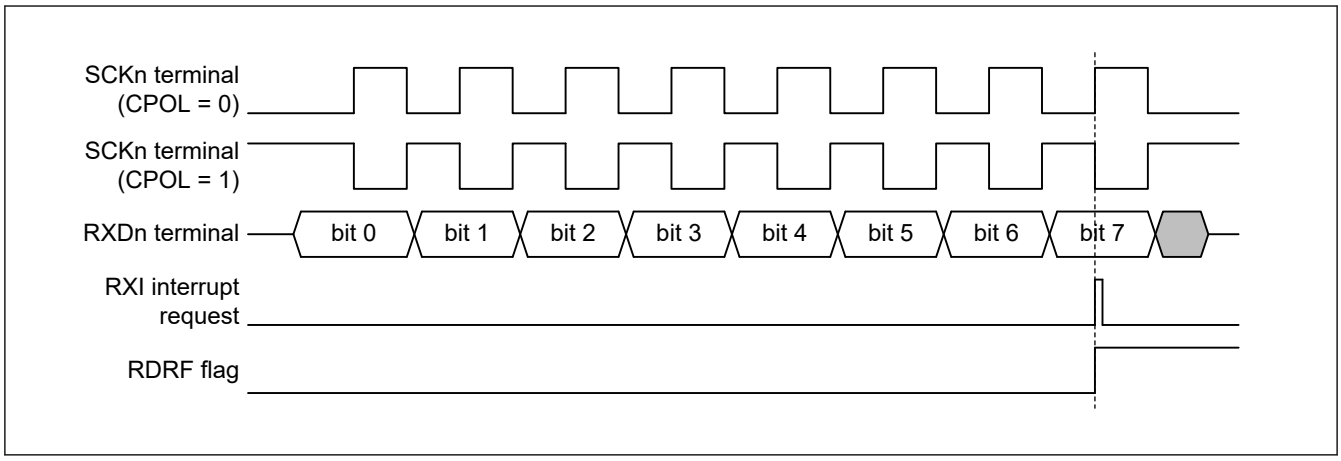


Figure 33.113 Timing of the RXI interrupt in simple SPI mode (with clock delay)

(2) Slave Mode

- It takes "1 PCLKM + synchronization delay time + data output delay time (AC spec)" from writing the transmit data to the TDR register until the data is output to the MSIOn pin. Take these into account when starting external clock input.
- Provide an external clock signal to the master the same as the data length for transfer.
- Secure the SS input setup time (AC spec) from the SS# low-level input to the start of external clock input.
- Control the input on the SSn# pin before the start and after the end of data transfer.
- When the level being input on the SSn# pin is to be changed from low to high while the current character is being transferred, the transmission and reception are stopped immediately. Set the TE and RE bits in the CCR0 to 0 and, after remaking the settings, restart transfer of the first byte.

33.18.9 Notes on Transmit Enable bit (TE)

In initial register value, when CCR0.TE = 0, and the terminal function is TXDn, the pin outputs high impedance.

So please make sure that the TXDn line will not be high impedance by the following one of ways.

1. The pull-up resistance is connected to the TXDn line.
2. Before CCR0.TE bit is 0, the function of the terminal is changed to general-purpose input port or output port. And after CCR0.TE bit is 1, the function of the pin is changed to TXDn.

3. In asynchronous mode, you can set CCR1 and decided level of TXDn pin during TE is 0.

In the simple SPI mode slave operation, the MSIOn pin operates in the same way as the above TXDn pin, so please deal with 1 or 2 in the same way. (3 can not be used.)

33.18.10 Notes on RS-485 Driver Control function

- RS-485 Driver control function is valid only in asynchronous mode.
- When RS-485 Driver control function is active (CCR3.DEN = 1), the TEND set timing/TEI output timing changes as follows. Wait for the TEI interrupt and set the TE bit in CCR0 to 0.
  When RS-485 Driver control function is inactive: When STOP bit output is completed.
  When RS-485 Driver control function is active: At the end of DE negation time.

33.18.11 Notes on Loopback function

The Loopback function is valid in asynchronous mode with internal clock, Manchester mode with internal clock, and clock synchronous mode with internal clock.

33.18.12 Notes Regarding Register Access When Operation Clock (PCLKSCIn) Is Slower Than Bus Clock (PCLKM)

If the operating clock (PCLKSCIn) is slower than the bus clock (PCLKM), the interval for writing access to the same register should be at least PCLKSCIn × 3 cycles + PCLKM × 3 cycles. Synchronization delay time and signal processing time are required to ensure that the setting value of the first write access is propagated to the subsequent logic circuit and the circuit is controlled correctly.

33.18.13 Notes on interrupting operation

If 0 is written to CCR0.RE during data reception and the reception operation is interrupted, there is a possibility of an invalid state, so please do not use the received data (RDR register stored value) and the flag value of each status register. To interrupt the reception operation, stop the interrupt or event link reception side and then write 0 to the CCR0.RE bit.

In addition, when 0 is written to each operation enable bit (CCR0.RE, CCR0.TE) and the operation is interrupted, the following time is required to safely stop the internal circuit. During this time, access to this register is prohibited.

PCLKSCIn × 3 cycles + PCLKM × 3 cycles

33.18.14 Notes on communication mode transition

When changing the communication mode setting bits CCR3.MOD[2:0] and switching the communication mode, set CCR0.RE = 0 and CCR0.TE = 0 to stop the communication operation. In order to transition the internal circuit state safely, the register access interval should be at least PCLKSCIn × 3 cycles + PCLKM × 3 cycles. During this time, write access to this register is prohibited. As an example, the following describes the transition from Asynchronous mode to Clock-synchronous mode.

1. Confirm stop of reception and transmission at asynchronous mode (CCR3.MOD[2:0] = 000b).
2. Write 0 to CCR0.TE and CCR0.RE, stop communication.
3. Wait "PCLKSCIn × 3 cycles + PCLKM × 3 cycles". During this time, access to this register is prohibited.
4. Write 010b to CCR3.MOD[2:0].
5. Wait "PCLKSCIn × 3 cycles + PCLKM × 3 cycles". During this time, access to this register is prohibited.

34. I²C Bus Interface (IIC)

34.1 Overview

The LSI has a two-channel I²C Bus Interface (IIC) module that conforms with and provides a subset of the NXP I²C bus (inter-integrated circuit bus) interface functions. Table 34.1 lists the IIC specifications, Figure 34.1 shows a block diagram, and Figure 34.2 shows an example of I/O pin connections to external circuits, with an I²C bus configuration. Table 34.2 lists the I/O pins.

Table 34.1 IIC specifications (1 of 2)

Parameter	Specifications
Number of channels	3 channels (ch0 to ch1 in NONSAFETY and ch2 in SAFETY)
Communications format	• I²C bus format or SMBus format. • Master or slave mode selectable. • Automatic securing of the setup times, hold times, and bus-free times for the transfer rate.
Transfer rate	Fast-mode supported, up to 400 kbps.
SCL clock	For master operation, the duty cycle of the SCL clock is selectable in the range from 4% to 96%.
Issuing and detecting conditions	• Start, restart, and stop conditions are automatically generated. • Start conditions (including restart conditions) and stop conditions are detectable.
Slave address	• Configurable for up to three different slave addresses. • 7-bit and 10-bit address formats supported, including simultaneous use. • General call addresses, device ID addresses, and SMBus host addresses detectable.
Acknowledgment	• For transmission, automatic loading of the acknowledge bit. Transfer of the next transmit data can be automatically suspended on detection of a not-acknowledge bit. • For reception, automatic transmission of the acknowledge bit. If a wait between the 8th and 9th clock cycles is selected, software can control the value in the acknowledge field in response to the received value.
Wait function	During reception, the following wait periods are available by holding the SCL clock low: • Waiting between the 8th and 9th clock cycles. • Waiting between the 9th clock cycle and the 1st clock cycle of the next transfer.
SDA output delay function	Output timing of transmitted data, including the acknowledge bit, can be delayed.
Arbitration	• For multi-master operation: – SCL clock synchronization is possible when conflict occurs with the SCL signal from another master. – When issuing the start condition creates conflict on the bus, loss of arbitration is detected by testing for mismatching between the internal signal for the SDA line and the level on the SDA line. – In master operation, loss of arbitration is detected by testing for mismatching between the signal on the SDA line and the internal signal for the SDA line. • Loss of arbitration because the start condition occurs while the bus is busy is detectable, to prevent the issuing of double start conditions. • Loss of arbitration is detectable on transfer of a not-acknowledge bit because the internal signal for the SDA line and the level on the SDA line do not match. • Loss of arbitration because mismatching of internal and line levels for data is detectable in slave transmission.
Timeout function	Internal detection of long-interval stops of the SCL clock.
Noise cancellation	• Digital noise filters for both the SCL and SDA signals. • Programmable window for noise cancellation by the filters.
Interrupt sources	• Transfer error or event generation: arbitration detection, NACK, timeout, start or restart condition, or stop condition. • Receive data full, including matching with a slave address. • Transmit data empty, including matching with a slave address. • Transmit end.
Module-stop function	Module-stop state can be set to reduce power consumption.

Table 34.1 IIC specifications (2 of 2)

Parameter	Specifications
IIC operating modes	• Master transmit • Master receive • Slave transmit • Slave receive

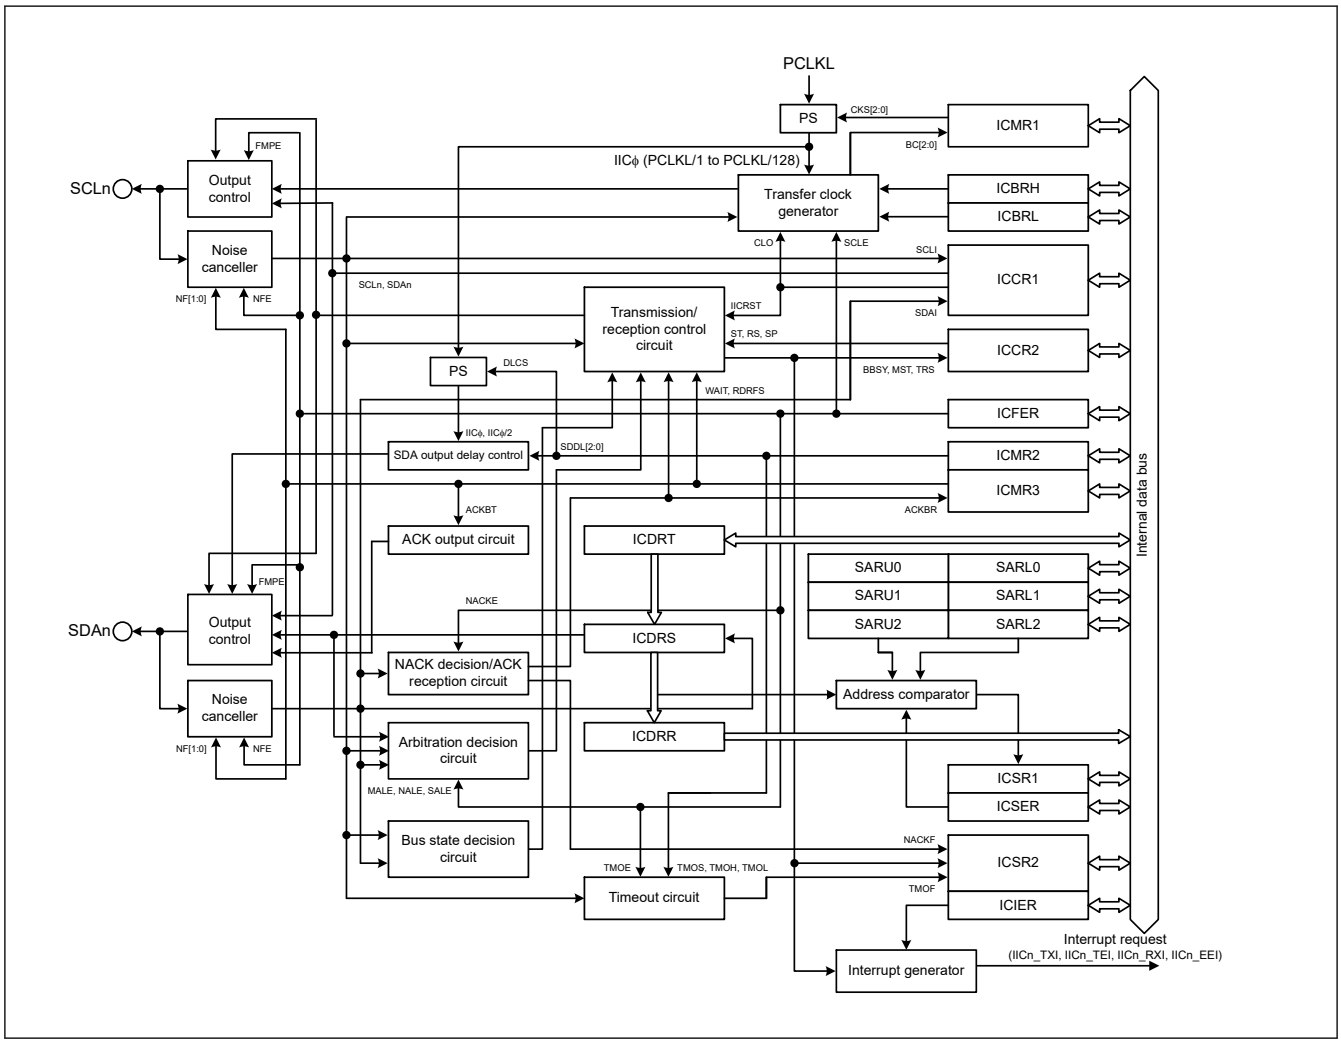

Figure 34.1 IIC block diagram

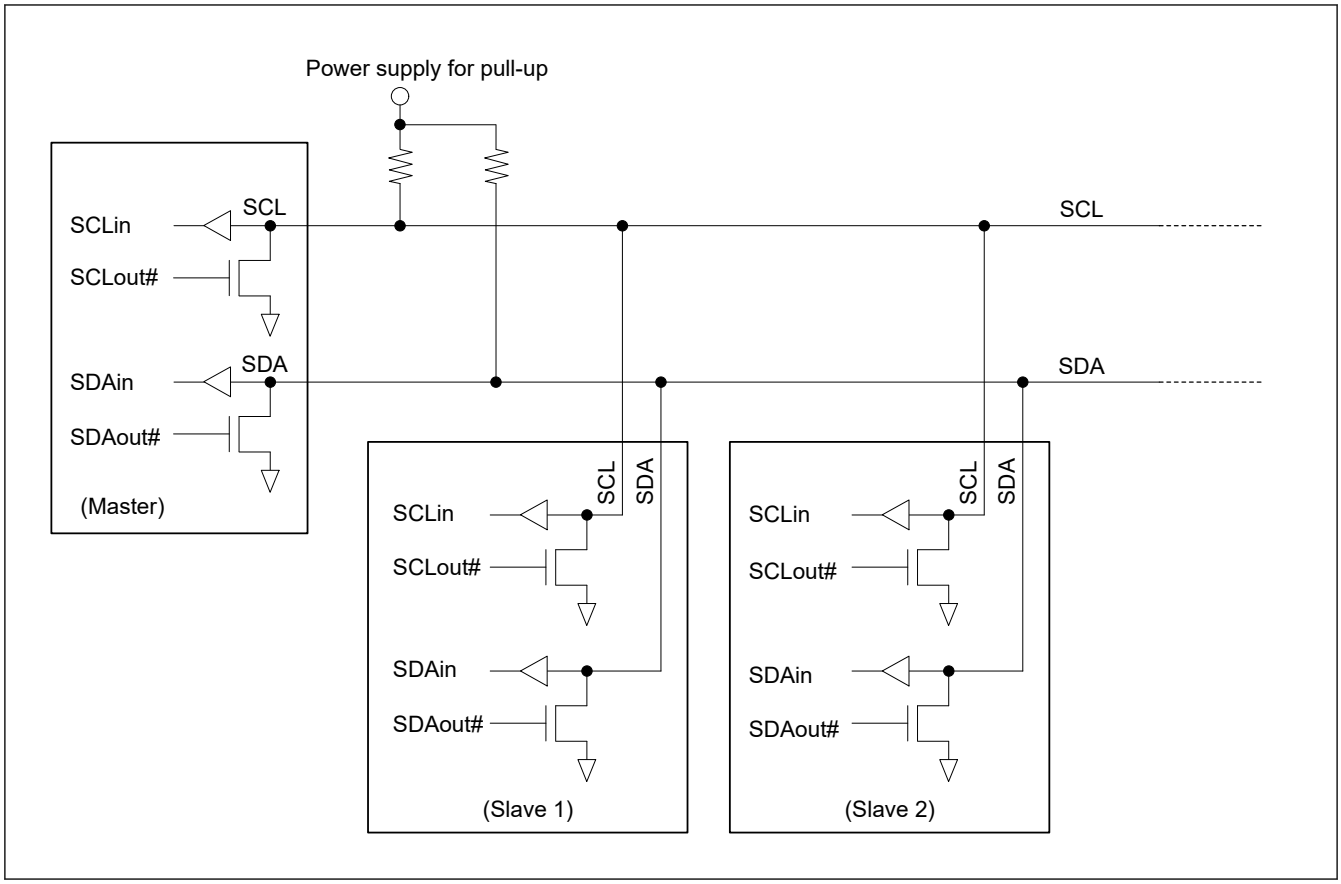

Figure 34.2 I/O pin connection to an external circuit (I^2C bus configuration example)

The input level of the signals for IIC is CMOS. Change to TTL is not supported.

Table 34.2 IIC I/O pins

Channel	Pin name*1	I/O	Function
IIC0	IIC_SCL0	I/O	IIC0 serial clock I/O pin
	IIC_SDA0	I/O	IIC0 serial data I/O pin
IIC1	IIC_SCL1	I/O	IIC1 serial clock I/O pin
	IIC_SDA1	I/O	IIC1 serial data I/O pin
IIC2	IIC_SCL2	I/O	IIC2 serial clock I/O pin
	IIC_SDA2	I/O	IIC2 serial data I/O pin

Note 1. For convention, pin names within this chapter are written without "IIC_" notation except this table.

Table 34.3 IIC interrupt sources

Name	Interrupt sources
IICn_EEI	Transfer error or event generation
IICn_RXI	Receive data full
IICn_TXI	Transmit data empty
IICn_TEI	Transmit end

Note: n = 0 to 2

34.2 Register Map

Table 34.4 IIC register map

Address	Register symbol	Register name	Write protection
0x8008_8000 + 0x0400 × n (n = 0, 1) 0x8100_8000 (n = 2)	ICCR1	I2C Bus Control Register 1	—

34.3 Register Descriptions

34.3.1 ICCR1 : I2C Bus Control Register 1

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ICE	IICRST	CLO	SOWP	SCLO	SDAO	SCLI	SDAI
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Function	R/W
0	SDAI	SDA Line Monitor 0: SDAn line is low 1: SDAn line is high	R
1	SCLI	SCL Line Monitor 0: SCLn line is low 1: SCLn line is high	R
2	SDAO	SDA Output Control/Monitor 0: Read: IIC drives SDAn pin low Write: IIC drives SDAn pin low 1: Read: IIC releases SDAn pin Write: IIC releases SDAn pin	R/W
3	SCLO	SCL Output Control/Monitor Use an external pull-up resistor to drive the signal high. 0: Read: IIC drives SCLn pin low Write: IIC drives SCLn pin low 1: Read: IIC releases SCLn pin Write: IIC releases SCLn pin	R/W
4	SOWP	SCLO/SDAO Write Protect 0: Write enable SCLO and SDAO bits 1: Write protect SCLO and SDAO bits	W
5	CLO	Extra SCL Clock Cycle Output This bit clears automatically after one clock cycle is output. 0: Do not output extra SCL clock cycle (default) 1: Output extra SCL clock cycle	R/W
6	IICRST	IIC-Bus Interface Internal Reset This setting clears the bit counter and the SCLn/SDAn output latch. 0: Release IIC reset or internal reset 1: Initiate IIC reset or internal reset	R/W
7	ICE	IIC-Bus Interface Enable Used in combination with the IICRST bit to select either IIC or internal reset. 0: Disable (SCLn and SDAn pins in inactive state) 1: Enable (SCLn and SDAn pins in active state)	R/W

SDAO bit (SDA Output Control/Monitor) and SCLO bit (SCL Output Control/Monitor)

The SDAO and SCLO bits directly control the SDAn and SCLn signals output from the IIC.

When writing to these bits, also write 0 to the SOWP bit. Setting these bits results in input to the IIC by the input buffer.

When slave mode is selected, a start condition might be detected and the bus might be released, depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, or during transmission or reception.

Operation after rewriting under the specified conditions is not guaranteed. When reading these bits, the state of signals output from the IIC can be read.

CLO bit (Extra SCL Clock Cycle Output)

The CLO bit allows the output of an extra SCL clock cycle for debugging or error processing. Normally, set this bit to 0.

Setting this bit to 1 in a normal communication state causes a communication error. For details on this function, see section 34.12.2. Extra SCL Clock Cycle Output Function.

IICRST bit (IIC-Bus Interface Internal Reset)

The IICRST bit initiates an internal state reset of the IIC. Setting this bit to 1 initiates an IIC reset or internal reset.

Whether an IIC reset or internal reset is initiated is determined by setting this bit in combination with the ICE bit.

Table 34.6 lists the IIC resets.

The IIC reset initializes all registers except ICCR1.ICE and ICCR1.IICRST bits, and internal states of the IIC. In addition to the internal states of the IIC, the internal reset initializes the following:

- Bit counter (ICMR1.BC[2:0] bits)
- I^2C Bus Shift Register (ICDRS)
- I^2C Bus Status Registers (ICSR1 and ICSR2)
- SDAO and SCLO Output Control/Monitor (ICCR1.SCLO and ICCR1.SDAO bits)
- I^2C Bus Control Register 2 (except ICCR2.BBSY bit)

For the reset conditions of each register, see section 34.15. Resets, Registers, and Function States When Issuing Each Condition.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the IIC without initializing the port settings and the control and setting registers of the IIC when the bus or IIC hangs up because of a communication error. If the IIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the SCLn pin and SDAn pin at high impedance.

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up that occurs during communication with the master device in slave mode, the slave and master devices might enter different states, because the bit counter information differs. For this reason, do not initiate an internal reset in slave mode. Initiate recovery processing from the master device. If an internal reset is necessary because the IIC hangs with the SCLn line in a low level output state in slave mode, initiate an internal reset, and then issue a restart condition from the master device, or issue a stop condition and resume communication from the start condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start or restart condition from the master device, synchronization is lost because the master and slave devices operate asynchronously.

Table 34.6 IIC resets

IICRST	ICE	State	Specifications
1	0	IIC reset	Resets all registers except ICCR1.ICE and ICCR1.IICRST bits, and the internal states of the IIC
	1	Internal reset	Resets the following: • ICMR1.BC[2:0] bits • ICCR1, ICSR2, ICDRS registers • SDAO and SCLO Output Control/Monitor (ICCR1.SCLO and ICCR1.SDAO bits) • I^2C Bus Control Register 2 (except ICCR2.BBSY bit) • Internal states of the IIC.

ICE bit (IIC-Bus Interface Enable)

The ICE bit selects the active or inactive state of the SCLn and SDAn pins. It can also be combined with the IICRST bit to initiate two types of resets. See Table 34.6 for the reset types.

Set the ICE bit to 1 when using the IIC. The SCLn and SDAn pins are placed in the active state when the ICE bit is set to 1. Set the ICE bit to 0 when the IIC is not used. The SCLn and SDAn pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCLn or SDAn pin to the IIC when setting up the pin function control. Slave address comparison is performed if the pins are assigned to the IIC.

34.3.2 ICCR2 : I²C Bus Control Register 2

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x01

Bit position:	7	6	5	4	3	2	1	0
Bit field:	BBSY	MST	TRS	—	SP	RS	ST	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	ST	Start Condition Issuance Request 0: Do not issue a start condition request 1: Issue a start condition request	R/W
2	RS	Restart Condition Issuance Request 0: Do not issue a restart condition request 1: Issue a restart condition request	R/W
3	SP	Stop Condition Issuance Request 0: Do not issue a stop condition request 1: Issue a stop condition request	R/W
4	—	This bit is read as 0. The write value should be 0.	R/W
5	TRS	Transmit/Receive Mode 0: Receive mode 1: Transmit mode	R/W*1
6	MST	Master/Slave Mode 0: Slave mode 1: Master mode	R/W*1
7	BBSY	Bus Busy Detection Flag 0: I²C bus released (bus free state) 1: I²C bus occupied (bus busy state)	R

Note 1. The MST and TRS bits can be written to when the ICMR1.MTWP bit is set to 1.

ST bit (Start Condition Issuance Request)

The ST bit requests transition to master mode and triggers a start condition.

When this bit is set to 1, a start condition is issued when the BBSY flag is set to 0 (bus free state). For details on issuing a start condition, see section 34.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the ST bit.

[Clearing conditions]

- When 0 is written to the ST bit.
- When a start condition is issued (a start condition is detected).
- When the AL (arbitration-lost) flag in ICSR2 is set to 1.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Set the ST bit to 1 (start condition issuance request) when the BBSY flag is set to 0 (bus free state). Arbitration might be lost if the ST bit is set to 1 (start condition request) when the BBSY flag is 1 (bus busy state).

RS bit (Restart Condition Issuance Request)

The RS bit requests that a restart condition be issued in master mode.

When this bit is set to 1 to request a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on issuing a restart condition, see section 34.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the RS bit with the BBSY flag in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the RS bit.
- When a restart condition is issued (a start condition is detected).
- When the AL (arbitration-lost) flag in ICSR2 is set to 1.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Do not set the RS bit to 1 while issuing a stop condition.

Note: If 1 (restart condition request) is written to the RS bit in slave mode, the restart condition is not issued, but the RS bit remains set to 1. If the operating mode changes to master mode without the bit being cleared, a restart condition might be issued.

SP bit (Stop Condition Issuance Request)

The SP bit requests that a stop condition be issued in master mode.

When this bit is set to 1, a stop condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 34.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the MST bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the SP bit.
- When a stop condition is issued (a stop condition is detected).
- When the AL (arbitration-lost) flag in ICSR2 is set to 1.
- When a start condition and a restart condition are detected.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Writing to the SP bit is not possible while the BBSY flag is 0 (bus free state).

Note: Do not set the SP bit to 1 while a restart condition is being issued.

TRS bit (Transmit/Receive Mode)

The TRS bit indicates transmit or receive mode.

The IIC is in receive mode when the TRS bit is 0 and in transmit mode when the bit is 1. The combination of the TRS bit and the MST bit indicates the operating mode of the IIC.

The value of the TRS bit automatically changes to 1 for transmit mode or 0 for receive mode when a start condition is issued or detected and the R/W# bit is set. Although writing to the TRS bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1).
- When a restart condition is issued normally because of a restart condition request (when a restart condition is detected with the RS bit set to 1).
- When the R/W# bit added to the slave address is set to 0 in master mode.
- When the address received in slave mode matches the address enabled in ICSER, with the R/W# bit set to 1.
- When 1 is written to the TRS bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected.
- When the AL (arbitration-lost) flag in ICSR2 is set to 1.
- In master mode, on the reception of a slave address to which a R/W# bit with the value 1 is appended.
- In slave mode, on a match between the received address and the address enabled in ICSER when the value of the received R/W# bit is 0, including when the received address is the general call address.
- In slave mode, when a restart condition is detected (a start condition is detected with ICCR2.BBSY = 1 and ICCR2.MST = 0).
- When 0 is written to the TRS bit with the MTWP bit in ICMR1 set to 1.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

MST bit (Master/Slave Mode)

The MST bit indicates master or slave mode. The IIC is in slave mode when the MST bit is set to 0 and is in master mode when the bit is set to 1. The combination of the MST bit and the TRS bit indicates the operating mode of the IIC.

The value of the MST bit automatically changes to 1 for master mode or 0 for slave mode when a start condition is issued, or when a stop condition is issued or detected. Although writing to the MST bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not necessary during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1).
- When 1 is written to the MST bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected.
- When the AL (arbitration-lost) flag in ICSR2 is set to 1.
- When 0 is written to the MST bit with the MTWP bit in ICMR1 set to 1.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

BBSY bit (Bus Busy Detection Flag)

The BBSY flag indicates whether the I^2C bus is occupied (bus busy state) or released (bus free state).

The flag is set to 1 when the SDAn line changes from high to low when the SCLn line is high, assuming that a start condition was issued.

The flag is set to 0 when the SDAn line changes from low to high with the SCLn line high, if the bus free time (ICBRL setting) start condition is not detected, assuming that a stop condition was issued.

[Setting condition]

- When a start condition is detected.

[Clearing conditions]

- When the bus free time (ICBRL setting) start condition is not detected after detecting a stop condition.
- When 1 is written to the IICRST bit in ICCR1 with the ICE bit in ICCR1 set to 0 (IIC reset).

34.3.3 ICMR1 : I²C Bus Mode Register 1

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	MTWP	CKS[2:0]			BCWP	BC[2:0]		
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
2:0	BC[2:0]	Bit Counter 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits	R/W*1
3	BCWP	BC Write Protect 0: Write enable BC[2:0] bits 1: Write protect BC[2:0] bits	W*1
6:4	CKS[2:0]	Internal Reference Clock Select Select the internal reference clock source (IICΦ) for the IIC. 0 0 0: PCLKL clock 0 0 1: PCLKL/2 clock 0 1 0: PCLKL/4 clock 0 1 1: PCLKL/8 clock 1 0 0: PCLKL/16 clock 1 0 1: PCLKL/32 clock 1 1 0: PCLKL/64 clock 1 1 1: PCLKL/128 clock	R/W
7	MTWP	MST/TRS Write Protect 0: Write protect MST and TRS bits in ICCR2 1: Write enable MST and TRS bits in ICCR2	R/W

Note 1. Rewrite the BC[2:0] bits and set the BCWP bit to 0 at the same time.

BC[2:0] bits (Bit Counter)

The BC[2:0] bits function as a counter that indicates the number of bits remaining to be transferred on detection of a rising edge on the SCLn line. Although BC[2:0] are read/write bits, it is not required to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one, for an additional acknowledge bit, between transferred frames when the SCLn line is at a low level.

The value in the BC[2:0] bits return to 000b at the end of a data transfer, including the acknowledge bit, or when a start or restart condition is detected.

34.3.4 ICMR2 : I²C Bus Mode Register 2

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x03

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DLCS	SDDL[2:0]			—	TMOH	TMOL	TMOS
Value after reset:	0	0	0	0	0	1	1	0

Bit	Symbol	Function	R/W
0	TMOS	Timeout Detection Time Select 0: Select long mode 1: Select short mode	R/W
1	TMOL	Timeout L Count Control 0: Disable count while SCLn line is low 1: Enable count while SCLn line is low	R/W
2	TMOH	Timeout H Count Control 0: Disable count while SCLn line is high 1: Enable count while SCLn line is high	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
6:4	SDDL[2:0]	SDA Output Delay Counter 0 0 0: No output delay 0 0 1: 1 IICΦ cycle (When ICMR2.DLCS = 0 (IICΦ)) 1 or 2 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2)) 0 1 0: 2 IICΦ cycles (When ICMR2.DLCS = 0 (IICΦ)) 3 or 4 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2)) 0 1 1: 3 IICΦ cycles (When ICMR2.DLCS = 0 (IICΦ)) 5 or 6 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2)) 1 0 0: 4 IICΦ cycles (When ICMR2.DLCS = 0 (IICΦ)) 7 or 8 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2)) 1 0 1: 5 IICΦ cycles (When ICMR2.DLCS = 0 (IICΦ)) 9 or 10 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2)) 1 1 0: 6 IICΦ cycles (When ICMR2.DLCS = 0 (IICΦ)) 11 or 12 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2)) 1 1 1: 7 IICΦ cycles (When ICMR2.DLCS = 0 (IICΦ)) 13 or 14 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2))	R/W
7	DLCS	SDA Output Delay Clock Source Select 0: Select internal reference clock (IICΦ) as clock source for SDA output delay counter 1: Select internal reference clock divided by 2 (IICΦ/2) as clock source for SDA output delay counter*1	R/W

Note 1. The setting DLCS = 1 (IICΦ/2) is only valid when SCL is low. When SCL is high, the DLCS = 1 setting becomes invalid and the clock source becomes the internal reference clock (IICΦ).

TMOS bit (Timeout Detection Time Select)

The TMOS bit selects long or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE = 1).

When this bit is set to 0, long mode is selected. When it is set to 1, short mode is selected.

In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14 bit counter. While the SCLn line is in the state that enables this counter as specified in the TMOH and TMOL bits, the counter counts up in synchronization with the internal reference clock (IICΦ) as a count source.

For details on this function, see section 34.12.1. Timeout Function.

TMOL bit (Timeout L Count Control)

The TMOLbit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held low and the timeout function is enabled (ICFER.TMOE = 1).

TMOH bit (Timeout H Count Control)

The TMOH bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held high and the timeout function is enabled (ICFER.TMOE = 1).

SDDL[2:0] bits (SDA Output Delay Counter)

The SDDL[2:0] bits can be used to delay the SDA output. This counter works with the clock source selected in the DLCS bit. This setting can be used for all types of SDA output, including the transmission of the acknowledge bit.

Set the SDA output delay to meet the I^2C bus standard for the data enable time/acknowledge enable time,*1 or the SMBus standard, within [data hold time (300 ns or more + the SCL-clock low-level period) - the data setup time (250 ns)]. If a

value outside the standard is set, communication between the devices might malfunction or falsely indicate a start or stop condition, depending on the bus state.

For details on this function, see section 34.6. SDA Output Delay Function.

Note 1. Data enable time/acknowledge enable time

3,450 ns for up to 100 kbps: Standard-mode (Sm)

900 ns for up to 400 kbps: Fast-mode (Fm)

34.3.5 ICMR3 : I2C Bus Mode Register 3

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SMBS	WAIT	RDRFS	ACKWP	ACKBT	ACKBR	NF[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	NF[1:0]	Noise Filter Stage Select 0 0: Filter out noise of up to 1 IICΦ cycle (single-stage filter) 0 1: Filter out noise of up to 2 IICΦ cycles (2-stage filter) 1 0: Filter out noise of up to 3 IICΦ cycles (3-stage filter) 1 1: Filter out noise of up to 4 IICΦ cycles (4-stage filter)	R/W
2	ACKBR	Receive Acknowledge 0: 0 received as the acknowledge bit (ACK reception) 1: 1 received as the acknowledge bit (NACK reception)	R
3	ACKBT	Transmit Acknowledge 0: Send 0 as the acknowledge bit (ACK transmission) 1: Send 1 as the acknowledge bit (NACK transmission)	R/W*1
4	ACKWP	ACKBT Write Protect 0: Write protect ACKBT bit 1: Write enable ACKBT bit	R/W*1
5	RDRFS	RDRF Flag Set Timing Select Low-hold is released by writing to ACKBT. 0: Set the RDRF flag on the rising edge of the 9th SCL clock cycle. The SCLn line is not held low on the falling edge of the 8th clock cycle. 1: Set the RDRF flag on the rising edge of the 8th SCL clock cycle. The SCLn line is held low on the falling edge of the 8th clock cycle.	R/W*2
6	WAIT	WAIT Low-hold is released by reading ICDRR. 0: No wait. SCLn is not held low during the period between 9th clock cycle and 1st clock cycle. 1: Wait. SCLn is held low during the period between 9th clock cycle and 1st clock cycle.	R/W*2
7	SMBS	SMBus/IIC-Bus Select 0: Select I2C bus 1: Select SMBus	R/W

Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If the application writes 1 to both the ACKWP and ACKBT bits at the same time, the ACKBT bit is not set to 1.

Note 2. The WAIT and RDRFS bits are only valid in receive mode (invalid in transmit mode).

NF[1:0] bits (Noise Filter Stage Select)

The NF[1:0] bits select the number of stages in the digital noise filter. For details on this function, see section 34.7. Digital Noise Filter Circuits.

Note: Set the noise range to be filtered out by the noise filter within a range less than the SCLn line high-level period or low-level period. If the noise range is set to a value of [SCL clock width: high-level period or low-level period,

whichever is shorter] - [1.5 internal reference clock (IICΦ) cycles] or more, the SCL clock is regarded as noise by the noise filter function of the IIC, which might prevent the IIC from operating normally.

ACKBR bit (Receive Acknowledge)

The ACKBR bit stores the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1.
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKBT bit (Transmit Acknowledge)

The ACKBT bit sets the acknowledge bit to be sent in receive mode.

[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1.

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1.
- When stop condition issuance is detected with the SP bit in ICCR2 set to 1.
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKWP bit (ACKBT Write Protect)

The ACKWP bit controls write enabling of the ACKBT bit.

RDRFS bit (RDRF Flag Set Timing Select)

The RDRFS bit selects the RDRF flag set timing in receive mode and also selects whether to hold the SCLn line low on the falling edge of the 8th SCL clock cycle.

When the RDRFS bit is 0, the SCLn line is not held low on the falling edge of the 8th SCL clock cycle, and the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 on the rising edge of the 8th SCL clock cycle, and the SCLn line is held low on the falling edge of the 8th SCL clock cycle. The low-hold of the SCLn line is released by a write to the ACKBT bit.

After data is received with this setting, the SCLn line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1), based on the receive data.

WAIT bit (WAIT)

The WAIT bit controls whether to forcefully hold the period between the 9th SCL clock cycle and the 1st SCL clock cycle low until the receive data buffer (ICDRR) is completely read each time a single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation is continued without holding the period between the 9th and the 1st SCL clock cycle low. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCLn line is held low from the falling edge of the 9th clock cycle until the ICDRR value is read each time a single-byte data is received. This enables the receive operation in byte units.

Note: When the value of the WAIT bit is to be read, be sure to first read the ICDRR.

SMBS bit (SMBus/IIC-Bus Select)

Setting the SMBS bit to 1 selects the SMBus and enables the HOAE bit in ICSER.

34.3.6 ICFER : I²C Bus Function Enable Register

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	SCLE	NFE	NACKE	SALE	NALE	MALE	TMOE
Value after reset:	0	1	1	1	0	0	1	0

Bit	Symbol	Function	R/W
0	TMOE	Timeout Function Enable 0: Disable 1: Enable	R/W
1	MALE	Master Arbitration-Lost Detection Enable 0: Disable the arbitration-lost detection function and disable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost 1: Enable the arbitration-lost detection function and enable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost	R/W
2	NALE	NACK Transmission Arbitration-Lost Detection Enable 0: Disable 1: Enable	R/W
3	SALE	Slave Arbitration-Lost Detection Enable 0: Disable 1: Enable	R/W
4	NACKE	NACK Reception Transfer Suspension Enable 0: Do not suspend transfer operation during NACK reception (disable transfer suspension) 1: Suspend transfer operation during NACK reception (enable transfer suspension)	R/W
5	NFE	Digital Noise Filter Circuit Enable 0: Do not use the digital noise filter circuit 1: Use the digital noise filter circuit	R/W
6	SCLE	SCL Synchronous Circuit Enable 0: Do not use the SCL synchronous circuit 1: Use the SCL synchronous circuit	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

TMOE bit (Timeout Function Enable)

The TMOE bit enables or disables the timeout function. For details on this function, see section 34.12.1. Timeout Function.

MALE bit (Master Arbitration-Lost Detection Enable)

The MALE bit specifies whether to use the arbitration-lost detection function in master mode. For normal operation, set this bit to 1.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

The NALE bit specifies whether to cause loss of arbitration when ACK is detected during the transmission of NACK in receive mode, for example, when slaves with the same address exist on the bus, or when two or more masters select the same slave device simultaneously with a different number of receive bytes.

SALE bit (Slave Arbitration-Lost Detection Enable)

The SALE bit specifies whether to cause loss of arbitration when a value different from the value being transmitted is detected on the bus in slave transmit mode, for example, when slaves with the same address exist on the bus, or when a mismatch with the transmit data occurs because of noise.

NACKE bit (NACK Reception Transfer Suspension Enable)

The NACKE bit specifies whether to continue or discontinue the transfer operation when NACK is received from the slave device in transmit mode. For normal operation, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended. When the NACKE bit is 0, the next transfer operation is continued regardless of the received acknowledge content.

For details, see section 34.9.2. NACK Reception Transfer Suspension Function.

SCLE bit (SCL Synchronous Circuit Enable)

The SCLE bit specifies whether to synchronize the SCL clock with the SCL input clock. For normal operation, set this bit to 1.

When the SCLE bit is set to 0 (no SCL synchronous circuit used), the IIC does not synchronize the SCL clock with the SCL input clock. With this setting, the IIC outputs the SCL clock with the transfer rate set in ICBRH and ICBRL, regardless of the SCLn line state. For this reason, if the bus load of the I^2C bus line is much larger than the specification value, or if the SCL clock output overlaps in multiple masters, a short-cycle SCL clock that does not meet the specification might be output. When no SCL synchronous circuit is used, it also affects the issuance of the start, restart, and stop conditions, and the continuous output of extra SCL clock cycles.

Do not set this bit to 0 except when checking the output of the set transfer rate.

34.3.7 ICSER : I^2C Bus Status Enable Register

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	HOAE	—	DIDE	—	GCAE	SAR2E	SAR1E	SAR0E
Value after reset:	0	0	0	0	1	0	0	1

Bit	Symbol	Function	R/W
0	SAR0E	Slave Address Register 0 Enable 0: Disable slave address in SARL0 and SARU0 1: Enable slave address in SARL0 and SARU0	R/W
1	SAR1E	Slave Address Register 1 Enable 0: Disable slave address in SARL1 and SARU1 1: Enable slave address in SARL1 and SARU1	R/W
2	SAR2E	Slave Address Register 2 Enable 0: Disable slave address in SARL2 and SARU2 1: Enable slave address in SARL2 and SARU2	R/W
3	GCAE	General Call Address Enable 0: Disable general call address detection 1: Enable general call address detection	R/W
4	—	This bit is read as 0. The write value should be 0.	R/W
5	DIDE	Device ID Address Detection Enable 0: Disable device ID address detection 1: Enable device ID address detection	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	HOAE	Host Address Enable 0: Disable host address detection 1: Enable host address detection	R/W

SARyE bit (Slave Address Register y Enable) (y = 0 to 2)

The SARyE bit enables or disables the received slave address and the slave address set in SARLy and SARUy.

When this bit is set to 1, the slave address set in SARLy and SARUy is enabled and is compared with the received slave address. When this bit is set to 0, the slave address set in SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

GCAE bit (General Call Address Enable)

The GCAE bit specifies whether to ignore the general call address (0000 000b + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the IIC recognizes the received slave address as the general call address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2), and performs the data receive operation. When this bit is set to 0, the received slave address is ignored even if it matches the

general call address.

DIDE bit (Device ID Address Detection Enable)

The DIDE bit specifies whether to recognize and execute the device ID address when a device ID (1111 100b) is received in the first frame after a start or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the IIC recognizes that the device ID address was received. When the next R/W# bit is 0 (W), the IIC recognizes the second and the subsequent frames as slave addresses and continues the receive operation. When this bit is set to 0, the IIC ignores the received first frame even if it matches the device ID address, and recognizes the first frame as a normal slave address.

For details on the device ID function, see section 34.8.3. Device ID Address Detection.

HOAE bit (Host Address Enable)

The HOAE bit specifies whether to ignore the received host address (0001 000b) when the SMBS bit in ICMR3 is 1.

When this bit is set to 1 while the SMBS bit in ICMR3 is 1, if the received slave address matches the host address, the IIC recognizes the received slave address as the host address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2), and performs the receive operation.

When the SMBS bit in ICMR3 or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

34.3.8 ICIER : I2C Bus Interrupt Enable Register

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x07

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TIE	TEIE	RIE	NAKIE	SPIE	STIE	ALIE	TMOIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMOIE	Timeout Interrupt Request Enable 0: Disable timeout interrupt IICn_EEI (TMOF) request 1: Enable timeout interrupt IICn_EEI (TMOF) request	R/W
1	ALIE	Arbitration-Lost Interrupt Request Enable 0: Disable arbitration-lost interrupt IICn_EEI (AL) request 1: Enable arbitration-lost interrupt IICn_EEI (AL) request	R/W
2	STIE	Start Condition Detection Interrupt Request Enable 0: Disable start condition detection interrupt IICn_EEI (START) request 1: Enable start condition detection interrupt IICn_EEI (START) request	R/W
3	SPIE	Stop Condition Detection Interrupt Request Enable 0: Disable stop condition detection interrupt IICn_EEI (STOP) request 1: Enable stop condition detection interrupt IICn_EEI (STOP) request	R/W

Bit	Symbol	Function	R/W
4	NAKIE	NACK Reception Interrupt Request Enable 0: Disable NACK reception interrupt IICn_EEI (NACKF) request 1: Enable NACK reception interrupt IICn_EEI (NACKF) request	R/W
5	RIE	Receive Data Full Interrupt Request Enable 0: Disable receive data full interrupt (IICn_RXI) request 1: Enable receive data full interrupt (IICn_RXI) request	R/W
6	TEIE	Transmit End Interrupt Request Enable 0: Disable transmit end interrupt (IICn_TEI) request 1: Enable transmit end interrupt (IICn_TEI) request	R/W
7	TIE	Transmit Data Empty Interrupt Request Enable 0: Disable transmit data empty interrupt (IICn_TXI) request 1: Enable transmit data empty interrupt (IICn_TXI) request	R/W

TMOIE bit (Timeout Interrupt Request Enable)

The TMOIE bit enables or disables timeout interrupt IICn_EEI (TMOF) requests when the TMOF flag in ICSR2 is 1. To cancel a IICn_EEI (TMOF) interrupt request, set the TMOF flag or the TMOIE bit to 0.

ALIE bit (Arbitration-Lost Interrupt Request Enable)

The ALIE bit enables or disables arbitration-lost interrupt IICn_EEI (AL) requests when the AL flag in ICSR2 is 1. To cancel an IICn_EEI (AL) interrupt request, set the AL flag or the ALIE bit to 0.

STIE bit (Start Condition Detection Interrupt Request Enable)

The STIE bit enables or disables start condition detection interrupt IICn_EEI (START) requests when the START flag in ICSR2 is 1. To cancel an IICn_EEI (START) interrupt request, set the START flag or the STIE bit to 0.

SPIE bit (Stop Condition Detection Interrupt Request Enable)

The SPIE bit enables or disables stop condition detection interrupt IICn_EEI (STOP) requests when the STOP flag in ICSR2 is 1. To cancel an IICn_EEI (STOP) interrupt request, set the STOP flag or the SPIE bit to 0.

NAKIE bit (NACK Reception Interrupt Request Enable)

The NAKIE bit enables or disables NACK reception interrupt IICn_EEI (NACKF) requests when the NACKF flag in ICSR2 is 1. To cancel an IICn_EEI (NACKF) interrupt request, set the NACKF flag or the NAKIE bit to 0.

RIE bit (Receive Data Full Interrupt Request Enable)

The RIE bit enables or disables receive data full interrupt (IICn_RXI) requests when the RDRF flag in ICSR2 is 1.

TEIE bit (Transmit End Interrupt Request Enable)

The TEIE bit enables or disables transmit end interrupt (IICn_TEI) requests when the TEND flag in ICSR2 is 1. To cancel an IICn_TEI interrupt request, set the TEND flag or the TEIE bit to 0.

TIE bit (Transmit Data Empty Interrupt Request Enable)

The TIE bit enables or disables transmit data empty interrupt (IICn_TXI) requests when the TDRE flag in ICSR2 is 1.

34.3.9 ICSR1 : I2C Bus Status Register 1

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	HOA	—	DID	—	GCA	AAS2	AAS1	AAS0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AAS0	Slave Address 0 Detection Flag 0: Slave address 0 not detected 1: Slave address 0 detected	R/W*1
1	AAS1	Slave Address 1 Detection Flag 0: Slave address 1 not detected 1: Slave address 1 detected	R/W*1
2	AAS2	Slave Address 2 Detection Flag 0: Slave address 2 not detected 1: Slave address 2 detected	R/W*1
3	GCA	General Call Address Detection Flag 0: General call address not detected 1: General call address detected	R/W*1
4	—	This bit is read as 0. The write value should be 0.	R/W
5	DID	Device ID Address Detection Flag This bit is set to 1 when the first frame received immediately after a start condition is detected, matches a value of (device ID (1111 100b) + 0 [W]). 0: Device ID command not detected 1: Device ID command detected	R/W*1
6	—	This bit is read as 0. The write value should be 0.	R/W
7	HOA	Host Address Detection Flag This bit is set to 1 when the received slave address matches the host address (0001 000b). 0: Host address not detected 1: Host address detected	R/W*1

Note 1. Only 0 can be written to clear the flag.

AASy bit (Slave Address y Detection Flag) (y = 0 to 2)

The AASy flag indicates whether slave address y was detected.

[Setting conditions]

For 7-bit address format (SARUy.FS = 0):

- When the received slave address matches the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1 on the rising edge of the 9th SCL clock cycle in the frame.

For 10-bit address format: (SARUy.FS = 1):

- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address matches the SARLy value, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1 on the rising edge of the 9th SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the AASy flag after reading AASy = 1
- When a stop condition is detected.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

For 7-bit address format (SARUy.FS = 0):

- When the received slave address does not match the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the 9th SCL clock cycle in the frame.

For 10-bit address format (SARUy.FS = 1):

- When the received slave address does not match a value of 11110b + SVA[1:0] in SARUy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the 9th SCL clock cycle in the frame.

- When the received slave address matches a value of 11110b + SVA[1:0] in SARUy, and the subsequent address does not match the SARLy value, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the 9th SCL clock cycle in the frame.

GCA bit (General Call Address Detection Flag)

The GCA flag indicates whether the general call address was detected.

[Setting condition]

- When the received slave address matches the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSER set to 1 (general call address detection enabled).
  The GCA flag is set to 1 on the rising edge of the 9th SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the GCA flag after reading GCA = 1.
- When a stop condition is detected.
- When the received slave address does not match the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSER set to 1 (general call address detection enabled).
  The GCA flag is set to 0 on the rising edge of the 9th SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

DID bit (Device ID Address Detection Flag)

The DID flag indicates whether the device ID address was detected.

[Setting condition]

- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), with the DIDE bit in ICSER set to 1 (device ID address detection enabled).
  The DID flag is set to 1 on the rising edge of the 9th SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the DID flag after reading DID = 1.
- When a stop condition is detected.
- When the first frame received immediately after a start or restart condition is detected does not match a value of the device ID (1111 100b), with the DIDE bit in ICSER set to 1 (device ID address detection enabled).
  The DID flag is set to 0 on the rising edge of the 9th SCL clock cycle in the frame.
- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), and the second frame does not match any slave address from 0 to 2, with the DIDE bit in ICSER set to 1 (device ID address detection enabled).
  The DID flag is set to 0 on the rising edge of the 9th SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to initiate an IIC reset or an internal reset.

HOA bit (Host Address Detection Flag)

The HOA flag indicates whether the host address was detected.

[Setting condition]

- When the received slave address matches the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled).
  The HOA flag is set to 1 on the rising edge of the 9th SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the HOA flag after reading HOA = 1.
- When a stop condition is detected.
- When the received slave address does not match the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled).
  The HOA flag is set to 0 on the rising edge of the 9th SCL clock cycle in the frame.

- When 1 is written to the IICRST bit in ICCR1 to initiate an IIC reset or an internal reset.

34.3.10 ICSR2 : I2C Bus Status Register 2

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x09

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TDRE	TEND	RDRF	NACKF	STOP	START	AL	TMOF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMOF	Timeout Detection Flag 0: Timeout not detected 1: Timeout detected.	R/W*1
1	AL	Arbitration-Lost Flag 0: Arbitration not lost 1: Arbitration lost	R/W*1
2	START	Start Condition Detection Flag 0: Start condition not detected 1: Start condition detected	R/W*1
3	STOP	Stop Condition Detection Flag 0: Stop condition not detected 1: Stop condition detected	R/W*1
4	NACKF	NACK Detection Flag 0: NACK not detected 1: NACK detected	R/W*1
5	RDRF	Receive Data Full Flag 0: ICDRR contains no receive data 1: ICDRR contains receive data	R/W*1
6	TEND	Transmit End Flag 0: Data being transmitted 1: Data transmit complete	R/W*1
7	TDRE	Transmit Data Empty Flag 0: ICDRT contains transmit data 1: ICDRT contains no transmit data	R

Note 1. Only 0 can be written, to clear the flag.

TMOF bit (Timeout Detection Flag)

The TMOF flag is set to 1 when IIC detects a timeout because the SCLn line state remains unchanged for the set period.

[Setting condition]

- When the SCLn line state remains unchanged for the period specified in the ICMR2.TMOH, TMOL, and TMOS bits while the ICFER.TMOE bit is 1 (timeout function enabled) in master or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF flag after reading TMOF = 1.
- When 1 is written to the IICRST bit in ICCR1 to initiate an IIC reset or an internal reset.

AL bit (Arbitration-Lost Flag)

The AL flag indicates that the bus mastership is lost in arbitration because of a bus conflict or because of some other reason, when a start condition was issued, or an address and data was transmitted.

The IIC monitors the level on the SDAn line during transmission. If the level on the line does not match the value of the bit being output, the IIC sets the AL flag to 1 to indicate that the bus is occupied by another device. The IIC can also set the flag to indicate the detection of arbitration loss during NACK transmission in master mode or during data transmission in slave mode.

[Setting conditions]

When master arbitration-lost detection is enabled (ICFER.MALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock except for the ACK period during data transmission in master transmit mode.
- When a start condition is detected while the ST bit in ICCR2 is 1 (start condition requested) or the internal SDA output state does not match the SDAn line level.
- When the ST bit in ICCR2 is 1 (start condition requested), with the BBSY flag in ICCR2 set to 1.

When NACK arbitration-lost detection is enabled (ICFER.NALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICFER.SALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock, except for the ACK period during data transmission in slave transmit mode.

[Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Table 34.7 Relationship between arbitration-lost generation sources and arbitration-lost enable functions

ICFER			ICSR2		
MALE	NALE	SALE	AL	Error	Arbitration-lost generation source
1	×	×	1	Start condition issuance error	When internal SDA output state does not match SDAn line level when a start condition is detected, while the ST bit in ICCR2 is 1.
					When ST in ICCR2 is set to 1 while BBSY in ICCR2 is 1.
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmit mode.
×	1	×	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master or slave receive mode.
×	×	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmit mode.

Note: ×: Don't care

START bit (Start Condition Detection Flag)

The START flag indicates whether a start or restart condition is detected.

[Setting condition]

- When a start or restart condition is detected.

[Clearing conditions]

- When 0 is written to the START flag after reading START = 1.
- When a stop condition is detected.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

STOP bit (Stop Condition Detection Flag)

The STOP flag indicates whether a stop condition is detected.

[Setting condition]

- When a stop condition is detected.

[Clearing conditions]

- When 0 is written to the STOP flag after reading STOP = 1.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

NACKF bit (NACK Detection Flag)

The NACKF flag indicates whether a NACK was detected.

[Setting condition]

- When acknowledge is not received (NACK received) from the receive device in transmit mode, with the NACKE bit in ICFER set to 1 (transfer suspension enabled).

[Clearing conditions]

- When 0 is written to the NACKF flag after reading NACKF = 1.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1, the IIC suspends data transmission and reception. Writing to ICDRT in transmit mode or reading from ICDRR in receive mode with the NACKF flag set to 1 does not enable data transmit or receive operation. To restart data transmission or reception, set the NACKF flag to 0.

RDRF bit (Receive Data Full Flag)

The RDRF flag indicates whether the IDCRR contains receive data.

[Setting conditions]

- When receive data is transferred from ICDRS to ICDRR.
  The RDRF flag is set to 1 on the rising edge of the 8th or 9th SCL clock cycle (selected in the RDRFS bit in ICMR3).
- When the received slave address matches after a start (or restart) condition is detected with the TRS bit in ICCR2 set to 0.

[Clearing conditions]

- When 0 is written to the RDRF flag after reading RDRF = 1.
- When data is read from ICDRR.
- When 1 is written to the IICRST bit in ICCR1 to initiate an IIC reset or an internal reset.

TEND bit (Transmit End Flag)

The TEND flag indicates whether data transmission is still being transmitted or is complete.

[Setting condition]

- On the rising edge of the 9th SCL clock cycle while the TDRE flag is 1.

[Clearing conditions]

- When 0 is written to the TEND flag after reading TEND = 1.
- When data is written to ICDRT.
- When a stop condition is detected.
- When 1 is written to the IICRST bit in ICCR1 to initiate an IIC reset or an internal reset.

TDRE bit (Transmit Data Empty Flag)

The TDRE flag indicates whether the ICDRT contains transmit data.

[Setting conditions]

- When data is transferred from ICDRT to ICDRS and ICDRT becomes empty.
- When the TRS bit in ICCR2 is set to 1.

- When the received slave address matches while the TRS bit is 1.

[Clearing conditions]

- When data is written to ICDRT.
- When the TRS bit in ICCR2 is set to 0.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1 while the NACKE bit in ICFER is 1, the IIC suspends data transmission and reception. In this case, if the TDRE flag is 0 (next transmit data written), data is transferred to the ICDRS register and the ICDRT register becomes empty on the rising edge of the 9th clock cycle, but the TDRE flag is not set to 1.

34.3.11 SARLy : Slave Address Register L y (y = 0 to 2)

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x0A + 0x02 × y

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SVA[6:0]							SVA0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SVA0	10-bit Address LSB Slave address setting	R/W
7:1	SVA[6:0]	7-bit Address/10-bit Address Lower Bits Slave address setting	R/W

SVA0 bit (10-bit Address LSB)

When the 10-bit address format is selected (SARUy.FS = 1), the SVA0 bit functions as the LSB of a 10-bit address and is combined with the SVA[6:0] bits to form the lower 8 bits of a 10-bit address.

This bit is valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in this bit is ignored.

SVA[6:0] bits (7-bit Address/10-bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS = 0), the SVA[6:0] bits function as a 7-bit address. When the 10-bit address format is selected (SARUy.FS = 1), these bits combined with the SVA0 bit to form the lower 8 bits of a 10-bit address. When the SARyE bit in ICSER is 0, the setting in these bits is ignored.

34.3.12 SARUy : Slave Address Register U y (y = 0 to 2)

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x0B + 0x02 × y

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SVA[1:0]		FS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FS	7-bit/10-bit Address Format Select 0: Select 7-bit address format 1: Select 10-bit address format	R/W

Bit	Symbol	Function	R/W
2:1	SVA[1:0]	10-bit Address Upper Bits Slave address setting	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

FS bit (7-bit/10-bit Address Format Select)

The FS bit selects a 7-bit or 10-bit address format for slave address y (in SARLy and SARUy).

When the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 0, the 7-bit address format is selected for slave address y, the SVA[6:0] setting in SARLy is valid, and the SVA[1:0] and SVA0 settings in SARLy are ignored.

When the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the SVA[1:0] and SARLy settings are valid.

When the SARyE bit in ICSER is 0 (SARLy and SARUy disabled), the SARUy.FS setting is invalid.

SVA[1:0] bits (10-bit Address Upper Bits)

When the 10-bit address format is selected (FS = 1), the SVA[1:0] bits function as the upper 2 bits of a 10-bit address.

These bits are valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in these bits is ignored.

34.3.13 ICBRL : I2C Bus Bit Rate Low-Level Register

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	BRL[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	BRL[4:0]	Bit Rate Low-Level Period Low-level period setting of SCL clock	R/W
7:5	—	These bits are read as 1. The write value should be 1.	R/W

ICBRL is a 5-bit register that sets the low-level period of the SCL clock. ICBRL also works to generate the data setup time for the automatic SCL low-hold operation (see section 34.9. Automatic Low-Hold Function for SCL). When the IIC is used only in slave mode, this register must be set to a value longer than the data setup time.*1

ICBRL counts the low-level period with the internal reference clock source (IICΦ) specified in the CKS[2:0] bits in ICMR1.

If the digital noise filter is enabled (the NFE bit in ICFER is 1), set the ICBRL register to a value at least one greater than the number of stages in the noise filter. For this number, see the description of the ICMR3.NF[1:0] bits.

Note 1. Data setup time (tSU: DAT)
250 ns for up to 100 kbps: Standard-mode (Sm)
100 ns for up to 400 kbps: Fast-mode (Fm)

34.3.14 ICBRH : I²C Bus Bit Rate High-Level Register

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x11

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	BRH[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	BRH[4:0]	Bit Rate High-Level Period High-level period setting of SCL clock	R/W
7:5	—	These bits are read as 1. The write value should be 1.	R/W

ICBRH is a 5-bit register that sets the high-level period of the SCL clock. ICBRH is valid in master mode. If the IIC is used only in slave mode, no setting is required in this register.

ICBRH counts the high-level period with the internal reference clock source (IICΦ) specified in the CKS[2:0] bits in ICMR1.

If the digital noise filter is enabled (the NFE bit in ICFER is 1), set the ICBRH register to a value at least one greater than the number of stages in the noise filter. For this number, see the description of the ICMR3.NF[1:0] bits.

The IIC transfer rate and the SCL clock duty are calculated using the following expressions (1) to (5):

(1) ICFER.SCLE = 0
Transfer rate = 1/{[(BRH + 1) + (BRL + 1)]/IICΦ*1 + tr*2 + tf*2}
Duty cycle = {tr + [(BRH + 1)/IICΦ]}/{tr + tf + [(BRH + 1) + (BRL + 1)]/IICΦ}

(2) ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] = 000b (IICΦ = PCLKL)
Transfer rate = 1/{[(BRH + 3) + (BRL+ 3)]/IICΦ + tr + tf}
Duty cycle = {tr + [(BRH + 3)/IICΦ]}/{tr + tf + [(BRH + 3) + (BRL + 3)]/IICΦ}

(3) ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] = 000b (IICΦ = PCLKL)
Transfer rate = 1/{[(BRH + 3 + nf*3) + (BRL + 3 + nf)]/IICΦ + tr + tf}
Duty cycle = {tr + [(BRH + 3 + nf)/IICΦ]}/{tr + tf + [(BRH + 3 + nf) + (BRL + 3 + nf)]/IICΦ}

(4) ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] ≠ 000b
Transfer rate = 1/{[(BRH + 2) + (BRL + 2)]/IICΦ + tr + tf}
Duty cycle = {tr + [(BRH + 2)/IICΦ]}/{tr + tf + [(BRH + 2) + (BRL + 2)]/IICΦ}

(5) ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] ≠ 000b
Transfer rate = 1/{[(BRH + 2 + nf) + (BRL + 2 + nf)]/IICΦ + tr + tf}
Duty cycle = {tr + [(BRH + 2 + nf)/IICΦ]}/{tr + tf + [(BRH + 2 + nf) + (BRL + 2 + nf)]/IICΦ}

Note 1. IICΦ = PCLKL × Division ratio.
Note 2. The SCLn line rise time (tr) and SCLn line fall time (tf) depend on the total bus line capacitance (Cb) and the pull-up resistor (Rp). For details, see the I²C bus standard from NXP Semiconductors.
Note 3. nf = Number of digital noise filter stages selected in the ICMR3.NF bit.

Table 34.8 Example of ICBRH/ICBRL settings for transfer rate when SCLE = 0

Transfer rate (kbps)	CKS[2:0]	BRH[4:0]	BRL[4:0]	PCLKL (MHz)	NF[1:0]	Computation expression
100	100b	16 (0x10)	16 (0x10)	62.5	—	(1)
400	001b	29 (0x1D)	29 (0x1D)	62.5	—	(1)

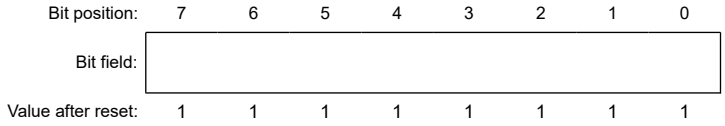
34.3.15 ICDRT : I2C Bus Transmit Data Register

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x12



Bit	Symbol	Function	R/W
7:0	n/a	Transmit Data	R/W

When ICDRT detects a space in the I2C Bus Shift Register (ICDRS), it transfers the transmit data that is written to ICDRT to ICDRS and starts transmitting data in transmit mode.

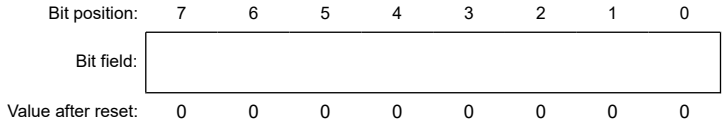
The double-buffer structure of ICDRT and ICDRS allows continuous transmit operation if the next transmit data is written to ICDRT while the ICDRS data is being transmitted.

ICDRT can always be read from and written to. Write transmit data to ICDRT when a transmit data empty interrupt (IICn_TXI) request is generated.

34.3.16 ICDRR : I2C Bus Receive Data Register

Base address: IICn = 0x8008_8000 + 0x0400 × n (n = 0, 1)
IIC2 = 0x8100_8000

Offset address: 0x13



Bit	Symbol	Function	R/W
7:0	n/a	Receive Data	R

When 1 byte of data is received, the received data is transferred from the I2C Bus Shift Register (ICDRS) to ICDRR to enable the next data to be received.

The double-buffer structure of ICDRS and ICDRR allows continuous receive operation if the received data is read from ICDRR while ICDRS is receiving data. ICDRR cannot be written to. Read data from ICDRR when a receive data full interrupt (IICn_RXI) request is generated.

If ICDRR receives the next receive data before the current data is read from ICDRR while the RDRF flag in ICSR2 is 1, the IIC automatically holds the SCL clock low for 1 cycle before the RDRF flag is set to 1 again.

34.3.17 ICDRS : I²C Bus Shift Register

Base address: n/a

Offset address: n/a

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	—	—	—	—	—	—	—	—

ICDRS is an 8-bit shift register to transmit and receive data.

During transmission, transmit data is transferred from ICDRT to ICDRS and is sent from the SDAn pin. During reception, data is transferred from ICDRS to ICDRR after 1 byte of data is received. ICDRS cannot be accessed directly.

34.4 Operation

34.4.1 Communication Data Format

The I²C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start or restart condition is an address frame that specifies a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 34.3 shows the I²C bus format, and Figure 34.4 shows the I²C bus timing.

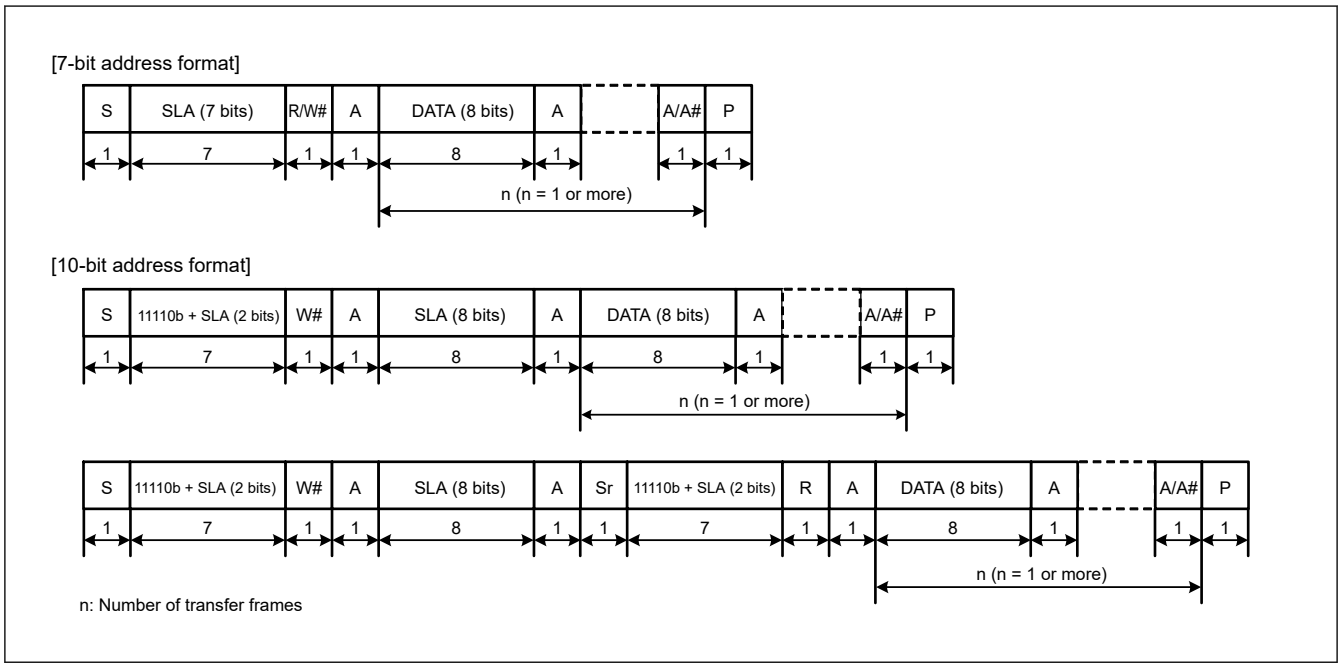


Figure 34.3 I²C bus format

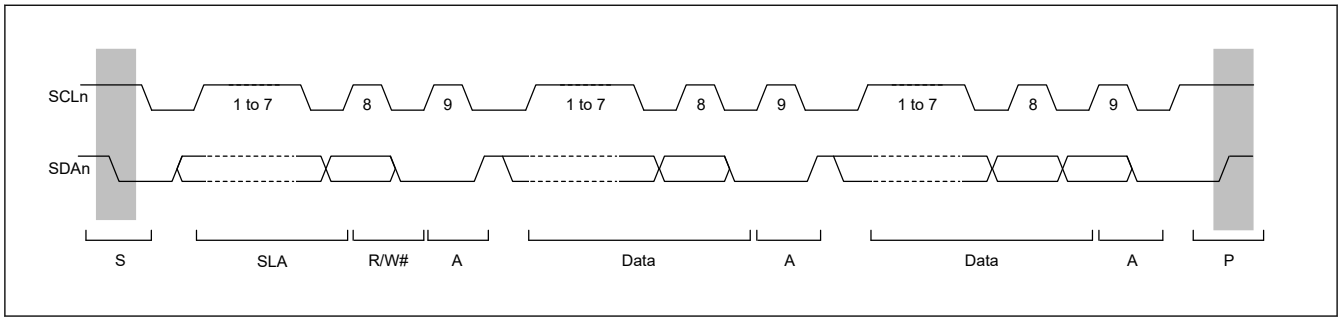

Figure 34.4 I²C bus timing when the SLA setting = 7 bits

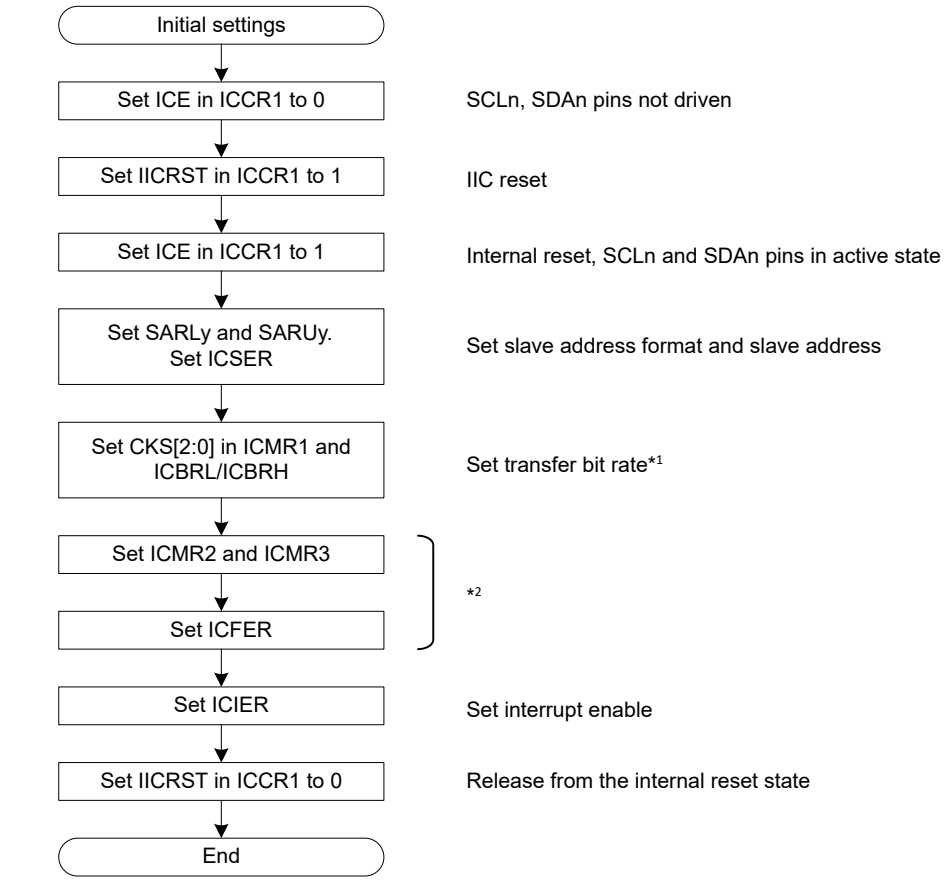
S:	Start condition. The master device drives the SDAn line low from high while the SCLn line is high.
SLA:	Slave address, by which the master device selects a slave device.
R/W#:	Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.
A:	Acknowledge. The receive device drives the SDAn line low. In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.
A#:	Not Acknowledge. The receive device drives the SDAn line high.
Sr:	Restart condition. The master device drives the SDAn line low from the high level after the setup time has elapsed with the SCLn line high.
DATA:	Transmitted or received data
P:	Stop condition. The master device drives the SDAn line high from low while the SCLn line is high.

34.4.2 Initial Settings

Before starting data transmission and reception, initialize the IIC using the procedure shown in Figure 34.5.

1. Set the ICCR1.ICE bit set to 0 to set the SCLn and SDAn pins to the inactive state.
2. Set the ICCR1.IICRST bit to 1 to initiate IIC reset.
3. Set the ICCR1.ICE bit to 1 to initiate internal reset, which initializes the flags and the internal state of the ICSR1 register.
4. Set the SARLy, SARUy, ICSER, ICMR1, ICBRH, and ICBRL registers (y = 0 to 2), and set the other registers as required. For the initial IIC settings, see Figure 34.5.
5. When the required register settings are complete, set the ICCR1.IICRST bit to 0, to release the IIC reset.

Note: This procedure is not necessary if the IIC initialization is already complete.



y = 0 to 2

Note 1. When the IIC is used only in slave mode, set the ICBRL register to a value longer than the data setup time.
Note 2. Set these registers as required.

Figure 34.5 Example IIC initialization flow

34.4.3 Master Transmit Operation

In master transmit operation, the IIC outputs the SCL clock and transmit data signals as the master device, and the slave device returns the acknowledgments. Figure 34.6 shows an example of master transmission, and Figure 34.7 to Figure 34.9 show the operation timing in master transmission.

To set up and perform master transmission:

1. To initialize the IIC, follow the procedure in section 34.4.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and START flags in ICSR2 automatically set to 1 and the ST bit is automatically set to 0. If the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that the start condition requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically sets to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag is automatically set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again sets to 1. After the byte containing the slave address and R/W# bit is transmitted, the value of the TRS bit automatically updates to select master transmit or master receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit is 0, the IIC continues in master transmit mode.

If the ICSR2.NACKF flag is 1, indicating that no slave device recognized the address or that there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
To transmit data with an address in the 10-bit format, start by writing 11110b, the 2 upper bits of the slave address, and W to ICDRT as the first address transmission. For the second address transmission, write the 8 lower bits of the slave address to ICDRT.

4. After confirming that the TDRE flag in ICSR2 is 1, write the transmit data to the ICDRT register. The IIC automatically holds the SCLn line low until the transmit data is ready or a stop condition is issued.
5. After all bytes of transmit data are written to the ICDRT register, wait until the value in the TEND flag in ICSR2 returns to 1, and then set the SP bit in ICCR2 to 1 (stop condition requested). On receiving a stop condition request, the IIC issues the stop condition.
6. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. In addition, the IIC automatically sets the TDRE and TEND flags to 0, and sets the STOP flag in ICSR2 to 1.
7. After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

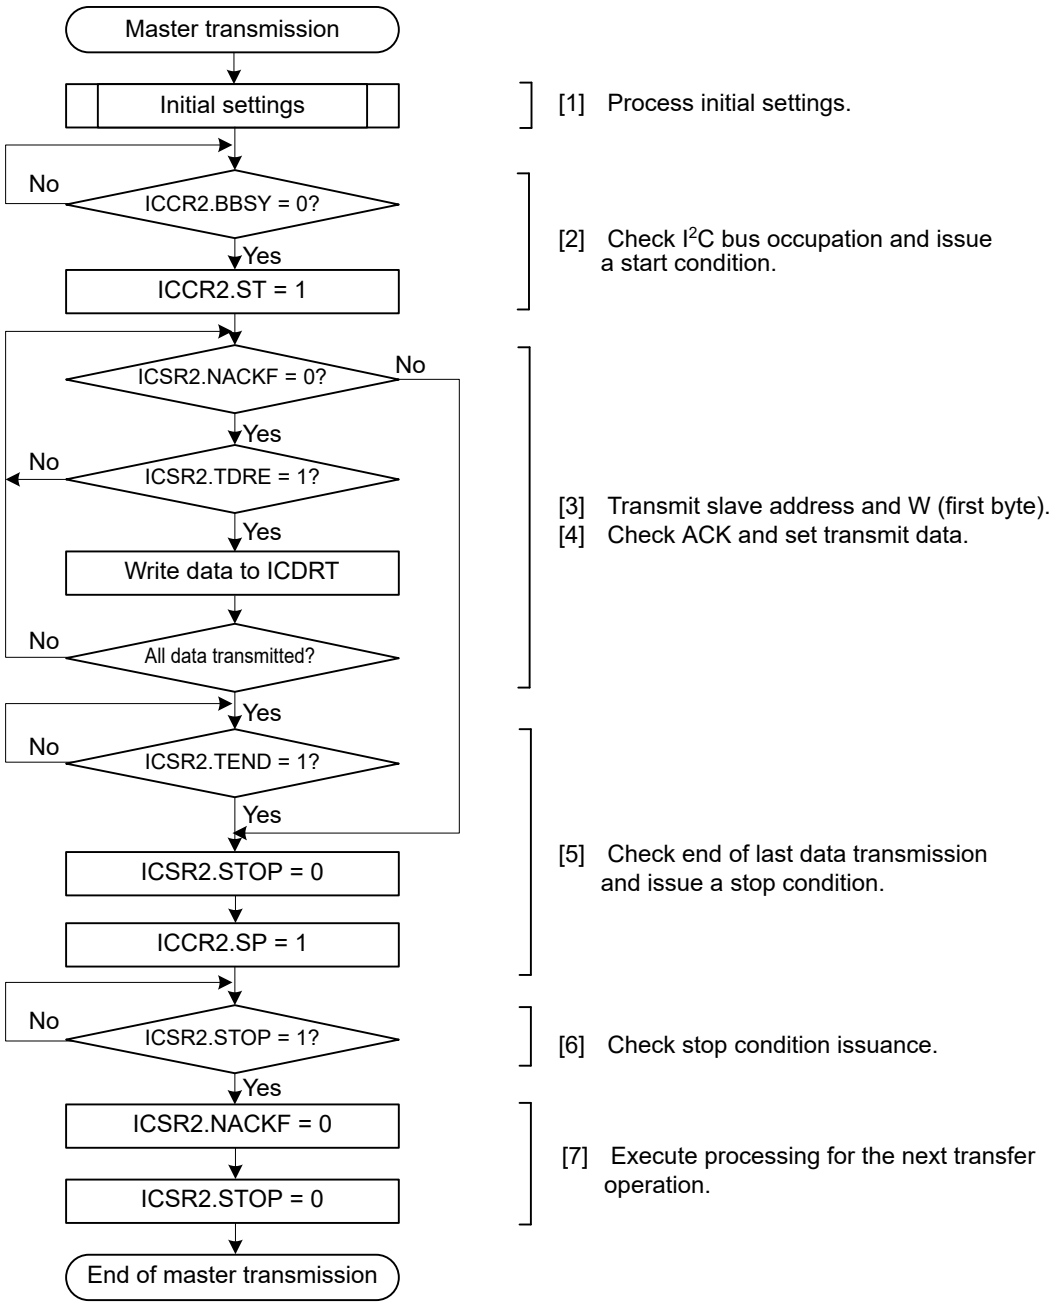


Figure 34.6 Example master transmission flow

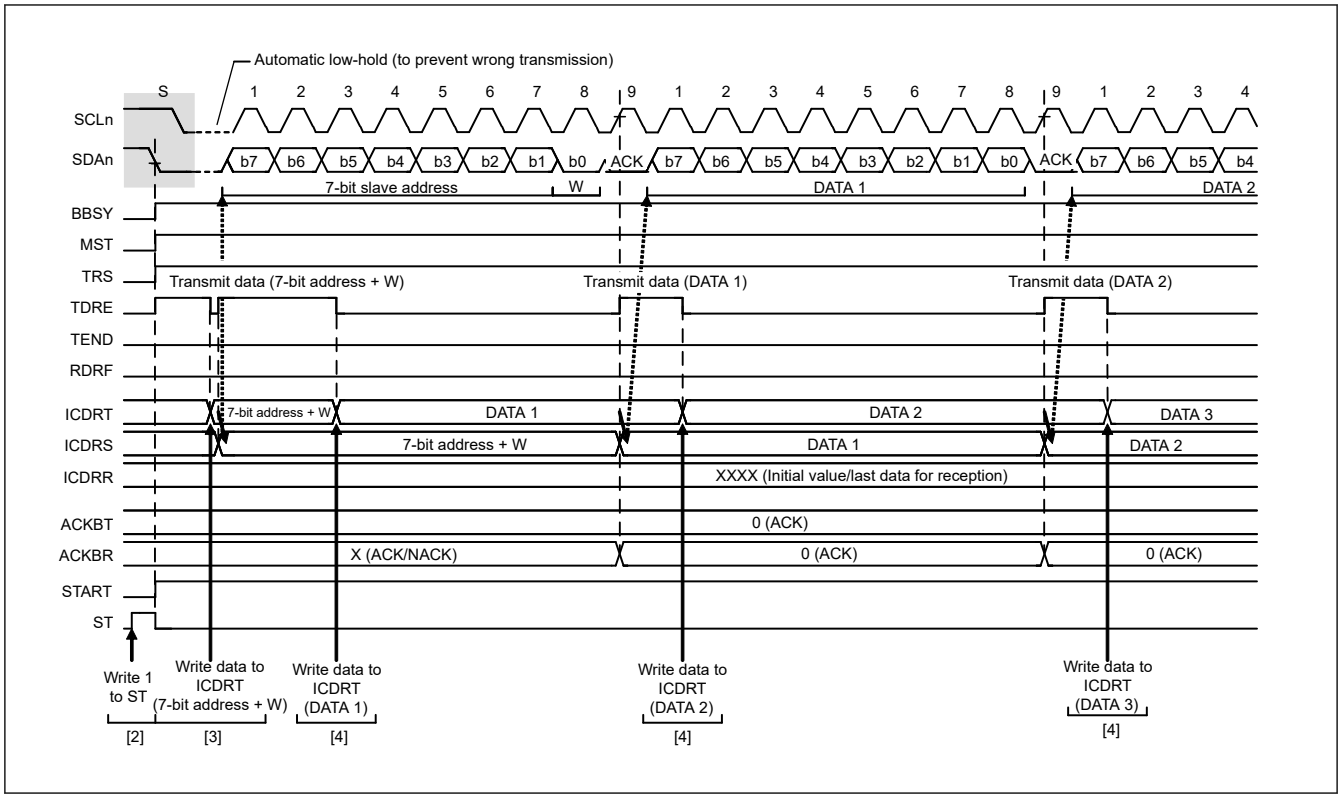

Figure 34.7 Master transmit operation timing (1) with 7-bit address format

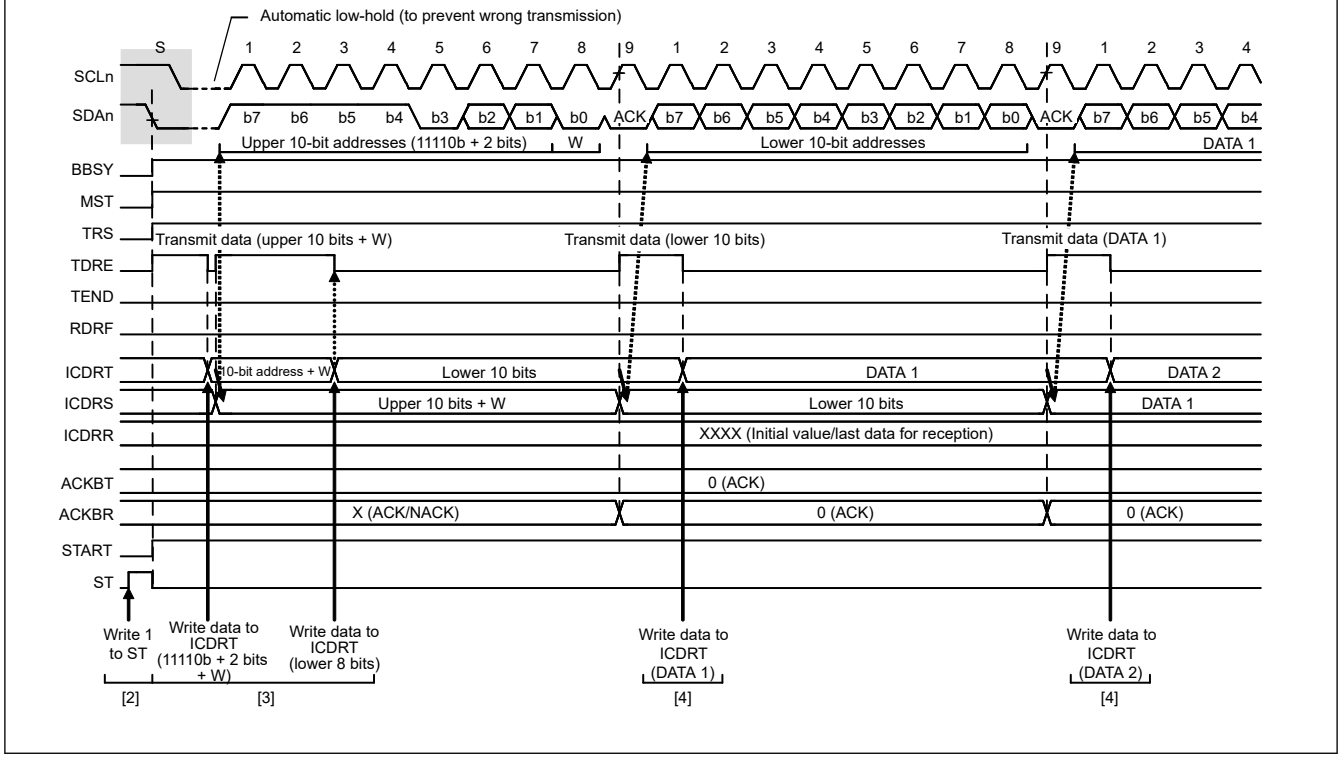

Figure 34.8 Master transmit operation timing (2) with 10-bit address format

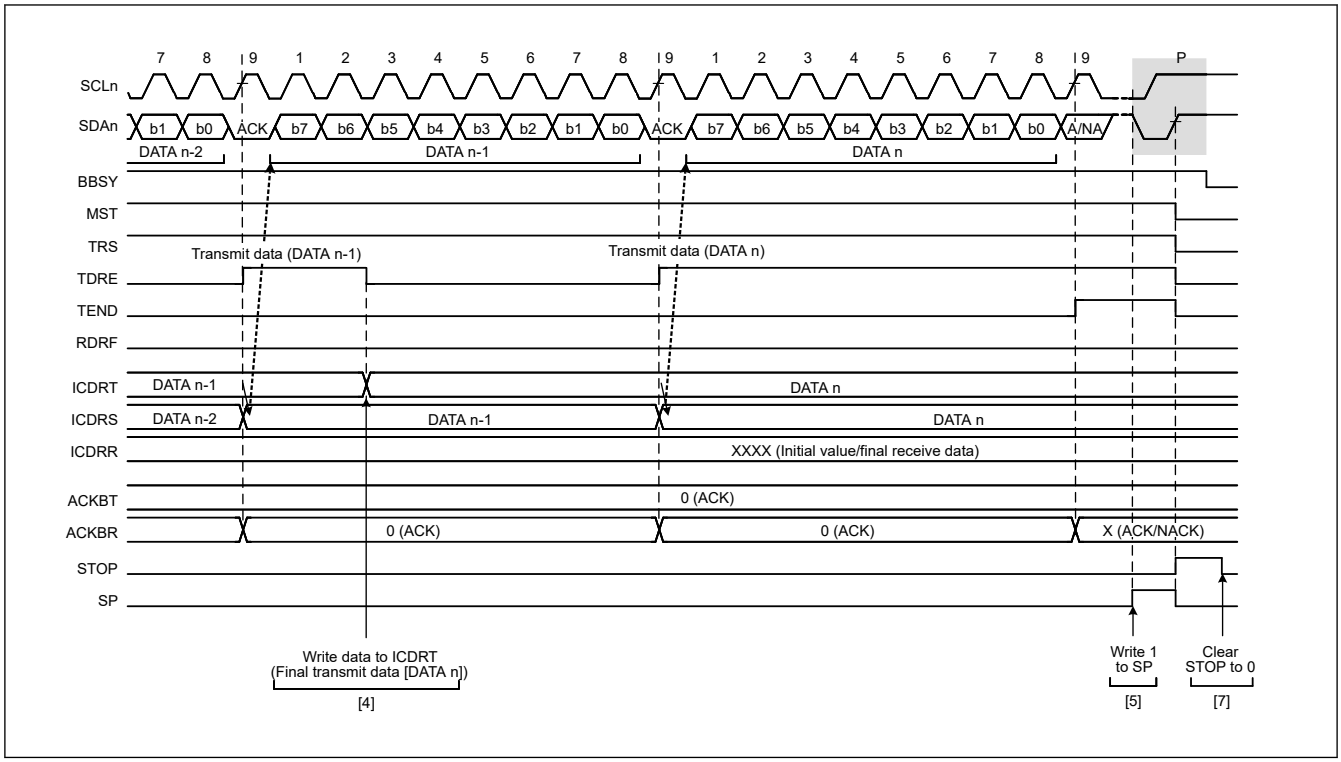

Figure 34.9 Master transmit operation timing (3)

34.4.4 Master Receive Operation

In master receive operation, the IIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because the IIC must start by sending a slave address to the associated slave device, the slave address part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 34.10 and Figure 34.11 show examples of master reception (7-bit address format), and Figure 34.12 to Figure 34.14 show the operation timing in master reception.

To set up and perform master reception:

1. To initialize the IIC, follow the procedure in section 34.4.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 to request the issue of a start condition. On receiving the request, the IIC issues a start condition. When the IIC detects the start condition, the BBSY and START flags in ICSR2 automatically set to 1, and the ST bit automatically sets to 0. If the start condition is detected and the levels for the SDA output and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also is automatically set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag is automatically set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. When the byte containing the slave address and R/W# bit is transmitted, the value of the ICCR2.TRS bit automatically updates to select transmit or receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit is 1, the TRS bit is set to 0 on the rising edge of the 9th cycle of the SCL clock, placing the IIC in master receive mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag is automatically set to 1.
   If the ICSR2.NACKF flag is 1, indicating that no slave device recognized the address or that there is an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmit 11110b, the two upper bits of the slave address, and the R bit to place the IIC in master receive mode.
4. Dummy read ICDRR after confirming that the RDRF flag in ICSR2 is 1. Doing so causes the IIC to start output of the SCL clock and start data reception.

5. After 1 byte of data is received, the RDRF flag in ICSR2 is set to 1 on the rising edge of the 8th or 9th cycle of the SCL clock, as selected in the RDRFS bit in ICMR3. Reading ICDRR produces the received data, and automatically sets the RDRF flag to 0. The value of the acknowledgment field received during the 9th cycle of the SCL clock is returned as the value set in the ICMR3.ACKBT bit. If the next byte to be received is the second-to-last byte, set the ICMR3.WAIT bit to 1 for wait insertion before reading ICDRR, containing the second-to-last byte. In addition to enabling NACK output, even when interrupts or other operations result in delays in setting the ICMR3.ACKBT bit to 1 (NACK) in step (6), this fixes the SCLn line to the low level on the rising edge of the 9th clock cycle in reception of the last byte, which enables the issuing of a stop condition.
6. When the ICMR3.RDRFS bit is 0, and the slave device must be notified that it is to end transfer for data reception after transfer of the next and final byte, set the ICMR3.ACKBT bit to 1 (NACK).
7. After reading the second-to-last byte from the ICDRR register, if the value of the ICSR2.RDRF flag is 1, write 1 to the SP bit in ICCR2 (stop condition requested), and then read the last byte from ICDRR. When ICDRR is read, the IIC is released from the wait state and issues the stop condition after low-level output in the 9th clock cycle is complete or the SCLn line is released from the low-hold state.
8. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, detection of the stop condition sets the ICSR2.STOP flag to 1.
9. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and ICSR2.STOP flags to 0 for the next transfer operation.

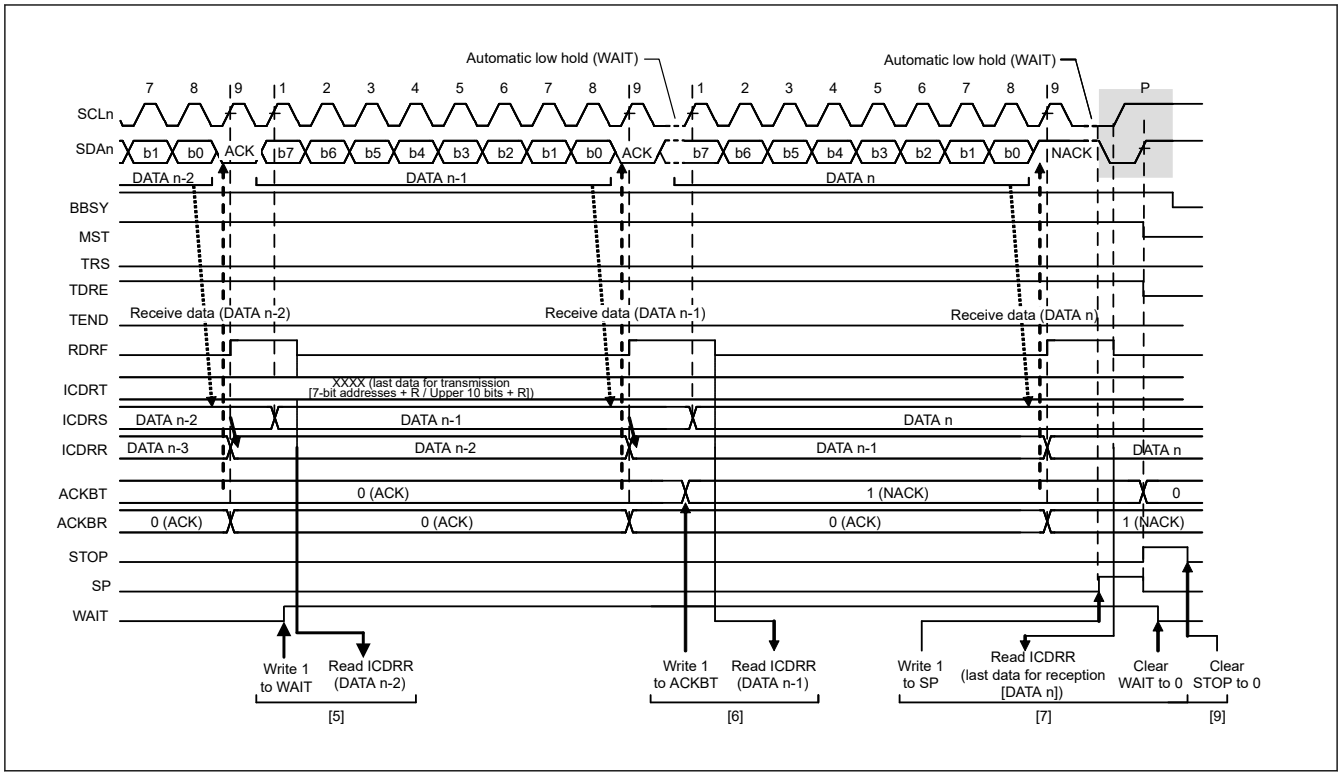

Figure 34.14 Master receive operation timing (3) when RDRFS = 0

34.4.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL clock, the IIC transmits data as a slave device, and the master device returns the acknowledgments.

Figure 34.15 shows an example of slave transmission, and Figure 34.16 and Figure 34.17 show the operation timing in slave transmission.

To set up and perform slave transmission:

1. To initialize the IIC, follow the procedure in section 34.4.2. Initial Settings.
   After the initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated bits ICSR1.HOA, GCA, and AASy (y = 0 to 2) flags to 1 on the rising edge of the 9th cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the 9th cycle of the SCL clock. If the value of the received R/W# bit is 1, the IIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.
3. Check that the ICSR2.TEND flag is 1, and write the transmit data to the ICDRT register. If the IIC receives no acknowledge from the master device (receives an NACK signal) while the ICFER.NACKE bit is 1, the IIC suspends transfer of the next data.
4. Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the IIC drives the SCLn line low on the 9th falling edge of the SCL clock.
5. When the ICSR2.NACKF flag or the ICSR2.TEND flag is 1, dummy read ICDRR to complete the processing. This releases the SCLn line.
6. On detecting the stop condition, the IIC automatically sets the ICSR1.HOA, GCA, and AASy (y = 0 to 2) flags, the ICSR2.TDRE and TEND flags, and the ICCR2.TRS bit to 0, and enters slave receive mode.
7. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

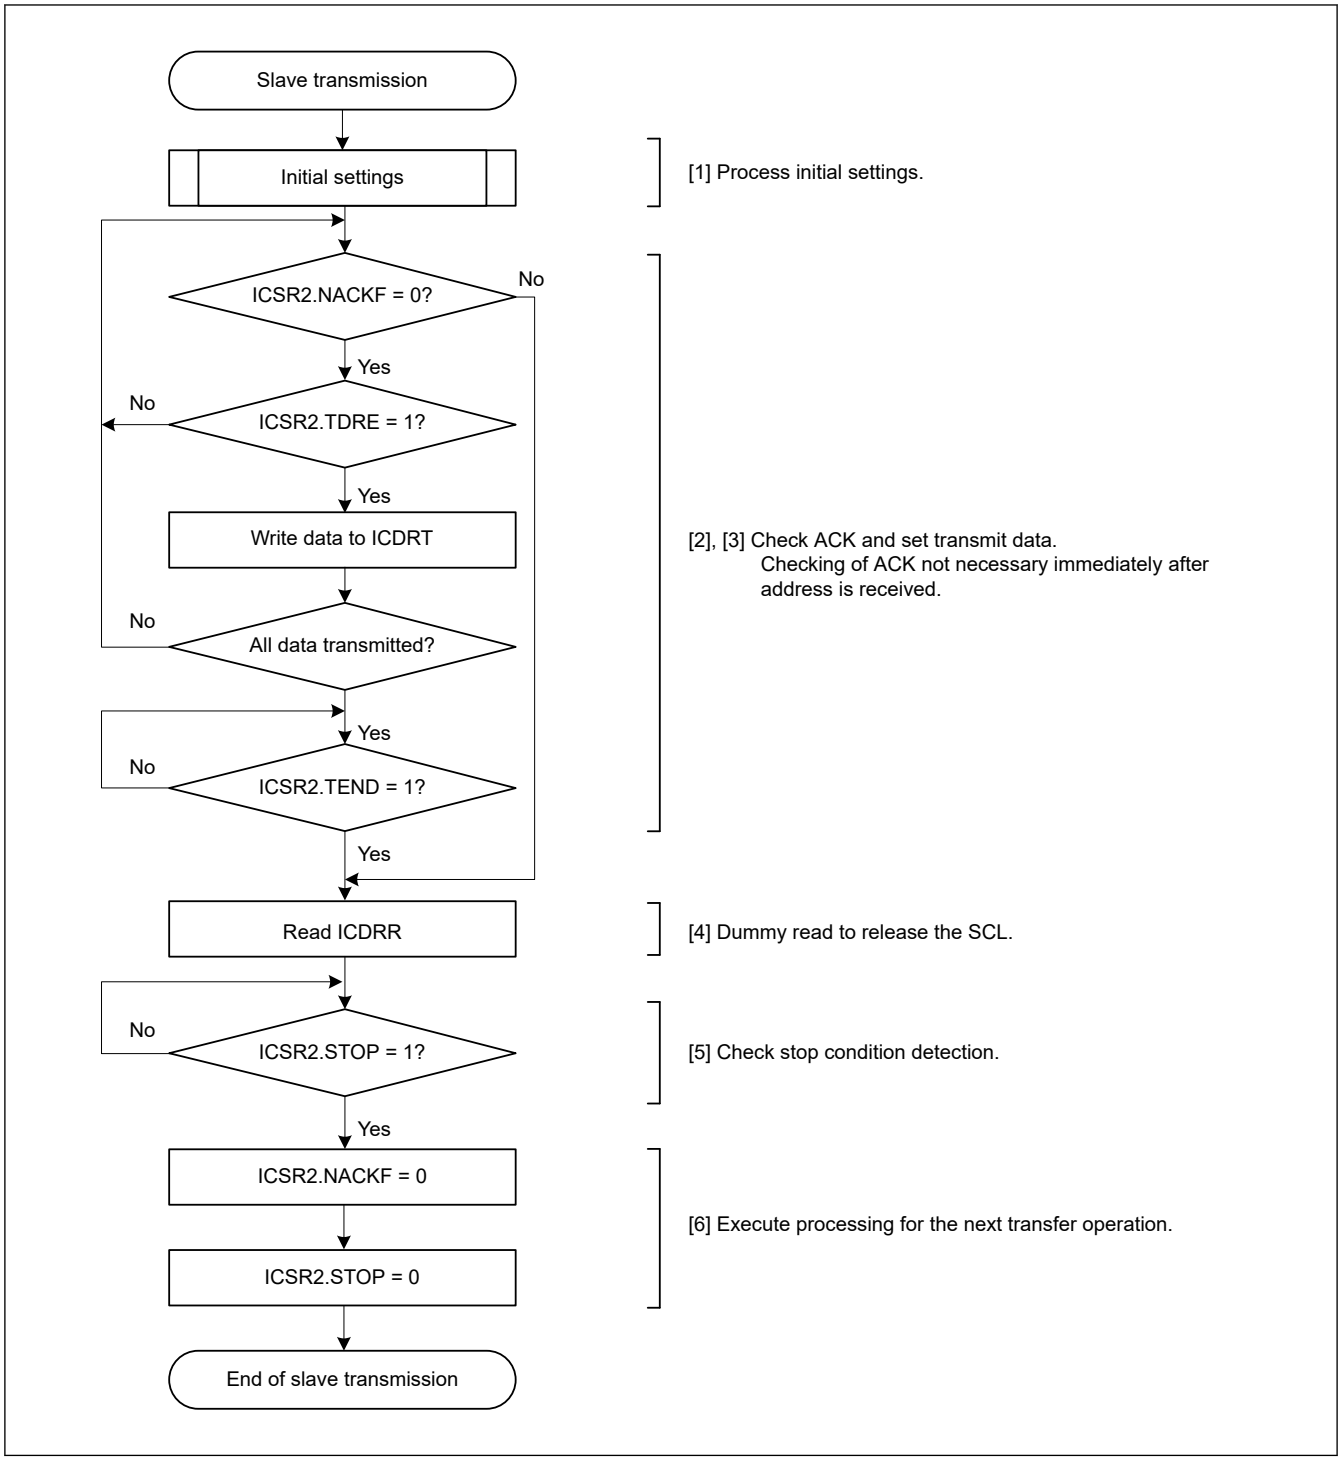

Figure 34.15 Example slave transmission flow

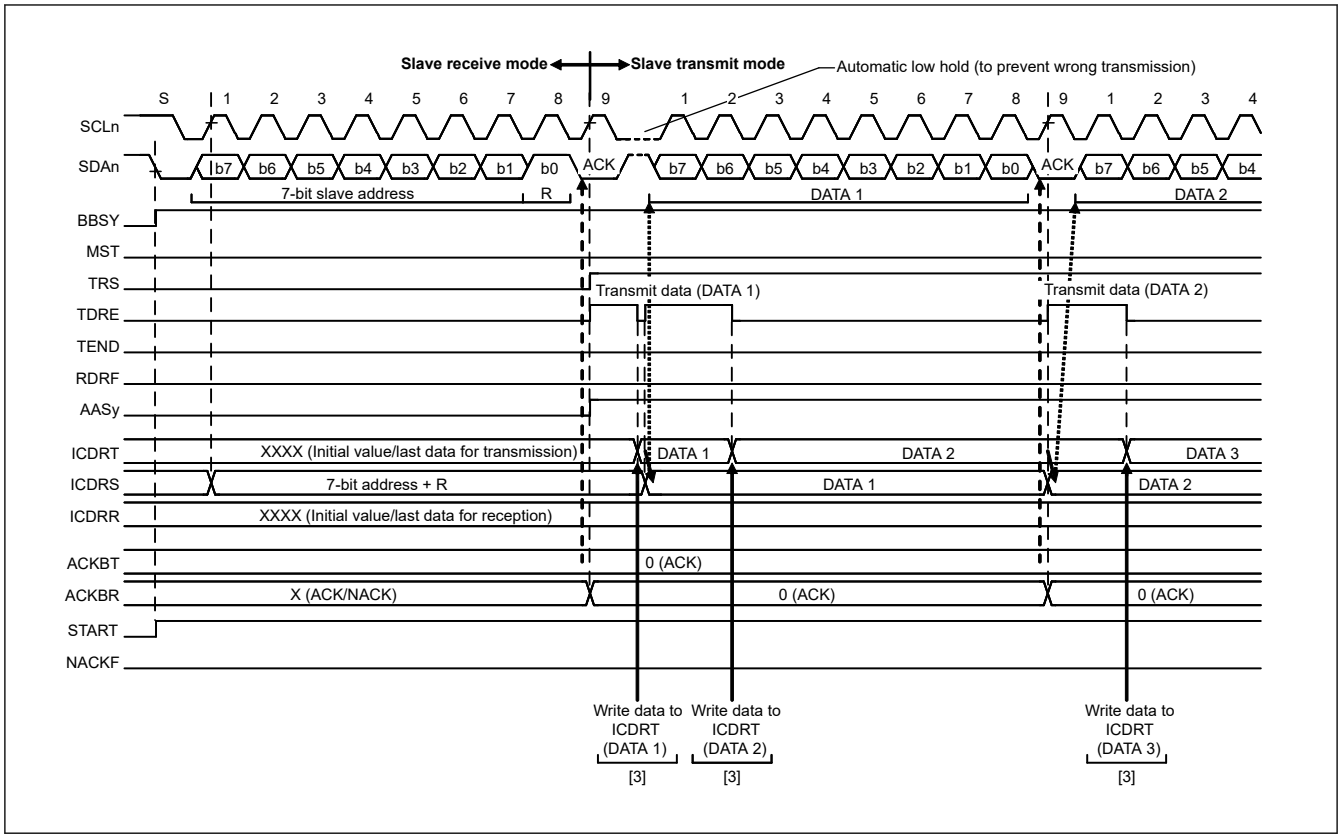

Figure 34.16 Slave transmit operation timing (1) with 7-bit address format

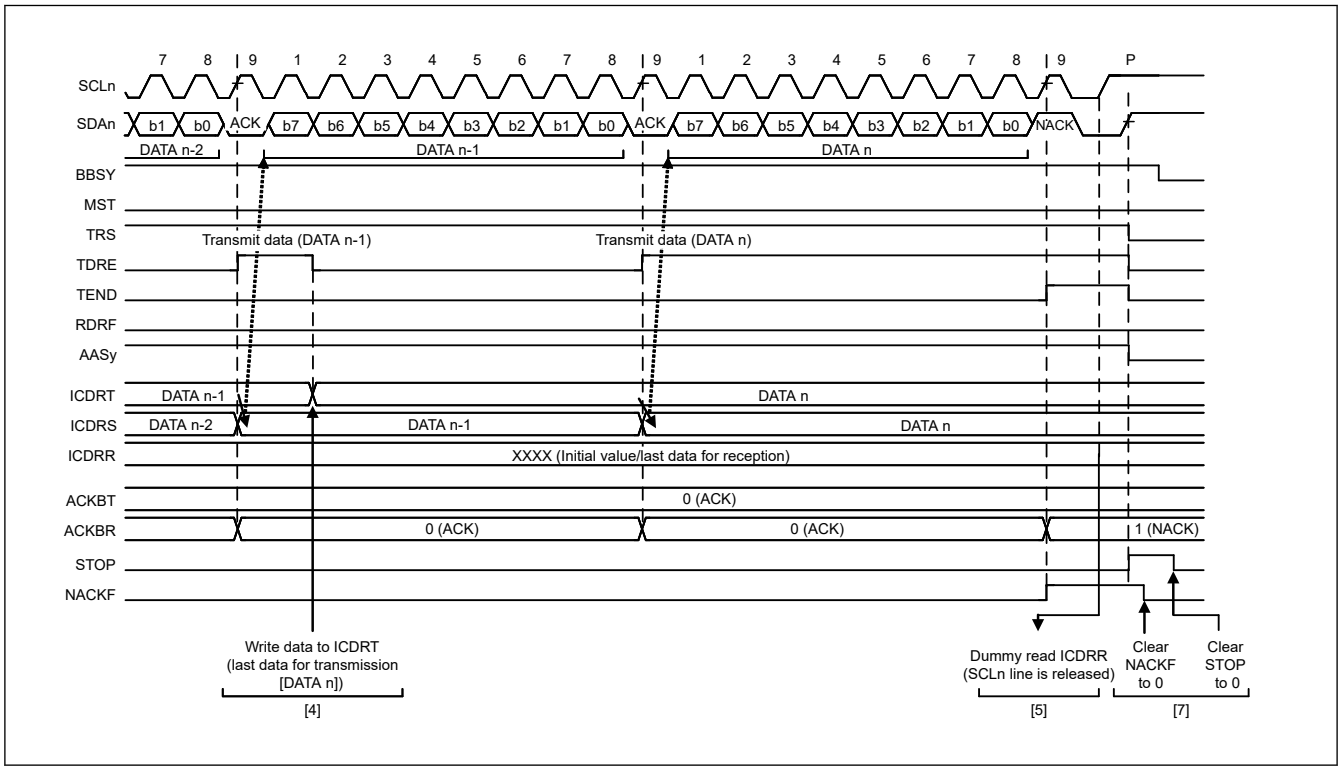

Figure 34.17 Slave transmit operation timing (2)

34.4.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the IIC returns acknowledgments as a slave device.

Figure 34.18 shows an example of slave reception, and Figure 34.19 and Figure 34.20 show the operation timing in slave reception.

To set up and perform slave reception:

1. To initialize the IIC, follow the procedure in section 34.4.2. Initial Settings.
   After the initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy (y = 0 to 2) flags to 1 on the rising edge of the 9th cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the 9th cycle of the SCL clock. If the value of the received R/W# bit is 0, the IIC continues to place itself in slave receive mode and sets the RDRF flag in ICSR2 to 1.
3. Check that the ICSR2.STOP flag is 0 and the ICSR2.RDRF flag is 1, and then dummy read the ICDRR register.
   The dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected.
4. When ICDRR is read, the IIC automatically sets the ICSR2.RDRF flag to 0. If reading of ICDRR is delayed and the next byte is received while the RDRF flag is still set to 1, the IIC holds the SCLn line low until 1 SCL cycle before the point where RDRF must be set. In this case, reading ICDRR releases the SCLn line from being held at the low level. When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1, read ICDRR until all the data is completely received.
5. On detecting the stop condition, the IIC automatically clears the ICSR1.HOA, GCA, and AASy (y = 0 to 2) flags to 0.
6. Check that the ICSR2.STOP flag is 1, then set the ICSR2.STOP flag to 0 for the next transfer operation.

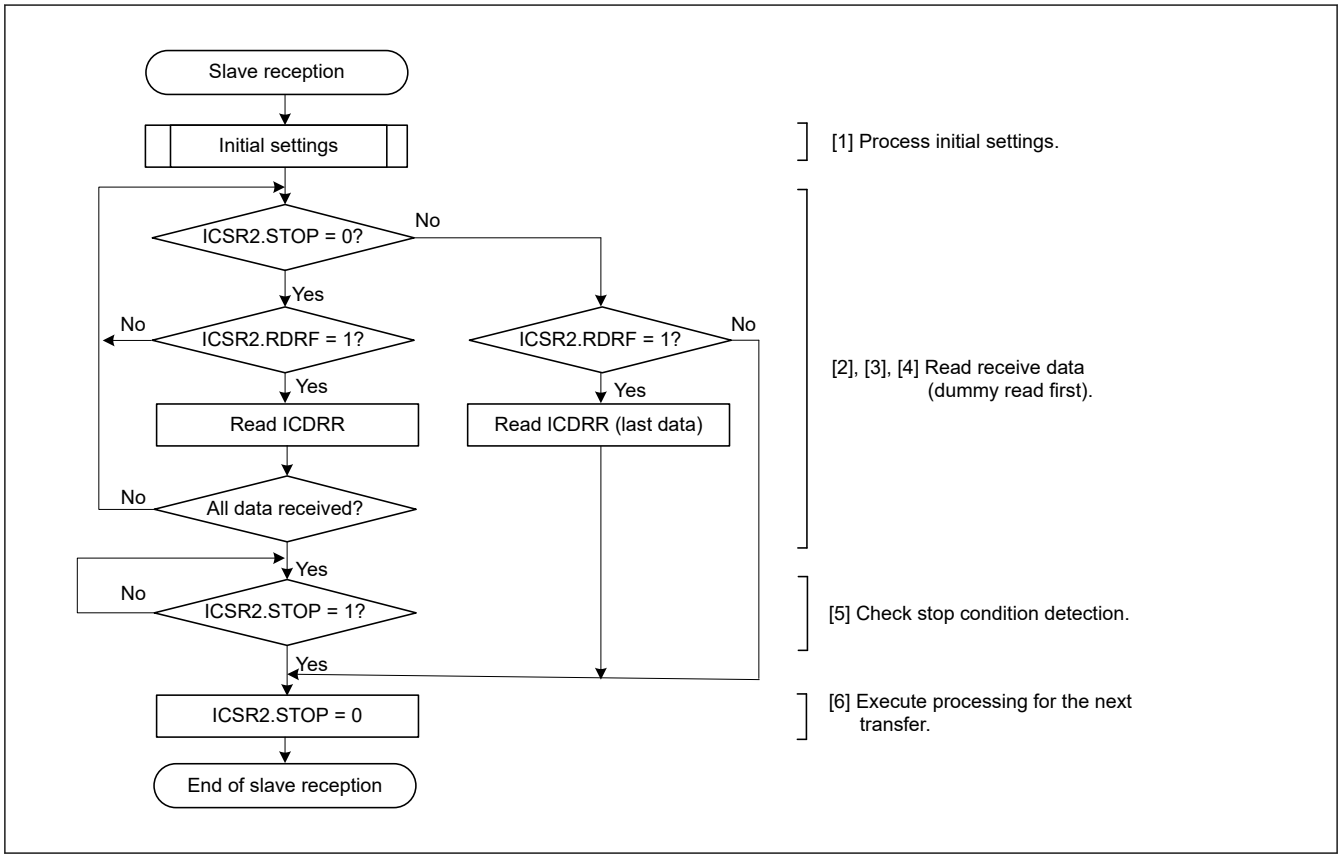

Figure 34.18 Example slave reception flow

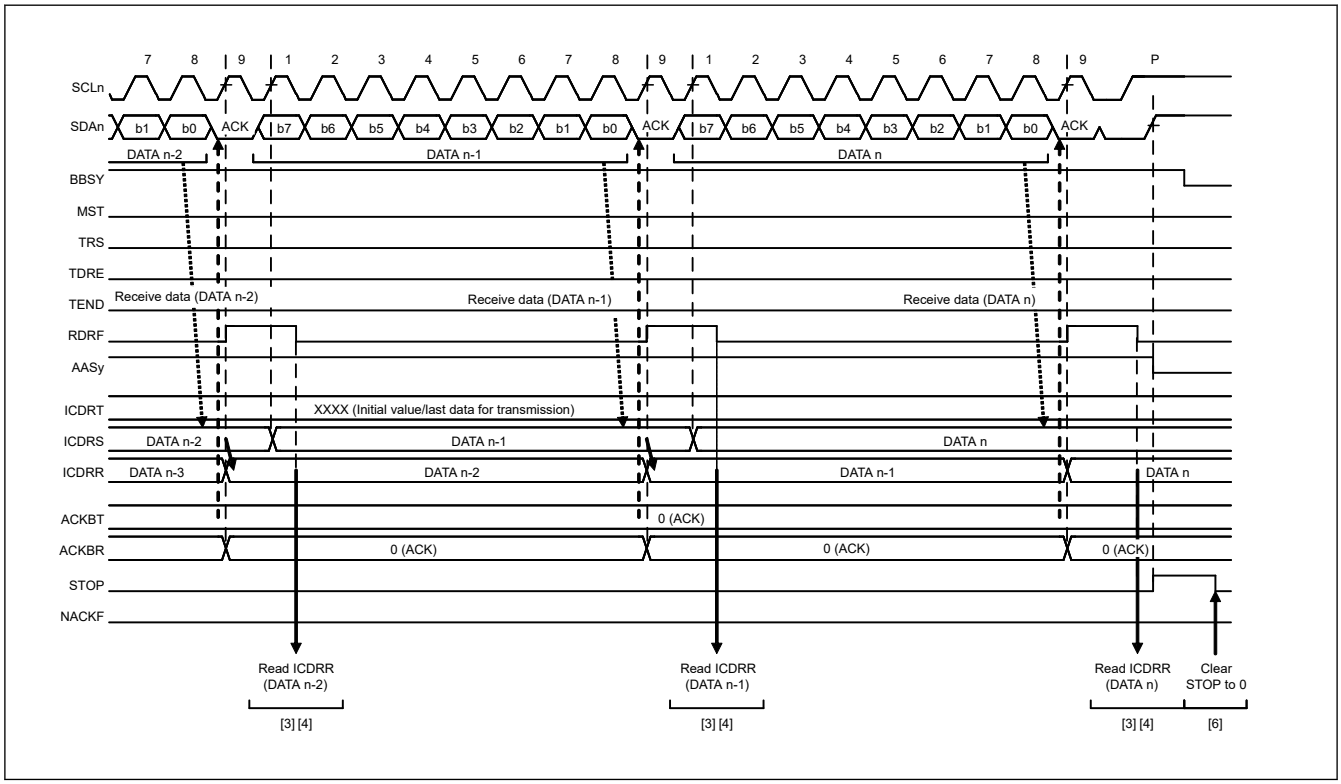

Figure 34.20 Slave receive operation timing (2) when RDRFS = 0

34.5 SCL Synchronization Circuit

For generation of the SCL clock, IIC starts counting the value for the high-level period specified in ICBRH when it detects a rising edge on the SCLn line, and drives the SCLn line low when it completes counting. When IIC detects the falling edge

of the SCLn line, it starts counting the value for the low-level period specified in ICBRL, and then stops driving the SCLn line, releasing the line when it completes counting. The IIC repeats this process to generate the SCL clock.

If multiple master devices are connected to the I^2C bus, a collision of SCL signals might arise because of contention with another master device. In such cases, the master devices must synchronize their SCL signals. Because this synchronization of SCL signals must be bit by bit, IIC is equipped with an SCL synchronization circuit to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When IIC detects a rising edge on the SCLn line and starts counting the high-level period specified in ICBRH, and the level on the SCLn line falls because an SCL signal is being generated by another master device, IIC performs the following:

1. Stops counting when it detects the falling edge.
2. Drives the level on the SCLn line low.
3. Starts counting the low-level period specified in ICBRL.

When the IIC finishes counting the low-level period, it stops driving the SCLn line low to release the line. If the lowlevel period of the SCL clock signal from the other master device is longer than the low-level period set in the IIC, the low-level period of the SCL signal is extended. When the low-level period for the other master device ends, the SCL signal rises because the SCLn line is released. When the IIC finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, when SCL signals from more than one master are contending, the high-level period of the SCL signal is synchronized with that of the clock with the narrower period, and the low-level period of the SCL signal is synchronized with that of the clock with the broader period. However, such synchronization of the SCL signal is only enabled when the SCLE bit in ICFER is set to 1.

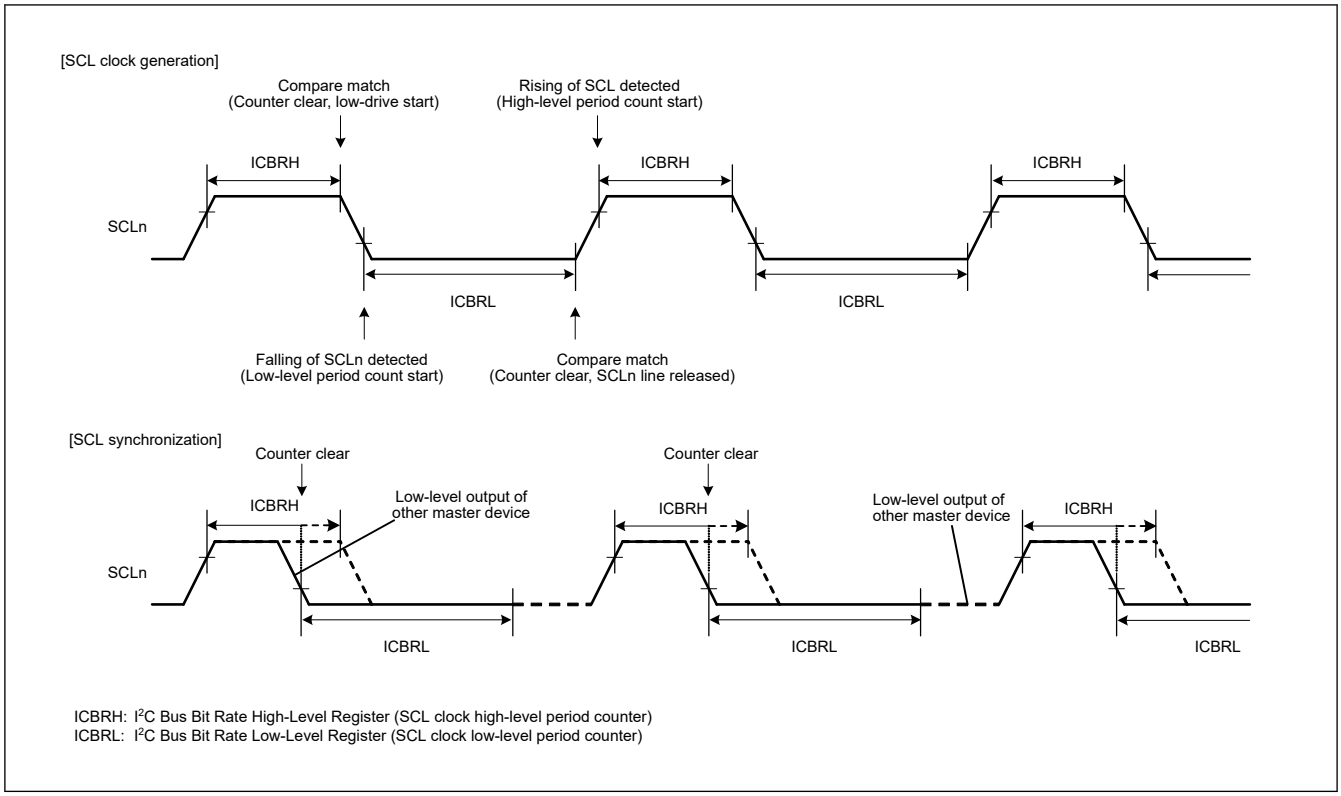

Figure 34.21 Generation and synchronization of SCL signal from IIC

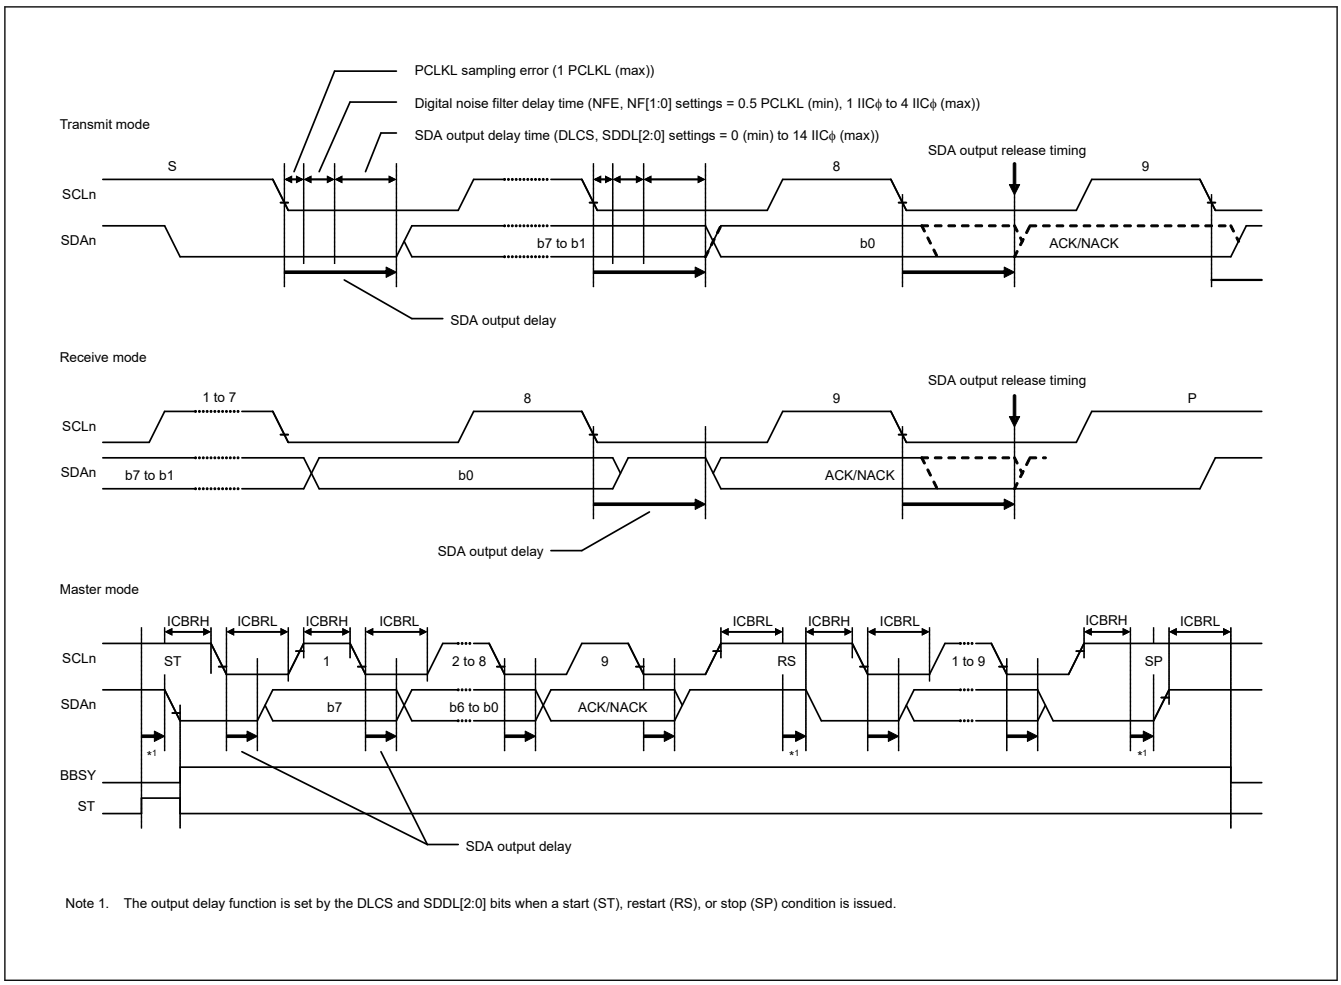
34.6 SDA Output Delay Function

The IIC module provides a function for delaying the output on the SDA line. The delay can be applied to all outputs on the SDA line, including the issuing of start, restart, and stop conditions, data, and the ACK and NACK signals.

With this function, SDA output is delayed from the detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval during which the SCL clock is low. This approach helps prevent erroneous operation of communications devices, with the aim of satisfying the 300 ns minimum data-hold time requirement of the SMBus

specification. The output delay function is enabled by setting the SDDL[2:0] bits in ICMR2 to any value other than 000b, and disabled by setting the same bits to 000b.

When the SDA output delay function is enabled, for example, the DLCS bit in ICMR2 selects the clock source for the SDA output delay counter, either as the internal base clock (IICΦ) for the IIC module or as the internal base clock divided by two (IICΦ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in ICMR2. When the delay count is reached, the IIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.



Note 1. The output delay function is set by the DLCS and SDDL[2:0] bits when a start (ST), restart (RS), or stop (SP) condition is issued.

Figure 34.22 SDA output delay function

34.7 Digital Noise Filter Circuits

The internal circuitry sees the states of the SCLn and SDAn pins through analog and digital noise-filter circuits. Figure 34.23 shows a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the IIC consists of four flip-flop circuit stages connected in series, and a match-detection circuit.

The number of valid stages in the digital noise filter is selected in the NF[1:0] bits in ICMR3. The selected number of valid stages determines the noise-filtering capability as a period from 1 to 4 IICΦ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on falling edges of the IICΦ signal. When the input signal level matches the output level of the number of valid flip-flop circuit stages as selected in the NF[1:0] bits in ICMR3, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is saved.

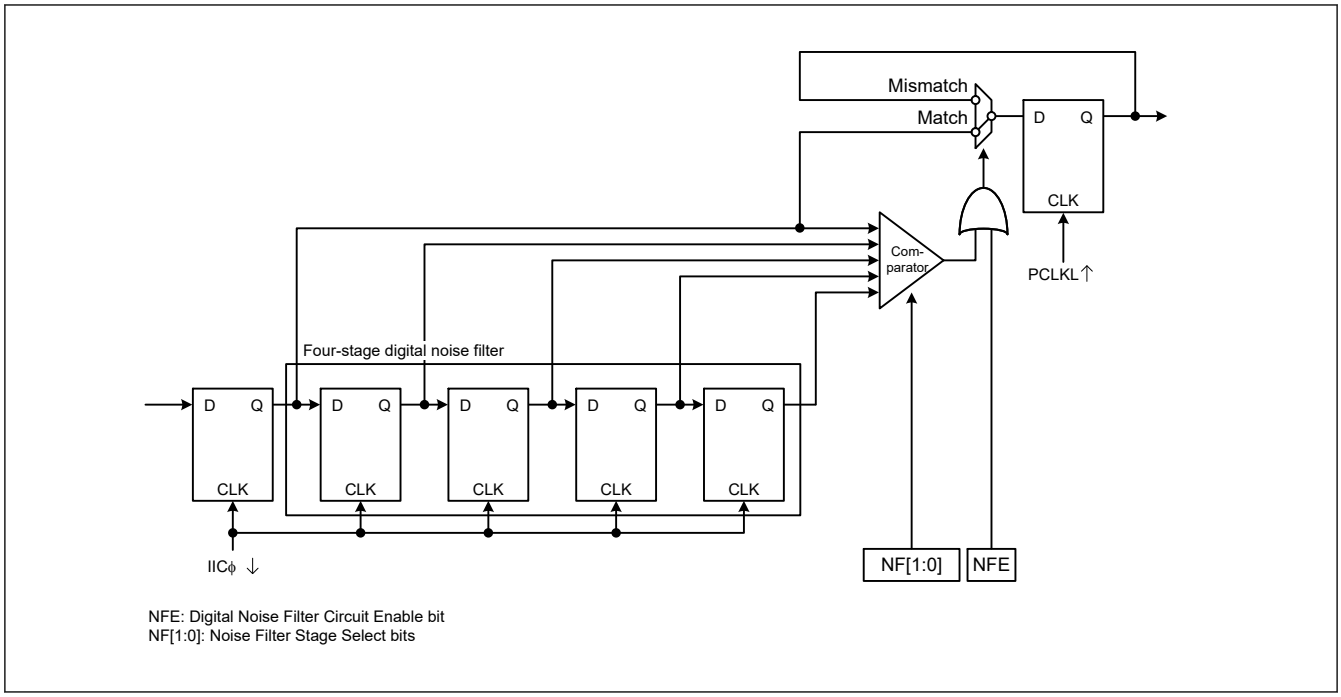


Figure 34.23 Digital noise filter circuit block diagram

34.8 Address Match Detection

IIC can set three unique slave addresses in addition to the general call address and host address. The slave addresses can be 7-bit or 10-bit slave addresses.

34.8.1 Slave-Address Match Detection

IIC can set three unique slave addresses and has a slave address detection function for each unique slave address. When the SARyE bit (y = 0 to 2) in ICSER is set to 1, the slave addresses set in SARUy and SARLy (y = 0 to 2) can be detected.

When the IIC detects a match of the set slave address, the associated AASy (y = 0 to 2) flag in ICSR1 is set to 1 on the rising edge of the 9th SCL clock cycle, and the RDRF flag in ICSR2 or the TDRE flag in ICSR2 is set to 1 by the subsequent R/W# bit. This causes a receive data full interrupt (IICn_RXI) or transmit data empty interrupt (IICn_TXI) to be generated. The AASy flag identifies which slave address is specified.

Figure 34.24 to Figure 34.26 show the AASy flag set timing in three cases.

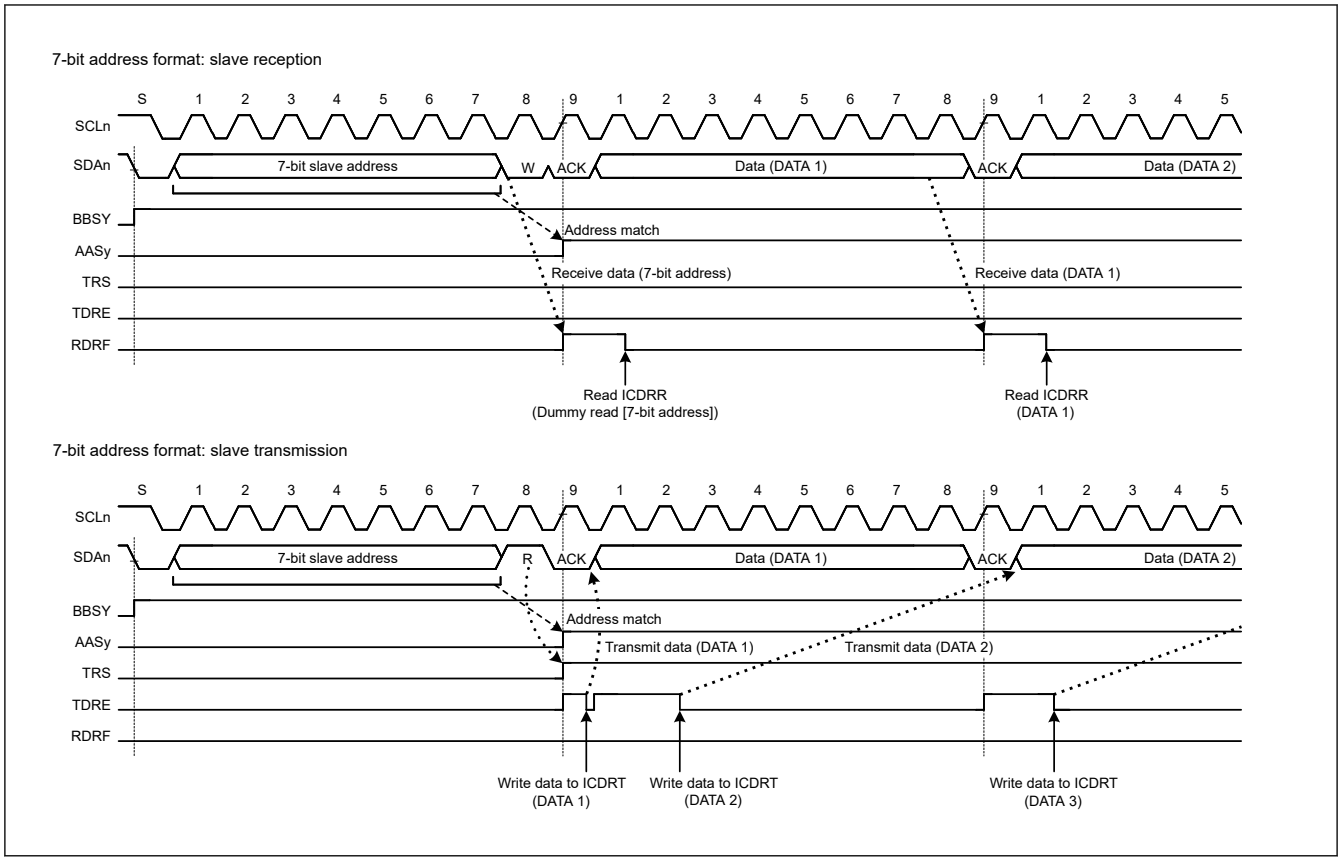

Figure 34.24 AASy flag set timing with 7-bit address format

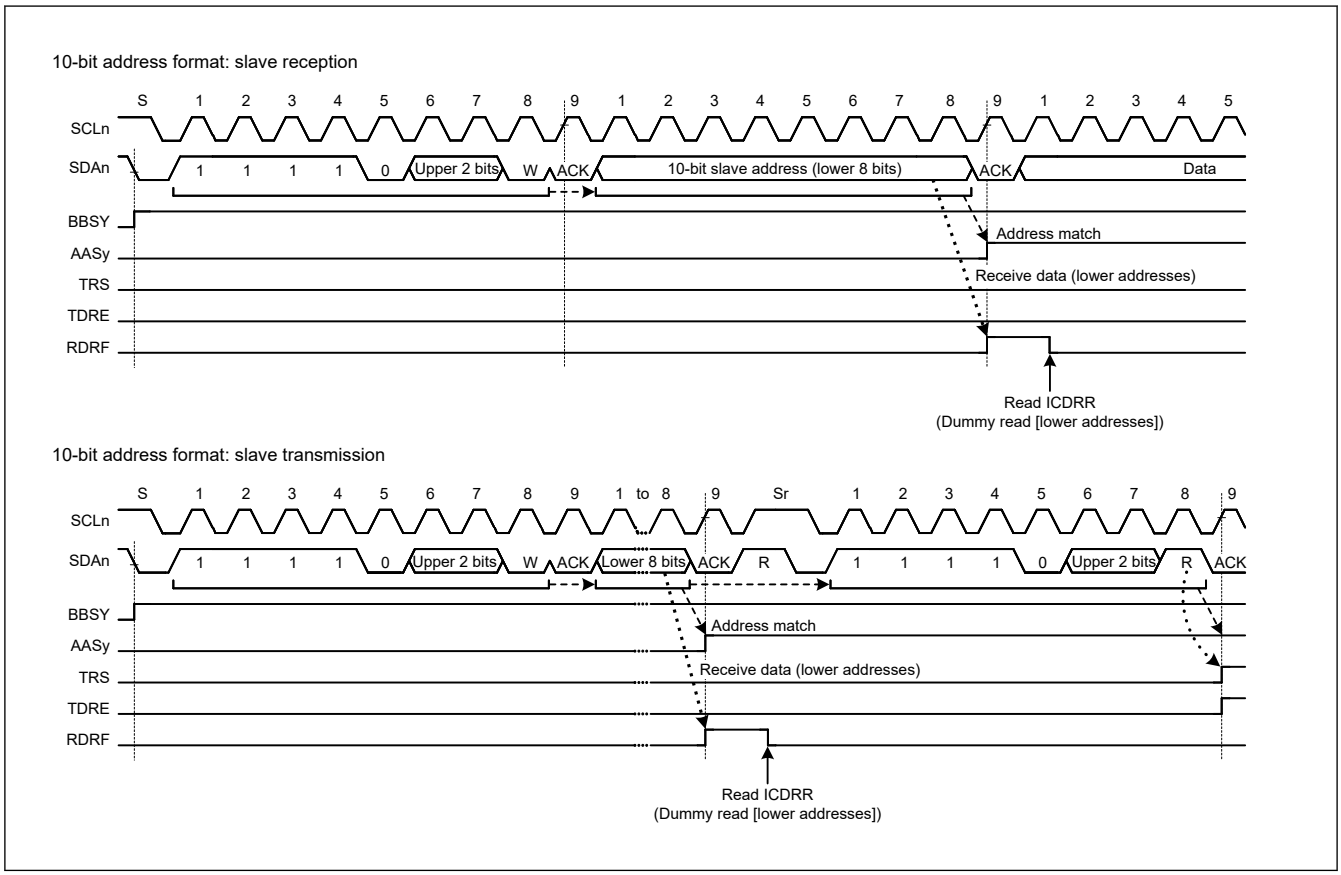

Figure 34.25 AASy flag set timing with 10-bit address format

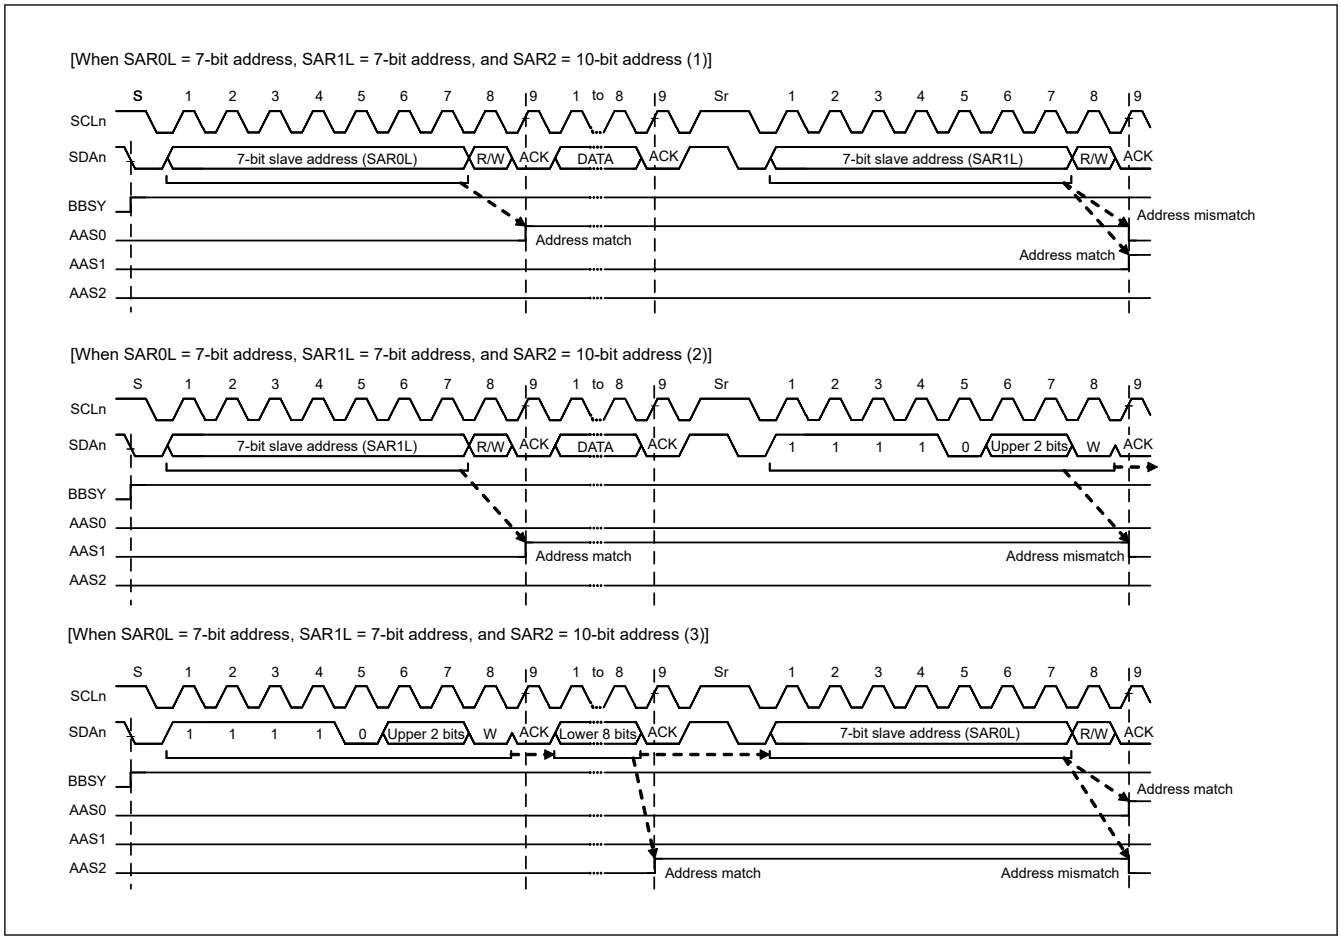

Figure 34.26 AASy flag set and clear timing with 7- and 10-bit address formats mixed

34.8.2 Detection of General Call Address

The IIC provides detection of the general call address (0000 000b + 0 [W]). General call address detection is enabled by setting the GCAE bit in ICSER to 1.

If the address received after a start or restart condition is issued is 0000 000b + 1 [R] (start byte), the IIC recognizes this as the address of a slave device with an all-zero address, but not as the general call address.

When the IIC detects the general call address, both the GCA flag in ICSR1 and the RDRF flag in ICSR2 set to 1 on the rising edge of the 9th cycle of the SCL clock. This leads to the generation of a receive data full interrupt (IICn_RXI). The value of the GCA flag can be checked to confirm that the general call address is transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

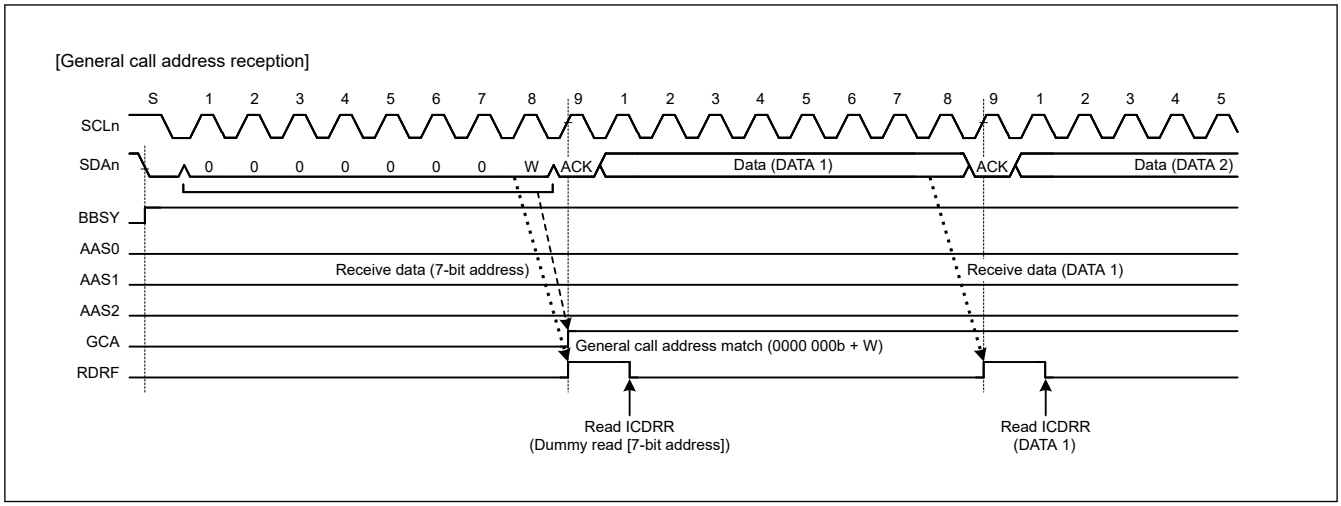

Figure 34.27 Timing of GCA flag setting during reception of general call address

34.8.3 Device ID Address Detection

The IIC module provides detection of the device ID address in compliance with the I^2C bus specification, revision 03.

When IIC receives 1111 100b as the first byte after a start or restart condition is issued with the DIDE bit in ICSER set to 1, it recognizes the address as a device ID, sets the DID flag in ICSR1 to 1 on the rising edge of the 8th SCL clock cycle when the subsequent R/W# bit is 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the IIC sets the associated AASy (y = 0 to 2) flag in ICSR1 to 1.

When the first byte received after the issue of a start or restart condition matches the device ID address (1111 100b) again and the subsequent R/W# bit is 1, IIC does not compare the second and subsequent bytes, and sets the ICSR2.TDRE flag to 1.

In the device ID address detection function, IIC sets the DID flag to 0 if a match with the IIC slave address is not obtained, or a match with the device ID address is not obtained after a match with the IIC slave address, and a restart condition is detected. If the first byte after the detection of a start or restart condition matches the device ID address (1111 100b) and the R/W# bit is 0, IIC sets the DID flag to 1 and compares the second and subsequent bytes with the slave address of IIC. If the R/W# bit is 1, the DID flag holds the previous value and IIC does not compare the second and subsequent bytes. In this way, reception of a device ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Additionally, prepare the device ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device ID field as normal transmit data. For details on the information that must be included in device ID fields, contact NXP Semiconductors.

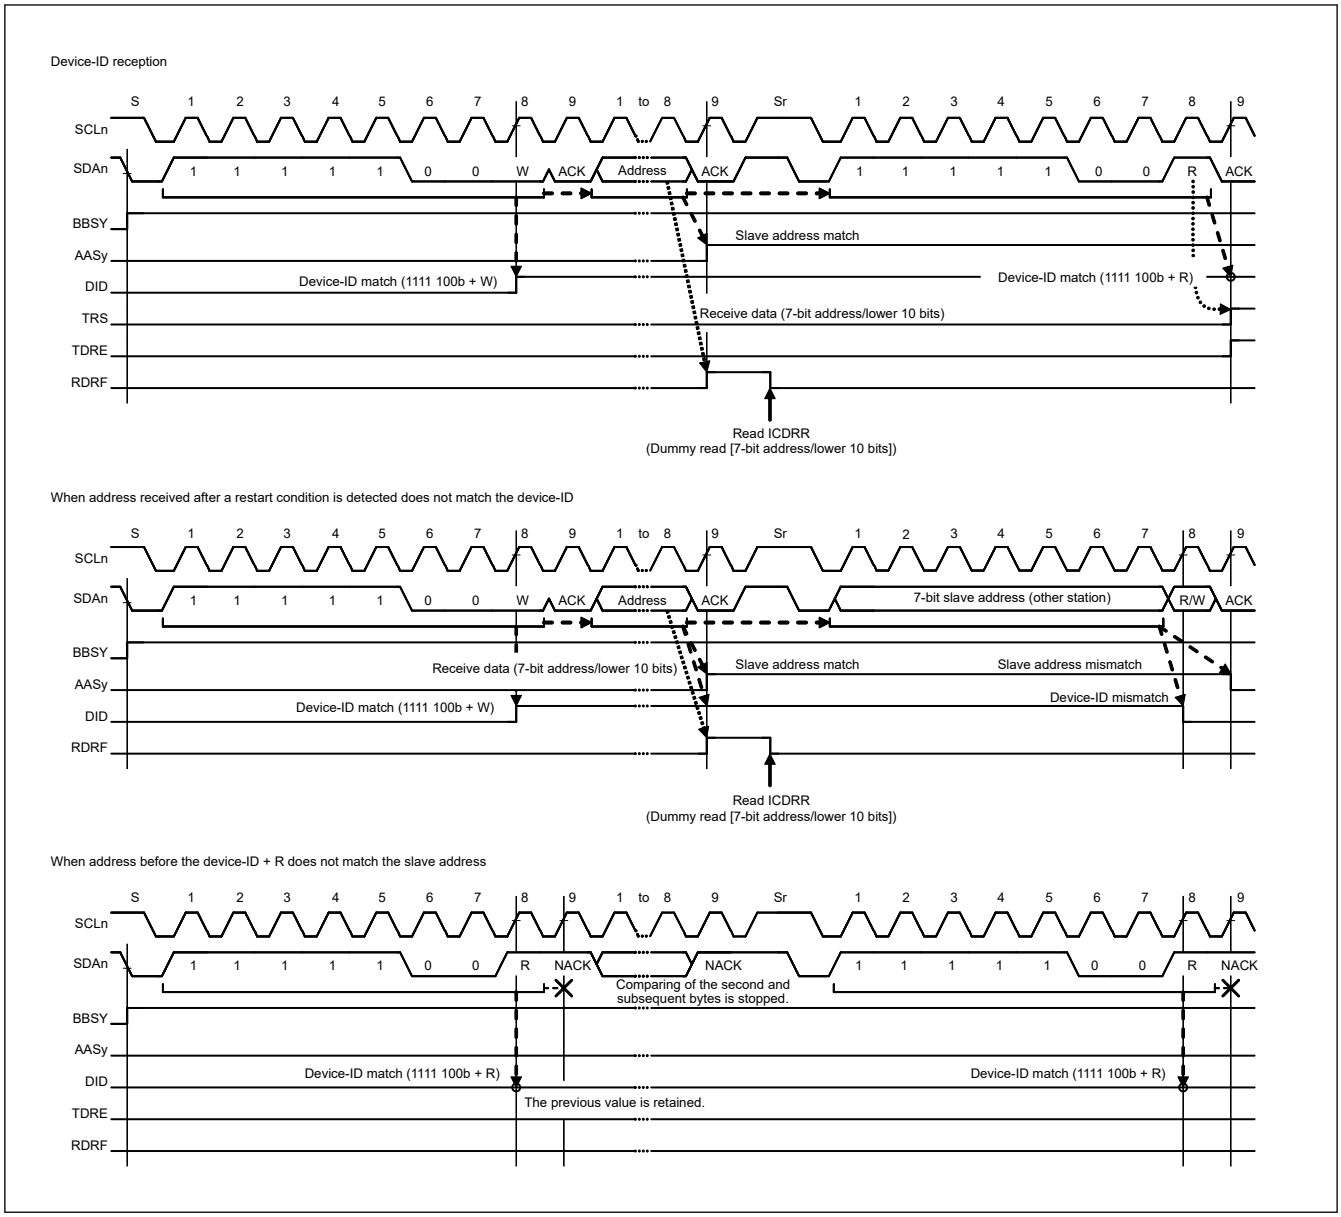

Figure 34.28 AASy and DID flag set and clear timing during reception of device ID

34.8.4 Host Address Detection

The IIC provides host address detection while the SMBus is operating. When the HOAE bit in ICSER is set to 1 while the SMBS bit in ICMR3 is 1, the IIC can detect the host address (0001 000b) in slave receive mode (MST and TRS bits = 00b in ICCR2).

When the IIC detects the host address, the HOA flag in ICSR1 is set to 1 on the rising edge of the 9th SCL clock cycle. At the same time, the RDRF flag in ICSR2 is set to 1 when the R/W# bit is 0. This causes a receive data full interrupt (IICn_RXI) to be generated. The HOA flag indicates that the host address was sent from another device.

If the bit following the host address (0001 000b) is a read bit (R/W# bit = 1), the IIC can also detect the host address. After the host address is detected, the IIC operates in the same manner as in normal slave operation.

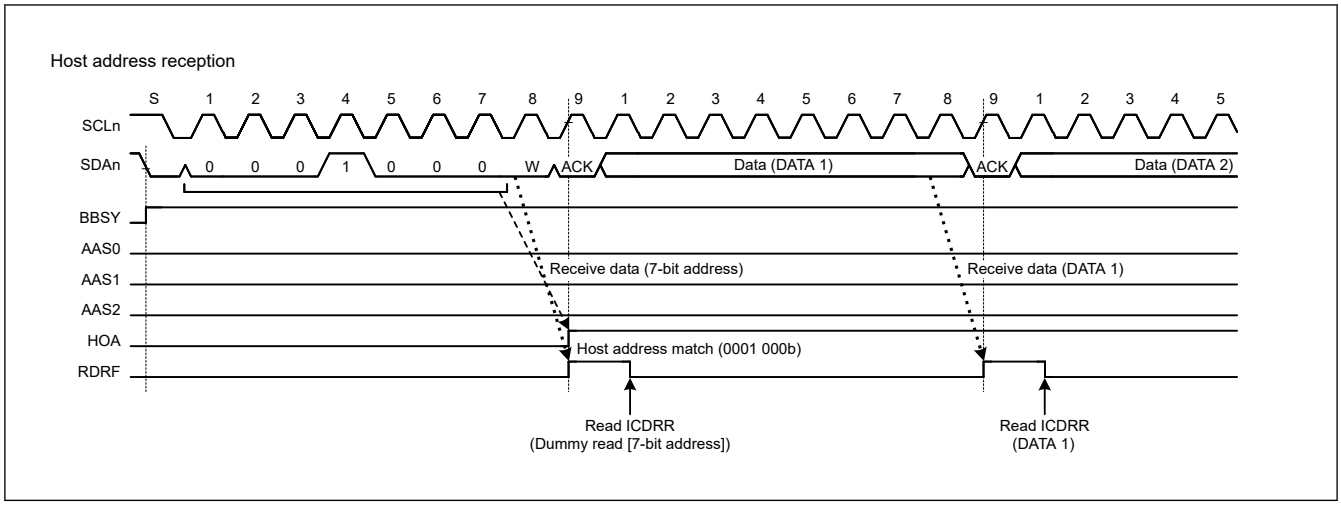

Figure 34.29 HOA flag set timing during reception of host address

34.9 Automatic Low-Hold Function for SCL

34.9.1 Function to Prevent Wrong Transmission of Transmit Data

If the I^{2}C Bus Shift Register (ICDRS) is empty when data has not been written to the I^{2}C Bus Transmit Data Register (ICDRT) with the IIC in transmission mode (TRS bit = 1 in ICCR2), the SCLn line is automatically held at the low level over subsequent intervals. This low-hold period is extended until the transmit data is written, which prevents the unintended transmission of erroneous data.

Master transmit mode

- Low-level interval after a start or restart condition is issued
- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

Slave transmit mode

- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

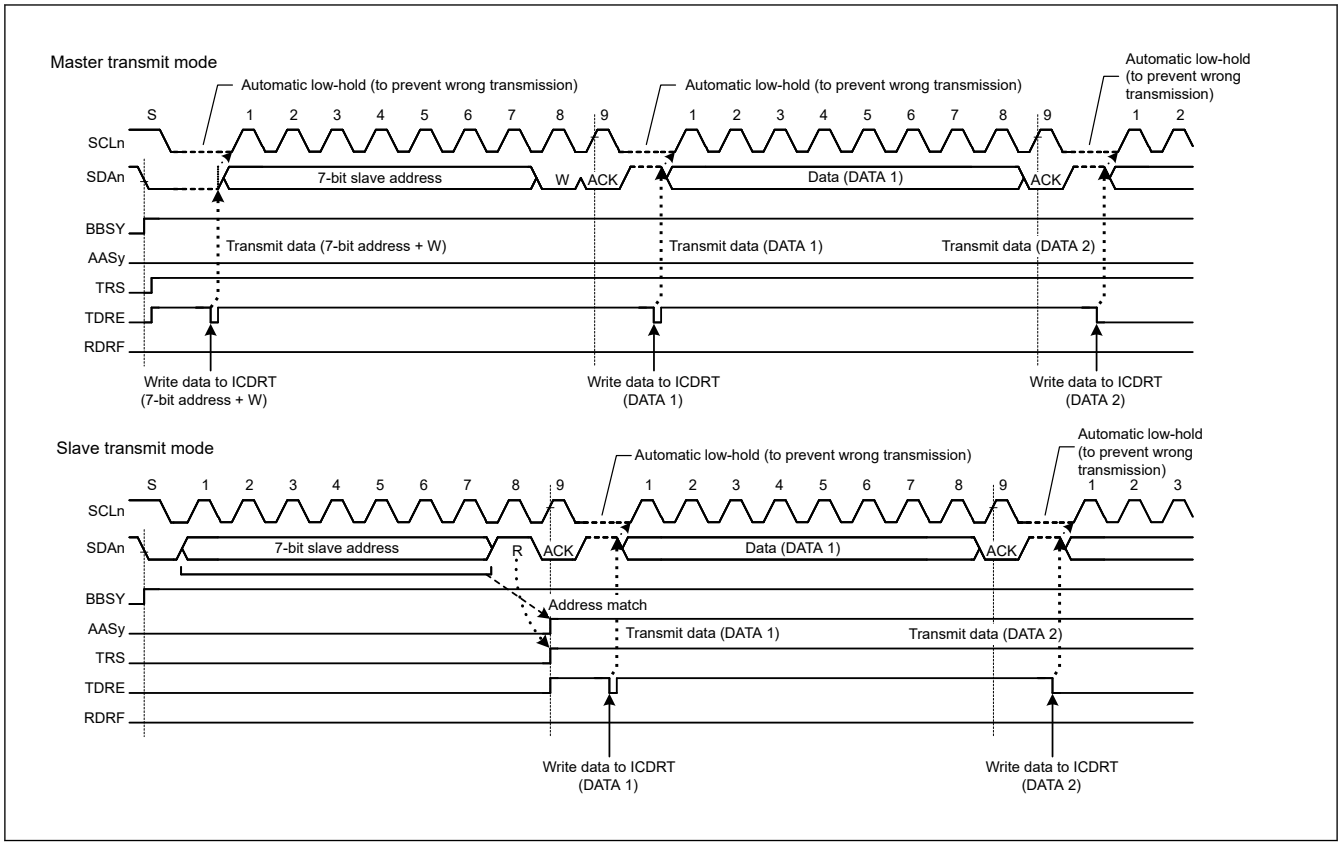

Figure 34.30 Automatic low-hold operation in transmit mode

34.9.2 NACK Reception Transfer Suspension Function

This function suspends transfer operation when NACK is received in transmit mode (TRS bit = 1 in ICCR2). This function is enabled when the NACKE bit in ICFER is set to 1. If the next transmit data is already written (TDRE flag = 0 in ICSR2) when NACK is received, the next data transmission on the falling edge of the 9th SCL clock cycle is automatically suspended. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (NACKF flag = 1 in ICSR2), transmit and receive operations are discontinued. To restore transmit or receive operations, set the NACKF flag to 0. In master transmit mode, after a restart or stop condition is issued, set the NACKF flag to 0, and then issue a start condition again.

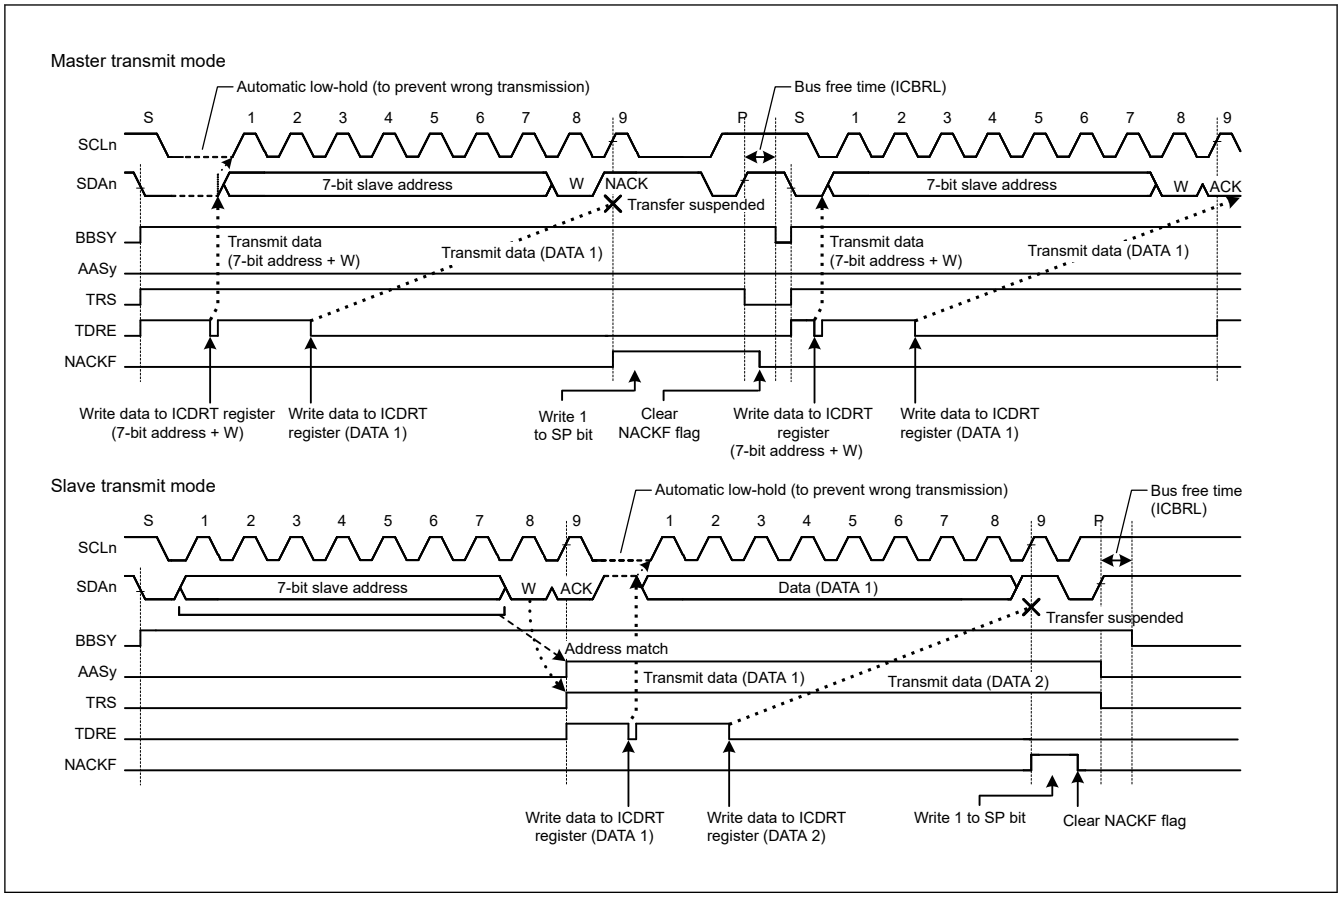

Figure 34.31 Suspension of data transfer when NACK is received, when NACKE = 1

34.9.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer frame or more with receive data full (RDRF flag = 1 in ICSR2) in receive mode (TRS = 0 in ICCR2), the IIC holds the SCLn line low automatically immediately before the next data is received to prevent failure to receive data.

This function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the IIC slave address is designated after a stop condition is issued. This function does not interfere with other communication because the IIC does not hold the SCLn line low when a mismatch with its own slave address occurs after a stop condition is issued.

Periods in which the SCLn line is held low can be selected with a combination of the WAIT and RDRFS bits in ICMR3.

(1) 1-byte receive operation and automatic low-hold function using the WAIT bit

When the WAIT bit in ICMR3 is set to 1, IIC performs a 1-byte receive operation using the WAIT bit function. Additionally, when the ICMR3.RDRFS bit is 0, IIC automatically sends the ACKBT bit value in ICMR3 for the acknowledge bit in the period from the falling edge of the 8th SCL clock cycle to the falling edge of the 9th SCL clock cycle, and automatically holds the SCLn line low on the falling edge of the 9th SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from ICDRR, which enables byte-wise receive operation.

The WAIT bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

(2) 1-byte receive operation (ACK/NACK transmission control) and automatic low-hold function using the RDRFS bit

When the RDRFS bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the RDRFS bit function.

When the RDRFS bit is set to 1, the RDRF (receive data full) flag in ICSR2 is set to 1 on the rising edge of the 8th SCL clock cycle, and the SCLn line is automatically held low on the falling edge of the 8th SCL clock cycle. This low-hold

is released by writing a value to the ACKBT bit in ICMR3, but cannot be released by reading data from ICDRR, which enables receive operation through the ACK or NACK transmission control based on the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

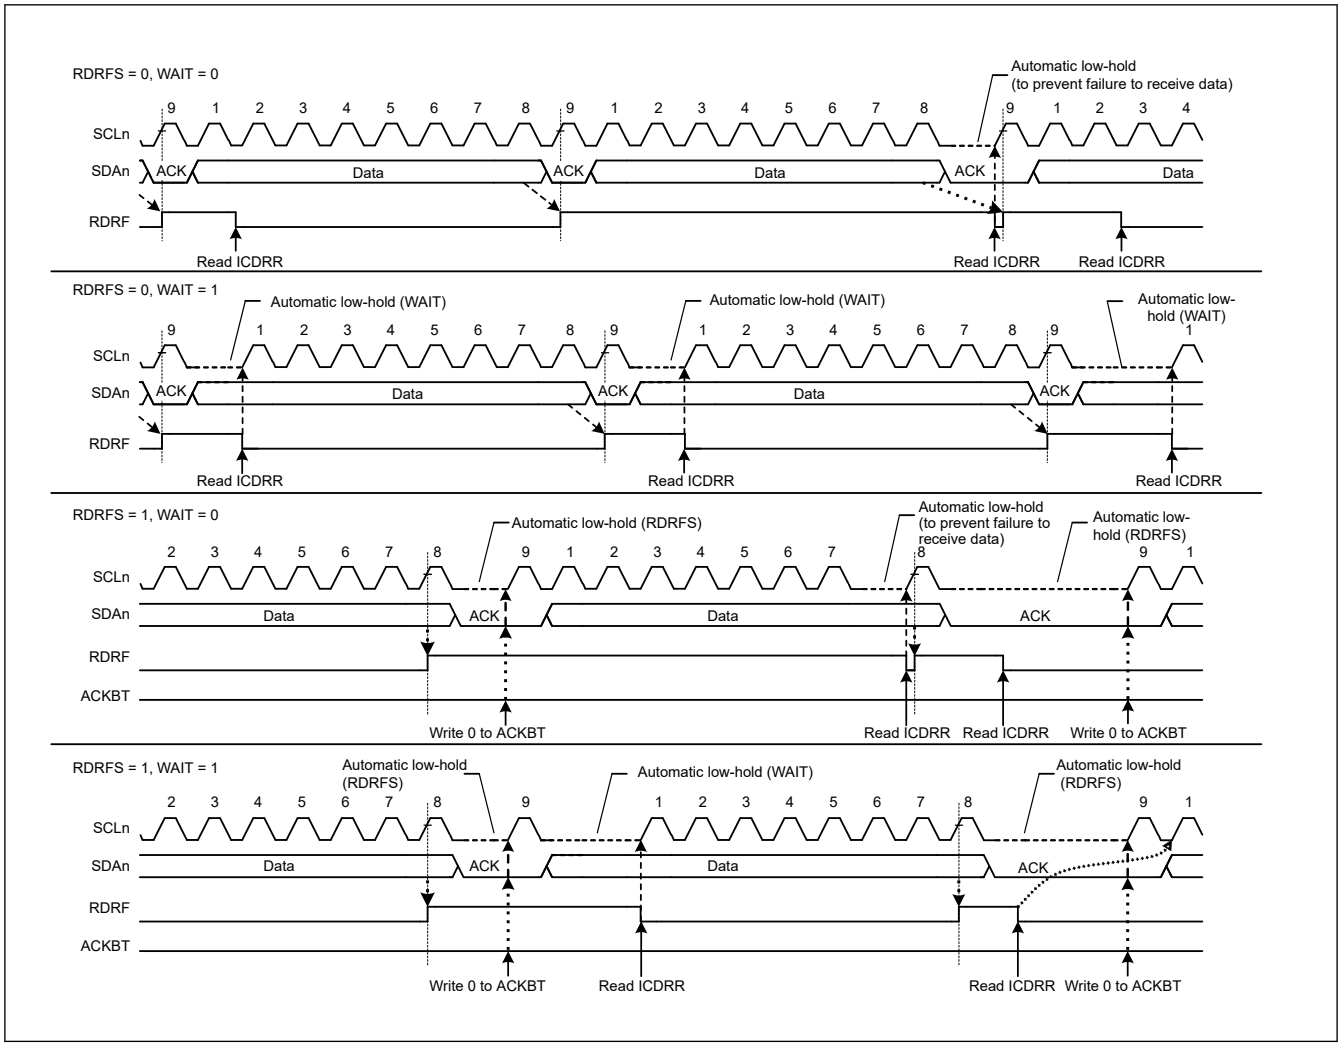

Figure 34.32 Automatic low-hold operation in receive mode using the RDRFS and WAIT bits

34.10 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I^2C bus standard, IIC provides functions to prevent double-issue of a start condition, detect arbitration-lost during the transmission of NACK, and detect arbitration lost in slave transmit mode.

34.10.1 Master Arbitration-Lost Detection (MALE Bit)

IIC drives the SDAn line low to issue a start condition. However, if the SDAn line was already driven low by another master device issuing a start condition, IIC regards its own start condition as an error and considers this a loss in arbitration.

Priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the ST bit in ICCR2 to 1 while the bus is busy (BBSY flag = 1 in ICCR2), IIC regards this as a double-issuing-of-start-condition error and considers itself to have lost the arbitration. This prevents a failure of transfer resulting from a start condition issued while transfer is in progress.

When a start condition is issued successfully, if the transmit data including the address bits (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state) and a low level is detected on the SDAn line, IIC loses the arbitration.

After a loss in arbitration of mastership, the IIC immediately enters slave receive mode. If a slave address, including the general call address, matches its own address at this time, the IIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the MALE bit in ICFER is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Mismatching of the internal level for output on SDA and the level on the SDAn line after a start condition was issued by setting the ST bit in ICCR2 to 1 while the BBSY flag in ICCR2 is set to 0 (erroneous issuing of a start condition)
- Setting of the ST bit in ICCR2 to 1 (start condition double-issue error) while the BBSY flag is 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDAn line in master transmit mode (MST and TRS bits = 11b in ICCR2).

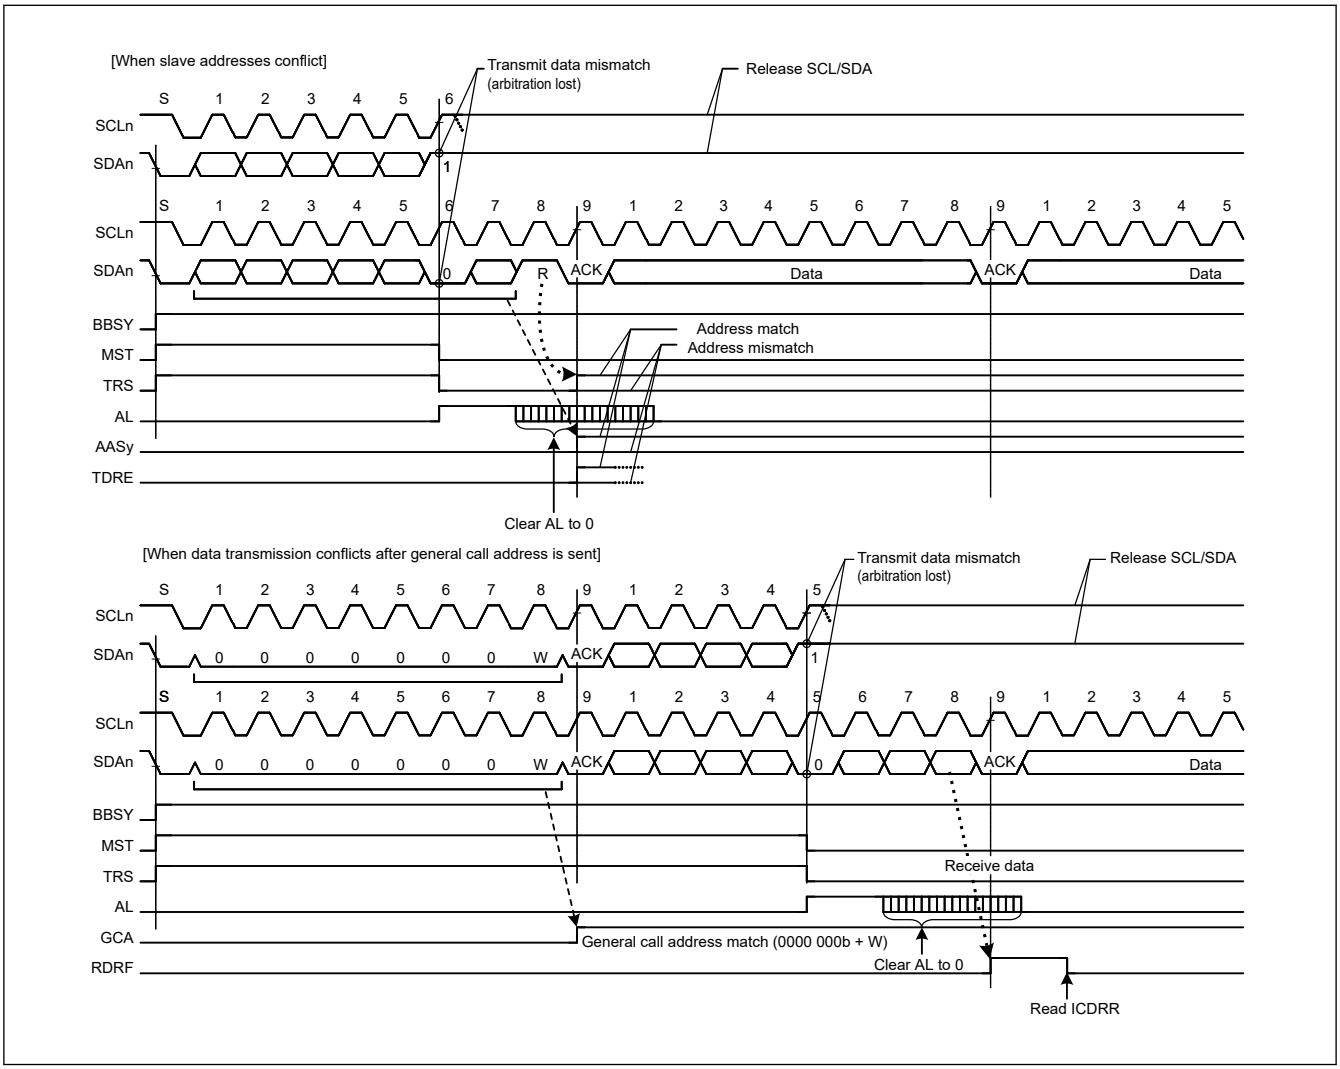

Figure 34.33 Examples of master arbitration-lost detection when MALE = 1

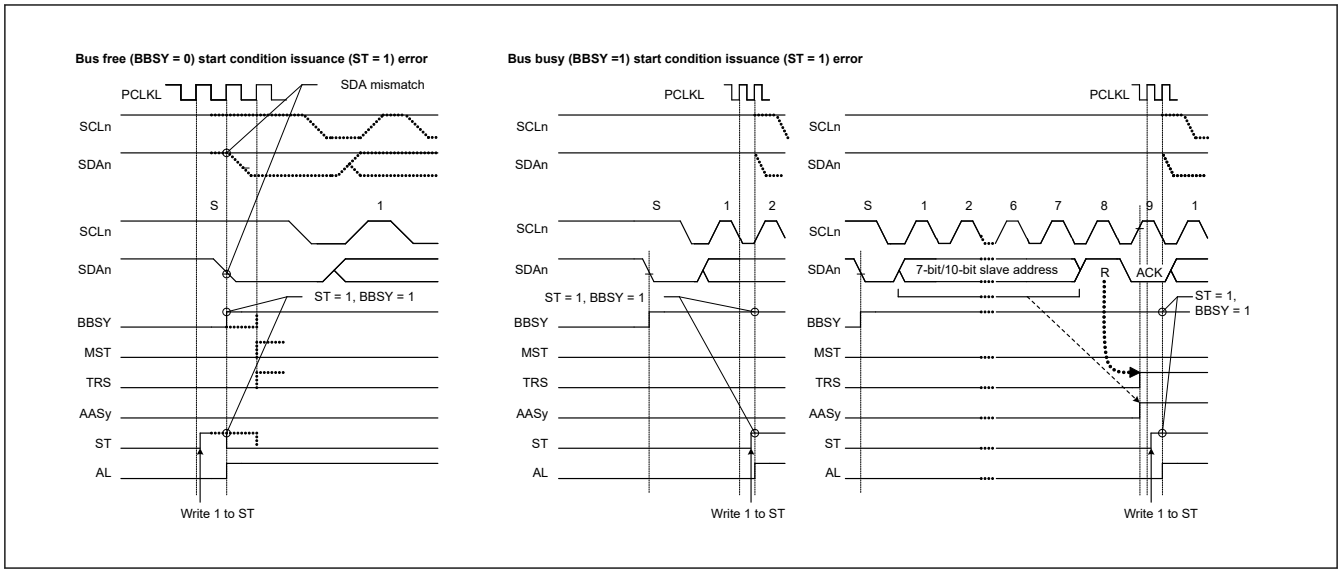

Figure 34.34 Arbitration-lost when start condition is issued when MALE = 1

34.10.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

This function causes arbitration to be lost if the internal SDA output level does not match the level on the SDAn line during transmission of NACK in receive mode. Arbitration is lost because of a conflict between NACK and ACK transmissions when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send or receive the same information through a single slave device. Figure 34.35 shows an example of arbitration-lost detection during the transmission of NACK.

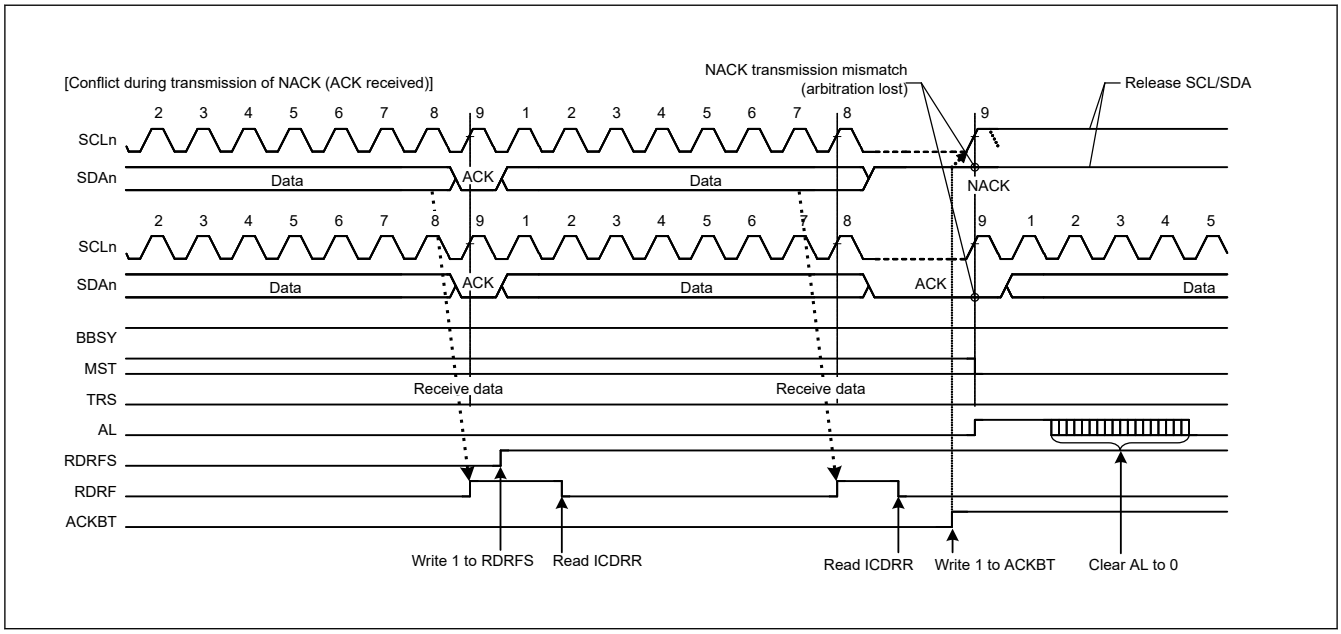

Figure 34.35 Example of arbitration-lost detection during transmission of NACK when NALE = 1

The following description explains arbitration-lost detection using an example in which two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in either master A or B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Master A sends NACK when it has received the 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the required 4 bytes of data.

The NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect the ACK transmitted by master B and issues a stop condition. The stop condition issue conflicts with the SCL clock output of master B, which disrupts communication.

When IIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost. If arbitration is lost during transmission of NACK, IIC immediately cancels the slave match condition and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing, such as 0xFF transmission processing, which is required if the UDID (Unique Device Identifier) of the assigned address does not match in the Get UDID general processing after the Assign Address command.

The IIC detects arbitration-lost during transmission of NACK when the following condition is met with the NALE bit in ICFER set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDAn line (ACK is received) during transmission of NACK (ACKBT bit = 1 in ICMR3).

34.10.3 Slave Arbitration-Lost Detection (SALE Bit)

This function causes arbitration to be lost if the transmit data (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state), and the low level is detected on the SDAn line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

When IIC loses slave arbitration, IIC is immediately released from the slave-matched state and enters slave receive mode.

This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminates subsequent redundant processing for the transmission of 0xFF.

IIC detects slave arbitration-lost when the following condition is met with the SALE bit in ICFER set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When transmit data excluding acknowledge (internal SDA output level) does not match the SDAn line in slave transmit mode (MST and TRS bits = 01b in ICCR2).

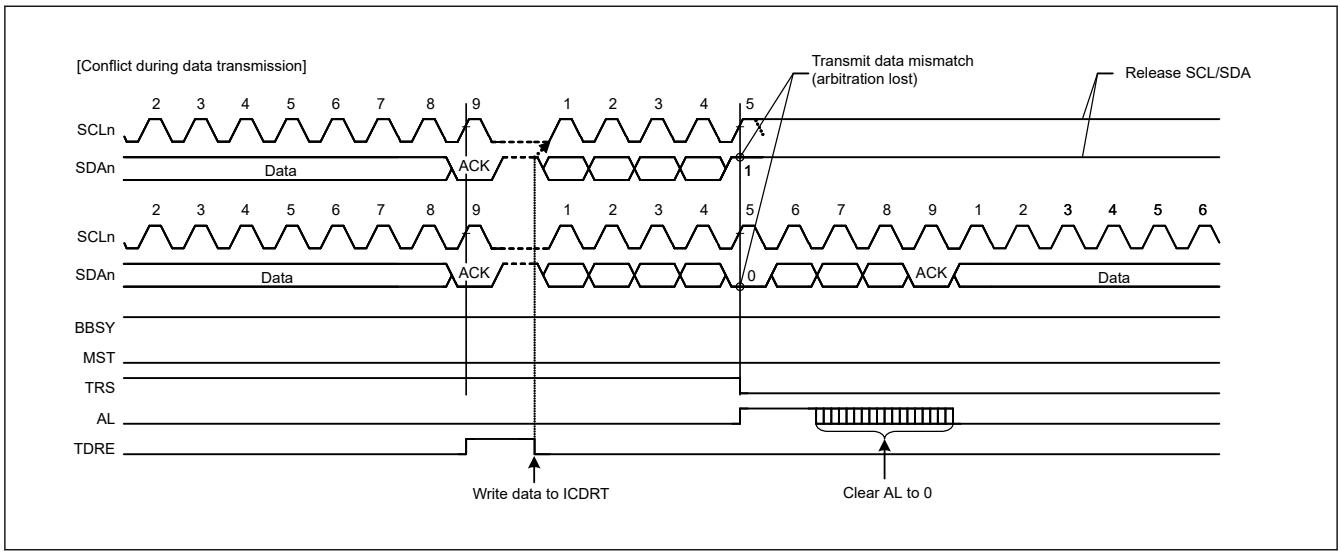

Figure 34.36 Example of slave arbitration-lost detection when SALE = 1

34.11 Start, Restart, and Stop Condition Issuing Function

34.11.1 Issuing a Start Condition

IIC issues a start condition when the ST bit in ICCR2 is set to 1. When the ST bit is set to 1, a start condition request is made, and IIC issues a start condition when the BBSY flag in ICCR2 is 0 (bus free state). When a start condition is issued normally, IIC automatically shifts to the master transmit mode.

To issue a start condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure that the time set in ICBRH and the start condition hold time elapse.
3. Drive the SCLn line low (high level to low level).
4. Detect low level on the SCLn line and ensure the low-level period of the SCLn line set in ICBRL elapses.

34.11.2 Issuing a Restart Condition

IIC issues a restart condition when the RS bit in ICCR2 is set to 1.

When the RS bit is set to 1, a restart condition request is made, and IIC issues a restart condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a restart condition:

1. Release the SDAn line.
2. Ensure that the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure the time set in ICBRL and the restart condition setup time elapse.
5. Drive the SDAn line low (high level to low level).
6. Ensure the time set in ICBRH and the restart condition hold time elapse.
7. Drive the SCLn line low (high level to low level).
8. Detect a low level on the SCLn line and ensure the low-level period of the SCLn line set in ICBRL elapses.

Note: When issuing restart condition requests, write the slave address to ICDRT after confirming that ICCR2.RS = 0. Data written while ICCR2.RS = 1 is not forwarded because of the retransmission condition before the occurrence.

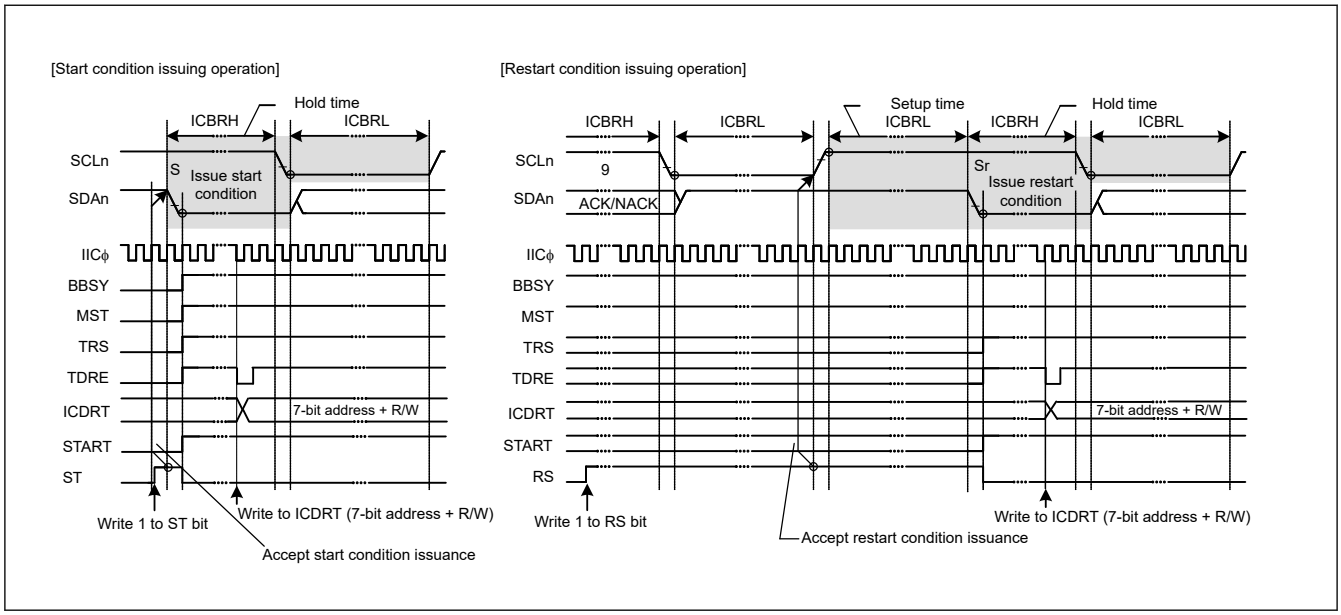

Figure 34.37 Start and restart condition issue timing using the ST and RS bits

Figure 34.38 shows the operation timing when a restart condition is issued after the master transmission.

To issue a restart condition after the master transmission:

1. Initialize the IIC using the details provided in section 34.4.2. Initial Settings.
2. Read the BBSY flag in IICR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition issuance request). On receiving the request, IIC issues a start condition. At the same time, the BBSY flag and the START flag in ICSR2 are automatically set to 1 and the ST bit automatically sets to 0. If the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1, IIC recognizes that a start condition is successfully issued as requested by the ST bit. The MST and TRS bits in ICCR2 automatically set to 1, placing IIC in master transmit mode. The TDRE flag in ICSR2 also automatically sets to 1 when the TRS bit is set to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. After the transmit data is written to ICDRT, the TDRE flag automatically sets to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again sets to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode according to the value of the transmitted R/W# bit. If the value of the R/W# bit is 0, IIC continues in master transmit mode. If the ICSR2.NACKF flag is 1 at this time, indicating that no slave device recognized the address or that there was an error in communications, write 1 to ICCR2.SP bit to issue a stop condition. To transmit data with an address in the 10-bit format, start by writing 11110b, the 2 upper bits of the slave address, and W to ICDRT as the first address transmission. Then, as the second address transmission, write the 8 lower bits of the slave address to ICDRT.
4. After confirming that the TDRE flag in ICSR2 is 1, write the data for transmission to the ICDRT register. IIC automatically holds the SCLn line low until the data for transmission is ready, and a restart or stop condition is issued.
5. After all bytes of data for transmission are written to the ICDRT register, wait until the value of the TEND flag in ICSR2 returns to 1. Then, after checking that the START flag in ICSR2 is 1, set the START flag in ICSR2 to 0.
6. Set the RS bit in ICCR2 to 1 (restart condition issuance request). Upon receiving the request, IIC issues a restart condition.
7. After checking that the START flag in ICSR2 is 1, write the value for transmission (the slave address and the R/W# bit) to ICDRT.

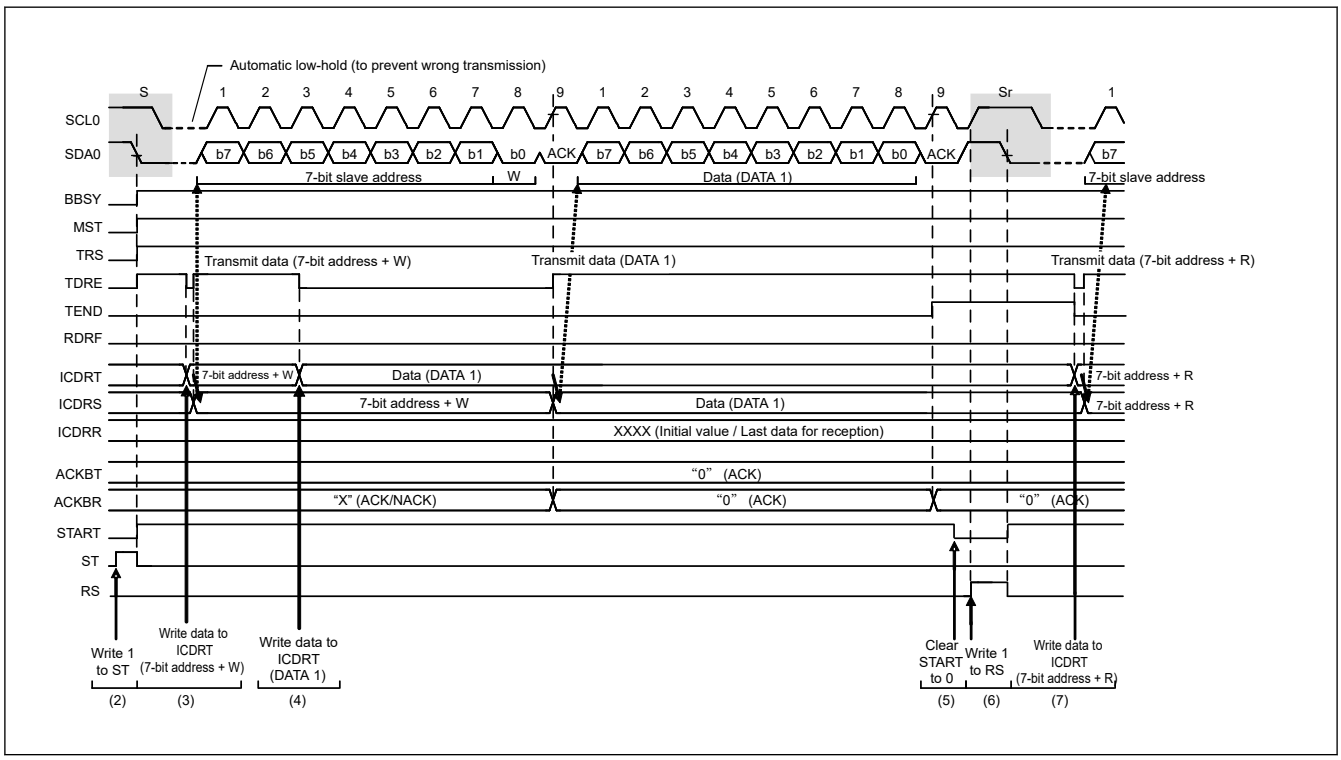

Figure 34.38 Restart condition issue timing after master transmission

34.11.3 Issuing a Stop Condition

IIC issues a stop condition when the SP bit in ICCR2 is set to 1. When the SP bit is set to 1, a stop condition request is made, and the IIC issues a stop condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a stop condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure that the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure that the time set in ICBRH and the stop condition setup time elapse.
5. Release the SDAn line (low level to high level).
6. Ensure the time set in ICBRL and the bus free time elapse.
7. Clear the BBSY flag to 0 to release the bus mastership.

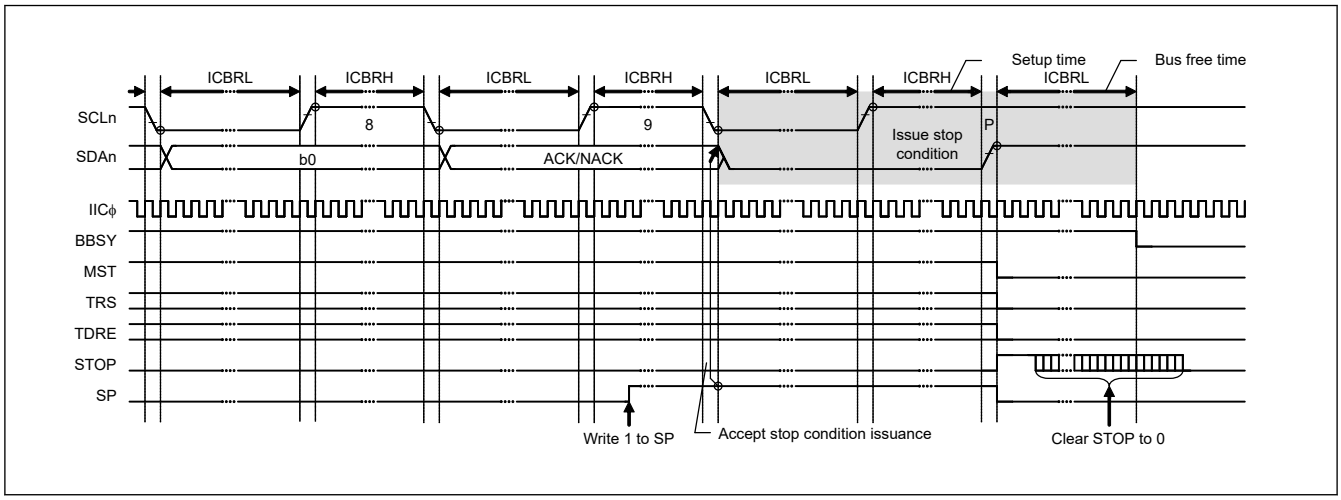

Figure 34.39 Stop condition issue timing using the SP bit

34.12 Bus Hanging

If the clock signals from the master and slave devices are out of synchronization because of noise or other factors, the I^2C bus might hang with a fixed level on the SCLn line or SDAn line.

To manage bus hanging, the IIC has the following:

- A timeout function to detect hanging by monitoring the SCLn line
- A function for the output of an extra SCL clock cycle to release the bus from a hung state because of clock signals being out of synchronization
- An IIC reset function
- An internal reset function

By checking the SCLO, SDAO, SCLI, and SDAI bits in ICCR1, it is possible to see whether the IIC or its communicating partner is placing the low level on the SCLn or SDAn lines.

34.12.1 Timeout Function

The timeout function can detect when the SCLn line is stuck longer than the predetermined time. IIC can detect an abnormal bus state by monitoring that the SCLn line is stuck low or high for a predetermined time.

The timeout function monitors the SCLn line state and counts the low-level or high-level period using the internal counter.

The timeout function resets the internal counter each time the SCLn line changes (rises or falls), but continues to count unless the SCLn line changes. If the internal counter overflows because no SCLn line changes, IIC can detect the timeout and report the bus hung state.

This timeout function is enabled when the ICFER.TMOE bit is 1. It detects a hung state when the SCLn line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1) in master mode (ICCR2.MST bit is 1)
- IIC slave address is detected (ICSR1 register is not 0x00) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0)
- The bus is free (ICCR2.BBSY flag is 0) while a start condition is requested (ICCR2.ST bit is 1)

The internal counter of the timeout function uses the internal reference clock (IICΦ) set in the CKS[2:0] bits in ICMR1 as a count source. It functions as a 16-bit counter when long mode is selected (TMOS bit = 0 in ICMR2) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCLn line level (low, high, or both levels) during which this counter is activated can be selected in the TMOH and TMOL bits in ICMR2. If both TMOL and TMOH bits are set to 0, the internal counter is disabled.

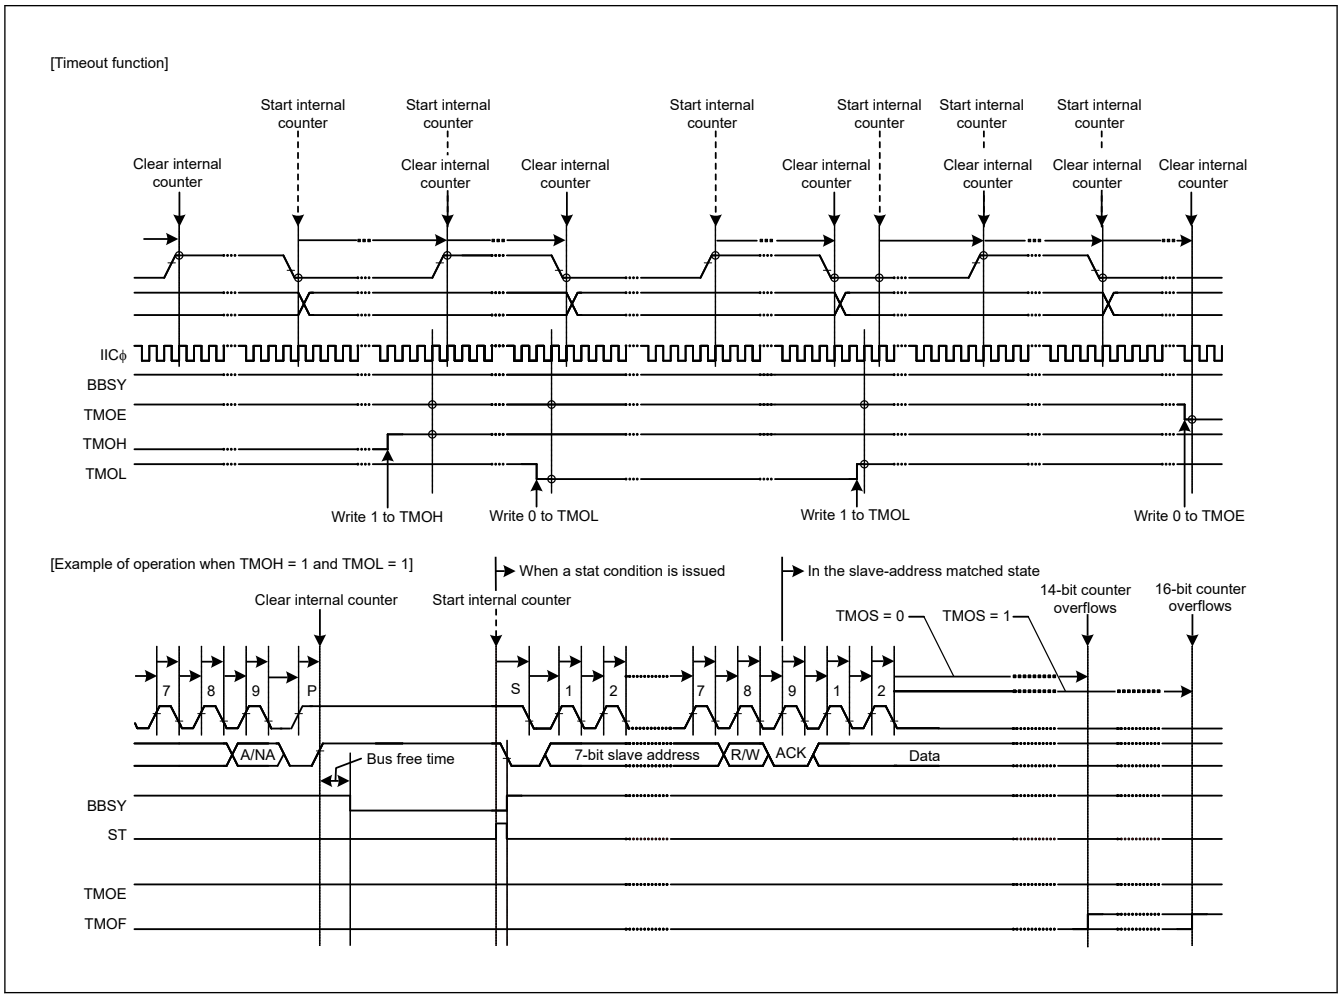

Figure 34.40 Timeout function using the TMOE, TMOS, TMOH, and TMOL bits

34.12.2 Extra SCL Clock Cycle Output Function

In master mode, this function outputs extra SCL clock cycles to release the SDAn line of the slave device from being held at the low level because the master is out of synchronization with the slave device.

This function is mainly used in master mode to release the SDAn line of the slave device from being fixed low by including extra cycles of SCL output from IIC. It uses single cycles of the SCL clock for a bus error where IIC cannot issue a stop condition because the slave device is holding the SDAn line at the low level. Do not use this function in normal situations.

Using it when communications are proceeding correctly leads to malfunctioning.

When the CLO bit in ICCR1 is set to 1 in master mode, a single cycle of the SCL clock at the transfer rate specified in the CKS[2:0] bits in ICMR1, and in the ICBRH and ICBRL registers, is output as an extra clock cycle. After output of this single cycle of the SCL clock, the CLO bit is automatically set to 0. More extra clock cycles can be output consecutively by writing 1 to the CLO bit through software after having read CLO = 0.

When the IIC module is in master mode and the slave device is holding the SDAn line at the low level because synchronization with the slave device is lost because of effects like noise, the output of a stop condition is not possible.

This function can be used to output extra cycles of SCL one by one to make the slave device release the SDAn line from being held at the low level, and recover the bus from an unusable state. Release of the SDAn line by the slave device can be monitored by reading the SDAI bit in ICCR1. After confirming the release of the SDAn line by the slave device, complete the communication by reissuing the stop condition.

Use this function with the MALE bit in ICFER set to 0 (master arbitration-lost detection disabled). If the MALE bit is set to 1 (enabled), arbitration is lost when the value of the SDAO bit in ICCR1 does not match the state of the SDAn line.

[Output conditions for using the CLO bit in ICCR1]

- When the bus is free (BBSY flag in ICCR2 = 0) or in master mode (MST bit = 1 and BBSY flag = 1 in ICCR2)
- When the communication device does not hold the SCLn line low.

Figure 34.41 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

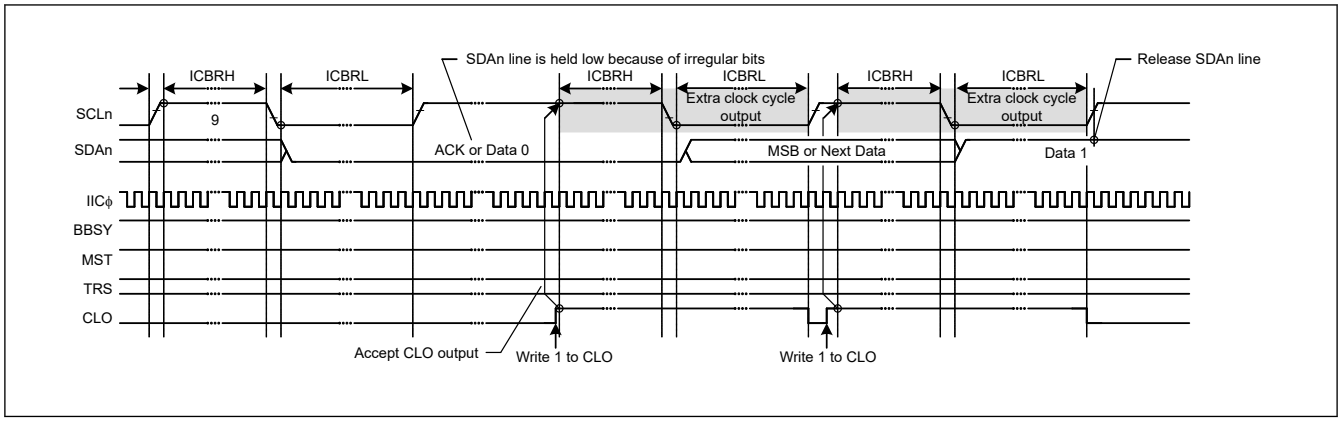

Figure 34.41 Extra SCL clock cycle output function using the CLO bit

34.12.3 IIC Reset and Internal Reset

The IIC module has two types of resets:

- IIC reset, which initializes all registers, including the BBSY flag in ICCR2
- Internal reset, which releases the IIC from the slave-address matched state and initializes the internal counter while saving other settings.

After issuing a reset, always set the IICRST bit in ICCR1 to 0.

Both types of resets are valid for release from bus-hung states, because both restore the output state of the SCLn and SDAn pins to the high-impedance state.

Issuing a reset during slave operation might lead to a loss of synchronization between the master device clock and the slave device clock, therefore, avoid this when possible. In addition, monitoring of the bus state, such as for the presence of a start condition, is not possible during an IIC reset (ICE and IICRST bits = 01b in ICCR1).

For a detailed description of the IIC and internal resets, see section 34.15. Resets, Registers, and Function States When Issuing Each Condition.

34.13 SMBus Operation

IIC supports data communication conforming to the SMBus Specification, version 2.0. To perform SMBus communication, set the SMBS bit in ICMR3 to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus standard, set the CKS[2:0] bits in ICMR1, ICBRH, and ICBRL. In addition, specify the values in the DLCS bit in ICMR2 and the

SDDL[2:0] bits in ICMR2 to meet the data hold time specification of 300 ns or more. When the IIC is used only as a slave device, the transfer rate setting is not required, but ICBRL must be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001b), use one of the slave address registers L0 to L2 (SARL0, SARL1, and SARL2), and set the associated FS bit (7- or 10-bit address format select) in SARUy (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the SALE bit in ICFER to 1 to enable the slave arbitration-lost detection function.

34.13.1 SMBus Timeout Measurement

(1) Measuring slave device timeout

The following period (timeout interval: $T_{LOW:\ SEXT}$) must be measured for slave devices in SMBus communication:

- From start condition to stop condition

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the internal timer using the IIC start condition detection interrupt (STIn) and stop condition detection interrupt (SPIn). The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:\ SEXT}$: 25 ms (maximum) of the SMBus standard.

If the time measured with the internal timer exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the slave device must release the bus by writing 1 to the IICRST bit in ICCR1 to issue an internal reset of the IIC. When an internal reset is issued, the IIC stops driving the bus for the SCLn and SDAn pins and makes the SCLn/SDAn pin output high-impedance, which releases the bus.

(2) Measuring master device timeout

The following periods (timeout interval: $T_{LOW:\ MEXT}$) must be measured for master devices in SMBus communication:

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition

To measure timeout for master devices, measure these periods with the internal timer using the IIC start condition detection interrupt (STIn), stop condition detection interrupt (SPIn), transmit end interrupt (IICn_TEI), or receive data full interrupt (IICn_RXI). The measured timeout period must be within the total clock low-level extended period (master device) $T_{LOW:\ MEXT}$: 10 ms (maximum) of the SMBus standard, and the total of all $T_{LOW:\ MEXT}$ values from the start condition to stop condition must be within $T_{LOW:\ SEXT}$: 25 ms (maximum).

For the ACK receive timing (rising edge of the 9th SCL clock cycle), monitor the TEND flag in ICSR2 in master transmit mode (master transmitter) and the RDRF flag in ICSR2 in master receive mode (master receiver). Perform byte-wise transmit operations in master transmit mode, and hold the RDRFS bit in ICMR3 at 0 until the byte immediately before the reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

If the period measured with internal timer exceeds the total clock low-level extended period (master device), $T_{LOW:\ MEXT}$: 10 ms (maximum) of the SMBus standard or the total of measured periods exceeds the clock low-level detection timeout, $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (stop writing data to ICDRT).

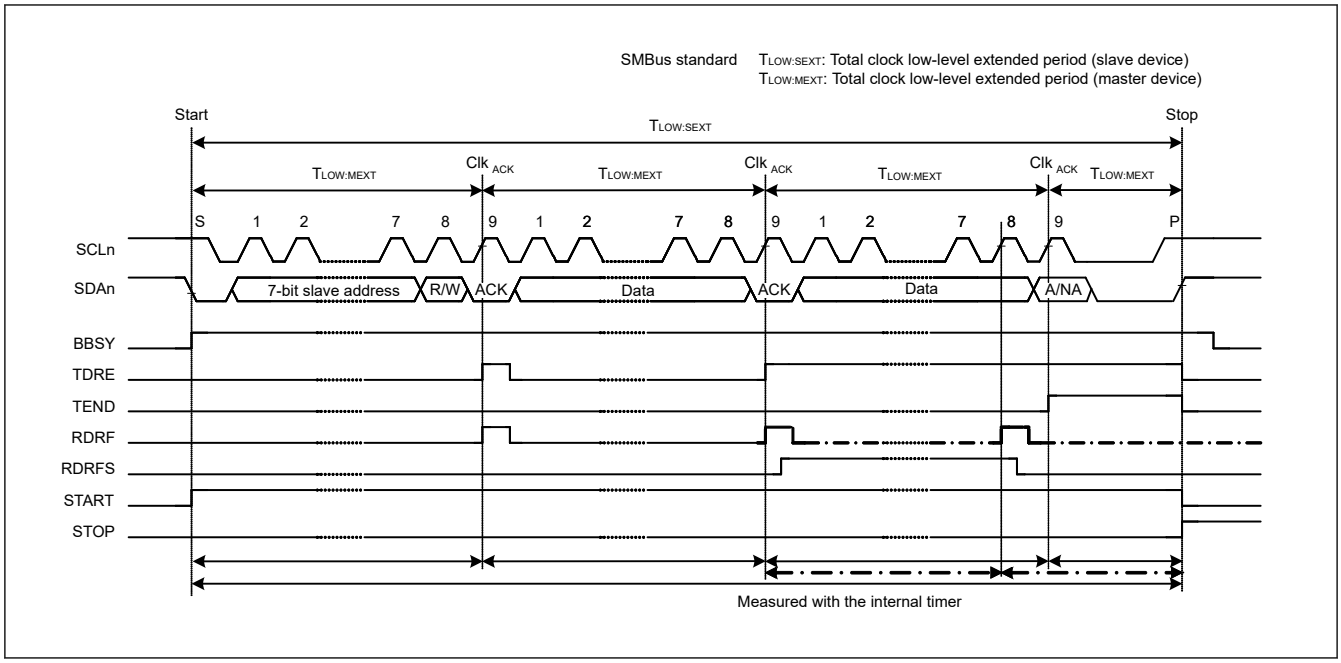

Figure 34.42 SMBus timeout measurement

34.13.2 Packet Error Code (PEC)

The LSI provides a CRC calculator, which enables transmission of a packet error code (PEC) or allows checking the received data in SMBus data communication for the IIC. For the CRC-generating polynomials of the CRC calculator, see section 38, CRC Operation Unit (CRC).

In master transmit mode, the PEC data can be generated by writing all transmit data to the CRC Data Input register (CRCDIR) in the CRC calculator.

In master receive mode, the PEC data can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC Data Output Register (CRCDOR) with the received PEC data.

To send ACK or NACK based on the match or mismatch result when the final byte is received as a result of the PEC code check, set the RDRFS bit in ICMR3 to 1 before the rising edge of the 8th SCL clock cycle during reception of the final byte, and hold the SCLn line low on the falling edge of the 8th clock cycle.

34.13.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address or to request its own slave address from the SMBus host.

For a product using the LSI to operate as an SMBus host or ARP master, the host address (0001 000b) sent from the slave device must be detected as a slave address, and so the IIC has a function for detecting the host address. To detect the host address as a slave address, set the SMBS bit in ICMR3 and the HOAE bit in ICSER to 1. Operation after the host address is detected is the same as normal slave operation.

34.14 Interrupt Sources

The IIC issues four types of interrupt requests:

- Transfer error or event occurrence (detection of arbitration-lost, NACK, timeout, start or restart condition, or stop condition)
- Receive data full
- Transmit data empty
- Transmit end

Table 34.11 lists details about the interrupt requests. The receive data full and transmit data empty interrupts can activate data transfer by the DMAC.

Table 34.11 Interrupt sources

Symbol	Interrupt source	Interrupt flag	DMAC activation	Interrupt condition
IICn_EEI*4	Transfer error or event generation	AL	Not possible	AL = 1, ALIE = 1
		NACKF		NACKF = 1, NAKIE = 1
		TMOF		TMOF = 1, TMOIE = 1
		START		START = 1, STIE = 1
		STOP		STOP = 1, SPIE = 1
IICn_RXI*2 *4	Receive data full	RDRF	Possible	RDRF = 1, RIE = 1
IICn_TXI*1 *4	Transmit data empty	TDRE	Possible	TDRE = 1, TIE = 1
IICn_TEI*3 *4	Transmit end	TEND	Not possible	TEND = 1, TEIE = 1

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. When an interrupt flag is cleared or masked, read the relevant flag again to check whether clearing or masking is complete, and then return from interrupt handling. Not doing so creates the possibility of repeated processing of the same interrupt.
Note 1. Because IICn_TXI is an edge-detected interrupt, it does not require clearing. Additionally, the TDRE flag in ICSR2 (condition for IICn_TXI) is automatically set to 0 when transmit data is written to ICDRT or a stop condition is detected (STOP flag = 1 in ICSR2).
Note 2. Because IICn_RXI is an edge-detected interrupt, it does not require clearing. Additionally, the RDRF flag in ICSR2 (condition for IICn_RXI) automatically is set to 0 when data is read from ICDRR.
Note 3. When using the IICn_TEI interrupt, clear the TEND flag in ICSR2 in the IICn_TEI interrupt handling. The TEND flag in ICSR2 automatically is set to 0 when transmit data is written to ICDRT or a stop condition is detected (STOP flag = 1 in ICSR2).
Note 4. Channel number (n = 0 to 2).

Clear or mask each flag during interrupt handling.

34.15 Resets, Registers, and Function States When Issuing Each Condition

IIC provides chip reset, IIC reset, and internal reset functions. Table 34.12 lists the IIC resets, registers, and function states when issuing each condition.

Table 34.12 Resets, registers, and function states when issuing each condition (1 of 2)

Registers		Chip reset	IIC reset (ICE = 0, IICRST = 1)	Internal reset (ICE = 1, IICRST = 1)	Start or restart condition detection	Stop condition detection

34.16 Usage Notes

34.16.1 Settings for the Module-Stop Function

IIC operation can be disabled or enabled using Module Stop Control Register G (MSTPCRG01). IIC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 9, Low-Power Consumption Function.

35. CAN-FD Interface (CANFD)

35.1 Overview

The LSI has a 2-channel CAN-FD module (CANFD) that complies with ISO 11898-1 (2015) Standards. CANFD transmits and receives both formats of messages, namely the standard identifier (11 bits) (identifier is hereafter referred to as ID) and extended ID (29 bits). Table 35.1 lists the specifications of the CANFD, Figure 35.1 shows a block diagram of the CANFD, and Table 35.2 lists the I/O pins.

Table 35.1 CANFD specifications (1 of 2)

Parameter	Description
Number of channels	Two channels
Protocol	CAN-FD ISO 11898-1 (2015)
Communication speed	• Classical CAN mode: 1 Mbps • CAN FD mode Nominal bit rate: max. 1 Mbps Data bit rate: max. 8 Mbps
Buffer	Total 192 buffers (when frame size is 76 bytes) • Individual buffers: 64 buffers (32 buffers × 2 channels) Transmit buffer: 32 buffers per channel Transmit queue: 4 queues per channel (shared with transmit buffer, up to 16 buffers allocatable) • Shared buffers: 128 buffers for all channels Receive buffer: 0 to 32 buffers Receive FIFO buffer: 8 FIFO buffers (up to 128 buffers allocatable to each) Transmit/receive FIFO buffer: 3 FIFO buffers per channel (up to 128 buffers allocatable to each)
Reception function	• Receives data frames and remote frames • Selects ID format (standard ID, extended ID, or both IDs) to be received • Sets interrupt enable/disable for each FIFO • Mirror function (reception of messages transmitted from the CAN node itself) • Timestamp function (to record message reception time as a 16-bit timer value)
Reception filter function	• Selects receive message according to 256 receive rules • Sets the number of receive rules (0 to 255) for each channel • Acceptance filter processing: Sets ID and mask for each receive rule • DLC filter processing: Enables DLC filter check for each acceptance rule
Receive message transfer function	• Routing function Transfers receive messages to arbitrary destinations (can be transferred to up to 8 buffers) Transfer destination: Receive buffer, receive FIFO buffer, and/or transmit/receive FIFO buffer • Label addition function Stores label information together with a message in a receive buffer and FIFO buffer
Transmission function	• Transmits data frames and remote frames • Selects ID format (standard ID, extended ID, or both IDs) to be transmitted • Sets interrupt enable/disable for each transmit buffer and transmit/receive FIFO buffer • Selects ID priority transmission or transmit buffer number priority transmission • Transmit request can be aborted (possible to confirm with a flag) • One-shot transmission function
Interval transmission function	Transmit message at configurable intervals (transmit mode or gateway mode of transmit/receive FIFO buffers)
Transmit ques function	Transmits all stored messages according to the ID priority
Transmit history function	Stores the history information of transmission-completed messages Adds timestamp (recording message transmission time as a 16-bit timer value) to the history information
Gateway function	Transmits a received message automatically

Table 35.1 CANFD specifications (2 of 2)

Parameter	Description
Bus off recovery mode selection	Selects the method for returning from bus-off state. ● ISO 11898-1 compliant ● Automatic entry to channel halt mode at bus-off entry ● Automatic entry to channel halt mode at bus-off end ● Transition to channel halt mode by program request ● Transition to the error-active state by program request (forcible return from the bus-off state)
Error status monitoring	● Monitors CAN protocol errors (stuff error, from error, ACK error, CRC error, bit error, ACK delimiter error, and bus dominant lock) ● Defects error status transitions (error warning, error passive, bus-off entry, and bus-off recovery) ● Reads the error counter ● Monitors DLC errors
Interrupt source	8 interrupt sources ● Global interrupts (2 sources) RX FIFO interrupt Global error interrupt ● Channel interrupts (3 sources/channel) Channel transmit interrupt Channel error interrupt Common RX FIFO interrupt 10 DMA requests ● 8 for RX FIFO ● 2 for the first common FIFO (1 source/channel)
CAN clock source	Selects the PCLKM or the PCLKCAN (40 MHz or 80 MHz)
Test function	Test function for user evaluation ● Listen-only mode ● Self-test mode 0 (external loopback) ● Self-test mode 1 (internal loopback) ● Restricted operation mode ● RAM test (read/write test) ● Inter-channel communication test (CRC error test enabled)
Low-power consumption function	Module-stop state can be set to reduce power consumption

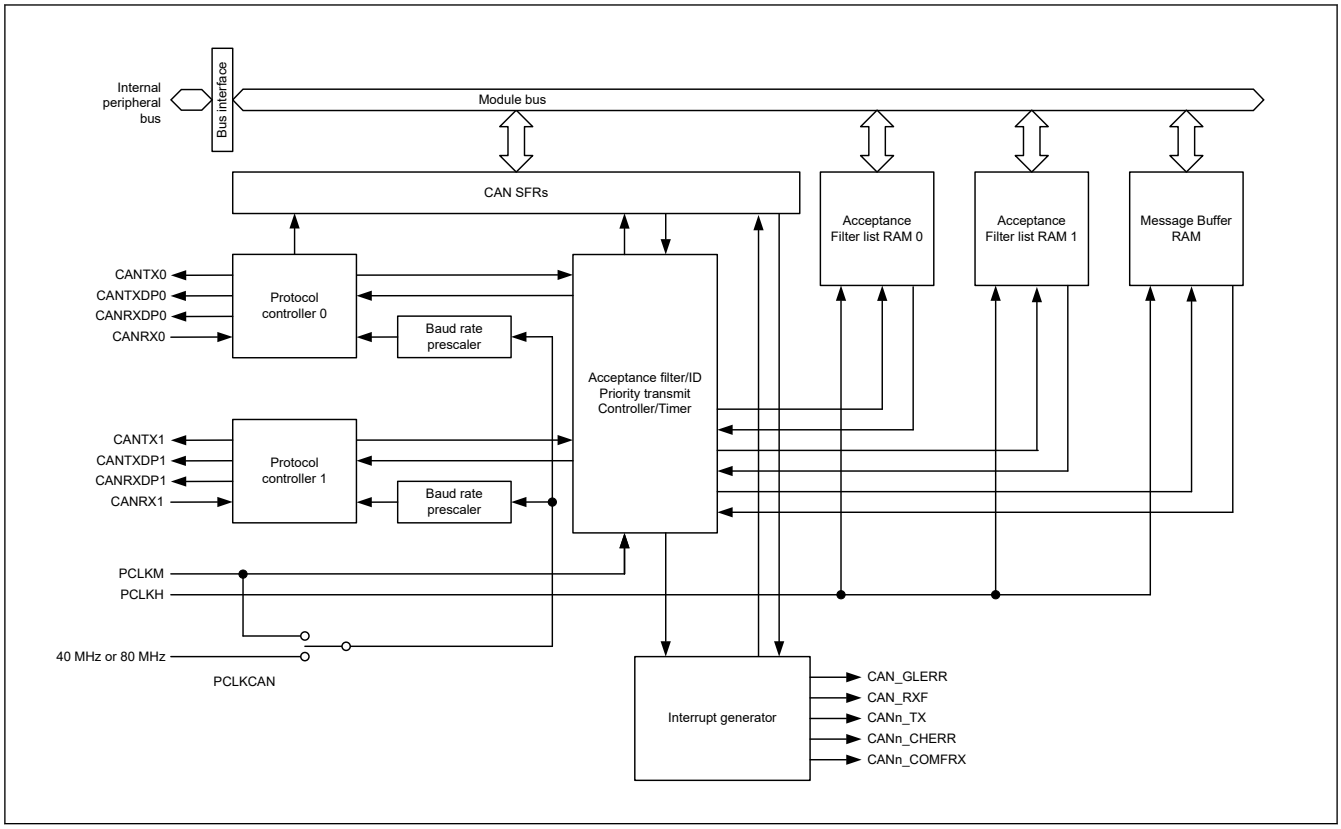

Figure 35.1 Block diagram of CANFD

Table 35.2 lists the input/output pins of the CANFD module.

Table 35.2 Pin configuration of CANFD

Channel	Pin name	I/O	Function
CAN0	CANRX0	Input	CAN0 receive data input
	CANTX0	Output	CAN0 transmit data output
	CANRXDP0	Output	CAN0 receive data phase output
	CANTXDP0	Output	CAN0 transmit data phase output
CAN1	CANRX1	Input	CAN1 receive data input
	CANTX1	Output	CAN1 transmit data output
	CANRXDP1	Output	CAN1 receive data phase output
	CANTXDP1	Output	CAN1 transmit data phase output

Table 35.3 CANFD interrupt sources

Name	Interrupt sources
CAN_RXF	RX FIFO interrupt
CAN_GLERR	Global error interrupt
CAN_RF_DMAREQm	RX FIFO m DMA request
CANn_TX	Channel n TX interrupt
CANn_CHERR	Channel n CAN error interrupt
CANn_COMFRX	Channel n Common RX FIFO or TXQ interrupt
CANn_CF_DMAREQ	Channel n First common FIFO DMA request

Note: m = 0 to 7, n = 0, 1

35.3 Register Descriptions

35.3.1 CFDCnNCFG : Channel n Nominal Bit Rate Configuration Register (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x0000 + 0x10 × n

Bit position:	31						25	24						17	16						10	9						0
Bit field:	NTSEG2[6:0]							NTSEG1[7:0]								NSJW[6:0]							NBRP[9:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	NBRP[9:0]	Nominal Bit Rate Prescaler Nominal bit rate prescaler division ratio setting	R/W
16:10	NSJW[6:0]	Nominal Bit Rate Resynchronization Jump Width Control 0x00: Setting prohibited 0x01: 2 Tq ⋮ 0x7E: 127 Tq 0x7F: 128 Tq	R/W
24:17	NTSEG1[7:0]	Nominal Bit Rate Time Segment 1 Control 0x00: Setting prohibited 0x01: 2 Tq 0x02: 3 Tq ⋮ 0xFE: 255 Tq 0xFF: 256 Tq	R/W
31:25	NTSEG2[6:0]	Nominal Bit Rate Time Segment 2 Control 0x00: Setting prohibited 0x01: 2 Tq ⋮ 0x7E: 127 Tq 0x7F: 128 Tq	R/W

The CFDCnNCFG register is used to configure the transmission/reception nominal bit rate parameters of the channels. Do not write this register in CH_OPERATION or CH_SLEEP mode. Set this register in CH_RESET or CH_HALT mode.

NBRP[9:0] bits (Nominal Bit Rate Prescaler)

The NBRP[9:0] bits are used to define the peripheral bus clock periods contained in a time quantum.

NSJW[6:0] bits (Nominal Bit Rate Resynchronization Jump Width Control)

The NSJW[6:0] bits set the synchronization jump width. A value from 1 to 128 time quanta can be set.

NTSEG1[7:0] bits (Nominal Bit Rate Time Segment 1 Control)

The NTSEG1[7:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. These bits contain the propagation segment. Configure a Tq value only between 2 and 256, inclusive. See section 35.5.1.2. CAN Bit Timing for more details.

NTSEG2[6:0] bits (Nominal Bit Rate Time Segment 2 Control)

The NTSEG2[6:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error. Configure a Tq value only between 2 and 128, inclusive.

35.3.2 CFDCnCTR : Channel n Control Register (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x0004 + 0x10 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ROM	CRCT	—	—	—	CTMS[1:0]		CTME	ERRD	BOM[1:0]		—	TDCVFIE	SOCOIE	EOCOIE	TAIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ALIE	BLIE	OLIE	BORIE	BOEIE	EPIE	EWIE	BEIE	—	—	—	—	RTBO	CSLPR	CHMDC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Function	R/W
1:0	CHMDC[1:0]	Mode Select 0 0: Channel Communication mode 0 1: Channel Reset mode 1 0: Channel Halt mode 1 1: Setting prohibited	R/W
2	CSLPR	Channel Stop Mode 0: Other than Channel Stop mode 1: Channel Stop mode	R/W
3	RTBO	Forcible Return from Bus-Off When this bit is set to 1, forcible return from the bus-off state is made. This bit is always read as 0.	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	BEIE	Bus Error Interrupt Enable 0: Bus error interrupt disabled 1: Bus error interrupt enabled	R/W
9	EWIE	Error Warning Interrupt Enable 0: Error warning interrupt disabled 1: Error warning interrupt enabled	R/W
10	EPIE	Error Passive Interrupt Enable 0: Error passive interrupt disabled 1: Error passive interrupt enabled	R/W
11	BOEIE	Bus-Off Entry Interrupt Enable 0: Bus-off entry interrupt disabled 1: Bus-off entry interrupt enabled	R/W

Bit	Symbol	Function	R/W
12	BORIE	Bus-Off Recovery Interrupt Enable 0: Bus-off recovery interrupt disabled 1: Bus-off recovery interrupt enabled	R/W
13	OLIE	Overload Interrupt Enable 0: Overload interrupt disabled 1: Overload interrupt enabled	R/W
14	BLIE	Bus Lock Interrupt Enable 0: Bus lock interrupt disabled 1: Bus lock interrupt enabled	R/W
15	ALIE	Arbitration Lost Interrupt Enable 0: Arbitration lost interrupt disabled 1: Arbitration lost interrupt enabled	R/W
16	TAIE	Transmission Abort Interrupt Enable 0: Transmission abort interrupt disabled 1: Transmission abort interrupt enabled	R/W
17	EOCOIE	Error Occurrence Counter Overflow Interrupt Enable 0: Error occurrence counter overflow interrupt disabled 1: Error occurrence counter overflow interrupt enabled	R/W
18	SOCOIE	Successful Occurrence Counter Overflow Interrupt Enable 0: Successful occurrence counter overflow interrupt disabled 1: Successful occurrence counter overflow interrupt enabled	R/W
19	TDCVFIE*1	Transceiver Delay Compensation Violation Interrupt Enable 0: Transceiver delay compensation violation interrupt disabled 1: Transceiver delay compensation violation interrupt enabled	R/W
20	—	This bit is read as 0. The write value should be 0.	R/W
22:21	BOM[1:0]	Bus-Off Recovery Mode Select 0 0: ISO11898-1 compliant 0 1: Entry to Channel Halt mode automatically at bus-off entry 1 0: Entry to Channel Halt mode automatically at bus-off end 1 1: Entry to Channel Halt mode (in bus-off state) by program request	R/W
23	ERRD	Error Display Mode Select 0: Error flags are displayed only for the first error information after bits [14:8] in the CFDCnERFL register are all cleared 1: Error flag for all error information are displayed	R/W
24	CTME	Communication Test Mode Enable 0: Communication test mode is disabled 1: Communication test mode is enabled	R/W
26:25	CTMS[1:0]	Communication Test Mode Select 0 0: Standard test mode 0 1: Listen-only mode 1 0: Self-test mode 0 (External loopback mode) 1 1: Self-test mode 1 (Internal loopback mode)	R/W
29:27	—	These bits are read as 0. The write value should be 0.	R/W
30	CRCT	CRC Error Test Enable 0: The first bit of reception ID field is not inverted 1: The first bit of reception ID field is inverted	R/W
31	ROM*1	Restricted Operation Mode Enable 0: Restricted operation mode disabled 1: Restricted operation mode enabled	R/W

Note 1. These bits are not available in the classical CAN function.

The CFDCnCTR register controls the modes of the related channel. It is used to enable generation of interrupts if errors are detected on the CAN bus connected to this channel. It is also used to configure the channel in test mode.

CHMDC[1:0] bits (Mode Select)

The CHMDC[1:0] bits can be used to configure modes of the CAN channel.

CAN mode transitions are described in more details in section 35.4.3. Channel Modes.

Setting CHMDC[1:0] bits to 11b has no effect. When the CAN-FD module is in GL_HALT mode, these bits can only be set to 10b or 01b. These bits cannot be set in CH_SLEEP mode.

These bits can change automatically when transitioning to Halt mode by the CFDCnCTR.BOM settings.

If CPU write access to CFDCnCTR.CHMDC occurs at the same time when the CAN channel enters Halt mode (at the start of bus-off when CFDCnCTR.BOM[1:0] = 01b, or at the end of bus-off when CFDCnCTR.BOM[1:0] = 10b), then the CPU write access has the highest priority.

The CAN channel changes the value of CFDCnCTR.CHMDC within the Channel Control Registers for the specified cases only if the CFDCnCTR.CHMDC[1:0] value is 00b (Operation mode).

CSLPR bit (Channel Stop Mode)

When the CSLPR bit is 1, a Sleep mode request is generated for the corresponding CAN channel

When this bit is 0, a request to exit Sleep mode is generated for the related CAN-FD channel.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

RTBO bit (Forcible Return from Bus-Off)

When the protocol controller of the CAN channel enters bus-off state, you can force a recovery from bus-off state by setting the RTBO bit in the Channel Control Register to 1.

The error state changes from bus-off state to integrating with a maximum delay of 1 CAN bit time.

When the RTBO bit is set to 1, the REC and TEC registers are initialized and the Bus-Off Status bit (Channel Bus-off Status, CFDCnSTS.BOSTS) is set to 0.

Registers other than the REC and TEC registers are not initialized by this command. Even if CFDCnCTR.BORIE is set, a bus-off recovery interrupt is not generated by this recovery from the bus-off state.

The RTBO bit cannot be set in CH_SLEEP mode. Setting this bit in any state other than bus-off state has no effect and the bit is cleared immediately. The read value is always 0.

Return from the Bus-Off command should be used only when CFDCnCTR.BOM[1:0] is set to 00b.

Only write to this bit when the related CAN-FD channel is in CH_OPERATION mode. This bit is automatically cleared when set by software.

BEIE bit (Bus Error Interrupt Enable)

When the BEIE and the CFDCnERFL.BEF bits are both 1, an error interrupt request is generated.

This bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

EWIE bit (Error Warning Interrupt Enable)

When the EWIE and the CFDCnERFL.EWF bits are both 1, an error interrupt request is generated.

The EWIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

EPIE bit (Error Passive Interrupt Enable)

An error interrupt request is generated when the EPIE bit and the CFDCnERFL.EPF are both 1.

The EPIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

BOEIE bit (Bus-Off Entry Interrupt Enable)

When the BOEIE and the CFDCnERFL.BOEF bits are both 1, an error interrupt request is generated.

The BOEIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

BORIE bit (Bus-Off Recovery Interrupt Enable)

When the BORIE and the CFDCnERFL.BORF bits are both 1, an error interrupt request is generated.

The BORIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

OLIE bit (Overload Interrupt Enable)

When the OLIE and the CFDCnERFL.OVLF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

BLIE bit (Bus Lock Interrupt Enable)

When the BLIE and the CFDCnERFL.BLF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

ALIE bit (Arbitration Lost Interrupt Enable)

When the ALIE and the CFDCnERFL.ALF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

TAIE bit (Transmission Abort Interrupt Enable)

When the TAIE bit is 1 and a transmission is successfully aborted from the transmit buffer, an interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

EOCOIE bit (Error Occurrence Counter Overflow Interrupt Enable)

When the EOCOIE bit is 1 and the CFDCnFDSTS.EOCO bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The EOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

SOCOIE bit (Successful Occurrence Counter Overflow Interrupt Enable)

When the SOCOIE bit is 1 and the CFDCnFDSTS.SOCO bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The SOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

TDCVFIE bit (Transceiver Delay Compensation Violation Interrupt Enable)

When the TDCVFIE bit is 1 and the CFDCnFDSTS.TDCVF bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The TDCVFIE bit cannot be set in CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET mode. Do not set this bit when in Classical-only mode.

Note: This bit is not available in the classical CAN function.

BOM[1:0] bits (Bus-Off Recovery Mode Select)

The BOM[1:0] bits control the timing of the recovery from Bus-Off mode of the CAN-FD Channel.

Do not write to these bits in CH_SLEEP mode. Only write to these bits when the related CAN-FD channel is in CH_RESET mode.

ERRD bit (Error Display Mode Select)

The ERRD bit controls the display mode of the error flag bits [14:8] in the Channel Error Flag Register (CFDCnERFL).

If the ERRD bit is 0 and more than one errors occur at the same time, the error flag bits are set for all the errors that occurred at the same time. No further errors are flagged until the error flag bits [14:8] are cleared.

Do not write to the ERRD bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

CTME bit (Communication Test Mode Enable)

The CTME bit enables the channel test modes.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_HALT mode.

CTMS[1:0] bits (Communication Test Mode Select)

The CTMS[1:0] bits are used to select the required test mode.

Do not write to these bits in CH_SLEEP or CH_RESET mode. Only write to these bits when the related CAN-FD channel is in CH_HALT mode.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

CRCT bit (CRC Error Test Enable)

The CRCT bit checks the internal CRC generator logic of the protocol controller.

This bit inverts the first bit (ID bit) of the CAN message data stream that is being received, so that the internal generated CRC result does not match the received CRC value of the frame. Refer to the bit stuffing rule when using this feature for the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The internal generated CRC value is always observed in the following registers:

- CFDCnERFL.CRCREG (classical CAN frames)
- CFDCnFDCRC.CRCREG (CAN-FD frames)

Some limitations exist when using this bit:

- It is not possible to use this feature with CAN nodes connected to the device externally, only with nodes connected to the internal CAN bus communication can be used
- One CAN node can send a reference message and the receiver node can invert one bit of the incoming bit stream

Note: The transmitter and receiver modes share the same CRC generator, therefore it is not necessary to consider the modes separately when testing this limitation.

The CRC Error Test mode is enabled if the CRCT (new control signal that inverts the first bit of the bit stream) and CTME bits are both 1.

Do not write to the CRCT bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_HALT mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

ROM bit (Restricted Operation Mode Enable)

When the ROM and CTME bits are both 1, the restricted operation mode is enabled. This mode should only be used in basic test mode (CFDCnCTR.CTMS[1:0] = 00b).

The ROM bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_HALT mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. Do not set this bit when in Classical-only mode.

Note: This bit is not available in the classical CAN function.

35.3.3 CFDCnSTS : Channel n Status Register (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x0008 + 0x10 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TEC[7:0]								REC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ESIF	COMSTS	RECSTS	TRMSTS	BOSTS	EPSTS	CSLPSTS	CHLTSTS	CRSTSTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Function	R/W
0	CRSTSTS	Channel Reset Status Flag 0: Not in Channel Reset mode 1: In Channel Reset mode	R
1	CHLTSTS	Channel Halt Status Flag 0: Not in Channel Halt mode 1: In Channel Halt mode	R
2	CSLPSTS	Channel Stop Status Flag 0: Not in Channel Sleep mode 1: In Channel Sleep mode	R
3	EPSTS	Error Passive Status Flag 0: Not in error passive state 1: In error passive state	R
4	BOSTS	Bus-Off Status Flag 0: Not in bus-off state 1: In bus-off state	R
5	TRMSTS	Transmit Status Flag 0: Bus idle or in reception 1: In transmission or bus off state	R
6	RECSTS	Receive Status Flag 0: Bus idle, in transmission or bus off state 1: In reception	R
7	COMSTS	Communication Status Flag 0: Communication is not ready 1: Communication is ready	R
8	ESIF*1	Error State Indication Flag 0: No CANFD message whose ESI bit is recessive has been received 1: At least one CANFD message whose ESI bit is recessive has been received	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
23:16	REC[7:0]	Reception Error Count The receive error counter (REC) can be read.	R
31:24	TEC[7:0]	Transmission Error Count The transmit error counter (TEC) can be read.	R

Note 1. This bit is not available in the classical CAN function.

The CFDCnSTS register shows the mode, error, and transmission/reception status of the related channel together with its reception and transmission error count values.

CRSTSTS bit (Channel Reset Status Flag)

The CRSTSTS bit indicates whether the related CAN channel is in Reset mode.

This bit is set automatically when the related CAN channel enters Channel Reset mode. When the mode is changed from Reset mode to Sleep mode, the CRSTSTS bit remains 1.

This bit is cleared automatically when the related CAN channel exits the Channel Reset mode, except when changing to Sleep mode.

CHLTSTS bit (Channel Halt Status Flag)

The CHLTSTS bit indicates whether the related CAN channel is in Halt mode.

This bit is set automatically when the related CAN module enters Halt mode, and is cleared automatically when the related CAN module exits Halt mode.

CSLPSTS bit (Channel Stop Status Flag)

The CSLPSTS bit indicates whether the related CAN channel is in Sleep mode.

This bit is set automatically when the related CAN-FD channel enters Sleep mode, and is cleared automatically when the related CAN-FD channel exits Sleep mode.

EPSTS bit (Error Passive Status Flag)

The EPSTS bit indicates whether the related CAN-FD channel has entered the error passive state.

This bit is set automatically when the value of the CAN Transmission or Reception Counter Register exceeds the value of 0x7F.

This bit is cleared automatically when the related CAN-FD channel exits the error passive state or enters Reset mode.

BOSTS bit (Bus-Off Status Flag)

The BOSTS bit indicates whether the related CAN-FD channel has entered the error bus-off state.

This bit is set automatically when the value of the related CAN Transmission Error Count Register exceeds 0xFF and the related CAN-FD channel is in the bus-off state (CAN Transmission Error Count Register > 0xFF).

This bit is cleared automatically when the related CAN-FD channel exits bus-off state.

TRMSTS bit (Transmit Status Flag)

The TRMSTS bit indicates whether the related CAN-FD channel is transmitting a message.

This bit is set automatically when the related CAN-FD channel is operating as a transmitter node or is in the bus-off state.

This bit is cleared automatically when the related CAN-FD channel is in the bus-idle state or starts operating as a receiver node.

RECSTS bit (Receive Status Flag)

The RECSTS bit indicates whether the related CAN-FD channel is receiving a message.

This bit is set automatically when the related CAN-FD channel is operating as a receiver node.

This bit is cleared automatically when the related CAN-FD channel is in the bus-idle state or starts operating as a transmitter node.

COMSTS bit (Communication Status Flag)

The COMSTS bit indicates whether the related CAN-FD channel is ready for communication.

This bit is set automatically when the related CAN-FD channel is ready to perform communication following the detection of 11 consecutive recessive bits after exiting the Reset or Halt mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

Note: This bit is 1 during bus-off state.

ESIF bit (Error State Indication Flag)

The ESIF bit is set when the ESI bit is sampled recessive for a reception CAN message without any error. When in Loopback or Mirror mode, the self-transmitted messages are considered reception messages.

If a set from the CAN-FD channel occurs simultaneously with a clear by a write access, then the bit is set.

This bit is cleared by writing 0 to it. This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Note: This bit is not available in the classical CAN function.

REC[7:0] bits (Reception Error Count)

The REC[7:0] bits increment or decrement the counter value according to error status of the CAN-FD channel during reception, and display the value of the REC error counter.

The value in bus-off state is indeterminate.

These bits are cleared automatically when the CAN-FD module enters GL_RESET or the CAN-FD channel is in CH_RESET mode.

TEC[7:0] bits (Transmission Error Count)

The TEC[7:0] bits increment or decrement the counter value according to error status of the CAN-FD channel during transmission, and display the value of the TEC error counter.

Only write to these bits when in test mode and CAN-FD channel is in CH_HALT mode.

Do not read data from this register while CFDCnCTR.TRWE is set.

These bits are cleared automatically when CAN-FD module is in GL_RESET or CAN-FD channel is in CH_RESET mode.

35.3.4 CFDCnERFL : Channel n Error Flag Register (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x000C + 0x10 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	CRCREG[14:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	ADERR	B0ERR	B1ERR	CERR	AERR	FERR	SERR	ALF	BLF	OVLF	BORF	BOEF	EPF	EWF	BEF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BEF	Bus Error Flag 0: Channel bus error not detected 1: Channel bus error detected	R/W*1
1	EWF	Error Warning Flag 0: Channel error warning not detected 1: Channel error warning detected	R/W*1
2	EPF	Error Passive Flag 0: Channel error passive not detected 1: Channel error passive detected	R/W*1
3	BOEF	Bus-Off Entry Flag 0: Channel bus-off entry not detected 1: Channel bus-off entry detected	R/W*1
4	BORF	Bus-Off Recovery Flag 0: Channel bus-off recovery not detected 1: Channel bus-off recovery detected	R/W*1
5	OVLF	Overload Flag 0: Channel overload not detected 1: Channel overload detected	R/W*1

Bit	Symbol	Function	R/W
6	BLF	Bus Lock Flag 0: Channel bus lock not detected 1: Channel bus lock detected	R/W*1
7	ALF	Arbitration Lost Flag 0: Channel arbitration-lost not detected 1: Channel arbitration-lost detected	R/W*1
8	SERR	Stuff Error Flag 0: Channel stuff error not detected 1: Channel stuff error detected	R/W*1
9	FERR	Form Error Flag 0: Channel form error not detected 1: Channel form error detected	R/W*1
10	AERR	Acknowledge Error Flag 0: Channel acknowledge error not detected 1: Channel acknowledge error detected	R/W*1
11	CERR	CRC Error Flag 0: Channel CRC error not detected 1: Channel CRC error detected	R/W*1
12	B1ERR	Recessive Bit Error Flag 0: Channel recessive bit error not detected 1: Channel recessive bit error detected	R/W*1
13	B0ERR	Dominant Bit Error Flag 0: Channel dominant bit error not detected 1: Channel dominant bit error detected	R/W*1
14	ADERR	Acknowledge Delimiter Error Flag 0: Channel acknowledge delimiter error not detected 1: Channel acknowledge delimiter error detected	R/W*1
15	—	This bit is read as 0. The write value should be 0.	R/W
30:16	CRCREG[14:0]	CRC Calculation Data (CRC length: 15 bits) These bits show the CRC value calculated based on the transmit message or receive message.	R
31	—	This bit is read as 0. The write value should be 0.	R/W

Note 1. To clear each flag of this register, software must write 0 to the corresponding bit. These flags cannot be set to 1 by software.

The CFDCnERFL register shows the status of various error conditions detectable regardless of the setting of the related CAN Channel Error Interrupt Enable Register. It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1) for a description of error occurrence conditions.

Only write to this register when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

BEF bit (Bus Error Flag)

The BEF bit indicates a detection of a CAN channel bus error state, flagged by bits [14:8] in this register.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically when a bus error is detected, and is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

EWF bit (Error Warning Flag)

The EWF bit indicates whether an error warning condition has been detected for the CAN channel.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically when either TEC or REC exceeds 0x5F.

The setting of this bit only occurs when the TEC or REC initially exceeds 0x5F. Therefore, if the TEC or REC remains > 0x5F and the EWF bit is cleared by software, it is not set again until both the TEC and REC go below 0x60 and either TEC or REC crosses over again from a value 0x5F to a value > 0x5F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

EPF bit (Error Passive Flag)

The EPF bit indicates a detection of a CAN channel error passive state.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state becomes error passive state.

The setting of this bit only occurs when the TEC or REC initially exceeds 0x7F. Therefore, if the TEC or REC remains > 0x7F and the bit is cleared by software, it is not set again until both the TEC and REC go below 0x80 and either TEC or REC crosses over again from a value ≤ 0x7F to a value > 0x7F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

BOEF bit (Bus-Off Entry Flag)

The BOEF bit indicates a detection of a CAN channel bus-off entry state.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state enters the bus-off state.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, then the bit is set.

BORF bit (Bus-Off Recovery Flag)

The BORF bit indicates a detection of a CAN channel bus-off recovery state.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically if CAN channel recovers from bus-off state in the following conditions:

- When CFDCnCTR.BOM[1:0] is 00b and normal recovery (11 consecutive recessive bits × 128 times detected) occurs
- When CFDCnCTR.BOM[1:0] is 10b and normal recovery (11 consecutive recessive bits × 128 times detected) occurs
- When CFDCnCTR.BOM[1:0] is 11b and normal recovery (11 consecutive recessive bits × 128 times detected) occurs.

The bit is not set if CAN channel recovers from bus-off state in the following conditions:

- When CAN Reset mode is requested
- When CFDCnCTR.RTBO is set to 1 (the CAN channel returns to error active)
- When CFDCnCTR.BOM[1:0] is 01b
- When CFDCnCTR.BOM[1:0] is 11b and a halt request is asserted before the CAN channel reaches the end of the bus-off state.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, the flag is set.

OVLF bit (Overload Flag)

The OVLF flag indicates a detection of a CAN channel overload state.

The OVLF bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically when an overload condition is detected. If a set condition occurs simultaneously with a clear condition, then the bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

BLF bit (Bus Lock Flag)

The BLF bit indicates a detection of a CAN channel bus lock condition.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically when 32 consecutive dominant bits are detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

ALF bit (Arbitration Lost Flag)

The ALF bit indicates a detection of a CAN channel bus arbitration-lost condition.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

The bit is set automatically when an arbitration-lost condition is detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

SERR bit (Stuff Error Flag)

The SERR bit indicates a detection of a CAN stuff error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a stuff error is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000000b.

FERR bit (Form Error Flag)

The FERR bit indicates a detection of a CAN form error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000000b.

AERR bit (Acknowledge Error Flag)

The AERR bit indicates a detection of a CAN acknowledge error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when an acknowledge error is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000000b.

CERR bit (CRC Error Flag)

The CERR bit indicates a detection of a CAN CRC error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a CRC error is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000000b.

B1ERR bit (Recessive Bit Error Flag)

The B1ERR bit indicates a detection of a recessive bit error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a recessive bit error (expected recessive bit, sampled as dominant bit) is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000001b.

B0ERR bit (Dominant Bit Error Flag)

The B0ERR bit indicates a detection of a dominant bit error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a dominant bit error (expected dominant bit, sampled as recessive bit) is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000000b.

ADERR bit (Acknowledge Delimiter Error Flag)

The ADERR bit indicates a detection of an acknowledge delimiter bit error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected during the acknowledge delimiter state of frame transmission. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000000b.

CRCREG[14:0] bits (CRC Calculation Data (CRC length: 15 bits))

The CRCREG[14:0] bits read the calculated CRC value when CFDCnCTR.CTME bit is 1 for the channel.

If CFDCnCTR.CTME bit is 0, then these bits are always read as 0.

These bits show the CAN2.0 CRC value calculated by the CAN-FD channel logic when the CTME bit is enabled.

The CFDCnERFL.CRCREG value is updated in the first bit of the CRC field of the CAN frame (reception and transmission).

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

35.3.5 CFDCnDCFG : Channel n Data Bit Rate Configuration Register (n = 0, 1)

This register is not available in the classical CAN function.

Base address: CANFD = 0x8004_0000

Offset address: 0x1400 + 0x20 × n

Bit position:	31				27				24				19				16				12				8	7							0
Bit field:	—	—	—	—	DSJW[3:0]				—	—	—	—	DTSEG2[3:0]				—	—	—	DTSEG1[4:0]					DBRP[7:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DBRP[7:0]	Data Bit Rate Prescaler Division Ratio Setting When the set value = P (0 to 255), the data bit rate prescaler divides fCAN by (P + 1).	R/W
12:8	DTSEG1[4:0]	Data Bit Rate Time Segment 1 Control 0x00: Setting prohibited 0x01: 2 Tq 0x02: 3 Tq 0x03: 4 Tq ⋮ 0x1E: 31 Tq 0x1F: 32 Tq	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
19:16	DTSEG2[3:0]	Data Bit Rate Time Segment 2 Control 0x0: Setting prohibited 0x1: 2 Tq 0x2: 3 Tq 0x3: 4 Tq ⋮ 0xE: 15 Tq 0xF: 16 Tq	R/W
23:20	—	These bits are read as 0. The write value should be 0.	R/W
27:24	DSJW[3:0]	Data Bit Rate Resynchronization Jump Width Control 0x0: 1 Tq 0x1: 2 Tq ⋮ 0xE: 15 Tq 0xF: 16 Tq	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

The CFDCnDCFG register configures the transmission/reception data bit rate parameters of the channels.

The channel of Classical-only mode does not perform configuration of this register.

Do not write to this register in CH_OPERATION or CH_SLEEP mode. Only write to this register in CH_RESET or CH_HALT mode.

DBRP[7:0] bits (Data Bit Rate Prescaler Division Ratio Setting)

The DBRP[7:0] bits define the peripheral bus clock periods contained in a time quantum.

DTSEG1[4:0] bits (Data Bit Rate Time Segment 1 Control)

The DTSEG1[4:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. A value from 2 to 32 time quanta can be set.

The DTSEG1[4:0] bits are also used to set the propagation segment.

Do not write any other value to these bits. See section 35.5.1.2. CAN Bit Timing for more details.

DTSEG2[3:0] bits (Data Bit Rate Time Segment 2 Control)

The DTSEG2[3:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error. A value from 2 to 16 time quanta can be set.

Do not write any other value to these bits.

DSJW[3:0] bits (Data Bit Rate Resynchronization Jump Width Control)

The DSJW[3:0] bits set the synchronization jump width. A value from 1 to 16 time quanta can be set.

35.3.6 CFDCnFDCFG : Channel n CAN-FD Configuration Register (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1404 + 0x20 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CFDTE	CLOE	REFE	FDOE	—	GWBRS	GWFDF	GWEN	TDCO[7:0]							
Value after reset:	0	0*1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	ESIC	TDCE	TDCOC	—	—	—	—	—	EOCCFG[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	EOCCFG[2:0]	Error Occurrence Counter Configuration 0 0 0: All transmit messages and receive messages 0 0 1: All transmit messages 0 1 0: All receive messages 0 1 1: Setting prohibited 1 0 0: Only data phase of transmitted or received CANFD message 1 0 1: Only data phase of transmitted CANFD message 1 1 0: Only data phase of received CANFD message 1 1 1: Setting prohibited	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	TDCOC*2	Transmitter Delay Compensation Offset Configuration 0: Measurement and offset 1: Offset-only	R/W
9	TDCE*2	Transceiver Delay Compensation Enable 0: Transceiver delay compensation disabled 1: Transceiver delay compensation enabled	R/W
10	ESIC*2	Error State Indication Configuration 0: The ESI bit in the frame represents the error state of the node itself 1: The ESI bit in the frame represents the error state of the message buffer if the node itself is not in error passive. If the node is in error passive, then the ESI bit is driven by the node itself.	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
23:16	TDCO[7:0]*2	Transceiver Delay Compensation Offset These bits are set to the transmitter delay compensation offset value.	R/W
24	GWEN*2	CAN2.0, CAN-FD Multi Gateway Enable 0: Multi gateway disabled 1: Multi gateway enabled	R/W
25	GWFDF*2	Gateway FDF Configuration Bit 0: Gateway frame is transmitted as Classical CAN frame 1: Gateway frame is transmitted as CAN-FD frame	R/W
26	GWBRS*2	Gateway BRS Configuration Bit 0: Gateway frame is transmitted with BRS = 0 1: Gateway frame is transmitted with BRS = 1	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W
28	FDOE*2	FD-Only Enable 0: FD-only mode disabled 1: FD-only mode enabled	R/W
29	REFE	RX Edge Filter Enable 0: RX edge filter disabled 1: RX edge filter enabled	R/W
30	CLOE*2	Classical CAN-Only Enable 0: Classical-only mode disabled 1: Classical-only mode enabled	R/W
31	CFDTE	CAN-FD Frame Distinction Enable 0: CAN-FD frame distinction disabled 1: CAN-FD frame distinction enabled	R/W

Note 1. This bit is set to 1 for RZ/T2M device with CANFD disabled.
Note 2. These bits are not available in the classical CAN function.

The CFDCnFDCFG register configures which communication direction (transmitter/receiver) errors are counted.

EOCCFG[2:0] bits (Error Occurrence Counter Configuration)

The EOCCFG[2:0] bits select which type of CAN frame configuration and direction, including protocol errors are counted.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

TDCOC bit (Transmitter Delay Compensation Offset Configuration)

The TDCOC bit selects which offset is used when defining the position of the secondary sample point (SSP) for the CAN-FD channel. If the bit is set to 0, the position of the SSP is the measured transceiver delay plus the fixed offset. If the bit is 1, the position of the SSP is defined only by the offset.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical-only mode.

This bit is not available in the classical CAN function.

TDCE bit (Transceiver Delay Compensation Enable)

The TDCE bit enables the transceiver delay compensation for the CAN-FD channel.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical-only mode.

This bit is not available in the classical CAN function.

ESIC bit (Error State Indication Configuration)

Bus controllers that are used as CAN-to-CAN gateway support that in every forwarded CAN-FD message. The ESI flag does not change to reflect the status of the gateway, bridge, or router but instead the flag is sent as it was in the original message.

The ESIC bit controls the transmission of either the ESI flag information or the message of ESI flag information (CFDCFFDCSTSn.CFESI or CFDTMFDCTRn.TMESI).

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical-only mode.

This bit is not available in the classical CAN function.

TDCO[7:0] bits (Transceiver Delay Compensation Offset)

The TDCO[7:0] bits set the secondary sample point offset. How this value is used, depends on the CFDCnFDCFG.TDCOC setting.

If CFDCnFDCFG.TDCOC = 0, the transceiver delay compensation result is equal to the Trv_Delay (measured delay) + the value in CFDCnFDCFG.TDCO, rounded down to the nearest integer number of time quanta. Otherwise, the result is equal to the value in CFDCnFDCFG.TDCO. See section 35.5.1.5. Transmitter Delay Compensation for details on how CFDCnFDCFG.TDCO is used.

The actual offset value is interpreted as TDCO + 1. For example, if 4 is set in TDCO, the offset is 5 clock cycles. Clock cycle is 1 cycle of CAN channel DLL clock.

Do not write to the TDCO[7:0] bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode. Do not set to this bit when in Classical-only mode.

This bit is not available in the classical CAN function.

GWEN bit (CAN2.0, CAN-FD Multi Gateway Enable)

When the GWEN bit is enabled, a multi gateway is enabled. Message received on one node can be routed to another node using the COM FIFO when they are configured as gateway FIFO (CFDCFCCn.CFM[1:0] = 10b). Furthermore, when TX Queue is set as Gateway mode, the message received on one node can be stored in TX Queue and can be sent to another node.

The FDF and BRS bits of the routed message can be changed by the configuration value of the CFDCnFDCFG.GWFDF and CFDCnFDCFG.GWBRS bits. By this, the transmitted value of these bits can be replaced.

Example:

CFDCnFDCFG.GWEN = 1 on channel y

CFDCnFDCFG.GWFDF = 1

If a Classical CAN frame is received on channel x and routed to a gateway FIFO or TX Queue of channel y, then this CAN frame is sent on channel y as a CAN-FD frame because of the CFDCnFDCFG.GWFDF bit.

Table 35.6 shows how the message information is changed depending on the received and configured data.

Table 35.6 Modified message information by received and configured data

Routed CAN frame	Routed received DLC	CAN BRS bit	Configured CFDCnFDCFG.GWFDF bit	Gateway message DLC	Gateway message BRS bit	Gateway message frame type
CAN2.0	≤ 8	N/A	1	≤ 8	Based on configuration of CFDCnFDCFG.GWBRS	CAN-FD
CAN2.0	> 8	N/A	1	= 8	Based on configuration of CFDCnFDCFG.GWBRS	CAN-FD
CAN-FD	≤ 8	None	1	≤ 8	Based on configuration of CFDCnFDCFG.GWBRS	CAN-FD
CAN-FD	> 8	None	1	> 8	Based on configuration of CFDCnFDCFG.GWBRS	CAN-FD
CAN2.0	≤ 8	N/A	0	≤ 8	N/A	CAN2.0
CAN2.0	> 8	N/A	0	> 8	N/A	CAN2.0
CAN-FD	≤ 8	None	0	≤ 8	N/A	CAN2.0
CAN-FD	> 8	None	0	= 8	N/A	CAN2.0

Note:
- This gateway is limited to an 8-byte data payload for different frame type. If routing and target frame type is the same, the data length code (DLC) value remains the same. If the source frame is a CAN-FD with more than 8 data bytes, then on classical destination node, the data payload is reduced to 8 bytes. Only the first 8 bytes of data perform gateway transmission.
- Transmission buffers other than the gateway FIFO are not affected by this feature.

Do not route remote frames through the gateway when CFDCnFDCFG.GWEN is set. When a destination node is CFDCnFDCFG.FDOE = 1, set CFDCnFDCFG.GWEN and CFDCnFDCFG.GWFDF to 1. When a destination node is CFDCnFDCFG.CLOE = 1, set CFDCnFDCFG.GWEN = 1 and CFDCnFDCFG.GWFDF = 0.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

This bit is not available in the classical CAN function.

GWFDF bit (Gateway FDF Configuration Bit)

When the GWEN bit is set to 1, the FDF bit of the transmitting gateway frame is replaced by the value of the GWFDF bit.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CAN-FD module is in CH_RESET mode. Do not set this bit when in Classical-only mode.

This bit is not available in the classical CAN function.

GWBRS bit (Gateway BRS Configuration Bit)

When the GWEN bit is set to 1, the BRS bit of the transmitting gateway frame is replaced by the value of CFDCnFDCFG.GWBRS.

In classical CAN frames, the GWBRS bit is invalid.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET mode. Do not set this bit when in Classical-only mode.

This bit is not available in the classical CAN function.

FDOE bit (FD-Only Enable)

The FDOE bit enables the reception and transmission of CAN-FD-only frames. If enabled, communication in Classical CAN frame format is disabled. Transmission of Classical CAN frames is not possible because the FDF bit of the message buffer is a don't care (CFDCFFDCSTSn.CFFDF/CFDTMFDCTRn.TMFDF).

If messages with Classical CAN frame format are received, the protocol controller treats them as invalid frames and response with error frames. When a Classical CAN frame is configured for transmitting, the FDF bit is sent as recessive, therefore an FD frame is sent. If the data length code (DLC) is configured of greater than 8 bytes, the remaining data bytes are padded with 0xCC.

The FDOE bit cannot be written in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Do not set CFDCnFDCFG.FDOE and CFDCnFDCFG.CLOE simultaneously.

This bit is not available in the classical CAN function.

REFE bit (RX Edge Filter Enable)

The REFE bit enables the RX edge filter during the IDLE detection (bus integration). When the bit is enabled, two consecutive dominant time quanta are required to detect a synchronization edge.

The REFE bit cannot be written in CH_OPERATION, CH_HALT and CH_SLEEP mode. Do not set this bit when in Classical-only mode and when CFDCnFDCFG.CFDTE = 0 (disabled CAN-FD frame distinction).

CLOE bit (Classical CAN-Only Enable)

The CLOE bit enables the Classical CAN-only mode. If this bit is 1, the protocol controller can only send classical frames and response with a form or CRC error on FD frames.

Do not set CFDCnFDCFG.CLOE and CFDCnFDCFG.FDOE simultaneously.

CFDCnFDCFG.CLOE	CFDCnFDCFG.FDOE	Channel mode
0	0	CAN-FD mode (Dual mode)
0	1	FD-only mode
1	0	Classical CAN-only mode
1	1	Reserved

Do not write to this bit in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Only write to these bits when the CAN-FD channel is in CH_RESET mode.

This bit is not available in the classical CAN function.

CFDTE bit (CAN-FD Frame Distinction Enable)

The CFDTE bit enables the CAN-FD frame distinction function. The CFDTE bit is required for Classical CAN-only mode (CFDCnFDCFG.CLOE = 1).

If this bit is 0, the protocol controller can only send Classical frames and response with a Form or CRC error on FD frames.

If this bit is 1, the protocol controller behaves according to the ISO 11898-1 (DIS 2015) specification. If the FDF bit is detected recessive, then the protocol controller enters the protocol exception state, and attempts to integrate back to the CAN communication.

Do not write this bit in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Only write to these bits when the related CAN-FD channel is in CH_RESET mode.

35.3.7 CFDCnFDCTR : Channel n CAN-FD Control Register (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1408 + 0x20 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOCCLR	EOCCLR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EOCCLR	Error Occurrence Counter Clear 0: No error occurrence counter clear 1: Clear error occurrence counter	R/W
1	SOCCLR	Successful Occurrence Counter Clear 0: No successful occurrence counter clear 1: Clear successful occurrence counter	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

The CFDCnFDCTR register (n = 0, 1) controls the error and successful occurrence counters.

EOCCLR bit (Error Occurrence Counter Clear)

The EOCCLR bit is used to clear the error occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0.

This bit is cleared automatically by the CAN-FD logic and when the related CAN-FD channel is in CH_RESET mode.

SOCCLR bit (Successful Occurrence Counter Clear)

The SOCCLR bit is used to clear the successful occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0.

This bit is cleared automatically by the CAN-FD logic and when the related CAN-FD channel is in CH_RESET mode.

35.3.8 CFDCnFDSTS : Channel n CAN-FD Status Register (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x140C + 0x20 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	SOC[7:0]								EOC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TDCVF	—	—	—	—	—	SOCO	EOCO	TDCR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TDCR[7:0]	Transceiver Delay Compensation Result	R

Bit	Symbol	Function	R/W
8	EOCO	Error Occurrence Counter Overflow Flag 0: Error occurrence counter has not overflowed 1: Error occurrence counter has overflowed	R/W
9	SOCO	Successful Occurrence Counter Overflow Flag 0: Successful occurrence counter has not overflowed 1: Successful occurrence counter has overflowed	R/W
14:10	—	These bits are read as 0. The write value should be 0.	R/W
15	TDCVF	Transceiver Delay Compensation Violation Flag 0: Transceiver delay compensation violation has not occurred 1: Transceiver delay compensation violation has occurred	R/W
23:16	EOC[7:0]	Error Occurrence Counter These bits show the error occurrence counter value.	R
31:24	SOC[7:0]	Successful Occurrence Counter These bits show the successful occurrence counter value.	R

The CFDCnFDSTS register (n = 0, 1) indicates the transceiver compensation delay result and its related FIFO message lost status.

TDCR[7:0] bits (Transceiver Delay Compensation Result)

The TDCR[7:0] bits are set when the transceiver delay has been measured.

The measured delay is a multiple of the CAN channel DLL clock. The result depends on the CFDCnFDCFG.TDCOC configuration and the offset value in CFDCnFDCFG.TDCO. See section 35.5.1.5. Transmitter Delay Compensation for details on how this value is derived.

The TDCR[7:0] bits are updated at the falling edge between the FDF bit and the RES bit when CFDCnFDCFG.TDCOC = 0 and the transceiver delay compensation is enabled (CFDCnFDCFG.TDCE = 1).

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

EOCO bit (Error Occurrence Counter Overflow Flag)

The EOCO bit indicates whether the related CAN channel error occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDCnFDSTS.EOC is 0xFF and a CAN bus error is detected based on the configuration defined in CFDCnFDCFG.EOCCFG.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit.

SOCO bit (Successful Occurrence Counter Overflow Flag)

The SOCO bit indicates whether the related CAN channel successful occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDCnFDSTS.SOC is 0xFF and a successful message reception or successful message transmission occurs.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit.

TDCVF bit (Transceiver Delay Compensation Violation Flag)

The CAN-FD module captures internally the transmitted data bit-by-bit. This data is then compared against the received CAN bus level which is delayed by the transceiver loop delay.

The transceiver delay has some variations depending on the physical parameters such as temperature. The result bit CFDCnFDSTS.TDCR is updated by each message. However, temporary maximum delay violation could be missed. Therefore, the TDCVF bit captures this violation.

This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when the transceiver delay compensation is greater than the maximum delay compensation (6 data bit times - 2 clk_dlc) and the internal bit is overrun.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit.

EOC[7:0] bits (Error Occurrence Counter)

The EOC[7:0] bits are used together with the SOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

This higher error rate can be detected depending on the configuration of the CFDCnFDCFG.EOCCFG bits.

The EOC[7:0] bits are set only by CAN-FD module logic. These bits are cleared by writing 1 to CFDCnFDCTR.EOCCLR. Writing any other value has no effect.

These bits are updated when an error occurs, according to the configuration of the CFDCnFDCFG.EOCCFG bits. When the counter reaches the value of 0xFF, the update stops.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

SOC[7:0] bits (Successful Occurrence Counter)

The SOC[7:0] bits are used together with the EOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

The SOC[7:0] bits are set only by CAN-FD module logic. Writing any other value has no effect.

These bits are updated when the occurrence of any error-free messages on the bus is detected through reception or transmission. When the counter reaches the value of 0xFF, the update stops. In Loopback mode, the counter is incremented twice.

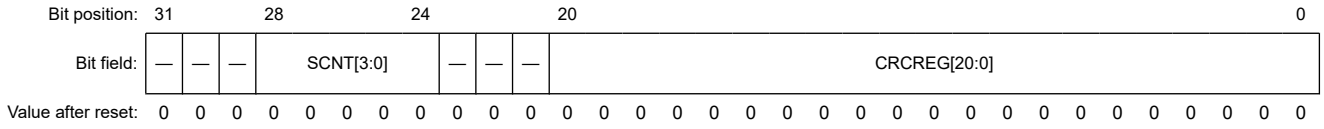
These bits are cleared by writing 1 to CFDCnFDCTR.SOCCLR.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

35.3.9 CFDCnFDCRC : Channel n CAN-FD CRC Register (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1410 + 0x20 × n



Bit	Symbol	Function	R/W
20:0	CRCREG[20:0]	CRC Register Value These bits show the CRC value calculated for the CAN-FD frame.	R
24:21	—	These bits are read as 0.	R
28:25	SCNT[3:0]	Stuff Bit Count These bits shows the stuff bit count (mod 8) for the CAN-FD frame.	R
31:29	—	These bits are read as 0.	R

The CFDCnFDCRC register (n = 0, 1) holds the CRC value calculated for the CAN-FD frame.

CRCREG[20:0] bits (CRC Register Value)

The CRCREG[20:0] bits contain the CRC value calculated by the CAN-FD channel logic when the CFDCnCTR.CTME bit is enabled.

The CFDCnFDCRC.CRCREG value is updated in the first bit of the CRC field of the CAN-FD frame (reception and transmission).

When the CFDCnCTR.CTME bit is 0, the CRCREG[20:0] bits are always read as 0.

When bit 17th of the CRC field is used, CRCREG[20:17] are always read as 0.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

SCNT[3:0] bits (Stuff Bit Count)

The SCNT[3:0] bits contain the stuff count value of the CAN-FD frame. These bits indicate the number of inserted stuff bits (modulo 8, Gray-coded) for a CAN-FD frame when the CFDCnCTR.CTME bit is enabled in CFDCnFDCRC.SCNT[3:1]. SCNT[0] is the parity bit.

When the CFDCnCTR.CTME bit is 0, the SCNT[3:0] bits are always read as 0.

The SCNT value is updated in the first bit of CRC field of the CAN-FD frame (reception and transmission).

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

35.3.10 CFDGIPV : Global IP Version Register

Base address: CANFD = 0x8004_0000

Offset address: 0x0080

Bit position:	31	29														16								9	8	7							0
Bit field:	—	—	PSI[13:0]														—	—	—	—	—	—	IPT[1:0]		IPV[7:0]								
Value after reset:	0	0	1	1	0	0	0	1	0	0	1	0	0	1	0	0	0	0	0	0	0	0	0	*1	0	1	0	0	0	0	1	0

Bit	Symbol	Function	R/W
7:0	IPV[7:0]	IP Version These bits show the main release number.	R
9:8	IPT[1:0]	IP Type These bits show the IP type used in the product. 0 0: CAN IP 0 1: CAN-FD IP 1 x: Reserved	R
15:10	—	These bits are read as 0.	R
29:16	PSI[13:0]	Parameter Status Information These bits show the IP configuration.	R
31:30	—	These bits are read as 0.	R

Bits	Description
[29:27]	Number of channel (110b: 2 channels)
[26:24]	Number of TXMB (001b: 32/channel)
[23:21]	Number of AFL entry (001b: 128/channel)
[20:17]	Number of pool buffer (0010b: 64/channel)
[16]	Same ID overwrite function of TXQ (0b: Support)

Note 1. The value depends on RZ/T2 package type.

The CFDGIPV register shows the release version of the CAN-FD module.

35.3.11 CFDGCFG : Global Configuration Register

Base address: CANFD = 0x8004_0000

Offset address: 0x0084

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ITRCP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSBTCS[2:0]			TSSS	TSP[3:0]				—	—	CMPOC	DCS	MME	DRE	DCE	TPRI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TPRI	Transmission Priority 0: ID priority 1: Message buffer number priority	R/W
1	DCE	DLC Check Enable 0: DLC check disabled 1: DLC check enabled	R/W
2	DRE	DLC Replacement Enable 0: DLC replacement disabled 1: DLC replacement enabled	R/W
3	MME	Mirror Mode Enable 0: Mirror mode disabled 1: Mirror mode enabled	R/W
4	DCS	Data Link Controller Clock Select 0: PCLKM 1: PCLKCAN	R/W
5	CMPOC	CAN-FD Message Payload Overflow Configuration 0: Message is rejected 1: Message payload is cut to fit to configured message size	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
11:8	TSP[3:0]	Timestamp Prescaler 0x0: Timestamp prescaler = 1 0x1: Timestamp prescaler = 2 0x2: Timestamp prescaler = 4 0x3: Timestamp prescaler = 8 ⋮ 0xD: Timestamp prescaler = 8192 0xE: Timestamp prescaler = 16384 0xF: Timestamp prescaler = 32768	R/W
12	TSSS	Timestamp Source Select 0: Source clock for timestamp counter is peripheral clock 1: Source clock for timestamp counter is bit time clock	R/W
15:13	TSBTCS[2:0]	Timestamp Bit Time Channel Select 0 0 0: Select clock from channel 0 0 0 1: Select clock from channel 1 Others: Setting prohibited	R/W
31:16	ITRCP[15:0]	Interval Timer Reference Clock Prescaler FIFO interval timer prescaler value	R/W

The CFDGCFG register is used to select the transmission priority to be used for all the TX message buffers and the clock source for the CAN protocol engine of all CAN channels. The CFDGCFG register is also used to select the source for the timestamp clock and to configure the frequency for the timestamp clock and interval timer reference clock.

TPRI bit (Transmission Priority)

The TPRI bit selects the transmission priority for all CAN channels.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

Message buffer number priority should not be used together with TX queue transmission.

DCE bit (DLC Check Enable)

The DCE bit enables data length code (DLC) check for all CAN channels.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

DRE bit (DLC Replacement Enable)

When the DRE bit is 1 and the DCE is 1, the CAN-FD stores the configured value (CFDGAFLP0n.GAFLDLC) of the DLC in the destination RX message buffer or FIFO buffer if the DLC check passes. Otherwise, the DLC value in the destination RX message buffer or FIFO buffer is unchanged.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

MME bit (Mirror Mode Enable)

The MME bit enables the Mirror mode for all CAN channels.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

DCS bit (Data Link Controller Clock Select)

The DCS bit selects the clock source for CAN communication.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

CMPOC bit (CAN-FD Message Payload Overflow Configuration)

The CMPOC bit controls the message payload acceptance mechanism when the received payload is higher than the message buffer payload size CFDRMNB.RMPLS, CFDRFCCn.RFPLS, and CFDCFCCn.CFPLS. The received message payload is always compared with the available message payload size in the message buffer.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

When this bit is set and payload overflow occurs, the DLC value is stored in the RX message buffer or FIFO buffer unchanged.

TSP[3:0] bits (Timestamp Prescaler)

The value configured in the TSP[3:0] bits defines the period of the clock source used for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

TSSS bit (Timestamp Source Select)

The TSSS bit allows the selection of the clock source for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode. Additionally, do not set this bit to 1 when CAN-FD communication is used.

Note: The bit time clock varies depending on the nominal and data rate bit configuration.

TSBTCS[2:0] bits (Timestamp Bit Time Channel Select)

The TSBTCS[2:0] bits allow the selection of the bit time clock of a particular channel for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

ITRCP[15:0] bits (Interval Timer Reference Clock Prescaler)

The ITRCP[15:0] bits allow the definition of a reference clock for the FIFO interval timer source clock.

When these bits are 0x0000, the timer is disabled.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

35.3.12 CFDGCTR : Global Control Register

Base address: CANFD = 0x8004_0000

Offset address: 0x0088

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MOWEIE	QMEIE	—	QOWEIE	CMPOFIE	THLEIE	MEIE	DEIE	—	—	—	—	—	GSLPR	GMDC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Function	R/W
1:0	GMDC[1:0]	Global Mode Control 0 0: Global operation mode request 0 1: Global reset mode request 1 0: Global halt mode request 1 1: Keep current value	R/W
2	GSLPR	Global Sleep Request 0: Global sleep request disabled 1: Global sleep request enabled	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	DEIE	DLC Check Interrupt Enable 0: DLC check interrupt disabled 1: DLC check interrupt enabled	R/W
9	MEIE	Message Lost Error Interrupt Enable 0: Message lost error interrupt disabled 1: Message lost error interrupt enabled	R/W
10	THLEIE	TX History List Entry Lost Interrupt Enable 0: TX history list entry lost interrupt disabled 1: TX history list entry lost interrupt enabled	R/W
11	CMPOFIE	CAN-FD Message Payload Overflow Flag Interrupt Enable 0: CAN-FD message payload overflow flag interrupt disabled 1: CAN-FD message payload overflow flag interrupt enabled	R/W
12	QOWEIE	TXQ Message Overwrite Error Interrupt Enable 0: TXQ message overwrite error interrupt disabled 1: TXQ message overwrite error interrupt enabled	R/W
13	—	This bit is read as 0. The write value should be 0.	R/W
14	QMEIE	TXQ Message Lost Error Interrupt Enable 0: TXQ message lost error interrupt disabled 1: TXQ message lost error interrupt enabled	R/W
15	MOWEIE	Message Lost Error Interrupt Enable 0: GW FIFO message lost error interrupt disabled 1: GW FIFO message lost error interrupt enabled	R/W
16	TSRST	Timestamp Reset 0: Timestamp not reset 1: Timestamp reset	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

The CFDGCTR register controls the global mode of the CAN-FD module and the timestamp function. The register also enables and disables the global error interrupts.

GMDC[1:0] bits (Global Mode Control)

The GMDC[1:0] bits can be used to configure the modes for the CAN-FD module. Additionally, if CFDGCTR.GSLPR bit is 1 when the CAN-FD module is in Reset mode, the CAN-FD module transits to Global Sleep mode. Additionally, if CFDGCTR.GSLPR is 1 when the CAN-FD module is in Reset Mode, then the CAN-FD module transits to Global Sleep Mode.

Setting the GMDC[1:0] bits to 11b has no effect. Mode transition is described in detail in section 35.4.2. Global Modes.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

GSLPR bit (Global Sleep Request)

The GSLPR bit globally selects the sleep request for CAN-FD module including all CAN channels. Channel sleep request is set automatically for all channels.

Only write to this bit when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

DEIE bit (DLC Check Interrupt Enable)

When the DEIE bit is 1, an interrupt is generated if a DLC error is detected in the received frames.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

MEIE bit (Message Lost Error Interrupt Enable)

When the MEIE bit is 1, an interrupt is generated if a message lost condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

THLEIE bit (TX History List Entry Lost Interrupt Enable)

When the THLEIE bit is 1, an interrupt is generated if a TX history list entry lost condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CMPOFIE bit (CAN-FD Message Payload Overflow Flag Interrupt Enable)

When the CMPOFIE bit is 1, an interrupt is generated when a CAN-FD message payload overflow condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

QOWEIE bit (TXQ Message Overwrite Error Interrupt Enable)

When the QOWEIE bit is 1, an interrupt is generated when a TXQ message overwrite condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

QMEIE bit (TXQ Message Lost Error Interrupt Enable)

When the QMEIE bit is 1, an interrupt is generated when a TXQ message lost condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

MOWEIE bit (Message Lost Error Interrupt Enable)

When the MOWEIE bit is 1, an interrupt is generated in GW mode and a GW FIFO message over write condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

TSRST bit (Timestamp Reset)

When the TSRST bit is 1, the Global Timestamp Register is reset to 0x0000.

Do not write to this bit when the CAN-FD module is in GL_SLEEP or GL_RESET mode.

Read value is always 0.

This bit is cleared automatically by the CAN-FD logic.

35.3.13 CFDGSTS : Global Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x008C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	GRAM INIT	GSLP STS	GHLT STS	GRST STS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1

Bit	Symbol	Function	R/W
0	GRSTSTS	Global Reset Status 0: Not in Reset mode 1: In Reset mode	R
1	GHLTSTS	Global Halt Status 0: Not in Halt mode 1: In Halt mode	R
2	GSLPSTS	Global Sleep Status 0: Not in Sleep mode 1: In Sleep mode	R
3	GRAMINIT	Global RAM Initialization 0: RAM initialization is complete 1: RAM initialization is ongoing	R
31:4	—	These bits are read as 0.	R

The CFDGSTS register indicates the global status of the CAN-FD module.

GRSTSTS bit (Global Reset Status)

The GRSTSTS bit indicates the status of Global CAN-FD module Reset mode.

This bit is set automatically when the CAN-FD module enters GL_RESET mode. When the mode changes from GL_RESET mode to GL_SLEEP mode, this bit remains set.

This bit is cleared automatically when the CAN-FD module exits the GL_RESET mode.

GHLTSTS bit (Global Halt Status)

The GHLTSTS bit indicates the status of Global CAN-FD module Halt mode.

This bit is set automatically when the CAN-FD module enters GL_HALT mode.

This bit is cleared automatically when the CAN-FD module exits the GL_HALT mode.

GSLPSTS bit (Global Sleep Status)

The GSLPSTS bit indicates the status of Global CAN-FD module Sleep mode.

This bit is set automatically when the CAN-FD module enters GL_SLEEP mode.

This bit is cleared automatically when the CAN-FD module exits the GL_SLEEP mode.

GRAMINIT bit (Global RAM Initialization)

The GRAMINIT bit indicates the status of Global CAN-FD module RAM initialization.

This bit is set automatically when the CAN-FD module enters GL_SLEEP mode after a hardware reset.

This bit is cleared automatically when the CAN-FD module completed RAM initialization.

35.3.14 CFDGERFL : Global Error Flag Register

Base address: CANFD = 0x8004_0000

Offset address: 0x0090

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	MOWES	QMES	—	QOWES	CMPOF	THLES	MES	DEF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DEF	DLC Error Flag 0: DLC error not detected 1: DLC error detected	R/W
1	MES	Message Lost Error Status 0: Message lost error not detected 1: Message lost error detected	R
2	THLES	TX History List Entry Lost Error Status 0: TX history list entry lost error not detected 1: TX history list entry lost error detected	R
3	CMPOF	CAN-FD Message Payload Overflow Flag 0: CAN-FD message payload overflow not detected 1: CAN-FD message payload overflow detected	R/W
4	QOWES	TXQ Message Overwrite Error Status 0: TXQ message overwrite error not detected 1: TXQ message overwrite error detected	R
5	—	This bit is read as 0. The write value should be 0.	R/W
6	QMES	TXQ Message Lost Error Status 0: TXQ message lost error not detected 1: TXQ message lost error detected	R
7	MOWES	Message Overwrite Error Status 0: Message overwrite error not detected 1: Message overwrite error detected	R
15:8	—	These bits are read as 0. The write value should be 0.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The CFDGERFL egister indicates the detection of global errors.

DEF bit (DLC Error Flag)

The DEF bit indicates the error status of the DLC.

Do not write to this bit when the CAN-FD module is in GL_SLEEP or GL_RESET mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when a DLC error is detected in a received frame.

The bit is cleared by writing 0 to it.

This bit is cleared automatically in GL_RESET mode.

MES bit (Message Lost Error Status)

The MES bit indicates status of the message lost error.

This bit is set automatically when a FIFO message lost error is detected.

This bit is cleared automatically when:

- All FIFO message lost flags are cleared
- The CAN-FD module is in GL_RESET mode.

THLES bit (TX History List Entry Lost Error Status)

The THLES bit indicates status of the TX history list entry lost error.

This bit is set automatically when a TX history list entry lost error is detected.

This bit is cleared automatically when:

- All TX history list entry lost flags are cleared
- The CAN-FD module is in GL_RESET mode.

CMPOF bit (CAN-FD Message Payload Overflow Flag)

The CMPOF bit is set automatically when a CAN-FD message payload overflow is detected on at least one channel.

Do not write to this bit when the CAN-FD module is in GL_SLEEP or GL_RESET mode.

This bit is cleared by writing 0 to it. Writing 1 to this bit has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is cleared automatically in GL_RESET mode.

QOWES bit (TXQ Message Overwrite Error Status)

The QOWES bit is set automatically when a TXQ message overwrite error is detected.

This bit is cleared automatically when all TXQ message overwrite flags are cleared.

This bit is cleared automatically in GL_RESET mode.

QMES bit (TXQ Message Lost Error Status)

The QMES bit is set automatically when a TXQ message lost error is detected.

This bit is cleared automatically when all TXQ message lost flags are cleared.

This bit is cleared automatically in GL_RESET mode.

MOWES bit (Message Overwrite Error Status)

The MOWES bit is set automatically when GW mode and COMFIFO message overwrite error is detected.

This bit is cleared automatically when all COMFIFO Message Overwrite flags are cleared.

This bit is cleared automatically in GL_RESET mode.

35.3.15 CFDGTINTSTS0 : Global TX Interrupt Status Register 0

Base address: CANFD = 0x8004_0000

Offset address: 0x1300

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	CFOTIF1	TQOFIF1	THIF1	CFTIF1	TQIF1	TAIF1	TSIF1	—	CFOTIF0	TQOFIF0	THIF0	CFTIF0	TQIF0	TAIF0	TSIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TSIF0	TX Successful Interrupt Flag Channel 0 0: Channel 0 TX Successful Interrupt flag not set 1: Channel 0 TX Successful Interrupt flag set	R
1	TAIF0	TX Abort Interrupt Flag Channel 0 0: Channel 0 TX Abort Interrupt flag not set 1: Channel 0 TX Abort Interrupt flag set	R
2	TQIF0	TX Queue Interrupt Flag Channel 0 0: Channel 0 TX Queue Interrupt flag not set 1: Channel 0 TX Queue Interrupt flag set	R
3	CFTIF0	COM FIFO TX/GW Mode Interrupt Flag Channel 0 0: Channel 0 COM FIFO TX/GW Mode Interrupt flag not set 1: Channel 0 COM FIFO TX/GW Mode Interrupt flag set	R
4	THIF0	TX History List Interrupt Channel 0 0: Channel 0 TX History List Interrupt flag not set 1: Channel 0 TX History List Interrupt flag set	R

6	CFOTIF0	COM FIFO One Frame Transmission Interrupt Flag Channel 0 0: Channel 0 COM FIFO One Frame Transmission Interrupt flag not set 1: Channel 0 COM FIFO One Frame Transmission Interrupt flag set	R
7	—	This bit is read as 0.	R
8	TSIF1	TX Successful Interrupt Flag Channel 1 0: Channel 1 TX Successful Interrupt flag not set 1: Channel 1 TX Successful Interrupt flag set	R
9	TAIF1	TX Abort Interrupt Flag Channel 1 0: Channel 1 TX Abort Interrupt flag not set 1: Channel 1 TX Abort Interrupt flag set	R
10	TQIF1	TX Queue Interrupt Flag Channel 1 0: Channel 1 TX Queue Interrupt flag not set 1: Channel 1 TX Queue Interrupt flag set	R
11	CFTIF1	COM FIFO TX/GW Mode Interrupt Flag Channel 1 0: Channel 1 COM FIFO TX/GW Mode Interrupt flag not set 1: Channel 1 COM FIFO TX/GW Mode Interrupt flag set	R
12	THIF1	TX History List Interrupt Channel 1 0: Channel 1 TX History List Interrupt flag not set 1: Channel 1 TX History List Interrupt flag set	R
13	TQOFIF1	TX Queue One Frame Transmission Interrupt Flag Channel 1 0: Channel 1 TX Queue One Frame Transmission Interrupt flag not set 1: Channel 1 TX Queue One Frame Transmission Interrupt flag set	R
14	CFOTIF1	COM FIFO One Frame Transmission Interrupt Flag Channel 1 0: Channel 1 COM FIFO One Frame Transmission Interrupt flag not set 1: Channel 1 COM FIFO One Frame Transmission Interrupt flag set	R
31:15	—	These bits are read as 0.	R

The CFDGTINTSTS0 register indicates the detection of transmit specific interrupts.

TSIFn bit (TX Successful Interrupt Flag Channel n (n = 0, 1))

The CFDGTINTSTS0.TSIFn bit is set to 1 when the TX Successful Interrupt flag of the related channel is set (when the interrupt is enabled).
This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TAIFn bit (TX Abort Interrupt Flag Channel n (n = 0, 1))

The CFDGTINTSTS0.TAIFn bit is set to 1 when the TX Abort Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TQIFn bit (TX Queue Interrupt Flag Channel n (n = 0, 1))

The CFDGTINTSTS0.TQIFn bit is set to 1 when the TX Queue Interrupt flag of the related channel is set (when the interrupt is enabled).
This bit is cleared automatically:

- When the related TX Queue Interrupt flag is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

CFTIFn bit (COM FIFO in TX/GW Mode Interrupt Flag Channel n (n = 0, 1))

The CFDGTINTSTS0.CFTIFn bit is set to 1 when the related COM TX/GW FIFO Mode Interrupt flag (CFDCFSTSn.CFTXIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related COM TX/GW FIFO Mode Interrupt flag (CFDCFSTSn.CFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

THIFn bit (TX History List Interrupt Flag Channel n (n = 0, 1))

The CFDGTINTSTS0.THIFn bit is set to 1 when the related TX History List Interrupt flag (CFDTHLSTSn.THLIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX History List Interrupt flag (CFDTHLSTSn.THLIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TQOFIFn bit (TX Queue One Frame Transmission Interrupt Flag Channel n (n = 0, 1))

The CFDGTINTSTS0.TQOFIFn bit is set to 1 when the TX Queue One Frame Transmission Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX Queue One Frame Transmission Interrupt flag is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

CFOTIFn bit (COM FIFO One Frame Transmission Interrupt Flag Channel n (n = 0, 1))

The CFDGTINTSTS0.CFOTIFn bit is set to 1 when the related COM FIFO One Frame Transmission Interrupt flag (CFDCFSTSn.CFOFTXIF) is set (when the Interrupt is enabled).

This bit is cleared automatically:

- When the related COM FIFO One Frame Transmission Interrupt flag (CFDCFSTSn.CFOFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

35.3.16 CFDGTSC : Global Timestamp Counter Register

Base address: CANFD = 0x8004_0000

Offset address: 0x0094

Bit position:	31																15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TS[15:0]	Timestamp value	R
31:16	—	These bits are read as 0.	R

The CFDGTSC register stores the timestamp based on the selected configuration.

TS[15:0] bits (Timestamp value)

The Timestamp value is stored in the Global Timestamp Counter register based on the configuration of TSSS, TSBTCS, and TSP. The proper incrementing of the timestamp counter cannot be guaranteed when transitioning to halt state.

Do not write to bits TS[15:0] when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

The TS[15:0] bits are cleared automatically in GL_RESET mode.

35.3.17 CFDGAFLECTR : Global Acceptance Filter List Entry Control Register

Base address: CANFD = 0x8004_0000

Offset address: 0x0098

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	AFLDAE	—	—	—	—	AFLPN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	AFLPN[3:0]	Acceptance Filter List Page Number Select an Acceptance Filter List page	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	AFLDAE	Acceptance Filter List Data Access Enable 0: Acceptance Filter List data access disabled 1: Acceptance Filter List data access enabled	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

The CFDGAFLECTR register is used to select the Global Acceptance Filter List page for reading or writing entries into the Global Acceptance Filter List.

AFLPN[3:0] bits (Acceptance Filter List Page Number)

The AFLPN[3:0] bits select the page number to access the desired RAM area of the Acceptance Filter List. One Acceptance Filter List page consists of 16 Acceptance Filter List entries.

Read/write accesses to the Acceptance Filter List can only be performed through a fixed window.

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode. Enter only the values between 0x0 and 0xF, inclusive.

AFLDAE bit (Acceptance Filter List Data Access Enable)

The AFLDAE bit prevents write access to the Acceptance Filter List when cleared after configuration of the Acceptance Filter List.

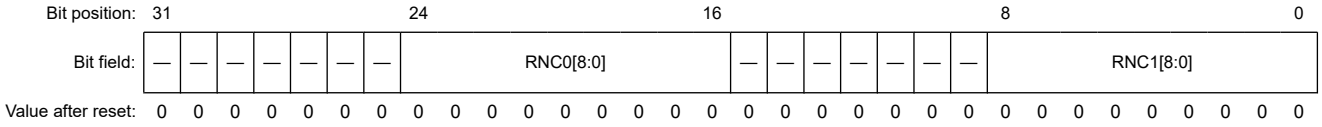
Data can be read from the Acceptance Filter List independent of the status of this bit.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. Set this bit to enable write access for the Acceptance Filter List.

35.3.18 CFDGAFLCFG0 : Global Acceptance Filter List Configuration Register 0

Base address: CANFD = 0x8004_0000

Offset address: 0x009C



Bit	Symbol	Function	R/W
8:0	RNC1[8:0]	Rule Number for Channel 1 Number of rules dedicated to channel 1	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
24:16	RNC0[8:0]	Rule Number for Channel 0 Number of rules dedicated to channel 0	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

The CFDGAFLCFG0 register is used to define the number of rules for entries in the Acceptance Filter List, applicable for channels 0 to 1.

The total number of available entries in the Acceptance Filter List is 256 for 2 CAN channels. However, the filters can be allocated flexibly to the different channels depending on requirements as long as both of the following conditions are satisfied:

- The maximum number of acceptance filter per channel is 256
- The total number of rules defined for all channels is not exceeding the number of available entries in the Acceptance Filter List.

RNCn[8:0] bits (Rule Number for Channel n (n = 0, 1))

The RNCn[8:0] bits define the number of rules in the Acceptance Filter List for channel n.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

35.3.19 CFDGAFLIDn : Global Acceptance Filter List ID Register n (n = 1 to 16)

Base address: CANFD = 0x8004_0000

Offset address: 0x1800 + 0x10 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	GAFLIDE	GAFLRTR	GAFLLB	GAFLID[28:16]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GAFLID[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
28:0	GAFLID[28:0]	Global Acceptance Filter List Entry ID Field ID part of the Global Acceptance Filter List entry	R/W
29	GAFLLB	Global Acceptance Filter List Entry Loopback Configuration 0: Global Acceptance Filter List entry ID for acceptance filtering with attribute RX 1: Global Acceptance Filter List entry ID for acceptance filtering with attribute TX	R/W
30	GAFLRTR	Global Acceptance Filter List Entry RTR Field 0: Data frame 1: Remote frame	R/W
31	GAFLIDE	Global Acceptance Filter List Entry IDE Field 0: Standard identifier of rule entry ID is valid for acceptance filtering 1: Extended identifier of rule entry ID is valid for acceptance filtering	R/W

The CFDGAFLIDn register (n = 1 to 16) is used to configure the ID field for the rules of entries in the Global Acceptance Filter List.

GAFLID[28:0] bits (Global Acceptance Filter List Entry ID Field)

The GAFLID[28:0] bits represent the CAN identifier (ID) field of each entry in the Global Acceptance Filter List.

The acceptance filter process compares this field against the ID of a received CAN message. For alignment of these bits in standard and extended frame formats, see section 35.3.88. Identifier Bits Alignment.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLLB bit (Global Acceptance Filter List Entry Loopback Configuration)

The GAFLLB bit selects whether entry in the Global Acceptance Filter List gets the attribute RX or TX.

This attribute determines the validity of the entry in Mirror mode, Loopback test mode, and during standard (non-loopback) reception. See section 35.6.5. Loopback Modes for detailed description of the validity of the Global Acceptance Filter List entry depending on transmitter/receiver case, the type of loopback mode, and RX/TX attribute.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLRTR bit (Global Acceptance Filter List Entry RTR Field)

The GAFLRTR bit allows the configuration of the specified frame format (data frame or remote frame) for each entry of the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the RTR bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLIDE bit (Global Acceptance Filter List Entry IDE Field)

The GAFLIDE bit allows the configuration of the ID format (standard ID or extended ID) for each entry in the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the IDE bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

35.3.20 CFDGAFLMn : Global Acceptance Filter List Mask Register n (n = 1 to 16)

Base address: CANFD = 0x8004_0000

Offset address: 0x1804 + 0x10 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	GAFLIDEM	GAFLRTRM	GAFLIFL1	GAFLIDM[28:16]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GAFLIDM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
28:0	GAFLIDM[28:0]	Global Acceptance Filter List ID Mask Field Global Acceptance Filter List Mask field bits for ID field	R/W
29	GAFLIFL1	Global Acceptance Filter List Information Label 1 Global Acceptance Filter List information label bit 1	R/W
30	GAFLRTRM	Global Acceptance Filter List Entry RTR Mask 0: RTR bit is not used for ID matching 1: RTR bit is used for ID matching	R/W
31	GAFLIDEM	Global Acceptance Filter List IDE Mask 0: IDE bit is not used for ID matching 1: IDE bit is used for ID matching	R/W

The CFDGAFLMn register (n = 1 to 16) is used to configure the Mask field of each rule for entries in the Global Acceptance Filter List.

GAFLIDM[28:0] bits (Global Acceptance Filter List ID Mask Field)

GAFLIDM[28:0] bits are the filter mask bits for the related bits in the CAN Identifier field of each Global Acceptance Filter List entry.

0	Corresponding STD-ID/EXT-ID bit is not used for ID matching
1	Corresponding STD-ID/EXT-ID bit is used for ID matching

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLIFL1 bit (Global Acceptance Filter List Information Label 1)

The GAFLIFL1 bit allows the configuration of a 2-bit information label to be attached to a received message accepted by the associated entry in the Global Acceptance Filter List. This bit is a MSB bit of an information label.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

This bit is stored in the Information Label Field [1] (CFDRMFDSTS.RMIFL[1], CFDRFFDSTS.RFIFL[1], CFDCFFDCSTSn.CFIFL[1]) of the storage location of an incoming message.

Note: This bit is stored in CFDTHLACC1n.TIFL[1] when CFDTHLCCn.THLDGE = 1 is set up using Gateway function.

GAFLRTRM bit (Global Acceptance Filter List Entry RTR Mask)

The GAFLRTRM bit allows the configuration of the RTR mask bit for each entry in the Global Acceptance Filter List.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLIDEM bit (Global Acceptance Filter List IDE Mask)

The GAFLIDEM bit allows the configuration of the IDE mask bit for each entry in the Global Acceptance Filter List.

When the IDE mask bit is 0, the ID comparison depends on the received IDE bit.

If the received IDE bit is 0, the STD-ID comparison takes place.

If the received IDE bit is 1, the EXT-ID comparison takes place.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

35.3.21 CFDGAFLP0n : Global Acceptance Filter List Pointer 0 Register n (n = 1 to 16)

Base address: CANFD = 0x8004_0000

Offset address: 0x1808 + 0x10 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	GAFLPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GAFL RMV	—	—	GAFLRMDP[4:0]					GAFLI FL0	GAFL SRD2	GAFL SRD1	GAFL SRD0	GAFLDLC[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	GAFLDLC[3:0]	Global Acceptance Filter List DLC Field Minimum number of data bytes in a data frame required for acceptance	R/W
4	GAFLSRD0	Global Acceptance Filter List Select Routing Destination 0 0: Routing target is CFIFO0 1: Routing target is TX Queue 0 instead of CFIFO0	R/W
5	GAFLSRD1	Global Acceptance Filter List Select Routing Destination 1 0: Routing target is CFIFO1 1: Routing target is TX Queue 1 instead of CFIFO1	R/W
6	GAFLSRD2	Global Acceptance Filter List Select Routing Destination 2 0: Routing target is CFIFO2 1: Routing target is TX Queue 2 instead of CFIFO2	R/W
7	GAFLIFL0	Global Acceptance Filter List Information Label 0	R/W
12:8	GAFLRMDP[4:0]	Global Acceptance Filter List RX Message Buffer Direction Pointer RX message buffer number for storage of received messages	R/W
14:13	—	These bits are read as 0. The write value should be 0.	R/W
15	GAFLRMV	Global Acceptance Filter List RX Message Buffer Valid 0: Single message buffer direction pointer is invalid 1: Single message buffer direction pointer is valid	R/W
31:16	GAFLPTR[15:0]	Global Acceptance Filter List Pointer	R/W

The CFDGAFLP0n register (n = 1 to 16) is used to configure the data length code (DLC), software pointer, single message buffer select, and message buffer direction pointer for each rule entry in the Global Acceptance Filter List.

GAFLDLC[3:0] bits (Global Acceptance Filter List DLC Field)

The GAFLDLC[3:0] bits allow the configuration of a minimum data length code (DLC) value for a message to be accepted by the associated entry in the Global Acceptance Filter List (automatic DLC filter function).

DLC filter process is only passed if the DLC value of the message accepted by an entry in the Global Acceptance Filter List is equal to or higher than the DLC value configured for this associated Global Acceptance Filter List entry. Automatic DLC filter function is disabled for the corresponding rule entry when this field is set to 0.

Table 35.7 shows DLC value that can be configured.

Table 35.7 Configuration of DLC value

Format	DLC[3:0]	Description
CAN and CAN-FD	0000b	DLC of received message = 0 or more (DLC filter check is disabled)
CAN and CAN-FD	0001b	DLC of received message = 1 or more
CAN and CAN-FD	0010b	DLC of received message = 2 or more
CAN and CAN-FD	0011b	DLC of received message = 3 or more
CAN and CAN-FD	0100b	DLC of received message = 4 or more
CAN and CAN-FD	0101b	DLC of received message = 5 or more
CAN and CAN-FD	0110b	DLC of received message = 6 or more
CAN and CAN-FD	0111b	DLC of received message = 7 or more
CAN	1xxxb	DLC of received message = 8 or more
CAN-FD	1000b	DLC of received message = 8 or more*1
CAN-FD	1001b	DLC of received message = 12 or more*1
CAN-FD	1010b	DLC of received message = 16 or more*1
CAN-FD	1011b	DLC of received message = 20 or more*1
CAN-FD	1100b	DLC of received message = 24 or more*1
CAN-FD	1101b	DLC of received message = 32 or more*1
CAN-FD	1110b	DLC of received message = 48 or more*1
CAN-FD	1111b	DLC of received message = 64*1

Note 1. This setting is not available in the classical CAN function.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLSRD0 bit (Global Acceptance Filter List Select Routing Destination 0)

The GAFLSRD0 bit changes a copy destination to CFIFO0 or TXQ0 by routing.

If this bit is set as 1, the preset value of CFDGAFLP1n.GAFLFDP selects TXQ0.

If this bit is set to 0, the preset value of CFDGAFLP1n.GAFLFDP selects CFIFO0.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLSRD1 bit (Global Acceptance Filter List Select Routing Destination 1)

The GAFLSRD1 bit changes a copy destination to CFIFO1 or TXQ1 by routing.

If this bit is set to 1, the preset value of CFDGAFLP1n.GAFLFDP selects TXQ1.

If this bit is set to 0, the preset value of CFDGAFLP1n.GAFLFDP selects CFIFO1.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLSRD2 bit (Global Acceptance Filter List Select Routing Destination 2)

The GAFLSRD2 bit changes a copy destination to CFIFO2 or TXQ2 by routing.

If this bit is set to 1, the preset value of CFDGAFLP1n.GAFLFDP selects TXQ2.

If this bit is set to 0, the preset value of CFDGAFLP1n.GAFLFDP selects CFIFO2.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the CAN-FD module is in CH_RESET or CH_HALT mode.

GAFLIFL0 bit (Global Acceptance Filter List Information Label 0)

The GAFLIFL0 bit allows the configuration of a 2-bit information label that can be attached to a received message accepted by the related Global Acceptance Filter List entry. This bit is a LSB bit of an information label.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

This bit is stored in Information Label Field[0] (CFDRMFDSTS.RMIFL[0], CFDRFFDSTS.RFIFL[0], CFDCFFDCSTSn.CFIFL[0]) of the storage location of an incoming message.

This bit is stored in CFDTHLACC1n.TIFL[0] when CFDTHLCCn.THLDGE = 1 is set up using the gateway function.

GAFLRMDP[4:0] bits (Global Acceptance Filter List RX Message Buffer Direction Pointer)

The GAFLRMDP[4:0] bits allow the configuration of a single reception message buffer as the destination target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry. The value entered is the single destination message buffer number.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

CFDRMNB.NRXMB[7:0] is the value entered in the RX Message Buffer Number Register to configure the number of RX message buffers. The value to be entered in CFDGAFLP0n.GAFLRMDP[4:0] bits should only be between 0x00 and CFDRMNB.NRXMB[7:0] to 1 less.

If CFDRMNB.NRXMB[7:0] = 0x00, the GAFLRMV bit should be configured as 0.

GAFLRMV bit (Global Acceptance Filter List RX Message Buffer Valid)

The GAFLRMV bit allows the enabling or disabling of a single reception message buffer as the target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLPTR[15:0] bits (Global Acceptance Filter List Pointer)

The GAFLPTR[15:0] bits allow the configuration of a 16-bit pointer to be attached to a received message accepted by the related Global Acceptance Filter List entry. The pointer is added during message storage in the Message Buffer area and can be used by the application as a support function. The pointer information can be used for example, to support PDU Identifier allocation for the received message in AUTOSAR systems.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

35.3.22 CFDGAFLP1n : Global Acceptance Filter List Pointer 1 Register n (n = 1 to 16)

Base address: CANFD = 0x8004_0000

Offset address: 0x180C + 0x10 × (n - 1)

Bit position:	31														13																0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	GAFLFDP[13:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	GAFLFDP[13:0]	Global Acceptance Filter List FIFO Direction Pointer FIFO direction pointer bits for received message storage	R/W
31:14	—	These bits are read as 0. The write value should be 0.	R/W

The CFDGAFLP1n register (n = 1 to 16) is used to configure the FIFO direction pointer fields in each Rule Entry of the Global Acceptance Filter List.

GAFLFDP[13:0] bits (Global Acceptance Filter List FIFO Direction Pointer)

The GAFLFDP[13:0] bits allow the configuration of FIFO buffers as the target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry. Each bit of the CFDGAFLP1n.GAFLFDP[13:0] is configured as dedicated FIFO.

Bit	Value (binary)	Function
0	0	Disable RX FIFO 0 as target for reception
	1	Enable RX FIFO 0 as target for reception
1	0	Disable RX FIFO 1 as target for reception
	1	Enable RX FIFO 1 as target for reception
2	0	Disable RX FIFO 2 as target for reception
	1	Enable RX FIFO 2 as target for reception
3	0	Disable RX FIFO 3 as target for reception
	1	Enable RX FIFO 3 as target for reception
4	0	Disable RX FIFO 4 as target for reception
	1	Enable RX FIFO 4 as target for reception
5	0	Disable RX FIFO 5 as target for reception
	1	Enable RX FIFO 5 as target for reception
6	0	Disable RX FIFO 6 as target for reception
	1	Enable RX FIFO 6 as target for reception
7	0	Disable RX FIFO 7 as target for reception
	1	Enable RX FIFO 7 as target for reception
8	0	Disable Common FIFO 0 and Channel 0 TX Queue 0 as target for reception
	1	GAFLSRD0 = 0: Enable Common FIFO 0 as target for reception GAFLSRD0 = 1: Enable Channel 0 TX Queue 0 as target for reception
9	0	Disable Common FIFO 1 and Channel 0 TX Queue 1 as target for reception
	1	GAFLSRD1 = 0: Enable Common FIFO 1 as target for reception GAFLSRD1 = 1: Enable Channel 0 TX Queue 1 as target for reception
10	0	Disable Common FIFO 2 and Channel 0 TX Queue 2 as target for reception
	1	GAFLSRD2 = 0: Enable Common FIFO 2 as target for reception GAFLSRD2 = 1: Enable Channel 0 TX Queue 2 as target for reception
11	0	Disable Common FIFO 3 and Channel 1 TX Queue 0 as target for reception
	1	GAFLSRD0 = 0: Enable Common FIFO 3 as target for reception GAFLSRD0 = 1: Enable Channel 1 TX Queue 0 as target for reception
12	0	Disable Common FIFO 4 and Channel 1 TX Queue 1 as target for reception
	1	GAFLSRD1 = 0: Enable Common FIFO 4 as target for reception GAFLSRD1 = 1: Enable Channel 1 TX Queue 1 as target for reception
13	0	Disable Common FIFO 5 and Channel 1 TX Queue 2 as target for reception
	1	GAFLSRD2 = 0: Enable Common FIFO 5 as target for reception GAFLSRD2 = 1: Enable Channel 1 TX Queue 2 as target for reception

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0. Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

For storage in TX queue, TX queue buffers of a target that is in GW mode is possible.

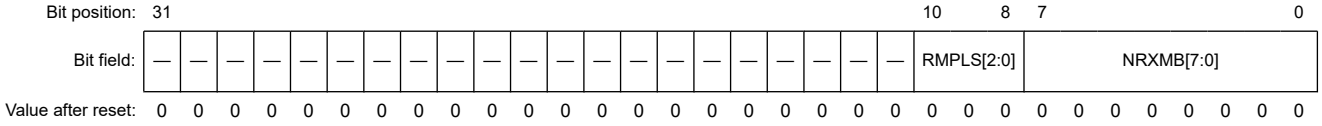
Only one of the following configurations is valid:

- Up to 8 destination FIFO buffers
- 7 destination FIFO buffers plus one RX message buffer
- 8 destination TX queue buffers
- 7 destination TX queue buffers plus one RX message buffer
- A maximum of 8 destinations in all at FIFO buffer and TX queue buffer.

35.3.23 CFDRMNB : RX Message Buffer Number Register

Base address: CANFD = 0x8004_0000

Offset address: 0x00AC



Bit	Symbol	Function	R/W
7:0	NRXMB[7:0]	Number of RX Message Buffers	R/W
10:8	RMPLS[2:0]*1	Reception Message Buffer Payload Data Size 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. These bits are not available in the classical CAN function.

The CFDRMNB register is used to configure the total number of RX message buffers allocated to all channels.

NRXMB[7:0] bits (Number of RX Message Buffers)

The NRXMB[7:0] bits are used to configure the number of RX message buffers.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

Enter only values between 0 and 32 inclusive, with 0x00 indicating that no RX message buffer is allocated.

RMPLS[2:0] bits (Reception Message Buffer Payload Data Size)

The RMPLS[2:0] bits are used to configure the message buffer payload data size.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

35.3.24 CFDRMND0 : RX Message Buffer New Data Register 0

Base address: CANFD = 0x8004_0000

Offset address: 0x00B0

Bit position:	31																												0
Bit field:	RMNS[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RMNS[31:0]	RX Message Buffer New Data Status 0: New data not stored in corresponding RX message buffer 1: New data stored in corresponding RX message buffer	R/W

The CFDRMND0 specifies the new data storage status of the RX message buffers.

RMNS[31:0] bits (RX Message Buffer New Data Status)

The RMNSu[31:0] bits indicate the status of new data for the corresponding RX message buffer. RMNS bit [0] corresponds to RX message buffer [0] and so on.

no_of_channels = 2

no_of_CFDRMBCPs_per_channel = (number of RX message buffer components per channel) = 16

no_of_CFDRMBCPs = no_of_channels × no_of_CFDRMBCPs_per_channel (2 * 16 = 32)

no_of_bits_per_register = 32

no_of_CFDRMNDs (number of CFDRMND Registers) = no_of_CFDRMBCPs / no_of_bits_per_register (32 / 32 = 1)

t = [0 ... no_of_CFDRMNDs - 1]

u = [t * 32 ... (no_of_CFDRMBCPs − ((no_of_CFDRMNDs − 1 − t) * 32) − 1)]

t can be calculated from the target of the New Data Status flag (u) using the formula t = floor (u / 32)

Bit position can be calculated using the formula (u − (t * 32))

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode. Writing 1 has no effect.

These bits cannot be cleared when message storage in the corresponding RX message buffer is in progress.
Do not use the bit clear instruction to clear these bits. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

These bits are set automatically when storage of new messages are in the corresponding RX message buffer. These bits are cleared by writing 0. These bits are cleared automatically when the CAN-FD module is in GL_RESET mode.

When CFDRMNB.RMPLS = 000b (maximum 8 bytes payload), the duration of message storage is 6 PCLKM cycles.

When CFDRMNB.RMPLS > 000b, the duration of message storage is 6 PCLKM cycles + 1 for each 4 bytes (maximum of 20 PCLKM cycles for 64 bytes).

Note: This feature is not available in the classical CAN function.

35.3.25 CFDRFCCn : RX FIFO Configuration/Control Register n (n = 0 to 7)

Base address: CANFD = 0x8004_0000

Offset address: 0x00C0 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFFIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RFIGCV[2:0]			RFIM	—	RFDC[2:0]			—	RFPLS[2:0]			—	—	RFIE	RFE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFE	RX FIFO Enable 0: FIFO disabled 1: FIFO enabled	R/W
1	RFIE	RX FIFO Interrupt Enable 0: FIFO interrupt generation disabled 1: FIFO interrupt generation enabled	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
6:4	RFPLS[2:0]*1	Rx FIFO Payload Data Size Configuration 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
10:8	RFDC[2:0]	RX FIFO Depth Configuration 0 0 0: FIFO Depth = 0 messages 0 0 1: FIFO Depth = 4 messages 0 1 0: FIFO Depth = 8 messages 0 1 1: FIFO Depth = 16 messages 1 0 0: FIFO Depth = 32 messages 1 0 1: FIFO Depth = 48 messages 1 1 0: FIFO Depth = 64 messages 1 1 1: FIFO Depth = 128 messages	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
12	RFIM	RX FIFO Interrupt Mode 0: Interrupt generated when RX FIFO counter reaches RFIGCV value from values smaller than RFIGCV 1: Interrupt generated at the end of every received message storage	R/W
15:13	RFIGCV[2:0]	RX FIFO Interrupt Generation Counter Value 0 0 0: Interrupt generated when FIFO is 1/8th full 0 0 1: Interrupt generated when FIFO is 1/4th full 0 1 0: Interrupt generated when FIFO is 3/8th full 0 1 1: Interrupt generated when FIFO is 1/2 full 1 0 0: Interrupt generated when FIFO is 5/8th full 1 0 1: Interrupt generated when FIFO is 3/4th full 1 1 0: Interrupt generated when FIFO is 7/8th full 1 1 1: Interrupt generated when FIFO is full	R/W
16	RFFIE	RX FIFO Full Interrupt Enable 0: FIFO interrupt generation disabled 1: FIFO interrupt generation enabled	R/W

Bit	Symbol	Function	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. These bits are not available in the classical CAN function.

The CFDRFCCn registers (n = 0 to 7) are used to configure and control the eight RX FIFOs.

RFE bit (RX FIFO Enable)

The RFE bit enables the FIFO. When this bit is set to 0, the RX FIFO is cleared to empty.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

This bit can only be set if the configured FIFO depth is greater than 000b (CFDRFCCn.RFDC[2:0] > 000b).

Set the RFE bit with a separate write access to the CFDRFCCn register, after all the other bits in the CFDRFCCn register are set.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

RFIE bit (RX FIFO Interrupt Enable)

The RFIE bit enables generation of the FIFO interrupt.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

RFPLS[2:0] bits (Rx FIFO Payload Data Size Configuration)

The RFPLS[2:0] bits define the message data payload allocation in the RAM.

This is the maximum number of bytes which can be received by this FIFO.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

RFDC[2:0] bits (RX FIFO Depth Configuration)

The RFDC[2:0] bits select the depth of the FIFO in terms of the number of messages. If the FIFO depth is configured to 0 messages, the FIFO cannot be used.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

RFIM bit (RX FIFO Interrupt Mode)

The RFIM bit selects the interrupt generation condition for the FIFO.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

RFIGCV[2:0] bits (RX FIFO Interrupt Generation Counter Value)

The RFIGCV[2:0] bits select the counter value of the FIFO for generation of FIFO interrupts. These values represent fractions of the FIFO depth for which an interrupt is generated.

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode.

The setting of the RFIGCV[2:0] bits should be synchronized with the RFDC[2:0] bits.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

RFFIE bit (RX FIFO Full Interrupt Enable)

The RFFIE bit enables generation of the RX FIFO full interrupt. Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

The following content shows examples of interruptions:

- Interruption output in number of arbitrary stages (CFDRFCCn.RFIGCV)
- Interruption output in FIFO full state.

Note: Management of the receiving data of FIFO can be performed by these notices of interruption.

35.3.26 CFDRFSTSn : RX FIFO Status Register n (n = 0 to 7)

Base address: CANFD = 0x8004_0000

Offset address: 0x00E0 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFFIF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RFMC[7:0]								—	—	—	—	RFIF	RFMLT	RFFLL	RFEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	RFEMP	RX FIFO Empty 0: FIFO not empty 1: FIFO empty	R
1	RFFLL	RX FIFO Full 0: FIFO not full 1: FIFO full	R
2	RFMLT	RX FIFO Message Lost 0: No message lost in FIFO 1: FIFO message lost	R/W
3	RFIF	RX FIFO Interrupt Flag 0: FIFO interrupt condition not satisfied 1: FIFO interrupt condition satisfied	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
15:8	RFMC[7:0]	RX FIFO Message Count Number of messages stored in FIFO	R
16	RFFIF	RX FIFO Full Interrupt Flag 0: FIFO full interrupt condition not satisfied 1: FIFO full interrupt condition satisfied	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

The CFDRFSTSn register (n = 0 to 7) shows the status of messages stored in the corresponding FIFO buffers.

RFEMP bit (RX FIFO Empty)

The RFEMP bit is set automatically when:

- The RFMC bit is 0
- RX FIFO is disabled by setting the CFDRFCCn.RFE bit to 0
- The CAN-FD module is in GL_RESET mode.

The RFEMP bit is cleared automatically when the first message is stored in the RX FIFO buffer.

RFFLL bit (RX FIFO Full)

The RFFLL bit is set automatically when the number of CAN messages stored in the FIFO buffer matches the configured FIFO depth.

The RFFLL is cleared automatically when:

- The number of CAN messages stored in the FIFO buffer is less than the configured FIFO depth
- RX FIFO is disabled by setting the CFDRFCCn.RFE bit to 0
- The CAN-FD module is in GL_RESET mode.

RFMLT bit (RX FIFO Message Lost)

Only write to the RFMLT bit when CAN-FD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically whenever a message is lost due to attempted storage when the FIFO buffer is already full. If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode.

RFIF bit (RX FIFO Interrupt Flag)

The RFIF bit is set automatically when the configured interrupt condition is satisfied. This bit is not automatically cleared when the RX FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

The bit is cleared by writing 0 to it. The bit is also cleared when CAN-FD module is in GL_RESET mode.

RFMC[7:0] bits (RX FIFO Message Count)

The RFMC[7:0] bits indicate the number of CAN messages stored in the RX FIFO buffer that can be read by the CPU.

These bits are cleared automatically when the FIFO is disabled and when the CAN-FD module is in GL_RESET mode.

RFFIF bit (RX FIFO Full Interrupt Flag)

The RFFIF bit is not cleared automatically when the RX FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the FIFO full interrupt condition is satisfied. If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared by writing 0 to it.

The bit is also cleared when the CAN-FD module is in GL_RESET mode.

35.3.27 CFDRFPCTRn : RX FIFO Pointer Control Register n (n = 0 to 7)

Base address: CANFD = 0x8004_0000

Offset address: 0x0100 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RFPC[7:0]	RX FIFO Pointer Control Increments read pointer of the corresponding RX FIFO buffers	R/W
31:8	—	The write value should be 0.	R/W

The CFDRFPCTRn register (n = 0 to 7) can be used to increment the read pointer of the corresponding RX FIFO buffers.

RFPC[7:0] bits (RX FIFO Pointer Control)

When the value 0xFF is written to the RFPC bits, the pointer of the corresponding RX FIFO buffer is moved to the next FIFO entry. Only write 0xFF to these registers when the corresponding RX FIFO buffer is enabled and not empty.

The read value from these bits is always 0x00.

Only write to these bits when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

Do not write to the RX FIFO Pointer Control registers when DMA is enabled.

35.3.28 CFDCFCCn : Common FIFO Configuration/Control Register n (n = 0 to 5)

Base address: CANFD = 0x8004_0000

Offset address: 0x0120 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CFITT[7:0]								CFDC[2:0]			CFTML[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CFIGCV[2:0]			CFIM	CFITR	CFITSS	CFM[1:0]		—	CFPLS[2:0]			—	CFTXIE	CFRXIE	CFE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CFE	Common FIFO Enable 0: FIFO disabled 1: FIFO enabled	R/W
1	CFRXIE	Common FIFO RX Interrupt Enable 0: FIFO interrupt generation disabled for Frame RX 1: FIFO interrupt generation enabled for Frame RX	R/W
2	CFTXIE	Common FIFO TX Interrupt Enable 0: FIFO interrupt generation disabled for Frame TX 1: FIFO interrupt generation enabled for Frame TX	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
6:4	CFPLS[2:0]*1	Common FIFO Payload Data Size Configuration 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
9:8	CFM[1:0]	Common FIFO Mode 0 0: RX FIFO mode 0 1: TX FIFO mode 1 0: CAN – CAN GW FIFO mode 1 1: Reserved	R/W
10	CFITSS	Common FIFO Interval Timer Source Select 0: Reference clock (× 1 / × 10 period) 1: Bit time clock of related channel (FIFO is linked to fixed channel)	R/W
11	CFITR	Common FIFO Interval Timer Resolution 0: Reference clock period × 1 1: Reference clock period × 10	R/W

Bit	Symbol	Function	R/W
12	CFIM	Common FIFO Interrupt Mode 0: RX FIFO mode: RX interrupt generated when Common FIFO counter reaches CFIGCV value from a lower value TX FIFO mode: TX interrupt generated when Common FIFO transmits the last message successfully GW FIFO mode: For RX interrupt flag: Interrupt generated when FIFO counter increments and reaches the value configured in CFIGCV For TX interrupt flag: Interrupt generated when FIFO transmits the last message successfully 1: RX FIFO mode: RX interrupt generated at the end of every received message storage TX FIFO mode: TX interrupt generated for every successfully transmitted message GW FIFO mode: For RX interrupt flag: Interrupt generated when a message is stored in the FIFO For TX interrupt flag: Interrupt generated when a message is successfully transmitted from the FIFO	R/W
15:13	CFIGCV[2:0]	Common FIFO Interrupt Generation Counter Value 0 0 0: Interrupt generated when FIFO is 1/8th full 0 0 1: Interrupt generated when FIFO is 1/4th full 0 1 0: Interrupt generated when FIFO is 3/8th full 0 1 1: Interrupt generated when FIFO is 1/2 full 1 0 0: Interrupt generated when FIFO is 5/8th full 1 0 1: Interrupt generated when FIFO is 3/4th full 1 1 0: Interrupt generated when FIFO is 7/8th full 1 1 1: Interrupt generated when FIFO is full	R/W
20:16	CFTML[4:0]	Common FIFO TX Message Buffer Link Transmission scan link position of the corresponding channel	R/W
23:21	CFDC[2:0]	Common FIFO Depth Configuration 0 0 0: FIFO Depth = 0 messages 0 0 1: FIFO Depth = 4 messages 0 1 0: FIFO Depth = 8 messages 0 1 1: FIFO Depth = 16 messages 1 0 0: FIFO Depth = 32 messages 1 0 1: FIFO Depth = 48 messages 1 1 0: FIFO Depth = 64 messages 1 1 1: FIFO Depth = 128 messages	R/W
31:24	CFITT[7:0]	Common FIFO Interval Transmission Time Delay the start of transmission from the FIFO if configured in TX or GW mode, delay is a multiple of basic Interval Timer Clock Source unit	R/W

Note 1. These bits are not available in the classical CAN function.

The CFDCFCCn register (n = 0 to 5) is used to configure the Common FIFOs.

CFE bit (Common FIFO Enable)

The CFE bit enables the FIFO when set. FIFO is disabled when this bit is cleared.

This bit can also be used, by clearing it, to abort transmission from Common FIFO when configured in TX mode or GW mode, or to stop reception into the Common FIFO in RX mode.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO.

This bit can only be set if the configured FIFO depth is greater than 0 (CFDC bit > 0).

Set the CFE bit with a separate write access to the CFDCFCCn register, after all the other bits in this register are set.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

This bit is also cleared automatically when the related channel is in CH_RESET mode if the FIFO is configured in TX or GW mode.

CFRXIE bit (Common FIFO RX Interrupt Enable)

The CFRXIE bit enables generation of FIFO interrupts when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFTXIE bit (Common FIFO TX Interrupt Enable)

The CFTXIE bit enables generation of common FIFO interrupts when the interrupt flag is set after transmission of a frame from the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFPLS[2:0] bits (Common FIFO Payload Data Size Configuration)

The CFPLS[2:0] bits define the message data payload allocation in the RAM. This is the maximum number of bytes which can be received or transmitted by the FIFO buffer.

For details, see section 35.7. FIFO Buffers and Normal Message Buffer Configuration.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

CFM[1:0] bits (Common FIFO Mode)

The CFM[1:0] bits select the mode of the FIFO. When a hardware reset is applied, all the Common FIFO buffers are configured in RX FIFO mode. Do not configure these bits to 11b.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

CFITSS bit (Common FIFO Interval Timer Source Select)

The CFITSS bit selects the basic clock source for the Interval Transmission Timer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. In addition, do not write to this bit when the CFE bit is set to 1.

Do not write 1 to this bit when CAN-FD communication is used.*1

Note: The bit time clock can vary depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

CFITR bit (Common FIFO Interval Timer Resolution)

The CFITR bit selects the resolution of the reference clock for the Interval Transmission Timer (peripheral clock is the source for the reference clock).

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. Also, do not write to this bit when the CFE bit is set to 1.

CFIM bit (Common FIFO Interrupt Mode)

The CFIM bit selects the interrupt generation condition for the FIFO buffer.

Do not write to this bit in GL_SLEEP mode.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

CFIGCV[2:0] bits (Common FIFO Interrupt Generation Counter Value)

The CFIGCV[2:0] bits select the message counter value for the generation of FIFO interrupts. These values represent fractions of the FIFO depth at which the interrupt is to be generated.

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode.

The setting of these bits should be synchronized with the CFDC[2:0] bits.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

CFTML[4:0] bits (Common FIFO TX Message Buffer Link)

The CFTML[4:0] bits select the normal transmit message buffer position where the TX or GW FIFO is linked to, for transmission scanning.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

CFDC[2:0] bits (Common FIFO Depth Configuration)

The CFDC[2:0] bits select the depth of the common FIFO in terms of the number of messages. If the FIFO depth is configured to 0 message, the FIFO cannot be used.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

CFITT[7:0] bits (Common FIFO Interval Transmission Time)

The CFITT[7:0] bits select the delay in the start of transmission for all messages transmitted from this FIFO buffer when configured in TX or GW mode. The delay is a multiple of the basic interval timer clock source period (reference clock × 1, reference clock × 10, or bit time clock of the related CAN channel).

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode.

Do not write to these bits when the CFE bit is set to 1.

When CFDGCFG.ITRCP[15:0] = 0x0000, set the CFITT[7:0] bits to 0x0000.

35.3.29 CFDCFCCEn : Common FIFO Configuration/Control Enhancement Register n (n = 0 to 5)

Base address: CANFD = 0x8004_0000

Offset address: 0x0180 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFBME
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CFMOWM	—	—	—	—	—	CFOFTXIE	CFOFRXIE	CFFIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CFFIE	Common FIFO Full Interrupt Enable 0: FIFO Interrupt generation disabled 1: FIFO Interrupt generation enabled	R/W
1	CFOFRXIE	Common FIFO One Frame Reception Interrupt Enable 0: One Frame RX interrupt generation disabled 1: One Frame RX interrupt generation enabled	R/W
2	CFOFTXIE	Common FIFO One Frame Transmission Interrupt Enable 0: One Frame TX interrupt generation disabled 1: One Frame TX interrupt generation enabled	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	CFMOWM	Common FIFO Message Overwrite Mode 0: Message discarded mode 1: Message overwrite mode	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
16	CFBME	Common FIFO Buffering Mode Enable 0: Transmission from Common FIFO 1: Transmission halt from Common FIFO	R/W

Bit	Symbol	Function	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

The CFDCFCCEn register (n = 0 to 5) is used to configure the Common FIFOs.

CFFIE bit (Common FIFO Full Interrupt Enable)

The CFFIE bit enables generation of the FIFO full interrupt when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

The following content shows examples of interruptions:

1. Interruption output in number of arbitrary stages (CFDCFCCn.CFIGCV).
2. Interruption output in FIFO full state.

Management of the receiving data of FIFO can be performed by these notices of interruption.

CFOFRXIE bit (Common FIFO One Frame Reception Interrupt Enable)

The CFOFRXIE bit enables generation of the one frame reception interrupt when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFOFTXIE bit (Common FIFO One Frame Transmission Interrupt Enable)

The CFOFTXIE bit enables generation of the one frame transmission interrupt when the interrupt flag is set after transmission of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFMOWM bit (Common FIFO Message Overwrite Mode)

When the CFMOWM bit is 0, a receiving message is discarded and FIFO is full. When the CFMOWM bit is 1, a receiving message is overwritten and FIFO is full.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

Only write 1 to this bit when the common FIFO is in GW mode.

Do not write 1 to this bit when the CFE bit is 1.

CFBME bit (Common FIFO Buffering Mode Enable)

When the CFBME bit is 0, messages are transmitted from FIFO. When the CFBME bit is 1, messages are not transmitted from FIFO.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. Additionally, do not write 1 to this bit when the CFE bit is 1.

35.3.30 CFDCFSTSn : Common FIFO Status Register n (n = 0 to 5)

Base address: CANFD = 0x8004_0000

Offset address: 0x01E0 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	CFMOW	—	—	—	—	—	CFOFTXIF	CFOFRXIF	CFFIF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CFMC[7:0]								—	—	—	CFTXIF	CFRXIF	CFMLT	CFFLL	CFEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	CFEMP	Common FIFO Empty 0: FIFO not empty 1: FIFO empty	R
1	CFFLL	Common FIFO Full 0: FIFO not full 1: FIFO full	R
2	CFMLT	Common FIFO Message Lost 0: FIFO message not lost 1: FIFO message lost	R/W
3	CFRXIF	Common RX FIFO Interrupt Flag 0: FIFO interrupt condition not satisfied after frame reception 1: FIFO interrupt condition satisfied after frame reception	R/W
4	CFTXIF	Common TX FIFO Interrupt Flag 0: FIFO interrupt condition not satisfied after frame transmission 1: FIFO Interrupt condition satisfied after frame transmission	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
15:8	CFMC[7:0]	Common FIFO Message Count Number of messages stored in FIFO	R
16	CFFIF	Common FIFO Full Interrupt Flag 0: Interrupt condition not satisfied for FIFO full interrupt 1: Interrupt condition satisfied for FIFO full interrupt	R/W
17	CFOFRXIF	Common FIFO One Frame Reception Interrupt Flag For each FIFO that receives a frame, a corresponding interrupt is set.	R/W
18	CFOFTXIF	Common FIFO One Frame Transmission Interrupt Flag For each FIFO that transmits a frame, a corresponding interrupt is set.	R/W
23:19	—	These bits are read as 0. The write value should be 0.	R/W
24	CFMOW	Common FIFO Message Overwrite 0: No message overwrite occurred in FIFO 1: Message overwrite occurred in FIFO	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

The CFDCFSTSn register (n = 0 to 5) shows the status of messages stored in the corresponding FIFO buffers.

CFEMP bit (Common FIFO Empty)

The CFEMP bit is set automatically when:

- The CPU has read all messages from the FIFO configured in RX mode
- All messages have been transmitted from the FIFO configured in TX or GW mode
- The FIFO is disabled by setting the CFE bit to 0
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET when FIFO configured in TX or GW mode.

The CFEMP bit is cleared automatically when:

- The first reception message is stored in the FIFO buffer when configured in RX mode
- The first message to be transmitted is stored in the FIFO buffer when configured in TX or GW mode.

CFFLL bit (Common FIFO Full)

The CFFLL bit is set automatically when the number of CAN messages stored in the FIFO matches the configured FIFO depth.

The CFFLL bit is cleared automatically when:

- The number of CAN messages stored in the FIFO is less than the configured FIFO depth
- The FIFO is disabled by setting the CFE bit to 0

- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode when FIFO buffer is configured in TX or GW mode.

CFMLT bit (Common FIFO Message Lost)

The CFMLT bit is set automatically whenever a message is lost due to attempted storage of a new message when FIFO is already full in RX or GW mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The CFMLT bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFRXIF bit (Common RX FIFO Interrupt Flag)

The CFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers when configured in GW mode or RX mode.

The CFRXIF bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in GW mode.

CFTXIF bit (Common TX FIFO Interrupt Flag)

The CFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO buffer configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers configured in GW or TX mode.

The CFTXIF bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFMC[7:0] bits (Common FIFO Message Count)

The CFMC[7:0] bits indicate the following:

- Number of CAN messages stored by the CPU in the FIFO buffer configured in TX mode pending for transmission
- Number of CAN messages stored in the FIFO buffer configured in RX mode by CAN-FD to be read by the CPU
- Number of CAN messages stored by the CAN-FD in the GW FIFO pending for transmission.

The CFMC[7:0] bits are cleared automatically when:

- The FIFO is disabled
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFFIF bit (Common FIFO Full Interrupt Flag)

The CFFIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the FIFO Full Interrupt condition is satisfied for Common FIFO buffers when configured in GW or RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The CFFIF bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFOFRXIF bit (Common FIFO One Frame Reception Interrupt Flag)

The CFOFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for the FIFO buffer configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the One Frame Reception Interrupt condition is satisfied for the Common FIFO buffers when configured in GW or RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The CFOFRXIF bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFOFTXIF bit (Common FIFO One Frame Transmission Interrupt Flag)

The CFOFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the One Frame Transmission Interrupt condition is satisfied for Common FIFO buffers configured in GW mode or TX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO is configured in TX or GW mode.

CFMOW bit (Common FIFO Message Overwrite)

The CFMOW bit is set automatically whenever a message is an overwrite storage of a new message when CFDCFCCEn.CFMOWM = 1 and FIFO is already full in GW mode.

If the set from the CAN channel occurs simultaneously with the clear by a write access, the bit is set.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO buffer configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The CFMOW bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

35.3.31 CFDCFPCTRn : Common FIFO Pointer Control Register n (n = 0 to 5)

Base address: CANFD = 0x8004_0000

Offset address: 0x0240 + 0x04 × n

Bit position:	31																								7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CFPC[7:0]	Common FIFO Pointer Control Increments read or write pointer of the corresponding Common FIFO buffers depending on the mode configuration.	W
31:8	—	The write value should be 0.	W

The CFDCFPCTRn register (n = 0 to 5) can be used to increment the read or write pointer of the corresponding Common FIFO buffer.

CFPC[7:0] bits (Common FIFO Pointer Control)

When the value 0xFF is written into the CFPC[7:0] bits, the read pointer of the corresponding Common FIFO buffer (when configured in RX mode), or the write pointer of the corresponding Common FIFO buffer (when configured in TX mode) moves to the next FIFO entry.

The read value from these bits is always 0x00.

Only write to these bits when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

Only write 0xFF to this register when:

- The Common FIFO buffer is enabled and is not empty if configured in RX mode
- The Common FIFO buffer is enabled and is not full if configured in TX mode
- The Common FIFO buffer is enabled and is not configured in GW mode.

Do not write to the Common FIFO Pointer Control registers when DMA is enabled.

35.3.32 CFDFESTS : FIFO Empty Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x02A0

Bit position:	31																	13					8	7						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXEMP[5:0]						RFXEMP[7:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	RFXEMP[7:0]	RX FIFO Empty Status 0: Corresponding FIFO not empty 1: Corresponding FIFO empty	R
13:8	CFXEMP[5:0]	Common FIFO Empty Status 0: Corresponding FIFO not empty 1: Corresponding FIFO empty	R
31:14	—	These bits are read as 0.	R

The CFDFESTS register shows status of the empty bits of the FIFO buffers.

RFXEMP[7:0] bits (RX FIFO Empty Status)

Bit [7] (RFXEMP[7]) is associated with FIFO index 7 and bit [0] (RFXEMP[0]) is associated with FIFO index 0.

The RFXEMP[7:0] bits are set when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFXEMP[5:0] bits (Common FIFO Empty Status)

Bit [13] (CFXEMP[5]) is associated with common FIFO index 5 and bit [8] (CFXEMP[0]) is associated with common FIFO index 0.

The CFXEMP[5:0] bits are set when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

35.3.33 CFDFFSTS : FIFO Full Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x02A4

Bit position:	31																	13					8	7						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXFLL[5:0]						RFXFLL[7:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RFXFLL[7:0]	RX FIFO Full Status 0: Corresponding FIFO not full 1: Corresponding FIFO full	R
13:8	CFXFLL[5:0]	Common FIFO Full Status 0: Corresponding FIFO not full 1: Corresponding FIFO full	R
31:14	—	These bits are read as 0.	R

The CFDFFSTS register shows status of the full bits of the FIFO buffers.

RFXFLL[7:0] bits (RX FIFO Full Status)

The RFXFLL[7:0] bits are cleared when CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFXFLL[5:0] bits (Common FIFO Full Status)

The CFXFLL[5:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

35.3.34 CFDFMSTS : FIFO Message Lost Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x02A8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXMLT[5:0]						RFXMLT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RFXMLT[7:0]	RX FIFO Message Lost Status 0: Corresponding FIFO Message Lost flag not set 1: Corresponding FIFO Message Lost flag set	R
13:8	CFXMLT[5:0]	Common FIFO Message Lost Status 0: Corresponding FIFO Message Lost flag not set 1: Corresponding FIFO Message Lost flag set	R
31:14	—	These bits are read as 0.	R

The CFDFMSTS register shows status of the message lost bits of the FIFO buffers.

RFXMLT[7:0] bits (RX FIFO Message Lost Status)

The RFXMLT[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFXMLT[5:0] bits (Common FIFO Message Lost Status)

The CFXMLT[5:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

35.3.35 CFDRFISTS : RX FIFO Interrupt Flag Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x02AC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	RFXFFLL[7:0]								—	—	—	—	—	—	—	—	RFXIF[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RFXIF[7:0]	RX FIFO[x] Interrupt Flag Status 0: Corresponding RX FIFO Interrupt flag not set 1: Corresponding RX FIFO Interrupt flag set	R
15:8	—	These bits are read as 0.	R
23:16	RFXFFLL[7:0]	RX FIFO[x] Interrupt Full Flag Status 0: Corresponding RX FIFO Interrupt Full flag not set 1: Corresponding RX FIFO Interrupt Full flag set	R
31:24	—	These bits are read as 0.	R

The CFDRFISTS register shows status of the interrupt flag bits of the RX FIFO buffers.

RFXIF[7:0] bits (RX FIFO[x] Interrupt Flag Status)

Each bit is set automatically when the corresponding interrupt flag bit is set in the RX FIFO Status Registers.

The RFXIF[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding interrupt flag bit is cleared in the RX FIFO Status Registers.

RFXFFLL[7:0] bits (RX FIFO[x] Interrupt Full Flag Status)

Each bit is set automatically when the corresponding interrupt full flag bit is set in the RX FIFO Status Registers.

The RFXFFLL[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding interrupt full flag bit is cleared in the RX FIFO Status Registers.

35.3.36 CFDCFRISTS : Common FIFO RX Interrupt Flag Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x02B0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXRXIF[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CFXRXIF[5:0]	Common FIFO RX Interrupt Flag Status 0: Corresponding Common FIFO RX Interrupt flag not set 1: Corresponding Common FIFO RX Interrupt flag set	R
31:6	—	These bits are read as 0.	R

The CFDCFRISTS register shows status of the interrupt flag bits of the Common FIFO buffers.

CFXRXIF[5:0] bits (Common FIFO RX Interrupt Flag Status)

Each bit is set automatically when the corresponding RX interrupt flag bit is set in the Common FIFO Status Registers.

The CFXRXIF[5:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding RX interrupt flag bit is cleared in the Common FIFO Status Registers.

35.3.37 CFDCFTISTS : Common FIFO TX Interrupt Flag Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x02B4

Bit position:	31																								5						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXTXIF[5:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CFXTXIF[5:0]	Common FIFO TX Interrupt Flag Status 0: Corresponding Common FIFO TX Interrupt flag not set 1: Corresponding Common FIFO TX Interrupt flag set	R
31:6	—	These bits are read as 0.	R

The CFDCFTISTS register shows status of the interrupt flag bits of the Common FIFO buffers.

CFXTXIF[5:0] bits (Common FIFO TX Interrupt Flag Status)

Each bit is set automatically when the corresponding TX interrupt flag bit is set in the Common FIFO Status Registers.

The CFXTXIF[5:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding TX interrupt flag bit is cleared in the Common FIFO Status Registers.

35.3.38 CFDFFFSTS : FIFO FDC Full Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x02C4

Bit position:	31																		13					8	7						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXFFLL[5:0]						RFXFFLL[7:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RFXFFLL[7:0]	RX FIFO FDC Level Full Status 0: Corresponding FIFO full interrupt not set 1: Corresponding FIFO full interrupt set	R
13:8	CFXFFLL[5:0]	COMMON FIFO FDC Level Full Status 0: Corresponding FIFO full interrupt not set 1: Corresponding FIFO full interrupt set	R
31:14	—	These bits are read as 0.	R

The CFDFFFSTS register shows status of the full interrupt flag bits of the FIFO buffers.

RFXFFLL[7:0] bits (RX FIFO FDC Level Full Status)

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

The RFXFFLL[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

CFXFFLL[5:0] bits (COMMON FIFO FDC Level Full Status)

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

The CFXFFLL[5:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

35.3.39 CFDCFMOWSTS : Common FIFO Message Overwrite Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x02C0

Bit position:	31																								5	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXMOW[5:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CFXMOW[5:0]	Common FIFO Massage Overwrite Status 0: Corresponding FIFO Overwrite flag not set 1: Corresponding FIFO Overwrite flag set	R
31:6	—	These bits are read as 0.	R

The CFDCFMOWSTS register shows the status of the Interrupt Flag bits of the Common FIFO Buffers.

CFXMOW[5:0] bits (Common FIFO Massage Overwrite Status)

The CFXMOW[5:0] bits are cleared when the CAN-FD module is in GL_RESET mode. This register is only valid in GW mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

35.3.40 CFDCFOFRISTS : Common FIFO One Frame RX Interrupt Flag Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x02B8

Bit position:	31																								5	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXOFRXIF[5:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CFXOFRXIF[5:0]	Common FIFO One Frame RX Interrupt Flag Status 0: Corresponding Common FIFO One Frame RX Interrupt flag not set 1: Corresponding Common FIFO One Frame RX Interrupt flag set	R
31:6	—	These bits are read as 0.	R

The CFDCFOFRISTS register shows status of the interrupt flag bits of the Common FIFO buffers.

CFXOFRXIF[5:0] bits (Common FIFO One Frame RX Interrupt Flag Status)

Each bit is set automatically when the corresponding One Frame RX Interrupt flag bit is set in the Common FIFO Status Registers.

The CFXOFRXIF[5:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding One Frame RX Interrupt flag bit is cleared in the Common FIFO Status Registers.

35.3.41 CFDCFOFTISTS : Common FIFO One Frame TX Interrupt Flag Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x02BC

Bit position:	31																								5	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXOFTXIF[5:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CFXOFTXIF[5:0]	Common FIFO One Frame TX Interrupt Flag Status 0: Corresponding Common FIFO One Frame TX Interrupt flag not set 1: Corresponding Common FIFO One Frame TX Interrupt flag set	R
31:6	—	These bits are read as 0.	R

The CFDCFOFTISTS register shows status of the interrupt flag bits of the Common FIFO buffers.

CFXOFTXIF[5:0] bits (Common FIFO One Frame TX Interrupt Flag Status)

Each bit is set automatically when the corresponding One Frame TX Interrupt flag bit is set in the Common FIFO Status Registers.

The CFXOFTXIF[5:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding One Frame TX Interrupt flag bit is cleared in the Common FIFO Status Registers.

35.3.42 CFDCDTCT : DMA Transfer Control Register

Base address: CANFD = 0x8004_0000

Offset address: 0x1330

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CFDMAE1	CFDMAE0	RFDMAE7	RFDMAE6	RFDMAE5	RFDMAE4	RFDMAE3	RFDMAE2	RFDMAE1	RFDMAE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFDMAE0	DMA Transfer Enable for RX FIFO 0 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
1	RFDMAE1	DMA Transfer Enable for RX FIFO 1 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
2	RFDMAE2	DMA Transfer Enable for RX FIFO 2 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
3	RFDMAE3	DMA Transfer Enable for RX FIFO 3 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W

Bit	Symbol	Function	R/W
4	RFDMAE4	DMA Transfer Enable for RX FIFO 4 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
5	RFDMAE5	DMA Transfer Enable for RX FIFO 5 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
6	RFDMAE6	DMA Transfer Enable for RX FIFO 6 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
7	RFDMAE7	DMA Transfer Enable for RX FIFO 7 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
8	CFDMAE0	DMA Transfer Enable for Common FIFO 0 of Channel 0 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
9	CFDMAE1	DMA Transfer Enable for Common FIFO 0 of Channel 1 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

The CFDCDTCT register controls the start and stop of DMA transfer operation.

RFDMAEn (n = 0 to 7) bit (DMA Transfer Enable for RX FIFOn)

Number of RX FIFOs = 8

The RFDMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

CFDMAEn (n = 0, 1) bit (DMA Transfer Enable for Common FIFO 0 of Channel 0, 1)

The CFDMAEn bit enables or disables DMA transfer request for common FIFO 0 of channel 0 or 1. Only Common FIFO 0 can be linked to a DMA channel with this bit. Common FIFO 1 cannot be linked to a DMA channel.

To link Common FIFO 2, see bit CFDCDTTCT.CFDMAEn in section 35.3.44. CFDCDTTCT : DMA TX Transfer Control Register.

The CFDMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

Do not enable a DMA transfer for a Common FIFO that is configured as TX or GW FIFO.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

35.3.43 CFDCDTSTS : DMA Transfer Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x1334

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CFDMASTS1	CFDMASTS0	RFDMASTS7	RFDMASTS6	RFDMASTS5	RFDMASTS4	RFDMASTS3	RFDMASTS2	RFDMASTS1	RFDMASTS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFDMASTS0	DMA Transfer Status for RX FIFO 0 0: DMA transfer stopped 1: DMA transfer on going	R
1	RFDMASTS1	DMA Transfer Status for RX FIFO 1 0: DMA transfer stopped 1: DMA transfer on going	R
2	RFDMASTS2	DMA Transfer Status for RX FIFO 2 0: DMA transfer stopped 1: DMA transfer on going	R
3	RFDMASTS3	DMA Transfer Status for RX FIFO 3 0: DMA transfer stopped 1: DMA transfer on going	R
4	RFDMASTS4	DMA Transfer Status for RX FIFO 4 0: DMA transfer stopped 1: DMA transfer on going	R
5	RFDMASTS5	DMA Transfer Status for RX FIFO 5 0: DMA transfer stopped 1: DMA transfer on going	R
6	RFDMASTS6	DMA Transfer Status for RX FIFO 6 0: DMA transfer stopped 1: DMA transfer on going	R
7	RFDMASTS7	DMA Transfer Status for RX FIFO 7 0: DMA transfer stopped 1: DMA transfer on going	R
8	CFDMASTS0	DMA Transfer Status only for Common FIFO 0 of Channel 0 0: DMA transfer stopped 1: DMA transfer on going	R
9	CFDMASTS1	DMA Transfer Status only for Common FIFO 0 of Channel 1 0: DMA transfer stopped 1: DMA transfer on going	R
31:10	—	These bits are read as 0.	R

The CFDCDTSTS register shows the status of the DMA transfer.

RFDMASTSn (n = 0 to 7) bit (DMA Transfer Status for RX FIFO n)

Number of RX FIFOs = 8

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.RFDMAEn (see CFDCDTCT.RFDMAEn bit in section 35.3.42. CFDCDTCT : DMA Transfer Control Register) is set to 0 while DMA transfer for the corresponding FIFO is on going, the RFDMASTSn bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

CFDMASTSn bit (DMA Transfer Status only for Common FIFO 0 of Channel 0, 1)

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.CFDMAEn (see CFDCDTCT.CFDMAEn bit in section 35.3.42. CFDCDTCT : DMA Transfer Control Register) is set to 0 while DMA transfer for the corresponding FIFO is on going, the CFDMASTSn bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

35.3.44 CFDCDTTCT : DMA TX Transfer Control Register

Base address: CANFD = 0x8004_0000

Offset address: 0x1340

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFDMAE1	CFDMAE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TQ3DMAE1	TQ3DMAE0	—	—	—	—	—	—	TQ0DMAE1	TQ0DMAE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TQ0DMAE0	DMA TX Transfer Enable for TXQ 0 of Channel 0 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled	R/W
1	TQ0DMAE1	DMA TX Transfer Enable for TXQ 0 of Channel 1 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	TQ3DMAE0	DMA TX Transfer Enable for TXQ 3 of Channel 0 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled	R/W
9	TQ3DMAE1	DMA TX Transfer Enable for TXQ 3 of Channel 1 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	CFDMAE0	DMA TX Transfer Enable for Common FIFO 2 of Channel 0 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled	R/W
17	CFDMAE1	DMA TX Transfer Enable for Common FIFO 2 of Channel 1 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The CFDCDTTCT register controls the start and stop of DMA transfer operation.

TQ0DMAEn (n = 0, 1) bit (DMA TX Transfer Enable for TXQ 0 of Channel n)

The TQ0DMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

TQ3DMAEn (n = 0, 1) bit (DMA TX Transfer Enable for TXQ 3 of Channel n)

The TQ3DMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

CFDMAEn (n = 0, 1) bit (DMA TX Transfer Enable for Common FIFO 2 of Channel n)

The CFDMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

Only common FIFO 2 can be linked to a DMA channel with this bit. Common FIFO 1 cannot be linked to a DMA channel.

To link Common FIFO 0, see CFDCDTCT.CFDMAEn bit in section 35.3.42. CFDCDTCT : DMA Transfer Control Register.

Do not enable a DMA transfer for a Common FIFO that is configured as RX or GW FIFO.

The CFDMAEn bit is cleared when the CAN-FD module is in GL_RESET mode.

35.3.45 CFDCDTTSTS : DMA TX Transfer Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x1344

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFDMASTS1	CFDMASTS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TQ3DMASTS1	TQ3DMASTS0	—	—	—	—	—	—	TQ0DMASTS1	TQ0DMASTS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TQ0DMASTS0	DMA TX Transfer Status for TXQ0 of Channel 0 0: DMA TX transfer stopped 1: DMA TX transfer enabled	R
1	TQ0DMASTS1	DMA TX Transfer Status for TXQ0 of Channel 1 0: DMA TX transfer stopped 1: DMA TX transfer enabled	R
7:2	—	These bits are read as 0.	R
8	TQ3DMASTS0	DMA TX Transfer Status for TXQ3 of Channel 0 0: DMA TX transfer stopped 1: DMA TX transfer enabled	R
9	TQ3DMASTS1	DMA TX Transfer Status for TXQ3 of Channel 1 0: DMA TX transfer stopped 1: DMA TX transfer enabled	R
15:10	—	These bits are read as 0.	R
16	CFDMASTS0	DMA TX Transfer Status for Common FIFO 2 of Channel 0 0: DMA TX transfer stopped 1: DMA TX transfer enabled	R
17	CFDMASTS1	DMA TX Transfer Status for Common FIFO 2 of Channel 1 0: DMA TX transfer stopped 1: DMA TX transfer enabled	R
31:18	—	These bits are read as 0.	R

The CFDCDTTSTS register shows the status of the DMA TX transfer.

TQ0DMASTSn (n = 0, 1) bit (DMA TX Transfer Status for TXQ 0 of Channel n)

The TQ0DMASTSn bit is set when the CFDCDTTCT.TQ0DMAEn bit in the corresponding CFDCDTTCT register is set (see section 35.3.44. CFDCDTTCT : DMA TX Transfer Control Register).

This bit is cleared when:

- The CFDCDTTCT.TQ0DMAEn bit in the corresponding CFDCDTTCT register is cleared
- The CAN-FD module is in GL_RESET mode.

TQ3DMASTSn (n = 0, 1) bit (DMA TX Transfer Status for TXQ 3 of Channel n)

The TQ3DMASTSn bit is set when the CFDCDTTCT.TQ3DMAEn bit in the corresponding CFDCDTTCT register is set (see section 35.3.44. CFDCDTTCT : DMA TX Transfer Control Register).

This bit is cleared when:

- The CFDCDTTCT.TQ3DMAEn bit in the corresponding CFDCDTTCT register is cleared

- The CAN-FD module is in GL_RESET mode.

CFDMASTSn (n = 0, 1) bit (DMA TX Transfer Status only for Common FIFO 2 of Channel n)

The CFDMASTSn bit is set when the CFDCDTTCT.CFDMAEn bit in the corresponding CFDCDTTCT register is set (see section 35.3.44. CFDCDTTCT : DMA TX Transfer Control Register).

This bit is cleared when:

- The CFDCDTTCT.CFDMAEn bit in the corresponding CFDCDTTCT register is cleared
- The CAN-FD module is in GL_RESET mode.

35.3.46 CFDGRINTSTSn : Global RX Interrupt Status Register n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1350 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7:6	—	These bits are read as 0.	R
10:8	QOFRIF[2:0]	TXQ One Frame RX Interrupt Flag Channel n (n = 0, 1) 0: Corresponding TXQ One Frame RX Interrupt flag is not set 1: Corresponding TXQ One Frame RX Interrupt flag is set	R
11	—	This bit is read as 0.	R
13:12	BQOFRIF[1:0]	Borrowed TXQ One Frame RX Interrupt Flag Channel n (n = 0, 1) 0: Corresponding TXQ One Frame RX Interrupt flag is not set 1: Corresponding TXQ One Frame RX Interrupt flag is set	R
15:14	—	These bits are read as 0.	R
18:16	CFRIF[2:0]	Common FIFO RX Interrupt Flag Channel n (n = 0, 1) 0: Corresponding Common FIFO RX Interrupt flag is not set 1: Corresponding Common FIFO RX Interrupt flag is set	R
23:19	—	These bits are read as 0.	R
26:24	CFRFIF[2:0]	Common FIFO FDC Level Full Interrupt Flag Channel n (n = 0, 1) 0: Corresponding Common FIFO Full Interrupt flag is not set 1: Corresponding Common FIFO Full Interrupt flag is set	R
27	—	This bit is read as 0.	R
30:28	CFOFRIF[2:0]	Common FIFO One Frame RX Interrupt Flag Channel n (n = 0, 1) 0: Corresponding Common FIFO One Frame RX Interrupt flag is not set 1: Corresponding Common FIFO One Frame RX Interrupt flag is set	R
31	—	This bit is read as 0.	R

QFIF[2:0] bits (TXQ Full Interrupt Flag Channel n (n = 0, 1))

The QFIF[2:0] bits are set automatically when the TXQ Full Interrupt flag of the related channel is set when the interrupt is enabled.

The QFIF[2:0] bits are cleared automatically when:

- The related TXQ result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

BQFIF[1:0] bits (Borrowed TXQ Full Interrupt Flag Channel n (n = 0, 1))

The BQFIF[1:0] bits are set when a flexible transmission buffer assignment function is used and the borrowed TXQ is in full status. Operation is the same as CFDGRINTSTSn.QFIF.

The bit of the channel that lends TXMB is a reserved bit.

QOFRIF[2:0] bits (TXQ One Frame RX Interrupt Flag Channel n (n = 0, 1))

The QOFRIF[2:0] bits are set automatically when the TXQ One Frame RX Interrupt flag of the related channel is set when the interrupt is enabled.

The QOFRIF[2:0] bits are cleared automatically when:

- The related TXQ result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET or CH_RESET mode.

BQOFRIF[1:0] bits (Borrowed TXQ One Frame RX Interrupt Flag Channel n (n = 0, 1))

The BQOFRIF[1:0] bits are set when a flexible transmission buffer assignment function is used and the borrowed TXQ receives one frame. Operation is the same as CFDGRINTSTSn.QOFRIF.

The bit of the channel that lends TXMB is a reserved bit.

CFRIF[2:0] bits (Common FIFO RX Interrupt Flag Channel n (n = 0, 1))

The CFRIF[2:0] bits are set automatically when the Common FIFO RX Interrupt flag of the related channel is set when the interrupt is enabled.

The CFRIF[2:0] bits are cleared automatically when:

- The related Common FIFO RX result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET or CH_RESET mode.

CFRFIF[2:0] bits (Common FIFO FDC Level Full Interrupt Flag Channel n (n = 0, 1))

The CFRFIF[2:0] bits are set automatically when the Common FIFO Full Interrupt flag of the related channel is set when the interrupt is enabled.

The CFRFIF[2:0] bits are cleared automatically when:

- The related Common FIFO RX result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

CFOFRIF[2:0] bits (Common FIFO One Frame RX Interrupt Flag Channel n (n = 0, 1))

The CFOFRIF[2:0] bits are set automatically when the Common FIFO One Frame RX Interrupt flag of the related channel is set when the interrupt is enabled.

The CFOFRIF[2:0] bits are cleared automatically when:

- The related Common FIFO RX result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

35.3.47 CFDTMCn : TX Message Buffer Control Register n (n = 0 to 127)

Base address: CANFD = 0x8004_0000

Offset address: 0x02D0 + 0x01 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	TMOM	TMTAR	TMTR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMTR	TX Message Buffer Transmission Request 0: TX Message buffer transmission not requested 1: TX message buffer transmission requested	R/W
1	TMTAR	TX Message Buffer Transmission Abort Request 0: TX message buffer transmission request abort not requested 1: TX message buffer transmission request abort requested	R/W
2	TMOM	TX Message Buffer One-shot Mode 0: TX message buffer not configured in one-shot mode 1: TX message buffer configured in one-shot mode	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

The CFDTMCn register (n = 0 to 127) configures the TX message buffer functions.

TMTR bit (TX Message Buffer Transmission Request)

When the TMTR bit is set, the CAN-FD module logic tries to transmit the message stored in the corresponding message buffer.

Only write to this bit when the related CAN-FD module is in CH_HALT or CH_OPERATION mode.

Do not set this bit if the corresponding TX message buffer is linked to a COM FIFO in TX or GW mode or is a part of TX Queue.

This bit cannot be directly cleared by a CPU write access.

This bit can only be set when the Transmission Result flag bits (CFDTMSTSn.TMTRF[1:0]) in the CFDTMSTSn register corresponding to the message buffer are cleared to 00b.

The TMTR bit is automatically cleared by the:

- CAN-FD module logic at the end of a successful transmission
- CAN-FD module logic at the end of a transmission abort, requested by the corresponding CFDTMCn.TMTAR bit
- CAN-FD module logic when there is a detection of a CAN bus error or arbitration loss if CFDTMCn.TMOM bit is set for the message buffer
- CAN-FD module logic when the CAN-FD module is in GL_RESET mode or the related channel is in CH_RESET mode.

TMTAR bit (TX Message Buffer Transmission Abort Request)

When the TMTAR bit is set, the CAN-FD module logic tries to abort the transmission of the frame stored in the corresponding message buffer.

In most cases, transmission cannot be aborted if the internal scan for transmission is complete and the message buffer has already been selected for transmission. In this case, frame may be transmitted successfully from the message buffer. The message buffer selection is released by entering CH_HALT mode.

However, message buffer selected for transmission can be aborted by an abort request when the CAN node detects a new message on the bus (RX pin) before it starts transmission from the selected message buffer.

Only write to the TMTAR bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode. This bit can only be set when the related transmit request TMTR bit is set.

The TMTAR bit cannot be cleared by a CPU write access. Clearing of this bit by CAN-FD has priority over setting by a CPU write access.

The TMTAR bit is automatically cleared by:

- The CAN-FD module logic at the end of a successful transmission
- The CAN-FD module logic at the end of a transmission abort
- The CAN-FD module logic when there is detection of a CAN bus error or arbitration loss
- The CAN-FD module logic when the CAN-FD module is in GL_RESET mode or the related channel enters CH_RESET mode.

TMOM bit (TX Message Buffer One-shot Mode)

When the TMOM bit is set, the CAN-FD module logic tries to transmit the message only once.

If the transmission is successful, the CFDTMSTSn.TMTRF[1:0] bits are set to 10b or 11b. Otherwise, the transmission is automatically aborted and CFDTMSTSn.TMTRF[1:0] bits are set to 01b due to a bus error or a bus arbitration lost.

The TMOM bit remains set if the transmission has completed successfully or aborted due to an error or a loss of arbitration.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Set this bit at the same time as the TMTR bit. Clear this bit with a write access.

If a message has already been requested for transmission, do not write to this bit until the message has been successfully transmitted or transmission has been aborted.

The TMOM bit is automatically cleared by the CAN-FD module logic when the CAN-FD module is in GL_RESET mode or the related channel is in CH_RESET mode.

35.3.48 CFDTMSTSn : TX Message Buffer Status Register n (n = 0 to 127)

Base address: CANFD = 0x8004_0000

Offset address: 0x07D0 + 0x01 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TMTARM	TMTRM	TMTRF[1:0]		TMTSTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMTSTS	TX Message Buffer Transmission Status 0: No on-going transmission 1: On-going transmission	R
2:1	TMTRF[1:0]	TX Message Buffer Transmission Result Flag 0 0: No result 0 1: Transmission aborted from the TX message buffer 1 0: Transmission successful from the TX message buffer and transmission abort was not requested 1 1: Transmission successful from the TX message buffer and transmission abort was requested	R/W
3	TMTRM	TX Message Buffer Transmission Request Mirrored 0: TX message buffer transmission not requested 1: TX message buffer transmission requested	R
4	TMTARM	TX Message Buffer Transmission Abort Request Mirrored 0: TX message buffer transmission request abort not requested 1: TX message buffer transmission request abort requested	R
7:5	—	These bits are read as 0. The write value should be 0.	R/W

The CFDTMSTSn register (n = 0 to 127) shows status of the transmission and transmission abort for the corresponding message buffers.

TMTSTS bit (TX Message Buffer Transmission Status)

The TMTSTS bit is set automatically at the start of the transmission from the corresponding TX message buffer.

This bit is cleared automatically when:

- Transmission stops
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

TMTRF[1:0] bits (TX Message Buffer Transmission Result Flag)

The TMTRF[1:0] bits show the result for the corresponding TX message buffer. The status is as follows:

- 00b: Transmission in progress or has not been requested
- 01b: Transmission has been aborted from the corresponding TX message buffer
- 10b: Transmission was successful from the corresponding TX message buffer and the CFDTMCn.TMTAR bit was not set for this TX message buffer
- 11b: Transmission was successful from the corresponding TX message buffer, but the CFDTMCn.TMTAR bit was set for this TX message buffer.

Only write to these bits when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

The TMTRF[1:0] bits are cleared automatically when the CAN-FD module is in GL_RESET mode or the related channel is in CH_RESET mode.

TMTRM bit (TX Message Buffer Transmission Request Mirrored)

The TMTRM bit is set when the CFDTMCn.TMTR bit in the corresponding CFDTMCn register is set.

This bit is cleared when the CFDTMCn.TMTR bit in the corresponding CFDTMCn register is cleared.

TMTARM bit (TX Message Buffer Transmission Abort Request Mirrored)

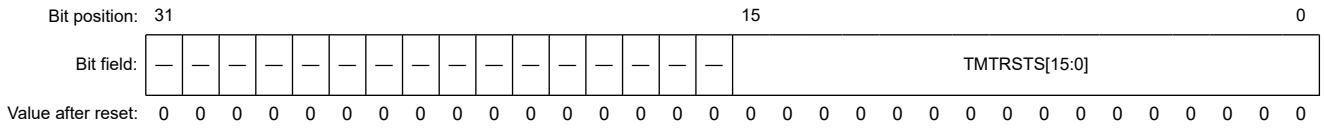
The TMTARM bit is set when the CFDTMCn.TMTAR bit in the corresponding CFDTMCn register is set.

This bit is cleared when the CFDTMCn.TMTAR bit in the corresponding CFDTMCn register is cleared.

35.3.49 CFDTMTRSTSf : TX Message Buffer Transmission Request Status Register f (f = 0 to 3)

Base address: CANFD = 0x8004_0000

Offset address: 0x0CD0 + 0x04 × f



Bit	Symbol	Function	R/W
15:0	TMTRSTS[15:0]	TX Message Buffer Transmission Request Status 0: Transmission not requested for corresponding TX message buffer 1: Transmission requested for corresponding TX message buffer	R
31:16	—	These bits are read as 0.	R

TMTRSTS[15:0] bits (TX Message Buffer Transmission Request Status)

The TMTRSTS[15:0] bits show status of the CFDTMCn.TMTR bits of the TX Message Buffer Control Registers.

Alignment of the TMTRSTS[15:0] bits is shown in Table 35.8.

Table 35.8 Alignment of TMTRSTS[15:0] mirror bits

Bit position	TX message buffer number
n × 64 - fmin × 32	n × 64 + 0
n × 64 + 1 - fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 31 - fmin × 32	n × 64 + 31
n × 64 + 32 - fmax × 32	n × 64 + 32
n × 64 + 33 - fmax × 32	n × 64 + 33
⋮	⋮
n ×64 + 62 - fmax × 32	n × 64 + 62
n × 64 + 63 - fmax × 32	n × 64 + 63

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers (CFDTMCn), and only when the message buffer does not belong to a TX Queue.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

35.3.50 CFDTMTARSTSf : TX Message Buffer Transmission Abort Request Status Register f (f = 0 to 3)

Base address: CANFD = 0x8004_0000

Offset address: 0x0D70 + 0x04 × f

Bit position:	31															15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TMTARSTS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TMTARSTS[15:0]	TX Message Buffer Transmission Abort Request Status 0: Transmission abort not requested for corresponding TX message buffer 1: Transmission abort requested for corresponding TX message buffer	R
31:16	—	These bits are read as 0.	R

TMTARSTS[15:0] bits (TX Message Buffer Transmission Abort Request Status)

The TMTARSTS[15:0] bits show status of the CFDTMCn.TMTAR bits of the TX Message Buffer Control Registers.

Alignment of the TMTARSTS[15:0] bits is shown in Table 35.9.

Table 35.9 Alignment of TMTARSTS[15:0] mirror bits (1 of 2)

Bit position	TX message buffer number
n × 64 - fmin × 32	n × 64 + 0
n × 64 + 1 - fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 31 - fmin × 32	n × 64 + 31
n × 64 + 32 - fmax × 32	n × 64 + 32
n × 64 + 33 - fmax × 32	n × 64 + 33

Table 35.9 Alignment of TMTARSTS[15:0] mirror bits (2 of 2)

Bit position	TX message buffer number
⋮	⋮
n × 64 + 62 - fmax × 32	n × 64 + 62
n × 64 + 63 - fmax × 32	n × 64 + 63

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers, and when the message buffer belongs to a TX Queue.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

35.3.51 CFDTMTCSTSf : TX Message Buffer Transmission Completion Status Register f (f = 0 to 3)

Base address: CANFD = 0x8004_0000

Offset address: 0x0E10 + 0x04 × f

Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TMTCSTS[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TMTCSTS[15:0]	TX Message Buffer Transmission Completion Status 0: Transmission not completed for corresponding TX message buffer 1: Transmission completed for corresponding TX message buffer	R
31:16	—	These bits are read as 0.	R

TMTCSTS[15:0] bits (TX Message Buffer Transmission Completion Status)

The TMTCSTS[15:0] bits show status of successful completion of the TX Message Buffer Status Registers.

Alignment of the TMTCSTS[15:0] bits is shown in Table 35.10.

Table 35.10 Alignment of TMTCSTS[15:0] mirror bits

Bit position	TX message buffer number
n × 64 - fmin × 32	n × 64 + 0
n × 64 + 1 - fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 31 - fmin × 32	n × 64 + 31
n × 64 + 32 - fmax × 32	n × 64 + 32
n × 64 + 33 - fmax × 32	n × 64 + 33
⋮	⋮
n × 64 + 62 - fmax × 32	n × 64 + 62
n × 64 + 63 - fmax × 32	n × 64 + 63

Note: When n = 0, fmin = 0, fmax = 1
When n = 1,fmin = 2, fmax = 3

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Status Registers.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Status Registers
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

If a CAN channel enters CH_RESET mode, then the bits related to that channel are cleared.

35.3.52 CFDTMTASTSf : TX Message Buffer Transmission Abort Status Register f (f = 0 to 3)

Base address: CANFD = 0x8004_0000

Offset address: 0x0EB0 + 0x04 × f

Bit position:	31																15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TMTASTS[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TMTASTS[15:0]	TX Message Buffer Transmission Abort Status 0: Transmission not aborted for corresponding TX message buffer 1: Transmission aborted for corresponding TX message buffer	R
31:16	—	These bits are read as 0.	R

TMTASTS[15:0] bits (TX Message Buffer Transmission Abort Status)

The TMTASTS[15:0] bits show status of the successful transmission abort of the corresponding TX message buffer.

Alignment of the TMTASTS[15:0] bits is shown in Table 35.11.

Table 35.11 Alignment of TMTASTS[15:0] mirror bits

Bit position	TX message buffer number
n × 64 - fmin × 32	n × 64 + 0
n × 64 + 1 - fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 31 - fmin × 32	n × 64 + 31
n × 64 + 32 - fmax × 32	n × 64 + 32
n × 64 + 33 - fmax × 32	n × 64 + 33
⋮	⋮
n × 64 + 62 - fmax × 32	n × 64 + 62
n × 64 + 63 - fmax × 32	n × 64 + 63

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3

Each bit is set automatically when the CFDTMSTSn.TMTRF[1:0] bits are set to 01b in the corresponding TX Message Buffer Status Register.

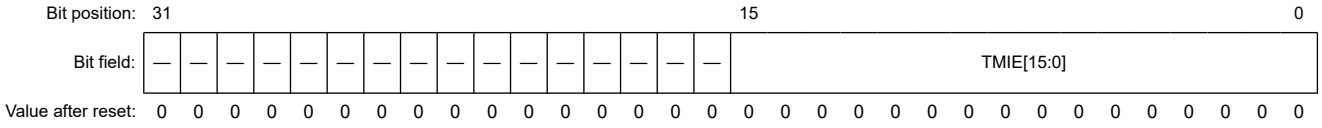
Each bit is cleared automatically when:

- The CFDTMSTSn.TMTRF[1:0] bits are cleared in the corresponding TX Message Buffer Status Register
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

35.3.53 CFDTMIECf : TX Message Buffer Transmission Interrupt Enable Register f (f = 0 to 3)

Base address: CANFD = 0x8004_0000

Offset address: 0x0F50 + 0x04 × f



Bit	Symbol	Function	R/W
15:0	TMIE[15:0]	TX Message Buffer Interrupt Enable 0: TX message buffer interrupt disabled for corresponding TX message buffer 1: TX message buffer interrupt enabled for corresponding TX message buffer	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

TMIE[15:0] bits (TX Message Buffer Interrupt Enable)

If the TMIE[15:0] bits are set, an interrupt is generated at the end of a successful transmission from the corresponding message buffer.

See section 35.8. Interrupt and DMA for TX Message Buffer Interrupt specification.

Alignment of the TMIE[15:0] bits is shown in Table 35.12.

Table 35.12 Alignment of TMIE[15:0] bits

Bit position	TX message buffer number
n × 64 - fmin × 32	n × 64 + 0
n × 64 + 1 - fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 31 - fmin × 32	n × 64 + 31
n × 64 + 32 - fmax × 32	n × 64 + 32
n × 64 + 33 - fmax × 32	n × 64 + 33
⋮	⋮
n × 64 + 62 - fmax × 32	n × 64 + 62
n × 64 + 63 - fmax × 32	n × 64 + 63

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3

Do not write to the TMIE[15:0] bits when:

- The CAN-FD module is in GL_SLEEP mode
- The related CAN-FD channel is in CH_SLEEP mode
- The corresponding TX message buffer is part of a TX Queue
- The corresponding TX message buffer is linked to a Common FIFO with the CFDCFCCn.CFTML[4:0] bits.

35.3.54 CFDTXQCC0n : TX Queue Configuration/Control Register 0n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1000 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQOFTXIE	TXQOFRXIE	TXQFIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TXQDC[4:0]					TXQIM	—	TXQTXIE	—	—	TXQOWE	TXQGWE	TXQE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TXQE	TX Queue Enable 0: TX Queue disabled 1: TX Queue enabled	R/W
1	TXQGWE	TX Queue Gateway Mode Enable 0: TX Queue GW mode disabled 1: TX Queue GW mode enabled	R/W
2	TXQOWE	TX Queue Overwrite Mode Enable 0: TX Queue OW mode disabled 1: TX Queue OW mode enabled	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	TXQTXIE	TX Queue TX Interrupt Enable 0: TX Queue TX interrupt disabled 1: TX Queue TX interrupt enabled	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	TXQIM	TX Queue Interrupt Mode 0: When the last message is successfully transmitted 1: At every successful transmission	R/W
12:8	TXQDC[4:0]	TX Queue Depth Configuration 0x00: 0 messages 0x01: Reserved 0x02: 3 messages 0x03: 4 messages ⋮ 0x0F: 16 messages Others: Setting prohibited	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
16	TXQFIE	TXQ Full Interrupt Enable 0: TX Queue full interrupt generation disabled 1: TX Queue full interrupt generation enabled	R/W
17	TXQOFRXIE	TXQ One Frame Reception Interrupt Enable 0: One Frame RX interrupt generation disabled 1: One Frame RX interrupt generation enabled	R/W
18	TXQOFTXIE	TXQ One Frame Transmission Interrupt Enable 0: One Frame TX interrupt generation disabled 1: One Frame TX interrupt generation enabled	R/W
31:19	—	These bits are read as 0. The write value should be 0.	R/W

The CFDTXQCC0n register (n = 0, 1) is used to configure the TX Queue transmission.

TXQ0 is composed of TXMB0 to TXMB31 (at the maximum) when TXQE is enabled.

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 0x00 (CFDTXQCC0n.TXQDC[4:0] = 0x00).

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

The TXQE bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQGWE bit (TX Queue Gateway Mode Enable)

When the TXQGWE bit is set, the TX Queue is in TX Queue GW mode.

When this bit is set, CPU must not access the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQOWE bit (TX Queue Overwrite Mode Enable)

When the TXQOWE bit is set, the TX Queue is in TX Queue Overwrite mode.

An overwrite function is valid when the same ID such as ID of the data written in from the gateway or CPU is in TX Queue. For example, when a frame is received and is stored into the TX Queue, if a message with the same ID is stored in the TX Queue, the old message is overwritten by the new message.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

When using the function in GW mode, the depth of TXQ (CFDTXQCC0n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3.

The function is valid for the standard ID frame but is invalid for the extended ID frame.

Do not modify this bit when the CFDTXQCC0n.TXQE bit is 1.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[4:0] bits (TX Queue Depth Configuration)

The TXQDC[4:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[0] up to MB[31] depending on the configured depth.

When using TXQ1 and TXQ0 simultaneously, the total depth of TXQ1 and TXQ0 should be 32 or less.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQFIE bit (TXQ Full Interrupt Enable)

When the TXQFIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS0n.TXQFIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit in Gateway mode (CFDTXQCC0n.TXQGWE = 1).

TXQOFRXIE bit (TXQ One Frame Reception Interrupt Enable)

When the TXQOFRXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS0n.TXQOFRXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit in GW mode (CFDTXQCC0n.TXQGWE = 1).

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS0n.TXQOFTXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

35.3.55 CFDTXQCC1n : TX Queue Configuration/Control Register 1n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1060 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

18	TXQOFTXIE	TXQ One Frame Transmission Interrupt Enable 0: One Frame TX interrupt generation disabled 1: One Frame TX interrupt generation enabled	R/W
31:19	—	These bits are read as 0. The write value should be 0.	R/W

The CFDTXQCC1n register (n = 0, 1) is used to configure the TX Queue transmission.

TXQ1 is composed of TXMB31 to TXMB0 (at the maximum) when TXQE is enabled.

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 0x00 (CFDTXQCC1n.TXQDC[4:0] = 0x00).

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQGWE bit (TX Queue Gateway Mode Enable)

When the TXQGWE bit is set, the TX Queue is in TX Queue Gateway mode.

When this bit is set, CPU must not access the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQOWE bit (TX Queue Overwrite Mode Enable)

When the TXQOWE bit is set, the TX Queue is in TX Queue Overwrite mode.

An overwrite function is valid when the same ID such as ID of the data written in from the gateway or CPU is in TX Queue. For example, when a frame is received and is stored into the TX Queue, if a message with the same ID is stored in the TX Queue, the old message is overwritten by the new message.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

When using the function in GW mode, the depth of TXQ (CFDTXQCC1n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3.

The function is valid for the standard ID frame but is invalid for the extended ID frame.

Do not modify this bit when the CFDTXQCC1n.TXQE bit is 1.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[4:0] bits (TX Queue Depth Configuration)

The TXQDC[4:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[31] down to MB[0] depending on the configured depth.

When using TXQ1 and TXQ0 simultaneously, the total depth of TXQ1 and TXQ0 should be 32 or less.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQFIE bit (TXQ Full Interrupt Enable)

When the TXQFIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS1n.TXQFIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit when in Gateway mode (CFDTXQCC1n.TXQGWE = 1).

TXQOFRXIE bit (TXQ One Frame Reception Interrupt Enable)

When the TXQOFRXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS1n.TXQOFRXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit when in Gateway mode (CFDTXQCC1n.TXQGWE = 1).

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS1n.TXQOFTXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

31:19	—	These bits are read as 0. The write value should be 0.	R/W

The CFDTXQCC2n register (n = 0, 1) is used to configure the TX Queue transmission.

TXQ2 is composed of TXMB32 to TXMB63 (at the maximum) when TXQE is enabled.

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 0x00 (CFDTXQCC2n.TXQDC[4:0] = 0x00).

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

TXQGWE bit (TX Queue Gateway Mode Enable)

When the TXQGWE bit is set, the TX Queue is in TX Queue Gateway mode. When this bit is set, CPU must not access the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQOWE bit (TX Queue Overwrite Mode Enable)

When the TXQOWE bit is set, the TX Queue is in TX Queue Overwrite mode.

An overwrite function is valid when the same ID such as ID of the data written in from the gateway or CPU is in TX Queue. For example, when a frame is received and is stored into the TX Queue, if a message with the same ID is stored in the TX Queue, the old message is overwritten by the new message.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

When using the function in GW mode, the depth of TXQ (CFDTXQCC2n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3.

The function is valid for the standard ID frame but is invalid for the extended ID frame.

Do not modify this bit when the CFDTXQCC2n.TXQE bit is 1.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[4:0] bits (TX Queue Depth Configuration)

The TXQDC[4:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[32] up to MB[63] depending on the configured depth.

When using TXQ3 and TXQ2 simultaneously, the total depth of TXQ3 and TXQ2 should be 32 or less.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION

TXQFIE bit (TXQ Full Interrupt Enable)

When the TXQFIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS2n.TXQFIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit when in GW mode (CFDTXQCC2n.TXQGWE = 1).

TXQOFRXIE bit (TXQ One Frame Reception Interrupt Enable)

When the TXQOFRXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS2n.TXQOFRXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit when in GW mode (CFDTXQCC2n.TXQGWE = 1).

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS2n.TXQOFTXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

35.3.57 CFDTXQCC3n : TX Queue Configuration/Control Register 3n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1120 + 0x04 × n

31:19	—	These bits are read as 0. The write value should be 0.	R/W

The CFDTXQCC3n register (n = 0, 1) is used to configure the TX Queue transmission.

TXQ3 is composed of TXMB63 to TXMB32 (at the maximum) when TXQE is enabled.

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 0x00 (CFDTXQCC3n.TXQDC[4:0] = 0x00).

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

TXQOWE bit (TX Queue Overwrite Mode Enable)

When the TXQOWE bit is set, the TX Queue is in TX Queue Overwrite mode.

An overwrite function is valid when the same ID such as ID of the data written in from the gateway or CPU is in TX Queue. For example, when a frame is received and is stored into the TX Queue, if a message with the same ID is stored in the TX Queue, the old message is overwritten by the new message.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

When using the function in GW mode, the depth of TXQ (CFDTXQCC3n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3.

The function is valid for the standard ID frame but is invalid for the extended ID frame.

Do not modify this bit when the CFDTXQCC3n.TXQE bit is 1.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[4:0] bits (TX Queue Depth Configuration)

The TXQDC[4:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[63] down to MB[32] depending on the configured depth.

When using TXQ3 and TXQ2 simultaneously, the total depth of TXQ3 and TXQ2 should be 32 or less.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS3n.TXQOFTXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

35.3.58 CFDTXQSTS0n : TX Queue Status Register 0n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1020 + 0x04 × n

31:21	—	These bits are read as 0. The write value should be 0.	R/W

The CFDTXQSTS0n register (n = 0, 1) shows the status of the TX Queue of corresponding CAN channel.

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[5:0] bits (TX Queue Message Count)

The TXQMC[5:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQFIF bit (TXQ Full Interrupt Flag)

The TXQFIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Only in Gateway mode (CFDTXQCC0n.TXQGWE = 1) that this bit is set automatically when the TX Queue transits to a buffer full status.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFRXIF bit (TXQ One Frame Reception Interrupt Flag)

The TXQOFRXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When receiving data is stored in the TX Queue in Gateway mode, this bit is set automatically.

This function can only be used in Gateway mode of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMLT bit (TXQ Message Lost)

The TXQMLT bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When a message lost occurs in Gateway mode of the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMOW bit (TXQ Message Overwrite)

The TXQMOW bit is not cleared automatically if the TX Queue is disabled.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When CFDTXQCC0n.TXQOWE = 1 and message overwrite occurs in TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

35.3.59 CFDTXQSTS1n : TX Queue Status Register 1n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1080 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:21	—	These bits are read as 0. The write value should be 0.	R/W

The CFDTXQSTS1n register (n = 0, 1) shows the status of the TX Queue of corresponding CAN channel.

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[5:0] bits (TX Queue Message Count)

The TXQMC[5:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQFIF bit (TXQ Full Interrupt Flag)

The TXQFIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Only in Gateway mode (CFDTXQCC1n.TXQGWE = 1) that this bit is set automatically when TX Queue transits to a buffer full status.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFRXIF bit (TXQ One Frame Reception Interrupt Flag)

The TXQOFRXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When receiving data is stored in the TX Queue in Gateway mode, this bit is set automatically.

This function can only be used in Gateway mode of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMLT bit (TXQ Message Lost)

The TXQMLT bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When a message lost occurs in Gateway mode of the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMOW bit (TXQ Message Overwrite)

The TXQMOW bit is not cleared automatically if the TX Queue is disabled.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When CFDTXQCC1n.TXQOWE = 1 and message overwrite occurs in TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

35.3.60 CFDTXQSTS2n : TX Queue Status Register 2n (n = 0, 1)

Base address: CANFD = 0x8004_0000

31:21	—	These bits are read as 0. The write value should be 0.	R/W

The CFDTXQSTS2n register (n = 0, 1) shows the status of the TX Queue of corresponding CAN Channel.

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[5:0] bits (TX Queue Message Count)

The TXQMC[5:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQFIF bit (TXQ Full Interrupt Flag)

The TXQFIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Only in Gateway mode (CFDTXQCC2n.TXQGWE = 1) that this bit is set automatically when the TX Queue transits to a buffer full status.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFRXIF bit (TXQ One Frame Reception Interrupt Flag)

The TXQOFRXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When receiving data is stored in the TX Queue in Gateway mode, this bit is set automatically.

This function can only be used in Gateway mode of the TX queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMLT bit (TXQ Message Lost)

The TXQMLT bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When a message lost occurs in Gateway mode of the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMOW bit (TXQ Message Overwrite)

The TXQMOW bit is not cleared automatically if the TX Queue is disabled.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When CFDTXQCC2n.TXQOWE = 1 and message overwrite occurs in TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

35.3.61 CFDTXQSTS3n : TX Queue Status Register 3n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1140 + 0x04 × n

31:21	—	These bits are read as 0. The write value should be 0.	R/W

The CFDTXQSTS3n register (n = 0, 1) shows the status of the TX Queue of corresponding CAN Channel.

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

This bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[5:0] bits (TX Queue Message Count)

The TXQMC[5:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMOW bit (TXQ Message Overwrite)

The TXQMOW bit is not cleared automatically if the TX Queue is disabled.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When CFDTXQCC3n.TXQOWE = 1 and message overwrite occurs in TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

35.3.62 CFDTXQPCTR0n : TX Queue Pointer Control Register 0n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1040 + 0x04 × n

Bit position:	31																							7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TXQPC[7:0]	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel	W
31:8	—	The write value should be 0.	W

The CFDTXQPCTR0n register (n = 0, 1) is used to confirm storage of a full message in the corresponding TX Queue buffers.

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value 0xFF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 0x00. Do not write to the FIFO control registers when DMA is enabled.

You cannot write to these bits when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

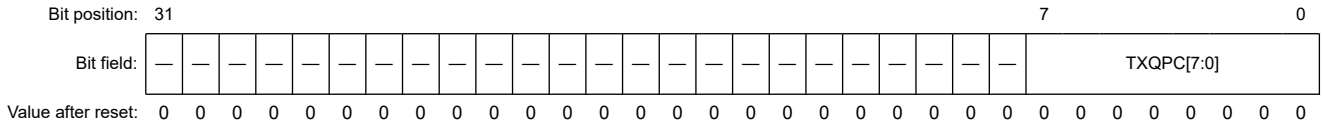
Only write 0xFF to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in GW mode.

35.3.63 CFDTXQPCTR1n : TX Queue Pointer Control Register 1n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x10A0 + 0x04 × n



Bit	Symbol	Function	R/W
7:0	TXQPC[7:0]	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel	W
31:8	—	The write value should be 0.	W

The CFDTXQPCTR1n register (n = 0, 1) is used to confirm storage of a full message in the corresponding TX Queue buffers.

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value 0xFF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 0x00. You cannot write to the FIFO control registers when DMA is enabled.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

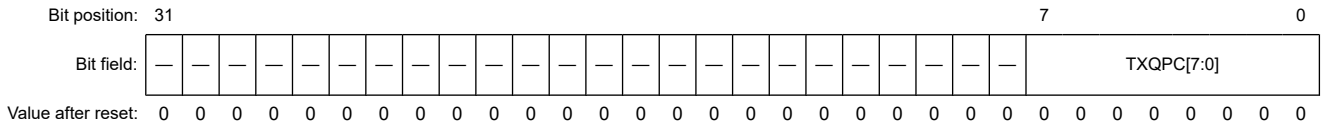
Only write 0xFF to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in GW mode.

35.3.64 CFDTXQPCTR2n : TX Queue Pointer Control Register 2n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1100 + 0x04 × n



Bit	Symbol	Function	R/W
7:0	TXQPC[7:0]	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel	W
31:8	—	The write value should be 0.	W

The CFDTXQPCTR2n register (n = 0, 1) is used to confirm storage of a full message in the corresponding TX Queue buffers.

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value 0xFF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 0x00. You cannot write to the FIFO control registers when DMA is enabled.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Only write 0xFF to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in GW mode.

35.3.65 CFDTXQPCTR3n : TX Queue Pointer Control Register 3n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1160 + 0x04 × n

Bit position:	31																						7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TXQPC[7:0]	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel	W
31:8	—	The write value should be 0.	W

The CFDTXQPCTR3n register (n = 0, 1) is used to confirm storage of a full message in the corresponding TX Queue buffers.

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value 0xFF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 0x00. Do not write to the FIFO control registers when DMA is enabled.

You cannot write to these bits when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Only write 0xFF to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in Gateway mode.

35.3.66 CFDTXQESTS : TX Queue Empty Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x1180

Bit position:	31																					8	7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQxEMP[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	TXQxEMP[7:0]	TXQ Empty Status 0: TXQ not empty 1: TXQ empty	R
31:8	—	These bits are read as 0.	R

The CFDTXQESTS register shows the status of the empty bits of the TXQ buffers.

TXQxEMP[7:0] bits (TXQ Empty Status)

Each bit is set automatically when the corresponding bit is set in the TX Queue Empty Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the TX Queue Empty Status Register.

This bit is set when the CAN-FD module is in GL_RESET mode.

Bit position	Corresponding TX Queue
0	Channel 0 TX Queue 0
1	Channel 0 TX Queue 1
2	Channel 0 TX Queue 2
3	Channel 0 TX Queue 3
4	Channel 1 TX Queue 0
5	Channel 1 TX Queue 1
6	Channel 1 TX Queue 2
7	Channel 1 TX Queue 3

35.3.67 CFDTXQFISTS : TX Queue Full Interrupt Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x1184

Bit position:	31																								6	4	2	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQ1FULL[2:0]	—	TXQ0FULL[2:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	TXQ0FULL[2:0]	TXQ Full Interrupt Status Flag for Channel 0 0: TXQ full interrupt not set 1: TXQ full interrupt set	R
3	—	This bit is read as 0.	R
6:4	TXQ1FULL[2:0]	TXQ Full Interrupt Status Flag for Channel 1 0: TXQ full interrupt not set 1: TXQ full interrupt set	R
31:7	—	These bits are read as 0.	R

The CFDTXQFISTS register shows the status of the full interrupt bits of the TXQ buffers.

TXQnFULL[2:0] (n = 0, 1) bits (TXQ Full Interrupt Status Flag)

Each bit is set automatically when the corresponding bit is set in the TX Queue Full Interrupt Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the TX Queue Full Interrupt Status Register.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

Bit position	Corresponding TX Queue
0	Channel 0 TX Queue 0
1	Channel 0 TX Queue 1
2	Channel 0 TX Queue 2
3	Reserved
4	Channel 1 TX Queue 0
5	Channel 1 TX Queue 1
6	Channel 1 TX Queue 2
7	Reserved

35.3.68 CFDTXQMSTS : TX Queue Message Lost Status Register

Base address: CANFD = 0x8004_0000

Offset address: 0x1188

Bit position:	31																								6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQ1ML[2:0]			—	TXQ0ML[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	TXQ0ML[2:0]	TXQ Message Lost Status Flag for Channel 0 0: TXQ message lost flag not set 1: TXQ message lost flag set	R
3	—	This bit is read as 0.	R
6:4	TXQ1ML[2:0]	TXQ Message Lost Status Flag for Channel 1 0: TXQ message lost flag not set 1: TXQ message lost flag set	R
31:7	—	These bits are read as 0.	R

The CFDTXQMSTS register shows the status of the message lost bits of the TXQ buffers.

TXQnML[2:0] (n = 0, 1) bits (TXQ Message Lost Status Flag)

Each bit is set automatically when the corresponding bit is set in the TX Queue Message Lost Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the TX Queue Message Lost Status Register.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

Bit position	Corresponding TX Queue
0	Channel 0 TX Queue 0
1	Channel 0 TX Queue 1
2	Channel 0 TX Queue 2
3	Reserved
4	Channel 1 TX Queue 0
5	Channel 1 TX Queue 1
6	Channel 1 TX Queue 2
7	Reserved

35.3.69 CFDTXQISTS : TX Queue Interrupt Status Register

Bit field:	—	—	—	—	THLDGE	THLDTE	THLIM	THLIE	—	—	—	—	—	—	—	THLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	THLE	TX History List Enable 0: TX History List disabled 1: TX History List enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	THLIE	TX History List Interrupt Enable 0: TX History List Interrupt disabled 1: TX History List Interrupt enabled	R/W
9	THLIM	TX History List Interrupt Mode 0: Interrupt generated if TX History List level reaches ¾ of the TX History List depth 1: Interrupt generated for every successfully stored entry	R/W
10	THLDTE	TX History List Dedicated TX Enable 0: TX FIFO + TX Queue 1: Flat TX MB + TX FIFO + TX Queue	R/W
11	THLDGE	TX History List Dedicated Gateway Enable 0: Not dedicated Gateway FIFO + Gateway TX Queue 1: Dedicated Gateway FIFO + Gateway TX Queue	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The CFDTHLCCn register (n = 0, 1) configures the TX History List functions.

THLE bit (TX History List Enable)

The THLE bit enables the TX History List buffer when it is set.

You cannot write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

THLIE bit (TX History List Interrupt Enable)

The THLIE bit enables the generation of the TX History List interrupt when it is set.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

THLIM bit (TX History List Interrupt Mode)

The THLIM bit selects the interrupt generation condition for the FIFO.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

THLDTE bit (TX History List Dedicated TX Enable)

The THLDTE bit selects the condition for storing an entry in the TX History List after successful transmission.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

THLDGE bit (TX History List Dedicated Gateway Enable)

The THLDGE bit selects the condition for storing an entry in the TX History List after successful transmission.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

35.3.74 CFDTHLSTSn : TX History List Status Register n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1220 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	THLMC[5:0]						—	—	—	—	THLIF	THLELT	THLFLL	THLEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	THLEMP	TX History List Empty 0: TX History List not empty 1: TX History List empty	R
1	THLFLL	TX History List Full 0: TX History List not full 1: TX History List full	R
2	THLELT	TX History List Entry Lost 0: No entry lost in TX History List 1: TX History List entry Lost	R/W
3	THLIF	TX History List Interrupt Flag 0: TX History List interrupt condition not satisfied 1: TX History List interrupt condition satisfied	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
13:8	THLMC[5:0]	TX History List Message Count Number of messages stored in TX History List	R
31:14	—	These bits are read as 0. The write value should be 0.	R/W

The CFDTHLSTSn register (n = 0, 1) shows the status of data stored in the TX History List buffer.

THLEMP bit (TX History List Empty)

The THLEMP bit is set automatically when the CPU has read all the entries from the TX History List buffer.

This bit is cleared automatically when the first entry is stored to the TX History List.

This bit is set automatically when:

- TX History List is disabled
- The related CAN-FD channel is in CH_RESET mode.

THLFLL bit (TX History List Full)

The THLFLL bit is set automatically when the number of entries in the TX History List buffer matches the TX History List depth.

Each TX History List can store up to 32 entries (each channel has a dedicated TX History List).

This bit is cleared automatically when:

- The number of entries in the TX History List buffer is less than the TX History List depth
- The TX History List is disabled
- The related CAN-FD channel is in CH_RESET mode.

THLELT bit (TX History List Entry Lost)

The THLELT bit is set when a new entry cannot be stored because the related TX History List buffer is already full.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

THLIF bit (TX History List Interrupt Flag)

The THLIF bit is set when the configured interrupt condition is satisfied.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

This bit is automatically cleared in CH_RESET mode.

THLMC[5:0] bits (TX History List Message Count)

The THLMC[5:0] bits show the number of transmitted messages stored in the TX History List.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

35.3.75 CFDTHLACC0n : Channel n TX History List Access Register 0 (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x8000 + 0x08 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TMTS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TGW	—	—	—	—	—	BN[6:0]							BT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	BT[2:0]	Buffer Type 0 0 1: Flat TX message buffer 0 1 0: TX FIFO message buffer number and gateway FIFO message number 1 0 0: TX Queue message buffer number Others: Setting prohibited	R
9:3	BN[6:0]	Buffer Number Number of the message buffer	R
14:10	—	These bits are read as 0.	R
15	TGW	Transmit Gateway Buffer Indication 0: No transmission from gateway 1: Transmission from gateway	R
31:16	TMTS[15:0]	Transmit Timestamp Transmit timestamp value for software drivers	R

The CFDTHLACC0n register (n = 0, 1) provides access to the entry in the TX History List based on the read timestamp value.

BT[2:0] bits (Buffer Type)

The BT[2:0] bits indicate whether data has been stored following a transmission from a FIFO buffer, a TX Queue or a TX message buffer.

BN[6:0] bits (Buffer Number)

The BN[6:0] bits show the message buffer from which transmission was successfully completed. If a message from a Common FIFO is transmitted, then these bits show the message buffer that is linked to the Common FIFO for transmission.

TGW bit (Transmit Gateway Buffer Indication)

The TGW bit is automatically set to 1 when transmission is completed in GW mode.

TMTS[15:0] bits (Transmit Timestamp)

The TMTS[15:0] bits indicate the timestamp for use by software drivers.

35.3.76 CFDTHLACC1n : Channel n TX History List Access Register 1 (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x8004 + 0x08 × n

Bit position:	31														17	16	15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TIFL[1:0]			TID[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TID[15:0]	Transmit ID These bits indicate that message buffer reference ID, TX FIFO reference ID, or AFL pointer field is stored for software drivers.	R
17:16	TIFL[1:0]	Transmit Information Label These bits indicate that message buffer information label, TX FIFO information label, or AFL information label is stored for software drivers.	R
31:18	—	These bits are read as 0.	R

The CFDTHLACC1n register (n = 0, 1) provides access to entry in the TX History List based on the read pointer value.

TID[15:0] bits (Transmit ID)

The TID[15:0] bits indicate whether the message buffer reference ID (CFDTMFDCTRn.TMPTR) or the TX FIFO reference ID (CFDCFFDCSTSn.CFPTR) is for use by software drivers.

When transmission in Gateway mode, these bits indicate the AFL pointer field (CFDGAFLP0n.GAFLPTR) instead of the message buffer reference ID (CFDTMFDCTRn.TMPTR).

TIFL[1:0] bits (Transmit Information Label)

The TIFL[1:0] bits indicate whether the message buffer information label (CFDTMFDCTRn.TMIFL) or the TX FIFO information label (CFDCFFDCSTSn.CFIFL) is for use by software drivers.

When transmission in Gateway mode, these bits indicate the AFL pointer field (CFDGAFLMn.GAFLIFL1 and CFDGAFLP0n.GAFLIFL0) instead of the MB information label (CFDTMFDCTRn.TMIFL).

35.3.77 CFDTHLPCTRn : TX History List Pointer Control Register n (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1240 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	THLPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	THLPC[7:0]	TX History List Pointer Control Increments the write pointer to the TX History List in the corresponding channel	W
31:8	—	The write value should be 0.	W

The CFDTHLPCTRn register (n = 0, 1) is used to increment the read pointer of the TX History List.

THLPC[7:0] bits (TX History List Pointer Control)

When 0xFF is written to the THLPC[7:0] bits, the read pointer of the TX History List is moved to the next TX History List entry address.

The read value from these bits is always 0x00. Only write to these bits when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Only write 0xFF to these registers when the corresponding TX History List is enabled and not empty.

35.3.78 CFDGRSTC : Global Reset Control Register

Base address: CANFD = 0x8004_0000

Offset address: 0x1380

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	KEY[7:0]								—	—	—	—	—	—	—	SRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRST	Software Reset 0: Normal state 1: Software reset state	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code These bits control the validity of rewriting of the SRST bit.	W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

SRST bit (Software Reset)

When the SRST bit is set, the CAN-FD module is in the same state as hardware reset. When a reset is required, write 1 then write 0 to this bit.

This bit is cleared when the CAN-FD module is in GL_SLEEP mode.

When this bit is cleared, the RAM initialization sequence does not operate. The configuration of RAM is performed by software.

The RAM is not initialized when software reset is performed during the initialization of RAM. Software must perform the initialization of RAM.

KEY[7:0] bits (Key Code)

When 0xC4 is written in the KEY[7:0] bits, a write to the SRST bit is valid.

The read value from these bits is always 0x00.

35.3.79 CFDGFCMC : Global Flexible CAN Mode Configuration Register

Base address: CANFD = 0x8004_0000

Offset address: 0x1384

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FLXC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FLXC0	Flexible CAN Mode between Channel 0 and Channel 1 0: Normal mode 1: Flexible CAN mode	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Flexible CAN mode configured in the CFDGFCMC register and Flexible transmission buffer assignment configured in the CFDGFTBAC register should not be used simultaneously.

FLXC0 bit (Flexible CAN Mode between Channel 0 and Channel 1)

When the FLXC0 bit is set, Channel 0 and Channel 1 of a CAN-FD module are in Flexible CAN mode.

Channel 1 uses TX/RX terminal of Channel 0. The TX/RX terminal of Channel 1 cannot be used.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

35.3.80 CFDGFTBAC : Global Flexible Transmission Buffer Assignment Configuration Register

Base address: CANFD = 0x8004_0000

Offset address: 0x138C

Bit position:	31																												3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FLXMB0[3:0]

0	C0ICBCE	Channel 0 Internal CAN Bus Communication Test Mode Enable 0: Channel 0 internal CAN bus communication disabled 1: Channel 0 internal CAN bus communication enabled	R/W
1	C1ICBCE	Channel 1 Internal CAN Bus Communication Test Mode Enable 0: Channel 1 internal CAN bus communication disabled 1: Channel 1 internal CAN bus communication enabled	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W
25:16	RTMPS[9:0]	RAM Test Mode Page Select Select a RAM test mode page	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

The CFDGTSTCFG register is used to configure the CAN channels joining the internal CAN bus communication test mode and the RAM test mode page.

CnICBCE (n = 0, 1) bits (Channel n Internal CAN Bus Communication Test Mode Enable)

When the C0ICBCE and C1ICBCE bits are set and CAN-FD module is configured in the internal CAN bus communication test mode, then CAN channel n joins the internal CAN bus communication test mode operation.

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

Only write to these bits when the CAN-FD module is in GL_HALT mode.

These bits are cleared automatically when the CAN-FD module is in GL_RESET mode.

RTMPS[9:0] bits (RAM Test Mode Page Select)

The RTMPS[9:0] bits select the RAM page mode for CPU read/write access when the CAN-FD module is configured in RAM test mode.

See section 35.10.2.1. RAM Test Mode for the RAM test mode specification.

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

Only enter values from 0 to 15 (0x00F) for the AFL RAM and 16 to 76 (0x04C) for the message buffer RAM.

The setting range of these bits depends on the combination of parameters.

Only write to these bits when the CAN-FD module is in GL_HALT mode.

These bits are cleared automatically when the related CAN-FD channel is in GL_RESET mode.

35.3.82 CFDGTSTCTR : Global Test Control Register

Base address: CANFD = 0x8004_0000

Offset address: 0x130C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	RTME	—	ICBCTME
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ICBCTME	Internal CAN Bus Communication Test Mode Enable 0: Internal CAN Bus Communication test mode disabled 1: Internal CAN Bus Communication test mode enabled	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	RTME	RAM Test Mode Enable 0: RAM test mode disabled 1: RAM test mode enabled	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

The CFDGTSTCTR register is used to control the global test modes of the CAN-FD module.

ICBCTME bit (Internal CAN Bus Communication Test Mode Enable)

When the ICBCTME bit is set, internal CAN bus communication is enabled for the CAN channels that are configured for internal CAN bus communication participation. See section 35.10.2.2. Internal CAN Bus Communication Mode for the specification of internal CAN bus communication test mode.

Only write to this bit when the CAN-FD module is in GL_HALT mode.

Clear this bit when the CAN-FD module is in GL_HALT mode.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

RTME bit (RAM Test Mode Enable)

When the RTME bit is set, the CAN-FD module is configured in RAM test mode. See section 35.10.2.1. RAM Test Mode for RAM test mode specification.

Only write to this bit when the CAN-FD module is in GL_HALT mode.

Clear this bit when the CAN-FD module is in GL_HALT mode.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

35.3.83 CFDGFDCFG : Global FD Configuration Register

Base address: CANFD = 0x8004_0000

Offset address: 0x1314

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TSCCFG[1:0]		—	—	—	—	—	—	—	RPED
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RPED	RES Bit Protocol Exception Disable 0: Protocol exception event detection enabled 1: Protocol exception event detection disabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
9:8	TSCCFG[1:0]	Timestamp Capture Configuration 0 0: Timestamp capture at the sample point of SOF (start of frame) 0 1: Timestamp capture at frame valid indication 1 0: Timestamp capture at the sample point of RES bit 1 1: Reserved	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

RPED bit (RES Bit Protocol Exception Disable)

The RPED bit configures the protocol exception event handling according to ISO 11898-1.

When this bit is enabled, the protocol exception event detection is disabled, and the protocol controller transmits an error frame when the protocol exception event is detected (RES bit is sampled recessive).

Only write to this bit when the CAN-FD module is in GL_RESET mode.

TSCCFG[1:0] bits (Timestamp Capture Configuration)

The TSCCFG[1:0] bits configure the different capture points of the timestamp for transmission and reception.

When CFDGFDCFG.TSCCFG[1:0] = 10b, the timestamp capture is performed for CAN-FD frames at RES bit and for Classical frames at the start of frame.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

35.3.84 CFDGLOCKK : Global Lock Key Register

Base address: CANFD = 0x8004_0000

Offset address: 0x131C

Bit position:	31																15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LOCK[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	LOCK[15:0]	Lock Key Key bits for unlocking the protection of test modes	W
31:16	—	The write value should be 0.	W

The CFDGLOCKK register is a write-only register that is used to unlock the protection for special test bits.

See section 35.10.2. Global Test Modes for Lock key specification.

LOCK[15:0] bits (Lock Key)

The unlock key sequence must be written in the LOCK[15:0] bits to configure the CAN-FD module in RAM test modes.

The read value from these bits is always 0x0000.

You cannot write to these bits when the CAN-FD module is in GL_SLEEP or GL_RESET mode.

Do not write to these bits when the CAN-FD module is in GL_OPERATION mode.

35.3.85 CFDRPGACCn : RAM Test Page Access Register n (n = 0 to 63)

Base address: CANFD = 0x8004_0000

Offset address: 0x8400 + 0x04 × n

Bit position:	31																													0
Bit field:	RDTA[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RDTA[31:0]	RAM Data Test Access RAM data bytes	R/W

RDTA[31:0] bits (RAM Data Test Access)

Data can be read from or written into the RDTA[31:0] bits when the CAN-FD module is configured in RAM test mode.

Only write to this bit when the CAN-FD module is in GL_HALT mode and RAM test mode is enabled.

If data is read when RAM test mode is not enabled, then it is always read as 0x00000000.

Software data should be read/written in the RAM Test Page Access registers during RAM test mode.

35.3.86 CFDCnBLCT : Channel n Bus Load Control Register (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x1418 + 0x20 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BLCLD	—	—	—	—	—	—	—	BLCE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BLCE	Bus Load Counter Enable 0: Bus load counter disabled 1: Bus load counter enabled	R/W

Bit	Symbol	Function	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	BLCLD	Bus Load Counter Load When CFDCnBLCT.BLCLD is set, it is reset after a bus load counter value is loaded.	W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

BLCE bit (Bus Load Counter Enable)

The BLCE bit indicates the enabling signal of a bus load counter. Write to this bit after setting up the CFDCnNCFG register.

When this bit is 0, the bus load counter stops but the counter is not clear.

The bit is cleared when the related CAN-FD channel is in CH_RESET mode.

Do not write to this bit in CH_SLEEP mode.

BLCLD bit (Bus Load Counter Load)

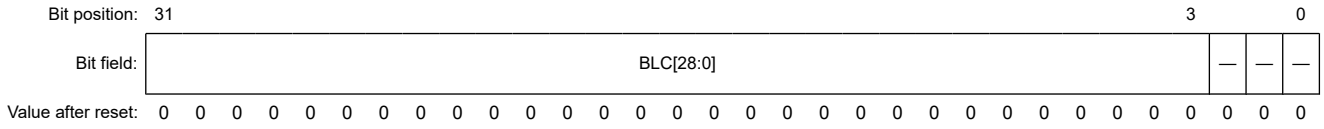
When the BLCLD bit is set, the bus load counter value is loaded into CFDCnBLSTS.BLC and the bus load counter is reset.

The read value is always 0.

35.3.87 CFDCnBLSTS : Channel n Bus Load Status Register (n = 0, 1)

Base address: CANFD = 0x8004_0000

Offset address: 0x141C + 0x20 × n



Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0.	R
31:3	BLC[28:0]	Bus Load Counter Status These bits indicate the bus load counter value.	R

BLC[28:0] bits (Bus Load Counter Status)

When the CFDCnBLCT.BLCLD bit is set, the bus load counter value is loaded to BLC[28:0] bits and the bus load counter is reset.

These bits are set only by the CAN-FD module. Writing any value has no effect.

35.3.88 Identifier Bits Alignment

Standard Identifier (11 bits) format: ID28 – ID18 is aligned to b10 to b0, b11 to b28 should be 0.

Extended Identifier (29 bits) format: ID28 – ID0 is aligned to b28 – b0

Table 35.13 Standard Identifier (11-bit format)

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

35.3.89 Message Buffer Component Structure

35.3.89.1 Start Addresses

The start address for each of the Message Buffer component is calculated using the number of related Message Buffer components and the number of channels.

number_of_channels	2
number_of_RMBCPs_per_channel	16
number_of_RFMBCPs	8
number_of_CFMBCPs_per_channel	3
number_of_TMBCPs_per_channel	64

The start addresses for each register in the Message Buffer component are depicted in Table 35.15.

Table 35.15 Message Buffer Component Register Start Addresses

b = Message buffer component index	MBCP	Register	p	Start address n = 0, 1
0 to number_of_RMBCPs_per_channel - 1	RMBCPb[i]	RMID	x	0x2000 + b × 0x0080 + n × 0x800
		RMPTR	x	0x2004 + b × 0x0080 + n × 0x800
		RMFDSTS	x	0x2008 + b × 0x0080 + n × 0x800
		RMDFp	0 to 15	0x200C + p × 0x0004 + b × 0x0080 + n × 0x800
0 to number_of_RFMBCPs - 1	RFMBCPb[i]	RFID	x	0x6000 + b × 0x0080
		RFPTR	x	0x6004 + b × 0x0080
		RFFDSTS	x	0x6008 + b × 0x0080
		RFDFp	0 to 15	0x600C + p × 0x0004 + b × 0x0080
0 to number_of_CFMBCPs_per_channel - 1	CFMBCPb[i]	CFID	x	0x6400 + b × 0x0080 + n × 0x180
		CFPTR	x	0x6404 + b × 0x0080 + n × 0x180
		CFFDCSTS	x	0x6408 + b × 0x0080 + n × 0x180
		CFDFp	0 to 15	0x640C + p × 0x0004 + b × 0x0080 + n × 0x180
0 to number_of_TMBCPs_per_channel - 1	TMBCPb[i]	TMID	x	0x10000 + b × 0x0080 + n × 0x2000
		TMPTR	x	0x10004 + b × 0x0080 + n × 0x2000
		TMFDCTR	x	0x10008 + b × 0x0080 + n × 0x2000
		TMDFp	0 to 15	0x1000C + p × 0x0004 + b × 0x0080 + n × 0x2000

The message buffer configuration consists of four types of Message Buffer components:

- RX Message Buffer Component (CFDRMBCPb[i])
- RX FIFO Access Message Buffer Component (CFDRFMBCPb[i])
- Common FIFO Access Message Buffer Component (CFDCFMBCPb[i])
- TX Message Buffer Component (CFDTMBCPb[i]).

Where b = the Message Buffer component index having a range that varies based on the type of Message Buffer component and i = channel index that has a range from 0 to n.

For a summary of this configuration, see Figure 35.28. For a detailed description of the number of and the different types of message buffers, see section 35.7. FIFO Buffers and Normal Message Buffer Configuration

As described in section 35.3. Register Descriptions, each Message Buffer component consists of the following registers:

- Identifier (ID)
- Pointer (PTR)
- Data Field (DFp).

p is the Data Field register index having a range that varies based on the type of Message Buffer component.

Rc is the Message Buffer Component register where c = Message Buffer Component register index having a range that varies based on the type of Message Buffer component.

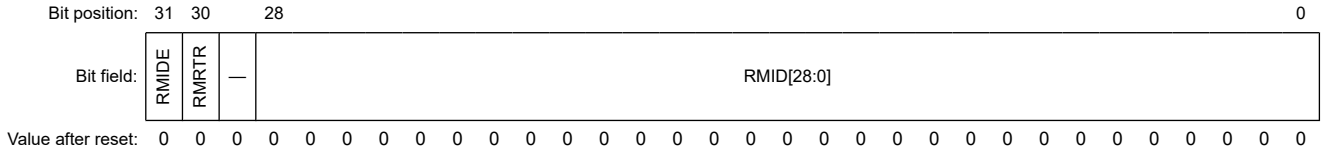
A description of the registers, their associated bits and their accessibility are shown below the summary and detailed figures of each component.

In each of the figures, a cell that contains '-' means reserved and has the same behavior as reserved bits for registers in section 35.3.89. Message Buffer Component Structure.

35.3.89.2 CFDRMIDn : RX Message Buffer ID Register n (n = 0 to 31)

Base address: CANFD = 0x8004_0000

Offset address: 0x2000 + 0x080 × n



Bit	Symbol	Function	R/W
28:0	RMID[28:0]	RX Message Buffer ID Field STD-ID/EXT-ID fields	R
29	—	These bits are read as 0.	R
30	RMRTR	RX Message Buffer RTR Bit 0: Data frame 1: Remote frame	R
31	RMIDE	RX Message Buffer IDE Bit 0: STD-ID is stored 1: EXT-ID is stored	R

The CFDRMIDn register (n = 0 to 31) stores the ID field, IDE bit, and RTR bit of the received message.

RMID[28:0] bits (RX Message Buffer ID Field)

The RMID[28:0] are the bits of the STD-ID/EXT-ID fields of the message stored in the RX message buffer.

For alignment of these bits in standard and extended frame format, see section 35.3.88. Identifier Bits Alignment

See section 35.3.89.1. Start Addresses for details on how to interpret the structure of this buffer component.

RMRTR bit (RX Message Buffer RTR Bit)

The RMRTR bit shows whether a data frame or a remote frame was stored in the RX message buffer.

Note: There are no remote frames in CAN-FD format. When a CAN-FD frame is received, the register reflects the state of the received value (the RRS bit in FD frame format).

RMIDE bit (RX Message Buffer IDE Bit)

The RMIDE bit shows whether message with Standard Identifier or Extended Identifier was stored in the RX message buffer.

35.3.89.3 CFDRMPTRn : RX Message Buffer Pointer Register (n = 0 to 31)

Base address: CANFD = 0x8004_0000

Offset address: 0x2004 + 0x080 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RMDLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—	RMTS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RMTS[15:0]	RX Message Buffer Timestamp Field Timestamp value stored for the message in the RX message buffer	R/W
27:16	—	These bits are read as 0. The write value should be 0.	R/W
31:28	RMDLC[3:0]	RX Message Buffer DLC Field Number of data bytes received in a CAN frame.	R/W

The CFDRMPTRn register (n = 0 to 31) stores the DLC and Timestamp fields for the received message.

RMTS[15:0] bits (RX Message Buffer Timestamp Field)

The RMTS[15:0] bits store the timestamp value taken at the capture point as configured by CFDGFDCFG.TSCCFG of the received message.

RMDLC[3:0] bits (RX Message Buffer DLC Field)

The RMDLC[3:0] bits store the number of data bytes that were received in the RX message buffer.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

Note: The maximum capacity of the buffer belongs to CFDRMNB.RMPLS and this is not available in the classical CAN function.

35.3.89.4 CFDRMFDSTSn : RX Message Buffer CAN-FD Status Register (n = 0 to 31)

Base address: CANFD = 0x8004_0000

Offset address: 0x2008 + 0x080 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RMPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	RMIFL[1:0]		—	—	—	—	—	RMFDF	RMBRS	RMESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RMESI*1	Error State Indicator bit 0: CAN-FD frame received from error active node 1: CAN-FD frame received from error passive node	R/W
1	RMBRS*1	Bit Rate Switch bit 0: CAN-FD frame received with no bit rate switch 1: CAN-FD frame received with bit rate switch	R/W

Bit	Symbol	Function	R/W
2	RMFDF*1	CAN FD Format bit 0: Non CAN-FD frame received 1: CAN-FD frame received	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
9:8	RMIFL[1:0]	RX Message Buffer Information Label Field	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
31:16	RMPTR[15:0]	RX Message Buffer Pointer Field	R/W

Note 1. This bit is not available in the classical CAN function.

The CFDRMFDSTSn register (n = 0 to 31) shows the status of the FDF, BRS, and ESI bits, and pointer of the received CAN-FD frame.

RMESI bit (Error State Indicator bit)

The RMESI bit has the same value as the ESI bit of the received CAN-FD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RMBRS bit (Bit Rate Switch bit)

The RMBRS bit has the same value as the BRS bit of the received CAN-FD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RMFDF bit (CAN FD Format bit)

The RMFDF bit has the same value as the FDF bit of the received CAN-FD frame.

Note: This bit is not available in the classical CAN function.

RMIFL[1:0] bits (RX Message Buffer Information Label Field)

The RMIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

RMPTR[15:0] bits (RX Message Buffer Pointer Field)

The RMPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

35.3.89.5 CFDRMDFp_n : RX Message Buffer Data Field p Register n (p = 0 to 15, n = 0 to 31)

Base address: CANFD = 0x8004_0000

Offset address: 0x200C + 0x004 × p + 0x080 × n

Bit position:	31 … 24	23 … 16	15 … 8	7 … 0
Bit field:	RMDB_HH[7:0]	RMDB_HL[7:0]	RMDB_LH[7:0]	RMDB_LL[7:0]
Value after reset:	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
7:0	RMDB_LL[7:0]	RX Message Buffer Data Byte (4 × p)	R/W
15:8	RMDB_LH[7:0]	RX Message Buffer Data Byte (4 × p + 1)	R/W
23:16	RMDB_HL[7:0]	RX Message Buffer Data Byte (4 × p + 2)	R/W
31:24	RMDB_HH[7:0]*1	RX Message Buffer Data Byte (4 × p + 3)	R/W

Note 1. These bits are not available in the classical CAN function.

The CFDRMDFp_n register (p = 0 to 15, n = 0 to 31) stores the data bytes (4 × p) to data bytes (4 × p + 3) of the received message.

RMDB_LL[7:0] bits (RX Message Buffer Data Byte (4 × p))

The RMDB_LL[7:0] bits store data bytes (4 × p) of the message in the RX message buffer. Unused data bytes are filled with 0x00.

RMDB_LH[7:0] bits (RX Message Buffer Data Byte (4 × p + 1))

The RMDB_LH[7:0] bits store data bytes (4 × p + 1) of the message in the RX message buffer. Unused Data Bytes are filled with 0x00.

RMDB_HL[7:0] bits (RX Message Buffer Data Byte (4 × p + 2))

The RMDB_HL[7:0] bits store data bytes (4 × p + 2) of the message in the RX message buffer. Unused data bytes are filled with 0x00.

RMDB_HH[7:0] bits (RX Message Buffer Data Byte (4 × p + 3))

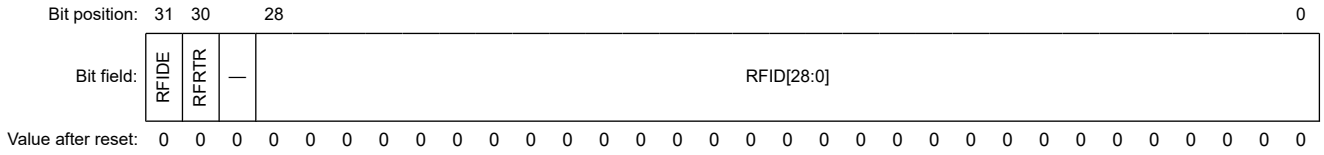
The RMDB_HH[7:0] bits store data bytes (4 × p + 3) of the message in the RX message buffer. Unused data bytes are filled with 0x00.

These bits are not available in the classical CAN function.

35.3.89.6 CFDRFIDn : RX FIFO Access ID Register n (n = 0 to 7)

Base address: CANFD = 0x8004_0000

Offset address: 0x6000 + 0x080 × n



Bit	Symbol	Function	R/W
28:0	RFID[28:0]	RX FIFO Buffer ID Field STD-ID/EXT-ID fields	R
29	—	This bit is read as 0.	R
30	RFRTR	RX FIFO Buffer RTR bit 0: Data frame 1: Remote frame	R
31	RFIDE	RX FIFO Buffer IDE bit 0: STD-ID has been received 1: EXT-ID has been received	R

The CFDRFIDn register (n = 0 to 7) stores the ID field, IDE bit, and RTR bit of the message.

RFID[28:0] bits (RX FIFO Buffer ID Field)

The RFID[28:0] bits are the bits of the STD-ID/EXT-ID fields of the message in the FIFO buffer.

For alignment of these bits in standard and extended frame format, see section 35.3.88. Identifier Bits Alignment.

RFRTR bit (RX FIFO Buffer RTR bit)

The RFRTR bit shows whether a data frame or a remote frame was stored in the FIFO buffer.

Note: There are no remote frames in CAN-FD format. When a CAN-FD frame was received, the register reflects the state of the received value (RRS bit in FD frame format).

RFIDE bit (RX FIFO Buffer IDE bit)

The RFIDE bit shows whether message with the Standard Identifier or Extended Identifier was received in the FIFO buffer.

35.3.89.7 CFDRFPTRn : RX FIFO Access Pointer Register n (n = 0 to 7)

Base address: CANFD = 0x8004_0000

Offset address: 0x6004 + 0x080 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RFDLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—	RFTS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RFTS[15:0]	RX FIFO Timestamp Value Timestamp value of the received CAN frame	R
27:16	—	These bits are read as 0.	R
31:28	RFDLC[3:0]	RX FIFO Buffer DLC Field Number of data bytes received in a CAN frame	R

The CFDRFPTRn register (n = 0 to 7) stores the DLC and Timestamp fields for the received message.

RFTS[15:0] bits (RX FIFO Timestamp Value)

The RFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message.

RFDLC[3:0] bits (RX FIFO Buffer DLC Field)

The RFDLC[3:0] bits store the number of data bytes that were received in the RX FIFO buffer.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

35.3.89.8 CFDRFFDSTSn : RX FIFO Access CAN-FD Status Register n (n = 0 to 7)

Base address: CANFD = 0x8004_0000

Offset address: 0x6008 + 0x080 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CFDRFPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	RFIFL[1:0]		—	—	—	—	—	RFFDF	RFBRS	RFESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFESI*1	Error State Indicator bit 0: CAN-FD frame received from error active node 1: CAN-FD frame received from error passive node	R
1	RFBRS*1	Bit Rate Switch bit 0: CAN-FD frame received with no bit rate switch 1: CAN-FD frame received with bit rate switch	R
2	RFFDF*1	CAN FD Format bit 0: Non CAN-FD frame received 1: CAN-FD frame received	R
7:3	—	These bits are read as 0.	R
9:8	RFIFL[1:0]	RX FIFO Buffer Information Label Field	R
15:10	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
31:16	CFDRFPTR[15:0]	RX FIFO Buffer Pointer Field	R

Note 1. This bit is not available in the classical CAN function.

The CFDRFFDSTSn register (n = 0 to 7) shows the status of the FDF, BRS, and ESI bits, including the pointer of the received CAN-FD frame.

RFESI bit (Error State Indicator bit)

The RFESI bit has the same value as the ESI bit of the received CAN-FD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RFBRS bit (Bit Rate Switch bit)

The RFBRS bit has the same value as the BRS bit of the received CAN-FD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RFFDF bit (CAN FD Format bit)

The RFFDF bit has the same value as the FDF bit of the received CAN-FD frame.

Note: This bit is not available in the classical CAN function.

RFIFL[1:0] bits (RX FIFO Buffer Information Label Field)

The RFIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

CFDRFPTR[15:0] bits (RX FIFO Buffer Pointer Field)

The CFDRFPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

35.3.89.9 CFDRFDFpn : RX FIFO Access Data Field p Register n (p = 0 to 15, n = 0 to 7)

Base address: CANFD = 0x8004_0000

Offset address: 0x600C + 0x004 × p + 0x080 × n

Bit position:	31							24	23							16	15							8	7							0
Bit field:	RFDB_HH[7:0]								RFDB_HL[7:0]								RFDB_LH[7:0]								RFDB_LL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RFDB_LL[7:0]	RX FIFO Buffer Data Byte (4 × p)	R
15:8	RFDB_LH[7:0]	RX FIFO Buffer Data Byte (4 × p + 1)	R
23:16	RFDB_HL[7:0]	RX FIFO Buffer Data Byte (4 × p + 2)	R
31:24	RFDB_HH[7:0]	RX FIFO Buffer Data Byte (4 × p + 3)	R

The CFDRFDFpn register (p = 0 to 15, n = 0 to 7) stores data bytes (4 × p) to data bytes (4 × p + 3) of the received message.

RFDB_LL[7:0] bits (RX FIFO Buffer Data Byte (4 × p))

The RFDB_LL[7:0] bits store data bytes (4 × p) of the message present in the FIFO buffer. Unused data bytes are filled with 0x00 according to the configured data payload size CFDRFCCn.RFPLS.

RFDB_LH[7:0] bits (RX FIFO Buffer Data Byte (4 × p + 1))

The RFDB_LH[7:0] bits store data bytes (4 × p + 1) of the message present in the FIFO buffer. Unused data bytes are filled with 0x00.

RFDB_HL[7:0] bits (RX FIFO Buffer Data Byte (4 × p + 2))

The RFDB_HL[7:0] bits store data bytes (4 × p + 2) of the message present in the FIFO buffer. Unused data bytes are filled with 0x00.

RFDB_HH[7:0] bits (RX FIFO Buffer Data Byte (4 × p + 3))

The RFDB_HH[7:0] bits store data bytes (4 × p + 3) of the message present in the FIFO buffer. Unused data bytes are filled with 0x00.

35.3.89.10 CFDCFIDn : Common FIFO Access ID Register n (n = 0 to 5)

Base address: CANFD = 0x8004_0000

Offset address: 0x6400 + 0x080 × n

Bit position:	31	30	29	28																											0
Bit field:	CFIDE	CFRTR	THLEN	CFID[28:0]																											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
28:0	CFID[28:0]	Common FIFO Buffer ID Field STD-ID/EXT-ID fields	R/W
29	THLEN	THL Entry Enable TX FIFO mode: 0: Entry is not to be stored in THL after successful TX 1: Entry is to be stored in THL after successful TX RX FIFO mode: Reserved, this bit is read as 0.	R/W
30	CFRTR	Common FIFO Buffer RTR bit 0: Data frame 1: Remote frame	R/W
31	CFIDE	Common FIFO Buffer IDE bit 0: STD-ID is to be transmitted or has been received 1: EXT-ID is to be transmitted or has been received	R/W

The CFDCFIDn register (n = 0 to 5) stores the ID field, IDE bit, and RTR bit of the message.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

CFID[28:0] bits (Common FIFO Buffer ID Field)

The CFID[28:0] bits are the bits of the STD-ID/EXT-ID fields of the message in the FIFO buffer.

For alignment of these bits in standard and extended frame format, see section 35.3.88. Identifier Bits Alignment.

In TX mode, you can write and read data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

THLEN bit (THL Entry Enable)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

In TX mode, you can write and read data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

CFRTR bit (Common FIFO Buffer RTR bit)

The CFRTR bit selects whether a data frame or a remote frame is to be transmitted from or was received in the FIFO buffer.

Note: There are no remote frames in CAN FD format. When a CAN-FD frame is received (RX mode), the register reflects the state of the received value (RRS bit in FD frame format). When CAN-FD transmission (TX or GW mode CFDCFID.CFFDF = 1), the bit is always transmitted dominant (data frame).

In TX mode, you can write and read data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

CFIDE bit (Common FIFO Buffer IDE bit)

The CFIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from or was received in the FIFO buffer.

In TX mode, you can write and read data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

35.3.89.11 CFDCFPTRn : Common FIFO Access Pointer Register n (n = 0 to 5)

Base address: CANFD = 0x8004_0000

Offset address: 0x6404 + 0x080 × n

Bit position:	31			28												15															0
Bit field:	CFDLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—	CFTS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CFTS[15:0]	Common FIFO Timestamp Value Timestamp value of the received CAN frame (FIFO in RX mode).	R/W
27:16	—	These bits are read as 0. The write value should be 0.	R/W
31:28	CFDLC[3:0]	Common FIFO Buffer DLC Field Number of data bytes received in a CAN frame, or transmitted in a CAN frame.	R/W

The CFDCFPTRn register (n = 0 to 5) stores the DLC and Timestamp fields.

In TX mode, you can read data from the FIFO buffer, only for the current entry based on the write pointer value, and not for the other entries.

CFTS[15:0] bits (Common FIFO Timestamp Value)

The CFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message (if FIFO is configured in RX mode).

In TX mode, you can read and write data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

CFDLC[3:0] bits (Common FIFO Buffer DLC Field)

The CFDLC[3:0] bits store the number of data bytes that were received in the FIFO buffer or are to be transmitted.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes.

In TX mode, you can read and write data from the FIFO buffers. Do not read data for the other entries in the FIFO when configured in TX mode.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

35.3.89.12 CFDCFFDCSTSn : Common FIFO Access CAN-FD Control/Status Register n (n = 0 to 5)

Base address: CANFD = 0x8004_0000

Offset address: 0x6408 + 0x080 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CFPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CFIFL[1:0]		—	—	—	—	—	CFFDF	CFBRS	CFESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CFESI*1	Error State Indicator bit 0: CAN-FD frame received or to transmit by error active node 1: CAN-FD frame received or to transmit by error passive node	R/W
1	CFBRS*1	Bit Rate Switch bit 0: CAN-FD frame received or to transmit with no bit rate switch 1: CAN-FD frame received or to transmit with bit rate switch	R/W
2	CFFDF*1	CAN FD Format bit 0: Non CAN-FD frame received or to transmit 1: CAN-FD frame received or to transmit	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
9:8	CFIFL[1:0]	COMMON FIFO Buffer Information Label Field	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
31:16	CFPTR[15:0]	Common FIFO Buffer Pointer Field	R/W

Note 1. This bit is not available in the classical CAN function.

The CFDCFFDCSTSn register (n = 0 to 5) shows the status of the FDF, BRS, and ESI bits, including the pointer of the received CAN-FD frame or the CAN-FD frame to transmit.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

CFESI bit (Error State Indicator bit)

In TX mode, you can read and write data from FIFO buffers. In this mode, when the CAN-FD module is not in error passive, the CFESI bit equals the write value. Otherwise, it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, the CFESI bit is updated with the ESI bit value of the CAN-FD frame when it has been received, indicating the error state of the transmitting node. In RX or GW mode, 0 is stored to this bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFBRS bit (Bit Rate Switch bit)

In TX mode, you can read and write data from FIFO buffers. In this mode, the CAN-FD module either transmits a 0 to indicate no bit rate switch in the frame to be transmitted or a 1 to indicate a bit rate switch in the frame to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, the CFBRS bit is updated with the BRS bit value of the CAN-FD frame when it has been received, indicating whether there is a bit rate switch (1) or (0) on the CAN-FD frame.

In RX or GW mode, 0 is stored to the CFBRS bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFFDF bit (CAN FD Format bit)

In TX mode, you can read and write data from FIFO buffers. In this mode, the CAN-FD module either transmits a 0 to indicate a CAN 2.0 frame is to be transmitted or a 1 to indicate a CAN-FD frame is to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, the CFFDF bit is updated with the FDF bit value of the CAN frame when it has been received, indicating whether it is a CAN 2.0 frame (0) or a CAN-FD frame (1).

Note: This bit is not available in the classical CAN function.

CFIFL[1:0] bits (COMMON FIFO Buffer Information Label Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTSn.CFIFL[1:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The information label value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX or GW mode).

In TX mode, you can read and write data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

CFPTR[15:0] bits (Common FIFO Buffer Pointer Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTSn.CFPTR[15:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The pointer value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX or GW mode).

In TX mode, you can read and write data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

35.3.89.13 CFDCFDFpn : Common FIFO Access Data Field p Register n (p = 0 to 15, n = 0 to 5)

Base address: CANFD = 0x8004_0000

Offset address: 0x640C + 0x004 × p + 0x080 × n

Bit position:	31 … 24	23 … 16	15 … 8	7 … 0
Bit field:	CFDB_HH[7:0]	CFDB_HL[7:0]	CFDB_LH[7:0]	CFDB_LL[7:0]
Value after reset:	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
7:0	CFDB_LL[7:0]	Common FIFO Buffer Data Byte (4 × p)	R/W
15:8	CFDB_LH[7:0]	Common FIFO Buffer Data Byte (4 × p + 1)	R/W
23:16	CFDB_HL[7:0]	Common FIFO Buffer Data Byte (4 × p + 2)	R/W

Bit	Symbol	Function	R/W
31:24	CFDB_HH[7:0]	Common FIFO Buffer Data Byte (4 × p + 3)	R/W

The CFDCFDFpn register (p = 0 to 15, n = 0 to 5) stores data bytes (4 × p) to data bytes (4 × p + 3) of the message.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

CFDB_LL[7:0] bits (Common FIFO Buffer Data Byte (4 × p))

The CFDB_LL[7:0] bits store data bytes (4 × p) of the message present in the FIFO buffer.

In TX mode, you can read and write data from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCCn.CFPLS.*1

CFDB_LH[7:0] bits (Common FIFO Buffer Data Byte (4 × p + 1))

The CFDB_LH[7:0] bits store data bytes (4 × p + 1) of the message present in the FIFO buffer.

In TX mode, you can read and write data from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCCn.CFPLS.*1

CFDB_HL[7:0] bits (Common FIFO Buffer Data Byte (4 × p + 2))

The CFDB_HL[7:0] bits store data bytes (4 × p + 2) of the message present in the FIFO buffer.

In TX mode, you can read and write data from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCCn.CFPLS.*1

CFDB_HH[7:0] bits (Common FIFO Buffer Data Byte (4 × p + 3))

The CFDB_HH[7:0] bits store data bytes (4 × p + 3) of the message present in the FIFO buffer.

In TX mode, you can read and write data from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

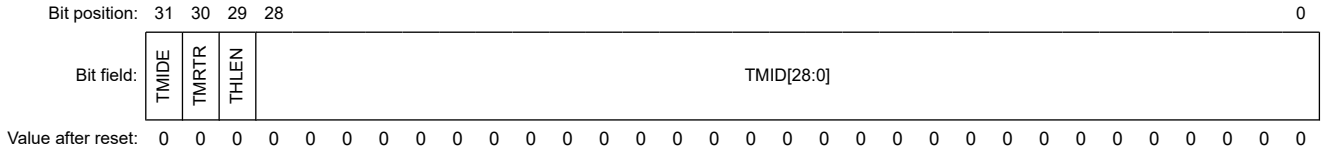
In RX or GW mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCCn.CFPLS.*1

Note 1. In RX or GW mode, unused data bytes are filled with 0x00 according to the configured data payload size CFDCFCCn.CFPLS, which is a CAN-FD feature not found in classical CAN.

35.3.89.14 CFDTMIDn : TX Message Buffer ID Register n (n = 0 to 127)

Base address: CANFD = 0x8004_0000

Offset address: 0x1_0000 + 0x080 × n



Bit	Symbol	Function	R/W
28:0	TMID[28:0]	TX Message Buffer ID Field STD-ID/EXT-ID fields	R/W
29	THLEN	Tx History List Entry 0: Entry not stored in THL after successful TX 1: Entry stored in THL after successful TX	R/W
30	TMRTR	TX Message Buffer RTR bit 0: Data frame 1: Remote frame	R/W
31	TMIDE	TX Message Buffer IDE bit 0: STD-ID is transmitted 1: EXT-ID is transmitted	R/W

The CFDTMIDn register (n = 0 to 127) stores the ID, IDE, RTR fields and history configuration of the message to be transmitted from the associated buffer.

TMID[28:0] bits (TX Message Buffer ID Field)

The TMID[28:0] bits are bits of the STD-ID/EXT-ID fields of the message stored in this TX message buffer.

For alignment of these bits in standard and extended frame format, see section 35.3.88. Identifier Bits Alignment.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

THLEN bit (Tx History List Entry)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMRTR bit (TX Message Buffer RTR bit)

The TMRTR bit selects whether a data frame or remote frame is to be transmitted from this TX message buffer.

Note: There are no remote frames in CAN-FD format. For a CAN-FD transmission (CFDTMFDCTR.CFFDF = 1), this bit is always transmitted dominant (data frame).

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMIDE bit (TX Message Buffer IDE bit)

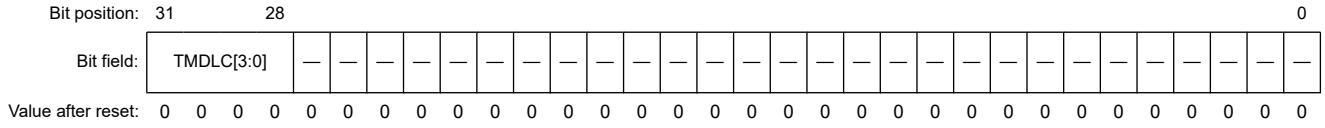
The TMIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from this TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

35.3.89.15 CFDTMPTRn : TX Message Buffer Pointer Register n (n = 0 to 127)

Base address: CANFD = 0x8004_0000

Offset address: 0x1_0004 + 0x080 × n



Bit	Symbol	Function	R/W
27:0	—	The read values are undefined. The write value should be 0.	R/W
31:28	TMDLC[3:0]	TX Message Buffer DLC Field Number of data bytes to be transmitted in a CAN frame.	R/W

The CFDTMPTRn register (n = 0 to 127) stores the DLC fields of the message to transmit from the associated buffer.

TMDLC[3:0] bits (TX Message Buffer DLC Field)

The TMDLC[3:0] bits select the number of data bytes to be transmitted from this TX message buffer when the corresponding TMRTR bit is configured as 0.

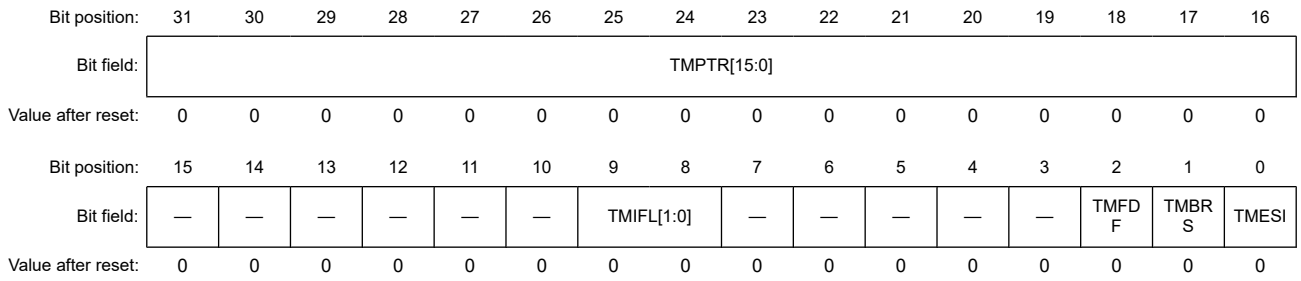
See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes to be transmitted.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

35.3.89.16 CFDTMFDCTRn : TX Message Buffer CAN-FD Control Register n (n = 0 to 127)

Base address: CANFD = 0x8004_0000

Offset address: 0x1_0008 + 0x080 × n



Bit	Symbol	Function	R/W
0	TMESI*1	Error State Indicator bit 0: CAN-FD frame to transmit by error active node 1: CAN-FD frame to transmit by error passive node	R/W
1	TMBRS*1	Bit Rate Switch bit 0: CAN-FD frame to transmit with no bit rate switch 1: CAN-FD frame to transmit with bit rate switch	R/W
2	TMFDF*1	CAN FD Format bit 0: Non CAN-FD frame to transmit 1: CAN-FD frame to transmit	R/W
7:3	—	The read values are undefined. The write value should be 0.	R/W
9:8	TMIFL[1:0]	TX Message Buffer Information Label Field	R/W
15:10	—	The read values are undefined. The write value should be 0.	R/W
31:16	TMPTR[15:0]	TX Message Buffer Pointer Field	R/W

Note 1. This bit is not available in the classical CAN function.

The CFDTMFDCTRn register (n = 0 to 127) shows the status of the FDF, BRS, and ESI bits, including the pointer fields of the CAN-FD frame to be transmitted.

TMESI bit (Error State Indicator bit)

If the channel is not in error passive, then the TMESI bit equals the write value, otherwise it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

Do not write to the TMESI bit when the related CAN-FD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMBRS bit (Bit Rate Switch bit)

Do not write to the TMBRS bit when the related CAN-FD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMFDF bit (CAN FD Format bit)

Do not write to the TMFDF bit when the related CAN-FD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMIFL[1:0] bits (TX Message Buffer Information Label Field)

The TMIFL[1:0] bits store the information label value to be copied, together with additional message information, in the TX History List after successful transmission of the message.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMPTR[15:0] bits (TX Message Buffer Pointer Field)

The TMPTR[15:0] bits store the pointer value to be copied, together with additional message information in the TX History List after successful transmission of the message.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

35.3.89.17 CFDTMDFp_n : TX Message Buffer Data Field p Register n (p = 0 to 15, n = 0 to 127)

Base address: CANFD = 0x8004_0000

Offset address: 0x1_000C + 0x004 × p + 0x080 × n

Bit position:	31 … 24	23 … 16	15 … 8	7 … 0
Bit field:	TMDB_HH[7:0]	TMDB_HL[7:0]	TMDB_LH[7:0]	TMDB_LL[7:0]
Value after reset:	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
7:0	TMDB_LL[7:0]	TX Message Buffer Data Byte (4 × p)	R/W
15:8	TMDB_LH[7:0]	TX Message Buffer Data Byte (4 × p + 1)	R/W
23:16	TMDB_HL[7:0]	TX Message Buffer Data Byte (4 × p + 2)	R/W
31:24	TMDB_HH[7:0]	TX Message Buffer Data Byte (4 × p + 3)	R/W

The CFDTMDFp_n register (p = 0 to 15, n = 0 to 127) stores data bytes (4 × p) to data bytes (4 × p + 3) of the message to transmit from the associated buffer.

TMDB_LL[7:0] bits (TX Message Buffer Data Byte (4 × p))

Data bytes (4 × p)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMDB_LH[7:0] bits (TX Message Buffer Data Byte (4 × p + 1))

Data bytes (4 × p + 1)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMDB_HL[7:0] bits (TX Message Buffer Data Byte (4 × p + 2))

Data bytes (4 × p + 2)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMDB_HH[7:0] bits (TX Message Buffer Data Byte (4 × p + 3))

Data bytes (4 × p + 3)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

35.4 Operation

35.4.1 Overview

The modes of the CAN-FD module can be classified into 2 groups:

- Global modes
- Channel modes

35.4.2 Global Modes

Global modes are applicable for the complete CAN-FD module. The global modes of the CAN-FD module are:

- Global Sleep
- Global Reset
- Global Halt
- Global Operation

Figure 35.2 shows the possible transitions between the Global modes.

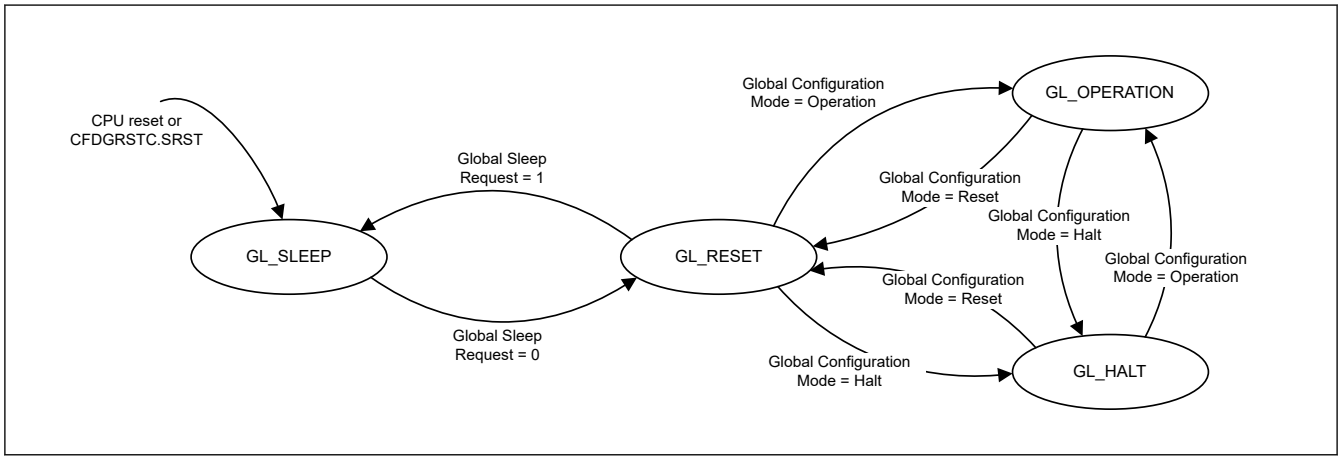


Figure 35.2 Transition between CAN-FD Global modes

Changes in the Global mode can affect the Channel mode. Table 35.16 shows the effect of a Global mode transition on a Channel mode.

Table 35.16 Possible CAN-FD Channel modes and Global modes

Current Global mode	Target Global mode			
	Sleep	**Reset**	**Halt**	**Operation**
Sleep	—	Ch-Sleep: Keep Ch-Reset: N/A Ch-Halt: N/A Ch-Oper: N/A	—	—
Reset	Ch-Sleep: Keep Ch-Reset: → Ch-Sleep Ch-Halt: N/A Ch-Oper: N/A	—	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A
Halt	—	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: N/A	—	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: N/A
Operation	—	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: → Ch-Reset	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: → Ch-Halt	—

35.4.2.1 Global Sleep Mode

After the release of a hardware reset or after setting and clearing the CFDGRSTC.SRST bit, the CAN-FD module automatically enters Global Sleep mode.

The CAN-FD module also enters the Global Sleep mode when the Global Sleep Request bit is set while it is in Global Reset mode. This control bit cannot be set in Global Halt mode or Global Operation mode.

Setting the Global Sleep Request bit sets all Channel Sleep Request bits and forces all channels into the Channel Sleep mode. Sleep mode is used for power saving purpose. When CAN-FD module is in Global Sleep mode, only the clock for CPU write access to the Global Sleep Mode Request bit is active. All other clocks are stopped and all other functions of the CAN-FD module are suspended.

Read access from all registers is still possible and all register values are preserved.

In Global Sleep mode, RAM access is prohibited because the logic which generates a RAM address does not operate.

After setting the Global Sleep Request bit, it is necessary to confirm that the Global Sleep status has been updated, indicating successful transition to Global Sleep mode before the Global Sleep Request bit can be cleared again.

Figure 35.3 shows the procedure for entering Global Sleep mode and Figure 35.4 shows the procedure for exiting Global Sleep mode.

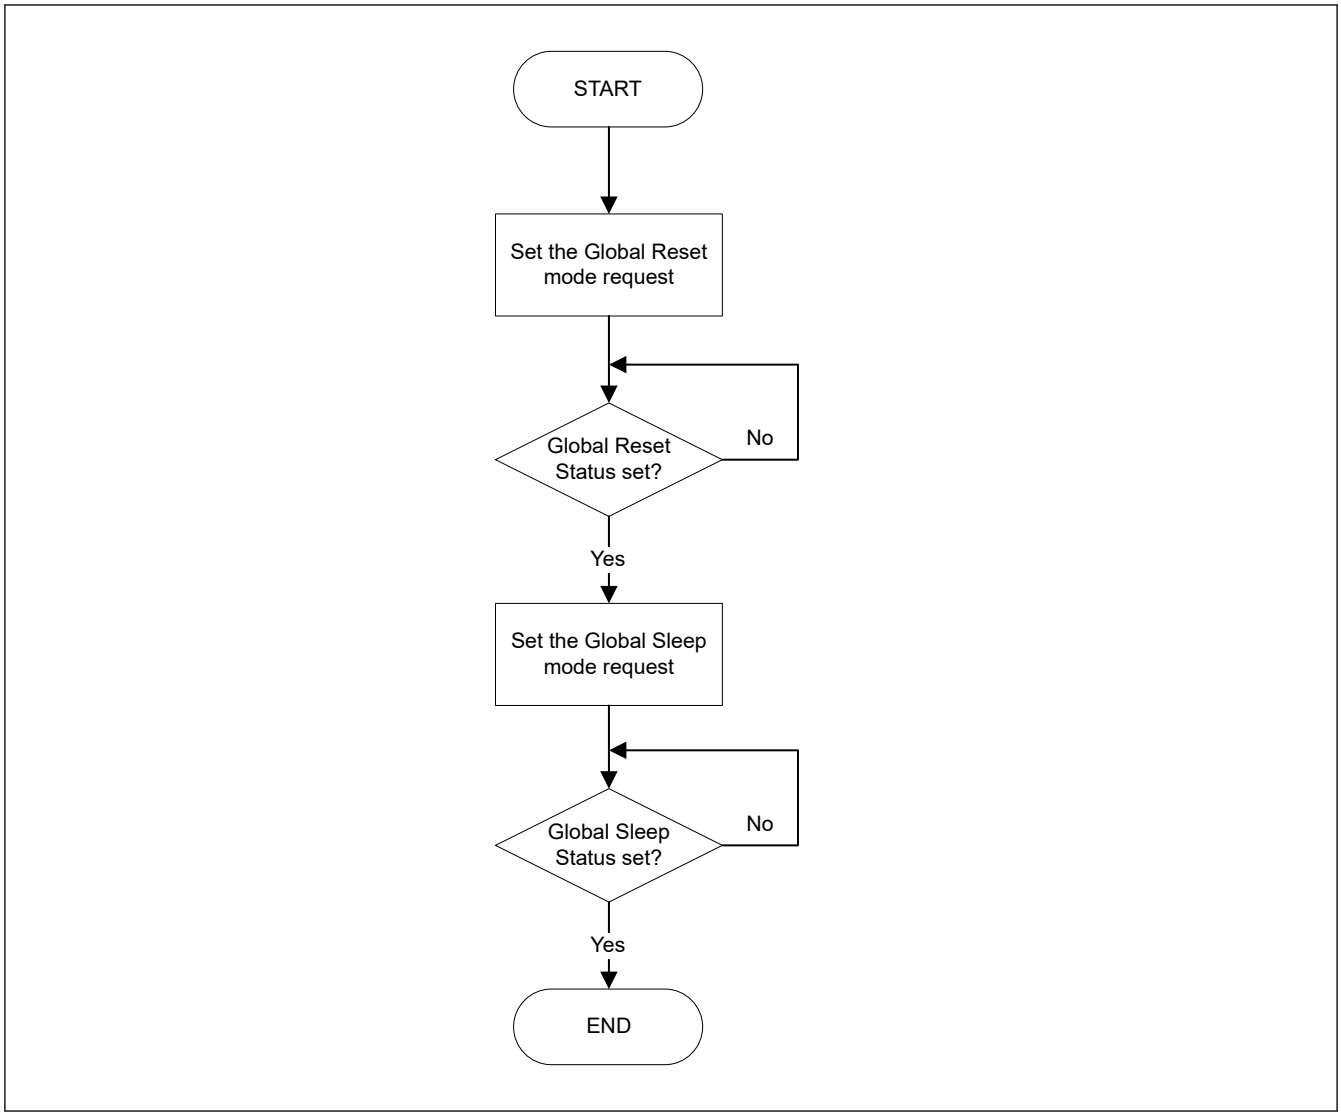

Figure 35.3 Procedure for entering Global Sleep mode

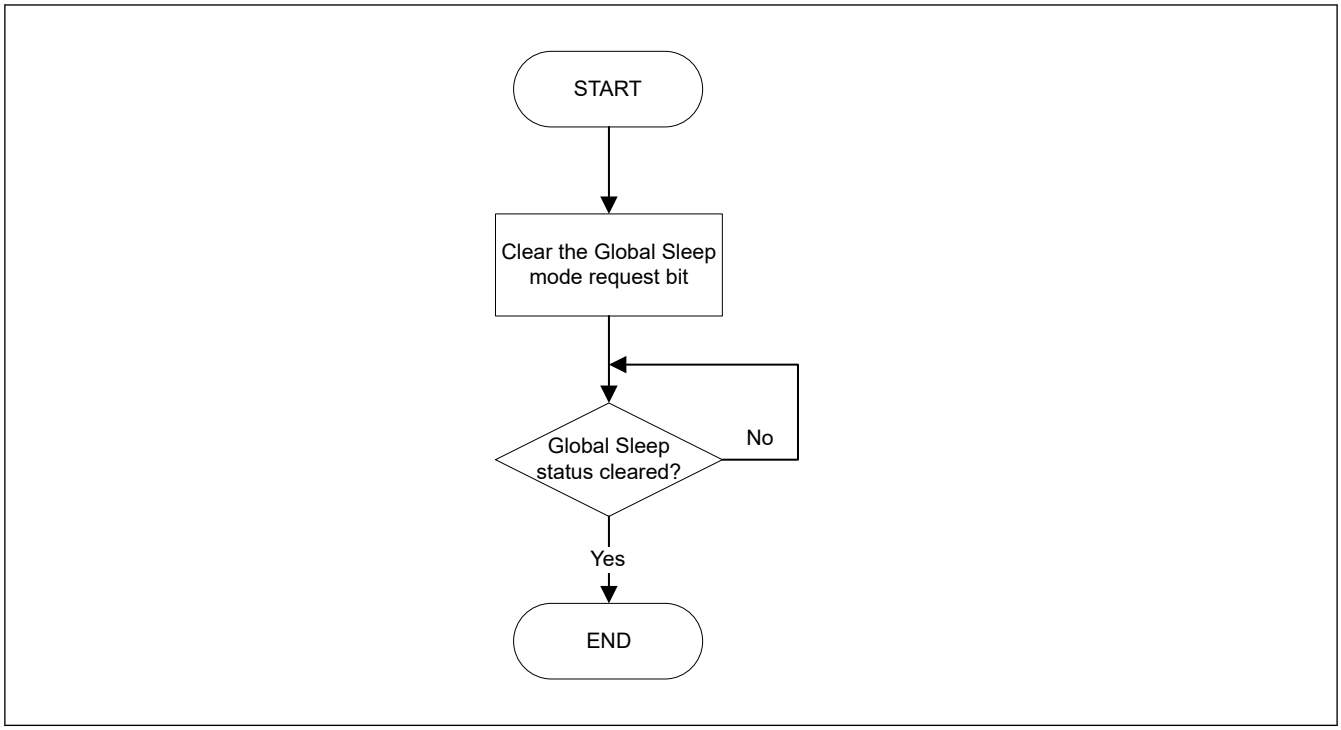

Figure 35.4 Procedure for exiting Global Sleep mode

35.4.2.2 Global Reset Mode

The CAN-FD module enters the Global Reset mode in the following ways:

- Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register is configured for Global Reset mode while the CAN-FD module is in Global Halt or Global Operation mode.
- Global Sleep Mode Request bit is cleared while CAN-FD module is in Global Sleep mode.

In Global Reset mode, all CAN-FD module functions are suspended and all status and flag registers are initialized.

Additionally all FIFOs and all channel TX Queues are disabled and transmission control bits are cleared.

Configuration registers (except the test mode registers) are not initialized in this mode to their device reset values and the CAN-FD module can be configured.

See section 35.4.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Global Reset mode.

Setting the Global mode to Reset by setting the Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register to 01b sets all Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers to 01b and forces all channels into the Channel Reset mode.

For channels that are already in Channel Reset mode or Channel Sleep mode, this automatic transition is not performed (CFDCnCTR.CHMDC[1:0] of related channel already set to 01b).

After setting Global Mode Control bits CFDGCTR.GMDC[1:0] to Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDGSTS.GRSTSTS in the Global Status Register has been updated, indicating successful transition to Global Reset mode before CFDGCTR.GMDC can be changed again.

Figure 35.5 shows the procedure for entering Global Reset mode and Figure 35.6 shows the procedure for exiting Global Reset mode.

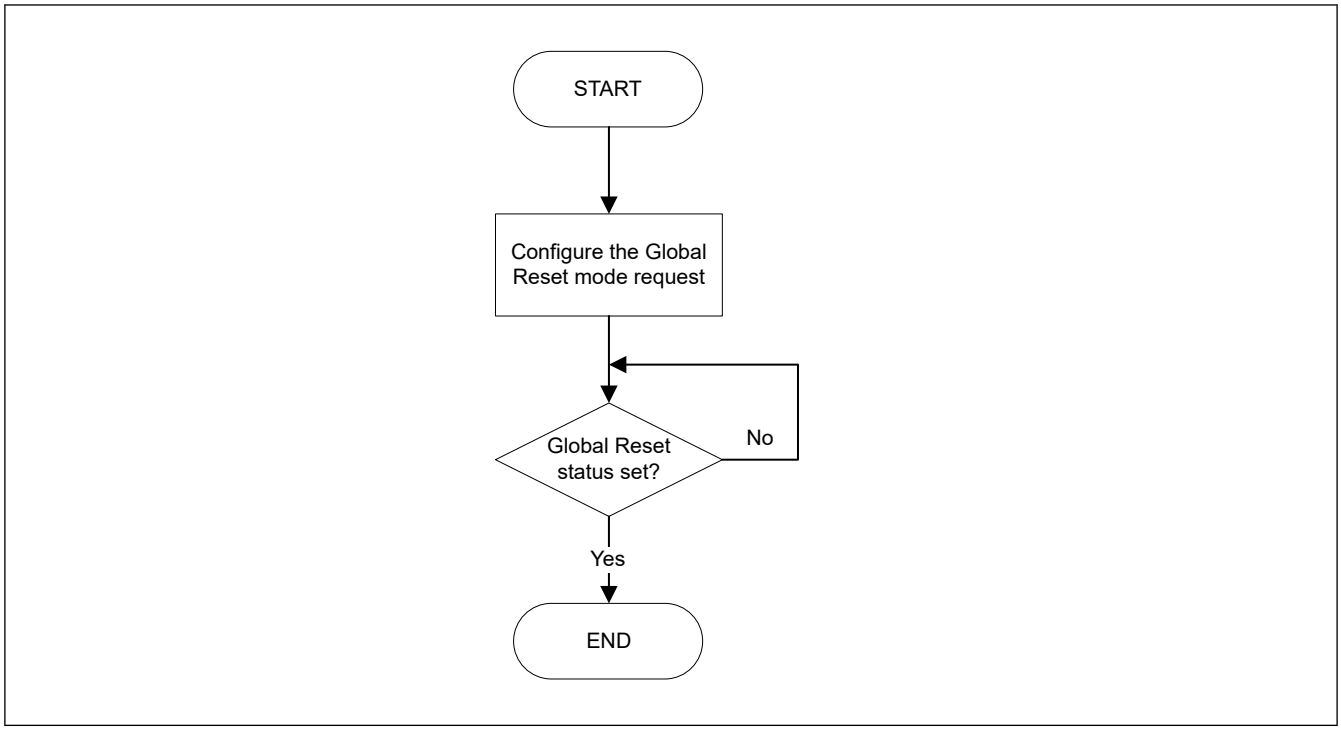

Figure 35.5 Procedure for entering Global Reset mode

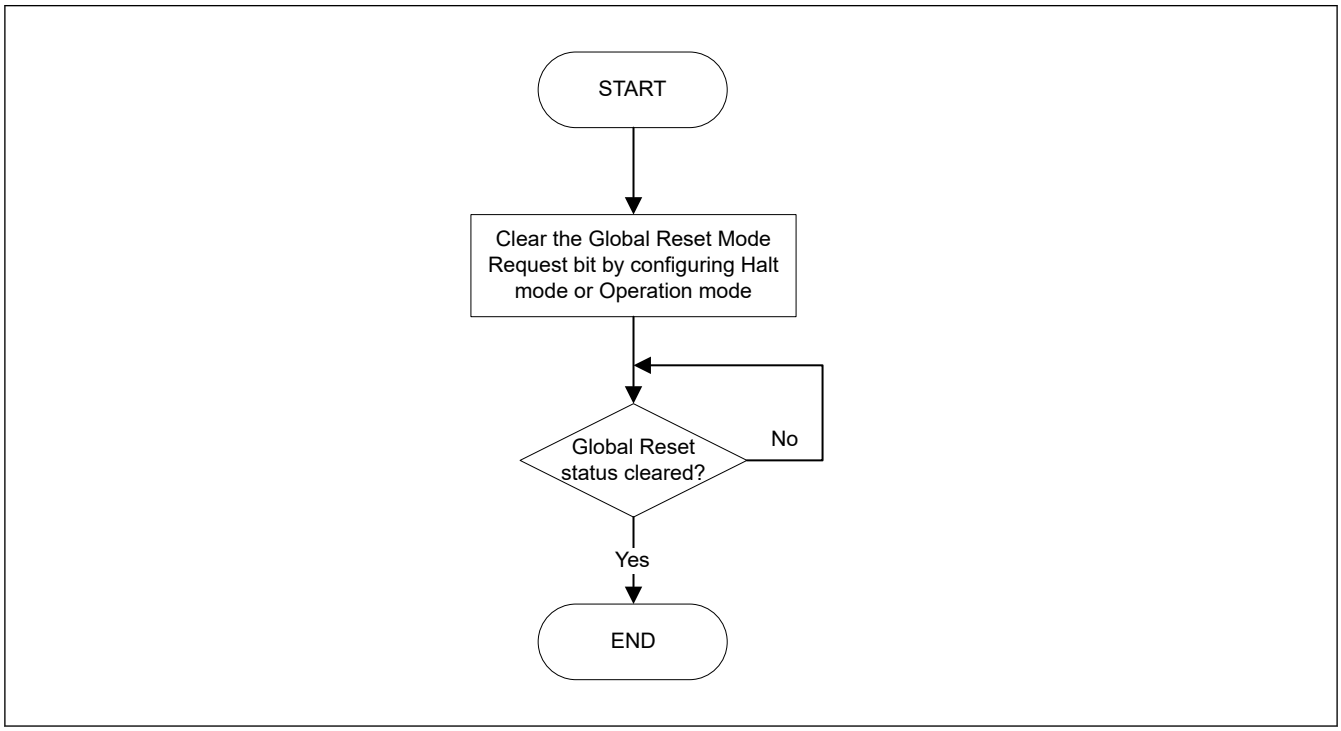

Figure 35.6 Procedure for exiting Global Reset mode

35.4.2.3 Global Halt Mode

The CAN-FD module enters the Global Halt mode in the following ways:

- Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register is configured for Global Halt mode while the CAN-FD module is in Global Reset mode:
  - The channel is in either Channel Reset or Channel Sleep mode and remains in this mode.

- Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register is configured for Global Halt mode while the CAN-FD module is in Global Operation mode:
  - All channels in Channel Reset, Channel Halt, or Channel Sleep mode remain in this mode
  - All channels in Channel Operation mode transit to Channel Halt mode
  - Global Halt Mode Status bit is set when all channels have left Channel Operation mode.

If a transmission or reception is ongoing for a channel, the transition to Channel Halt mode is delayed until completion of the communication.

Similarly, if a channel is in bus-off state, the full bus-off recovery sequence may be delayed depending on the channel configuration.

In Global Halt mode, all communications are suspended and CAN-FD logic does not cause any change to the Status and Flag registers (only when a channel is in the bus-off state that its REC and TEC values are cleared). Additionally, the test mode configuration and control registers are not initialized in this mode.

The Global Halt mode should be used to configure global module test modes.

See section 35.4.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Global Halt mode is performed.

Setting the Global mode to Halt mode by setting the Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register to 10b sets all Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers to 10b for the channels that are in Channel Operation mode and forces these channels into the Channel Halt mode.

For channels that are already in Channel Reset, Channel Halt, or Channel Sleep mode, this automatic transition is not performed.

Therefore, the Global Halt mode request can be used to shut down all CAN-FD channel communications without loss of messages and disruption on the related CAN bus (no interruption of reception/transmission processes on the channels).

After setting the Global Mode Control bits CFDGCTR.GMDC[1:0] to Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register has been updated to indicate a successful transition to Global Halt mode. Do not specify any other SFR setting until confirming CFDGSTS.GHLTSTS is set.

Figure 35.7 shows the procedure for entering Global Halt mode and Figure 35.8 shows the procedure for exiting Global Halt mode.

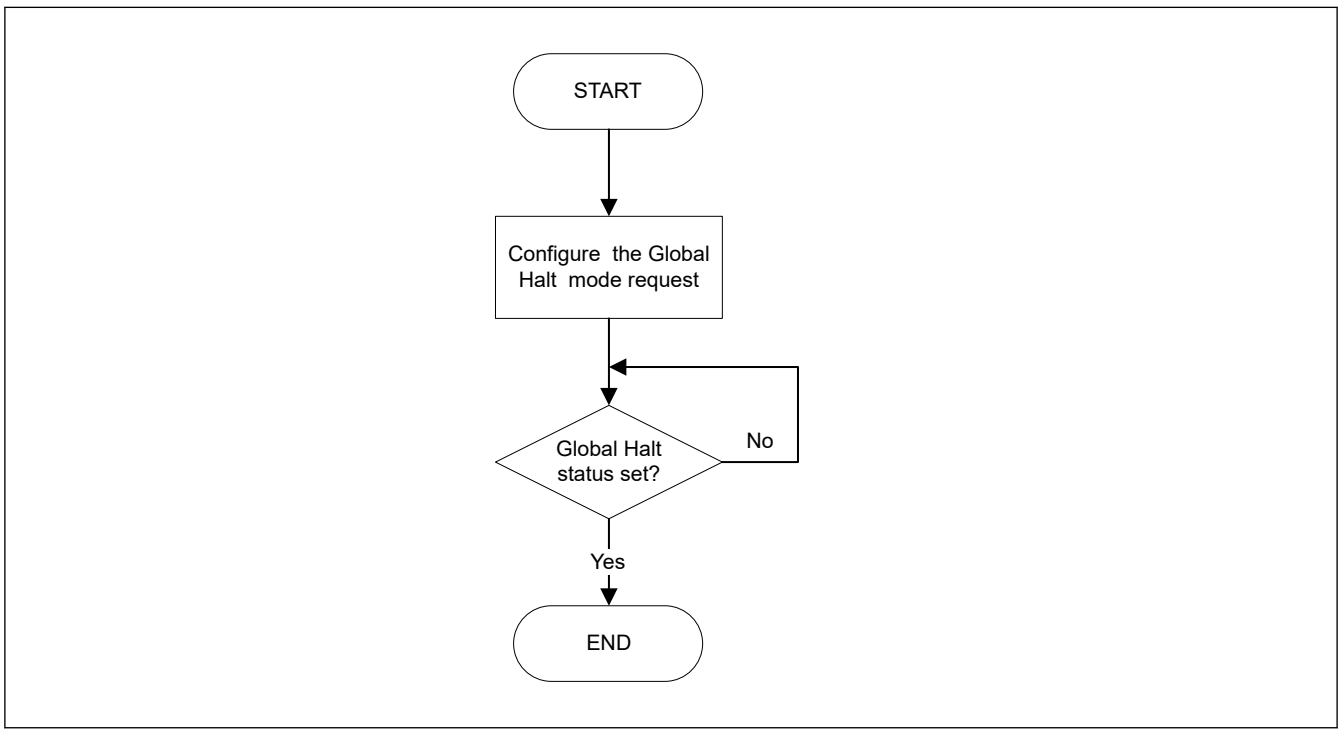

Figure 35.7 Procedure for entering Global Halt mode

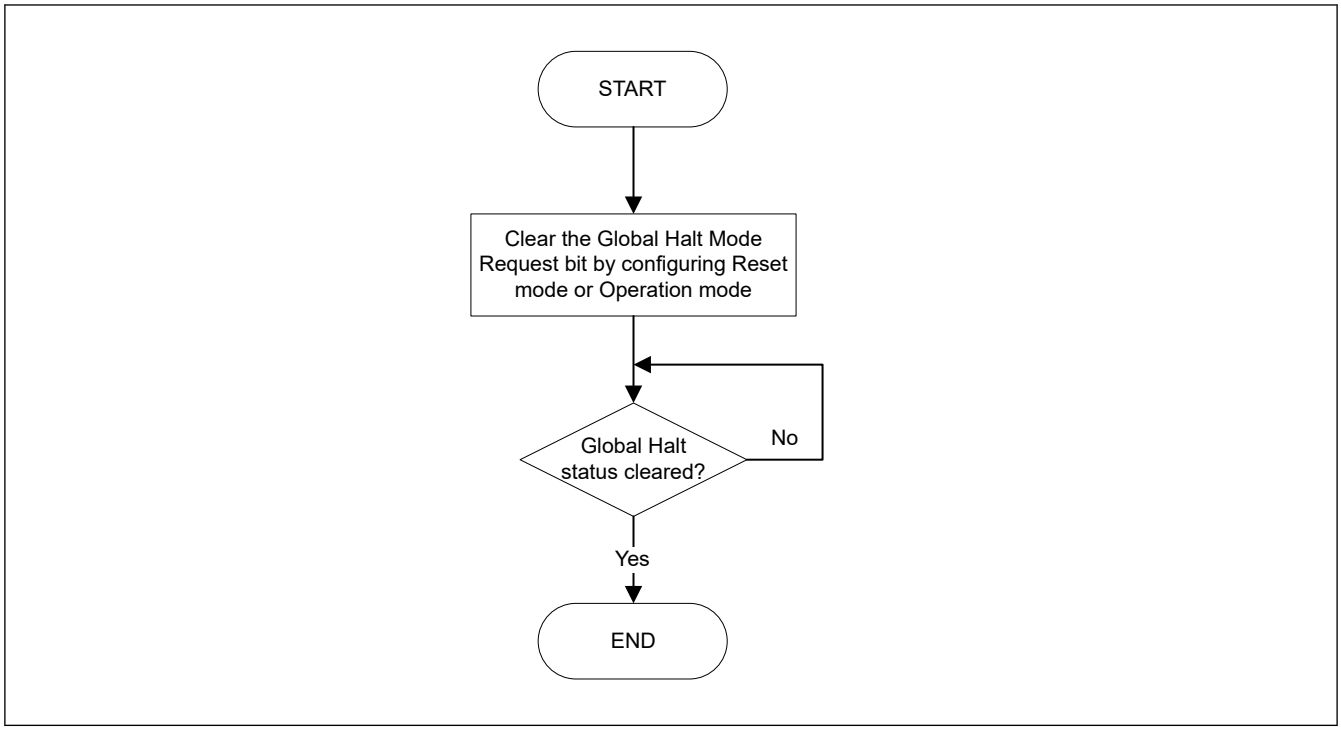

Figure 35.8 Procedure for exiting Global Halt mode

35.4.2.4 Global Operation Mode

The CAN-FD module enters the Global Operation mode when the Global Mode Configuration bits are set to Global Operation mode.

The CAN-FD channels can only be set to Channel Operation mode and start CAN communication when CAN-FD is in Global Operation mode.

After setting the Global Mode Control bits CFDGCTR.GMDC[1:0] to Global Operation mode, it is necessary to confirm that the Global Reset Mode Status bit CFDGSTS.GRSTSTS and the Global Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register have been cleared to indicate a successful transition to Global Operation mode before CFDGCTR.GMDC can be modified again.

Figure 35.9 shows the procedure for entering Global Operation mode and Figure 35.10 shows the procedure for exiting Global Operation mode.

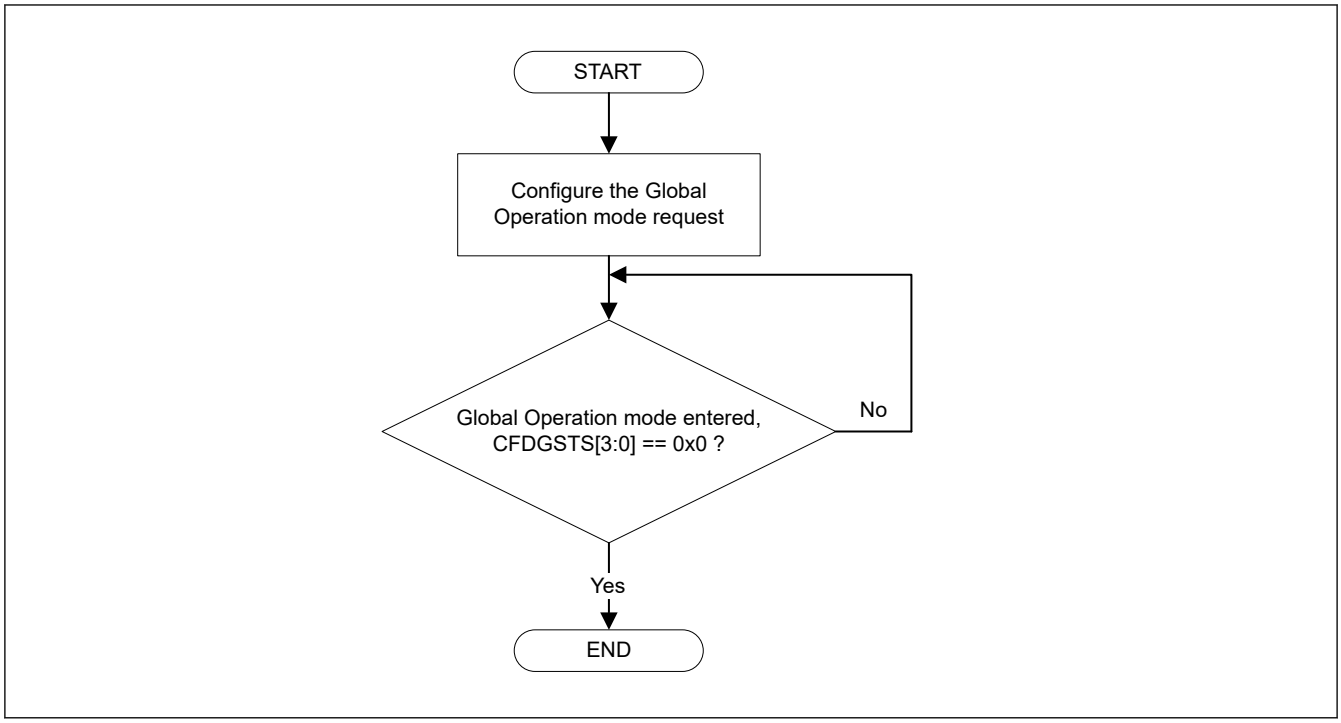

Figure 35.9 Procedure for entering Global Operation mode

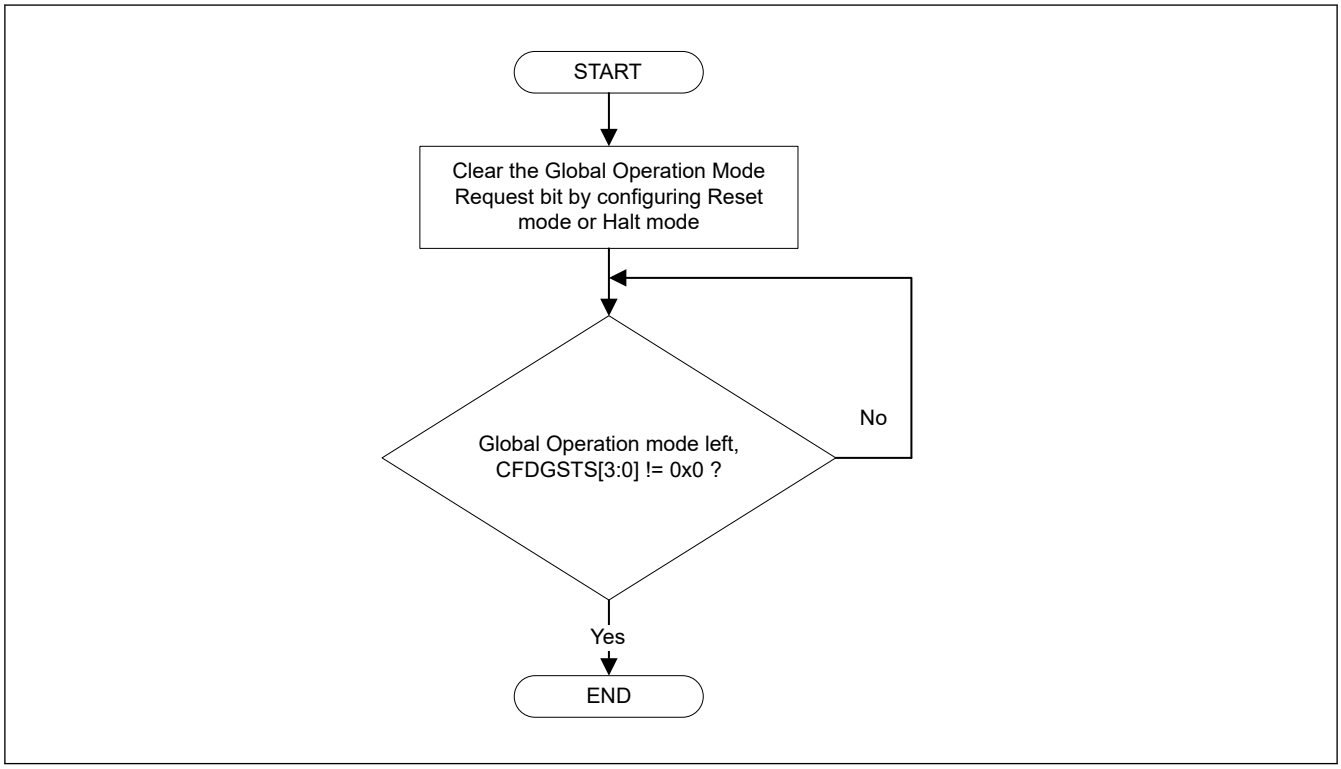

Figure 35.10 Procedure for exiting Global Operation mode

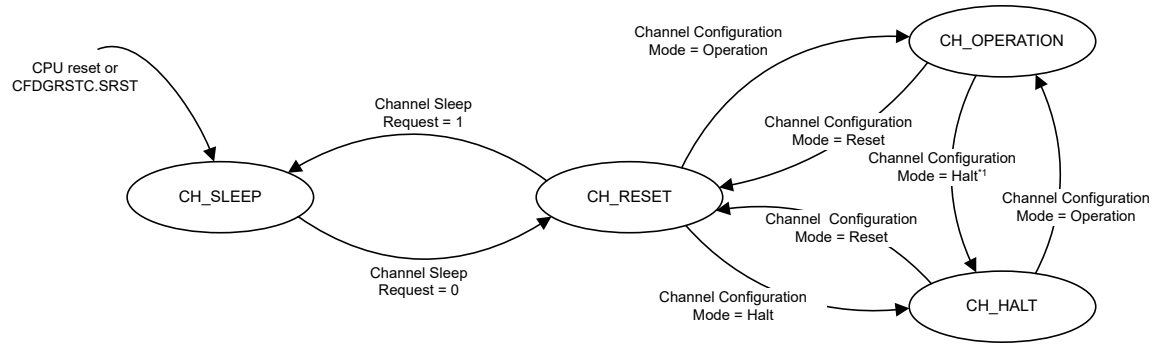
35.4.3 Channel Modes

Each CAN channel can be in one of the following four channel modes:

- Reset
- Halt
- Operation

- Sleep

Figure 35.11 shows possible transitions between the channel modes.



Note 1. The transition timing depends on BOM[1:0] setting in the Channel Control Register (CFDCnCTR):
When BOM[1:0] = 01b, the state transition timing is immediate after entering bus-off state
When BOM[1:0] = 10b, the state transition timing is at the end of bus-off state
When BOM[1:0] = 11b, the state transition timing is matching with the setting of CHMDC to HALT mode

Figure 35.11 Transition between CAN channel modes

35.4.3.1 CAN Channel Sleep Mode

After the release of a hardware reset or after setting and clearing the CFDGRSTC.SRST bit, each CAN channel of the CAN-FD module automatically enters Channel Sleep mode.

Each CAN channel also enters Channel Sleep mode when the related Channel Sleep Mode Request bit is set while the CAN channel is in Channel Reset mode. Do not set this control bit in Channel Halt mode or Channel Operation mode.

Entering the CAN Channel Sleep mode instantly stops the clock supplied to the CAN channel unit and therefore reduces power consumption.

After setting the Channel Sleep Mode Request bit, it is necessary to confirm that the Channel Sleep mode status has been updated to indicate a successful transition to Channel Sleep mode before the Channel Sleep Mode Request bit can be cleared again.

During Channel Sleep mode, do not write to channel related registers. Read operation is still possible.

35.4.3.2 CAN Channel Reset Mode

A CAN-FD CAN channel enters the CAN Channel Reset mode in the following ways:

- Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers is configured for Channel Reset mode while the related CAN channel is in Channel Halt mode or Channel Operation mode
- Channel Sleep Mode Request bit is cleared while the related CAN channel is in Channel Sleep mode
- Global Mode Control bits CFDGCTR.GMDC[1:0] is set to Global Reset mode and CAN channel is not in Channel Sleep mode or Channel Reset mode.

In Channel Reset mode, all CAN channel status and flag registers are initialized.

Additionally all channel-related transmission control bits are cleared and the channel-related TX Queue is disabled.

Configuration registers (except the Channel Test Mode registers) are not initialized in this mode and the CAN channel can be configured for communication.

See section 35.4.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Channel Reset mode is performed.

After setting the Channel Mode Control bits CFDCnCTR.CHMDC[1:0] to Channel Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDCnSTS.CRSTSTS in the related Channel Status Registers has been updated to indicate a successful transition to Channel Reset mode before the related CFDCnCTR.CHMDC[1:0] bits can be modified again.

See Table 35.17 for the behavior of transitioning to Channel Reset mode while CAN communication is ongoing.

Table 35.17 Transition behavior in CAN Reset mode and Halt mode

Mode	State		
	Receiver	Transmitter	Bus-Off
CAN Channel Reset mode (CFDCnCTR.CHMDC[1:0] = 01b)	The CAN channel transits to Channel Reset mode without waiting for the completion of the ongoing reception.*1	The CAN channel transits to Channel Reset mode without waiting for the completion of the ongoing transmission.*1	The CAN channel transits to Channel Reset mode without waiting for the completion of the bus-off recovery.
CAN Channel Halt Mode (CFDCnCTR.CHMDC[1:0] = 10b)	The CAN channel transits to Channel Halt mode at the end of the ongoing reception or error.*2	The CAN channel transits to Channel Halt mode after completion of the ongoing transmission.	When CFDCnCTR.BOM[1:0] is set to 00b, a Channel Halt mode request is accepted only after the completion of the full bus-off recovery sequence. When CFDCnCTR.BOM[1:0] is set to 10b, the CAN channel transits automatically to Channel Halt mode after waiting for the completion of the bus-off recovery. When CFDCnCTR.BOM[1:0] is set to 01b, the CAN channel transits automatically to Channel Halt mode without waiting for the completion of the bus-off recovery. When CFDCnCTR.BOM[1:0] is set to 11b, the CAN channel transits to Channel Halt mode as soon as Channel Halt mode is requested (without waiting for the completion of the bus-off recovery).

Note 1. If the entry to Channel Reset is required only at the end of an ongoing communication, then Channel Halt mode can be requested first to prevent interruption of CAN communication by direct transition to Channel Reset mode. After the CAN channel enters Channel Halt mode, the Channel Reset mode can be requested.

Note 2. If CAN communication is locked at a dominant level after an error flag, software can detect this situation by monitoring the channel related Bus Lock flag and resolve the lock condition by setting the CAN channel to Channel Reset mode.

35.4.3.3 CAN Channel Halt Mode

A CAN-FD CAN channel enters the CAN Channel Halt mode in the following ways:

- Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers are configured for Channel Halt mode while the related CAN channel is in Channel Reset mode or Channel Operation mode
- Global Mode Control bits CFDGCTR.GMDC[1:0] are set to Global Halt mode and CAN channel is in Channel Operation mode.

In Channel Halt mode, all channel CAN communication is suspended but all status and flag registers remain unchanged during Channel Halt mode entry (except for the bus-off case where REC and TEC values are cleared for the channel).

In addition, the Channel Test Mode Configuration and Control registers are not initialized in this mode.

The Channel Halt mode should be used to configure Channel Test modes.

See section 35.4.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Channel Halt mode is performed.

After setting the Channel Mode Control bits CFDCnCTR.CHMDC[1:0] to Channel Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDCnSTS.CHLTSTS in the related Channel Status Register is updated to indicate a successful transition to Channel Halt mode before the related CFDCnCTR.CHMDC[1:0] bits can be modified again.

See Table 35.17 for the behavior of transitioning to Channel Halt mode while CAN communication is ongoing.

35.4.3.4 CAN Channel Operation Mode

The Channel Operation mode is activated by setting the CFDCnCTR.CHMDC[1:0] bits to 00b. If 11 consecutive recessive bits are detected after entering CAN Channel Operation mode, the CFDCnSTS.COMSTS bit is set and the CAN channel:

- Enables the functions of the channel communication by allowing the channel to become an active node on the CAN network
- Releases the internal fault confinement logic including receive and transmit error counters

At this point, the CAN channel can start transmission and reception of CAN messages.

Within the CAN Channel Operation mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (see Figure 35.12):

- Channel idle: The CAN channel is neither receiving nor transmitting
- Channel receives: The channel is receiving a CAN message sent by another CAN node
- Channel transmits: The channel is transmitting a CAN message

  Note: The channel may receive its own message simultaneously when Self Test mode is enabled.
- Channel is in bus-off state: The CAN channel is cut-off from CAN bus communication.

After setting the Channel Mode Control bits CFDCnCTR.CHMDC[1:0] to Channel Operation mode, it is necessary to confirm that the Channel Reset Mode Status bit CFDCnSTS.CRSTSTS and the Channel Halt Mode Status bit CFDCnSTS.CHLTSTS in the Channel Status Register have been updated to indicate a successful transition to Channel Operation mode before the related CFDCnCTR.CHMDC[1:0] bits can be changed again.

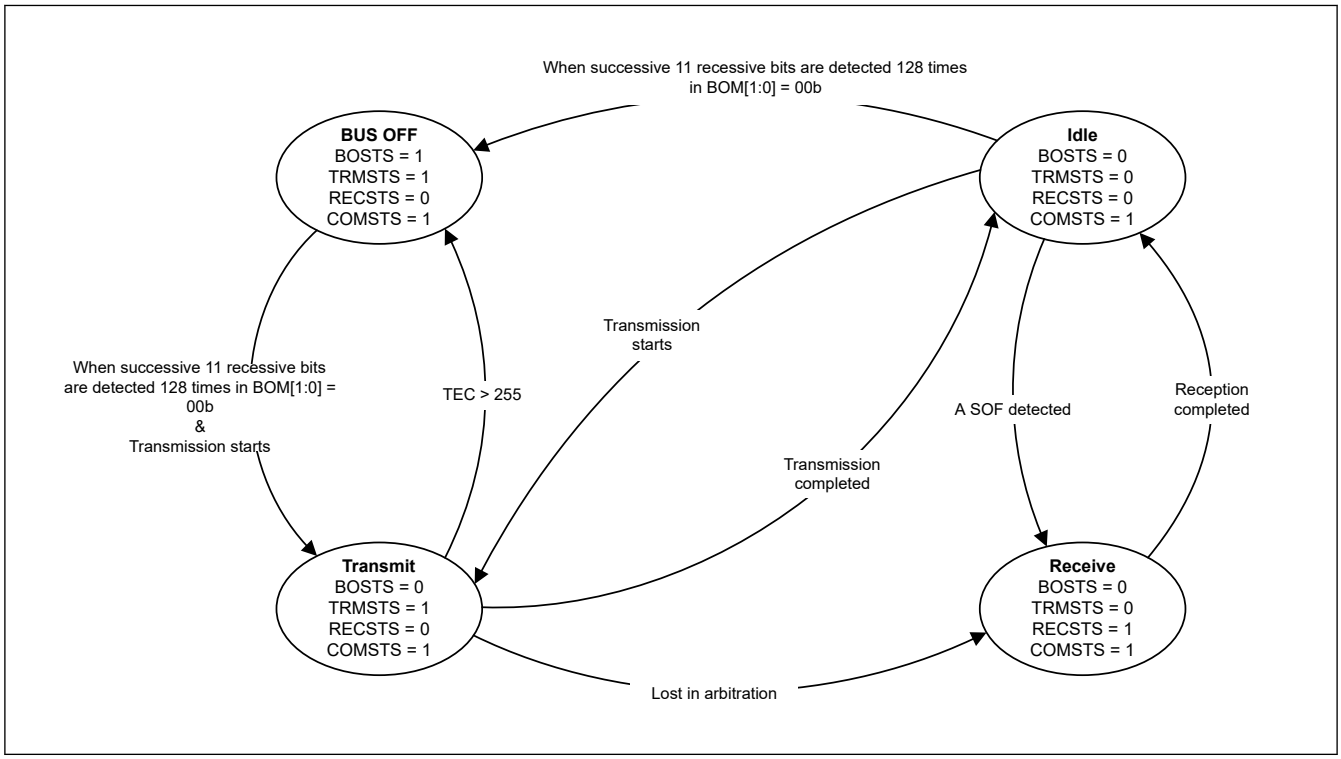


Figure 35.12 Sub-modes of CAN Channel Operation mode (only when BOM[1:0] = 00b)

35.4.3.5 CAN Channel Bus-Off State

The CAN channel bus-off state is entered according to the fault confinement rules of the CAN specification. The following modes can be configured for returning to the CAN Channel Operation mode from the bus-off state:

- CFDCnCTR.BOM[1:0] = 00b:

Bus-Off recovery is compliant to ISO 11898-1, namely the CAN channel re-enters CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. TEC and REC counters are initialized to 0. The Bus-Off Recovery Flag CFDCnERFL.BORF is set in this case.

- CFDCnCTR.BOM[1:0] = 01b:
  The CAN channel changes the value of the CFDCnCTR.CHMDC[1:0] bits within the CAN Channel Control Register to 10b and switches immediately to Channel Halt mode automatically after entering bus-off state. TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDCnERFL.BORF is not set in this case.
- CFDCnCTR.BOM[1:0] = 10b:
  The CAN channel changes the value of the CFDCnCTR.CHMDC[1:0] bits within the CAN Channel Control Register to 10b as soon as it reaches bus-off state and enters Channel Halt mode automatically after the CAN channel has completed the bus-off recovery sequence (after 11 consecutive recessive bits are detected 128 times). TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDCnERFL.BORF is set in this case.
- CFDCnCTR.BOM[1:0] = 11b:
  Bus-off recovery is initiated but CAN channel can immediately enter Channel Halt mode when still in bus-off state if a request is made to enter Channel Halt mode.
  TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDCnERFL.BORF is not set.
  Without setting CFDCnCTR.CHMDC[1:0] = 10b and when 11 recessive bits is detected 128 times continuously, transition conditions become the same as CFDCnCTR.BOM[1:0] = 00b.

Note: If the recovery from bus-off occurs normally in Channel Halt mode (after waiting for 128 sequences of 11 consecutive recessive bits), and no halt request has been generated during this period, then the Bus-Off Recovery flag CFDCnERFL.BORF is set.

When software writes to the CFDCnCTR.CHMDC[1:0] bit at the same time as the CAN channel enters Halt mode (at the start of bus-off when CFDCnCTR.BOM[1:0] = 01b, or at the end of bus-off when CFDCnCTR.BOM[1:0] = 10b), the software request has the highest priority.

Note: In the above case, the automatic setting of the CFDCnCTR.CHMDC[1:0] bits to Channel Halt mode request is performed when the CFDCnCTR.CHMDC[1:0] bits value is previously 00b (Channel Operation mode).

Additionally, it is possible to force the CAN channel to recover from the bus-off state by setting CFDCnCTR.RTBO to 1. The error state changes from bus-off state to integrating state with a maximum delay of 1 CAN bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The Bus-Off Recovery Flag is not set in this case, and the TEC and REC counters are initialized to 0.

Before setting CFDCnCTR.RTBO to 1, all pending transmissions from the TX message buffers, TX Queues and/or Common FIFO in TX or GW mode should be disabled.

The disable of the pending transmission message buffer, TX Queue or FIFO must be confirmed by the corresponding acknowledge flags.

For the TX message buffer, the acknowledge flags are the Transmission Result Flags (CFDTMSTSn.TMTRF[1:0]). For the TX Queue, it is the TX Queue Empty flag (CFDTXQSTSn.TXQEMP). For the FIFO, it is the FIFO Empty flag (CFDCFSTSn.CFEMP).

The CFDCnCTR.RTBO bit should be used for bus-off recovery only when CFDCnCTR.BOM[1:0] is set to 00b.

Setting this bit in any state other than bus-off has no effect and the bit is cleared immediately.

Table 35.18 shows the settings for the Bus-Off Entry flag CFDCnERFL.BOEF and the Bus-Off Recovery flag CFDCnERFL.BORF for the different configurations of CFDCnCTR.BOM[1:0].

Table 35.18 Behavior of Bus-off Entry and Recovery flags (1 of 2)

BOM[1:0]	BOEF bit setting	BORF bit setting
00b	Always (on entry to bus-off)	Always (on exit from bus-off)
00b CFDCnCTR.RTBO set to 1	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software sets CFDCnCTR.RTBO to 1
01b	Always (on entry to bus-off)	Never
10b	Always (on entry to bus-off)	Always (on exit from bus-off)

Table 35.18 Behavior of Bus-off Entry and Recovery flags (2 of 2)

BOM[1:0]	BOEF bit setting	BORF bit setting
11b	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software issues a Halt request

For an efficient software procedure, it is not necessary to wait for the bus-off recovery sequence to end.

It is possible to perform a transmission re-initialization during bus-off recovery. To do this, follow the recommended software flow in Figure 35.13.

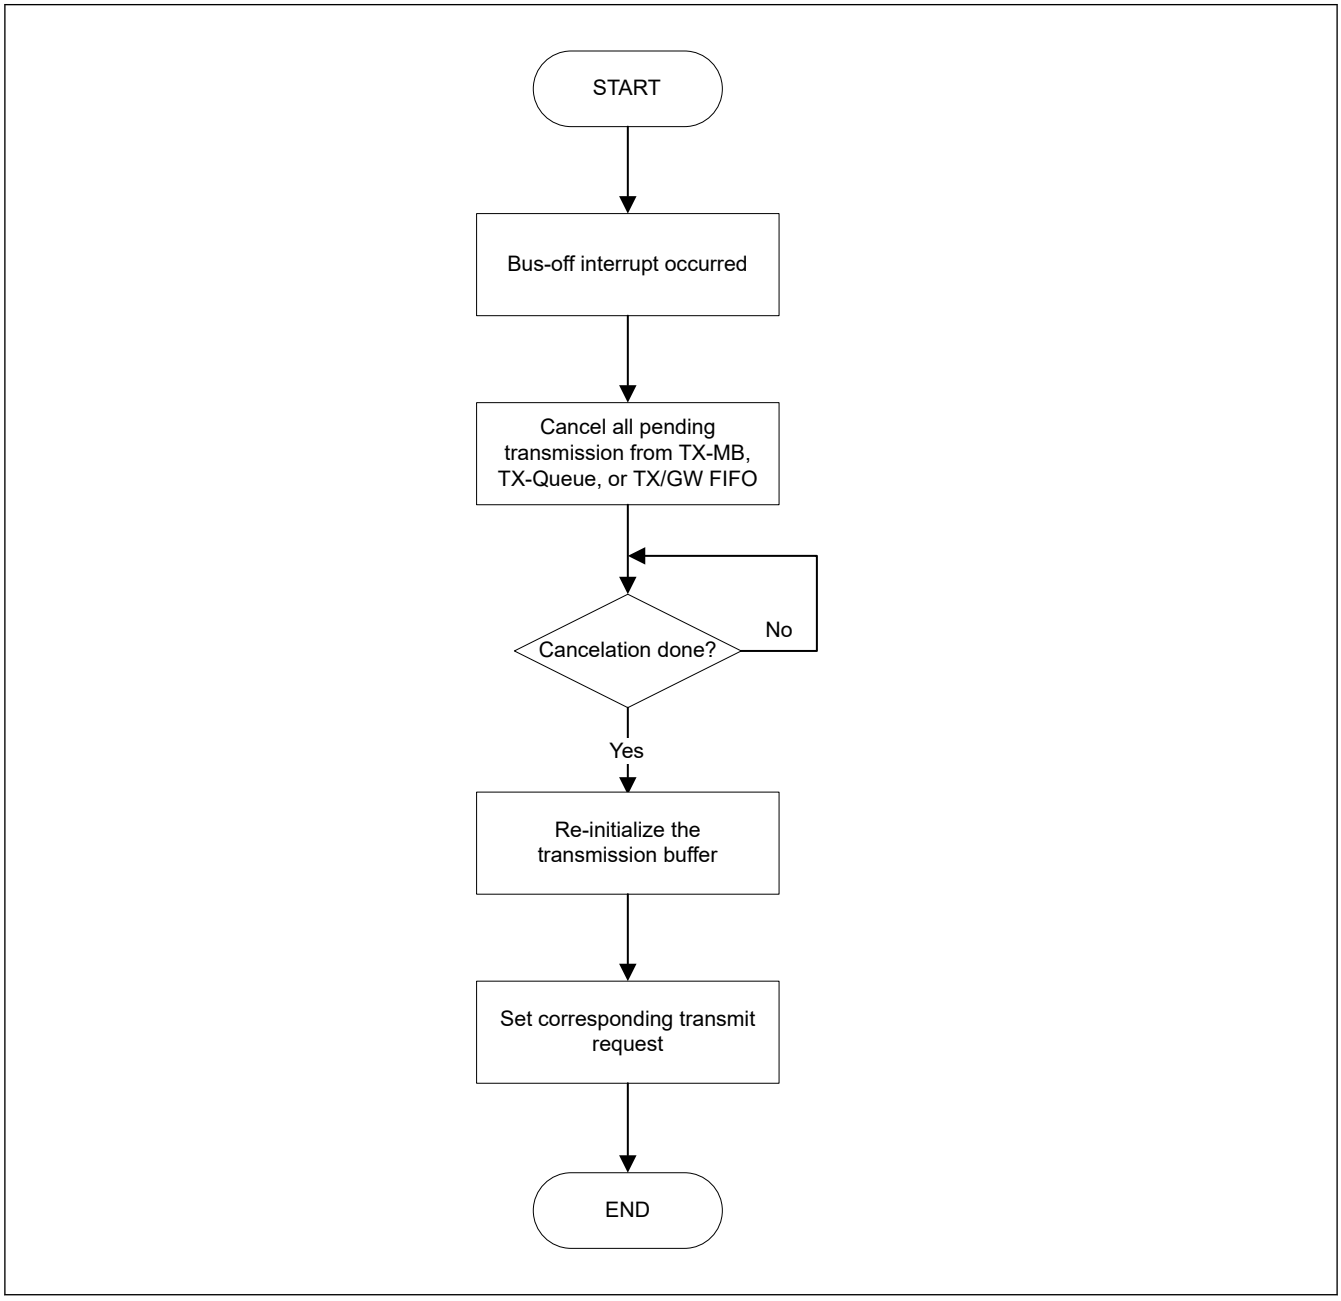

Figure 35.13 Transmission re-initialization during bus-off state

35.4.4 Global Mode and Channel Mode Transition Interactions

The interaction between Global mode setting and Channel mode setting is as follows:

- Changing the Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers does not affect the Global Mode Control bits CFDGCTR.GMDC[1:0].

- Changing the Global Mode Control bits CFDGCTR.GMDC[1:0] affects the channel mode control as described in Table 35.19.

Table 35.19 Instruction between Global and Channel mode transition

Global mode change	Channel mode	Channel mode transition action
Sleep → Reset	Sleep	Channel remains in Sleep mode
Sleep → Halt	— (Global mode change not possible)	
Sleep → Operation	— (Global mode change not possible)	
Reset → Sleep	Sleep	Channel remains in Sleep mode
	Reset	Channel Sleep request bit is set automatically, channel transits to Sleep mode
Reset → Halt	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
Reset → Operation	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
Halt → Sleep	— (Global mode change not possible)	
Halt → Reset	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel mode control is set to Reset mode, channel transits to Reset mode
Halt → Operation	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel remains in Halt mode
Operation → Sleep	— (Global mode change not possible)	
Operation → Reset	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel mode control is set to Reset mode, channel transits to Reset mode
	Operation	Channel mode control is set to Reset mode, channel transits to Reset mode
Operation → Halt	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel remains in Halt mode
	Operation	Channel mode control is set to Halt mode, channel transits to Halt mode after communication finished

35.4.4.1 Timing of Global Mode Change

The transition time for the Global mode changes are shown in the following table.

From	To	Maximum transition time
GL_SLEEP	GL_RESET	3 peripheral clock cycles*2
GL_RESET	GL_SLEEP	3 peripheral clock cycles
GL_RESET	GL_HALT	10 peripheral clock cycles
GL_RESET	GL_OPERATION	10 peripheral clock cycles
GL_HALT	GL_RESET	2 CAN bit times
GL_HALT	GL_OPERATION	3 peripheral clock cycles
GL_OPERATION	GL_RESET	2 CAN bit times
GL_OPERATION	GL_HALT	3 CAN frames*1, *3

Note 1. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.

Note 2. Exit GL_SLEEP mode only when CFDGSTS.GRAMINIT is cleared.
Note 3. TQ, CAN frame, and CAN bits are related to the individual channels. For maximum transition time, the channel with the lowest baud rate must be used.

35.4.4.2 Timing of Channel Mode Change

The transition time for the Channel mode changes are shown in the following table.

From	To	Maximum transition time
CH_SLEEP	CH_RESET	3 peripheral clock cycles
CH_RESET	CH_SLEEP	3 peripheral clock cycles
CH_RESET	CH_HALT	3 CAN bit times
CH_RESET	CH_OPERATION	4 CAN bit times
CH_HALT	CH_RESET	2 CAN bit times
CH_HALT	CH_OPERATION	4 CAN bit times*2
CH_OPERATION	CH_RESET	2 CAN bit times
CH_OPERATION	CH_HALT	2 CAN frames*1 *3

Note 1. The time specified for this transition does not include the case where channel enters bus-off state. For bus-off, the timing depends on the configuration of the CFDCnCTR.BOM[1:0] bits.
Note 2. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.
Note 3. In general, if the baud rate prescaler value CFDCnNCFG.NBRP is changed in CH_HALT mode, the transition time can deviate. The internal prescaler is a free running down counter that creates the TQ clock, and new BRP value is captured when the counter reaches the value 0.

35.5 Initialization

Before joining CAN communications, configure the following settings:

- Clock setting
- Bit timing setting (nominal and data rate)
- Baud rate setting (nominal and data rate)
- CAN-FD setting
- Acceptance filter setting (configuration of Global Acceptance Filter List)
- Reception, Transmission and GW-FIFO setting
- CAN Operation mode setting

35.5.1 Initialization of CAN Clock, Bit Timing and Baud Rate

35.5.1.1 Bit Timing Conditions

The following lines describe the composition of each segment and the limitations that apply to the segment setting.

1. Each segment setting
   SS = Fixed to 1 TQ
   TSEG1 = Refer to (CFDCnNCFG) and (CFDCnDCFG)
   TSEG2 = Refer to (CFDCnNCFG) and (CFDCnDCFG)
   SJW = Refer to (CFDCnNCFG) and (CFDCnDCFG)
   SS + TSEG1 + TSEG2 = 5 to 49 TQs for data bit rate and 8 to 385 for nominal bit rate
2. Limitations on TSEG1, TSEG2 and SJW
   TSEG1 (N) > TSEG2 (N) ≥ SJW (N)
   TSEG1 (D) ≥ TSEG2 (D) ≥ SJW (D)
   When only classical frames are used, configure the bit fields TSEG1 and TSEG2 of CFDCnDCFG to valid values.
   Table 35.20 shows an example of how to set the bit timing to achieve the required Sample Point settings.

Table 35.20 Transition behavior in CAN Reset mode and Halt mode

1 Bit	Set value (TQ)				Sample Point*1 (%)
	SS	TSEG1	TSEG2	SJW	
5 TQ	1	2	2	1	60.00
8 TQ	1	4	3	1	62.50
	1	5	2	1	75.00
10 TQ	1	6	3	1	70.00
	1	7	2	1	80.00
12 TQ	1	8	3	1	75.00
	1	9	2	1	83.33
15 TQ	1	10	4	1	73.33
	1	11	3	1	80.00
16 TQ	1	10	5	1	68.75

Note 1. Sample point (in case of 75%)

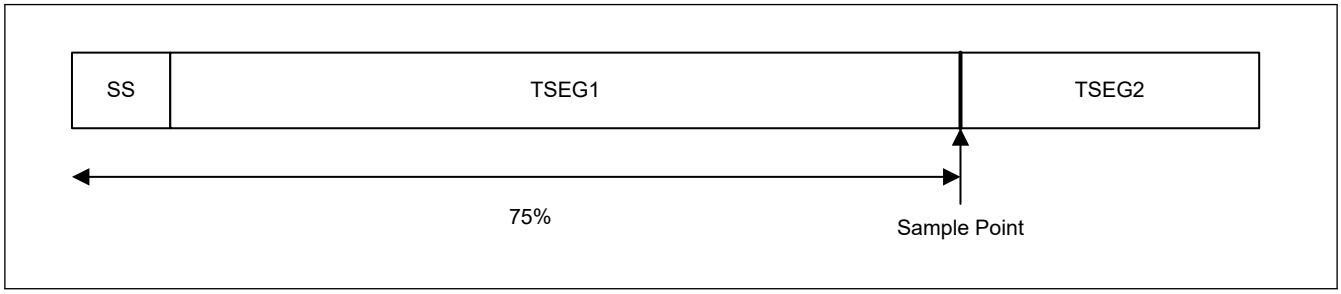

Figure 35.14 Sample point (in case of 75%)

35.5.1.2 CAN Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments that can be configured individually for each channel using the related CFDCnNCFG and CFDCnDCFG registers.

Figure 35.15 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (TQ), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the baud rate prescaler (nominal and data rate).

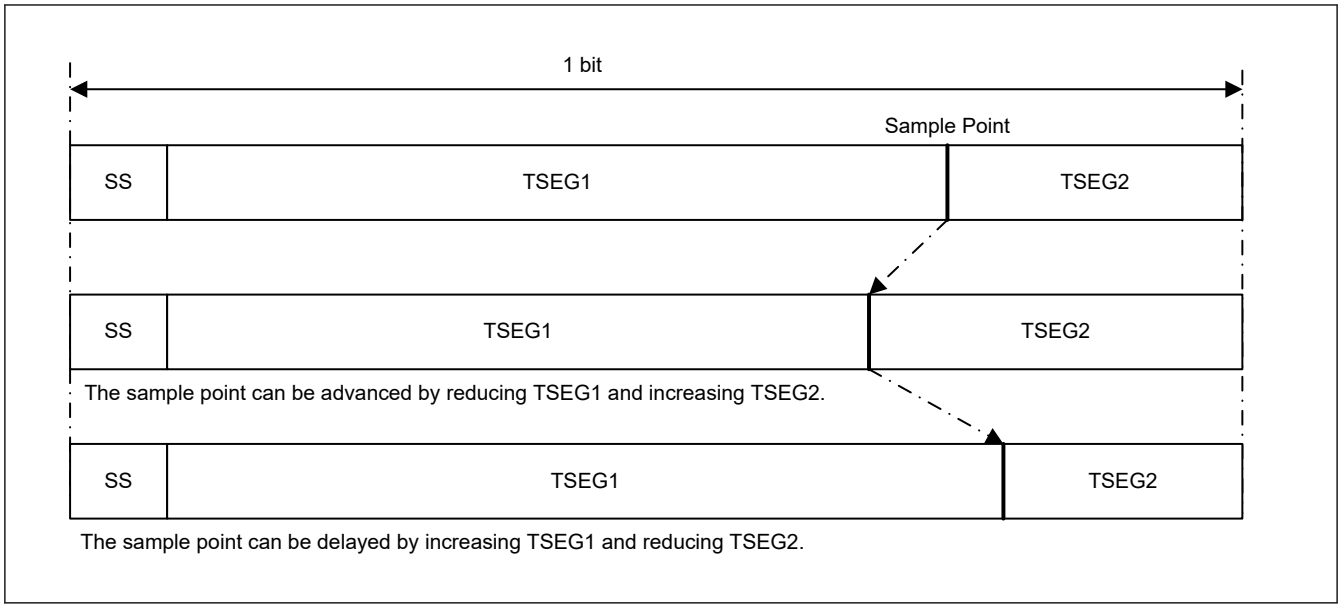

Figure 35.15 Segment composition of a bit and the sample point

1. SS: Synchronization Segment
   This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the interframe space. This comprises of intermission, suspend transmission, bus idle, during bus idle, and all nodes that can start transmission.
2. TSEG1: Time Segment 1
   This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.
3. TSEG2: Time Segment 2
   This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW. While sending or receiving a message, communication frames between some nodes may get out of sync due to a drift in the oscillator frequency or a delay in the transmission path. This is referred to as a phase error.
4. SJW: Resynchronization Jump Width
   This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.

Figure 35.15 shows only one symbolic sample point.

35.5.1.3 Baud Rate

Either PCLKM or PCLKCAN can be selected globally for all CAN channels as CAN communication clock.

The transfer speed is determined by the DLL clock, the divide-by-N value of the baud rate prescaler, and the number of TQs in one bit.

$$\text{baud rate} = \frac{\text{DLL\_Clock}}{(\text{number\_of\_time\_quanta\_per\_bit}) \times (\text{BRP} + 1)}$$

Figure 35.16 shows a block diagram of the circuit that generates the CAN channel system clock, Table 35.21 and Table 35.22 show baud rate examples.

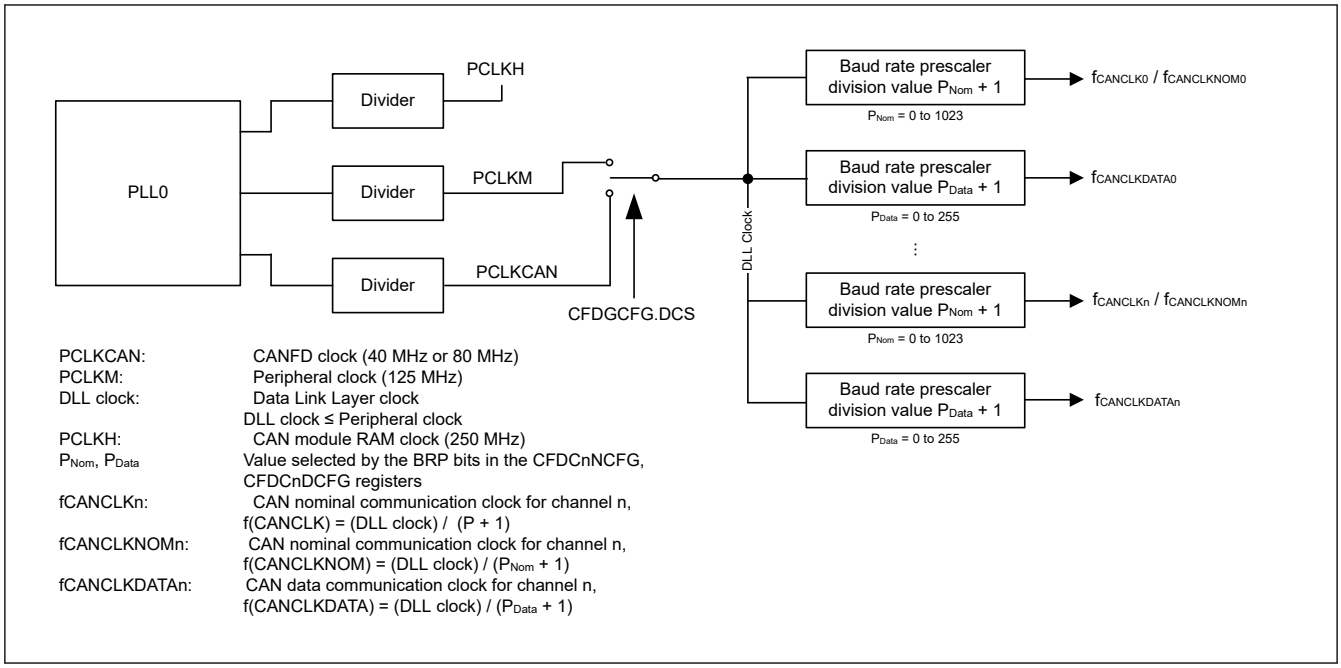

Figure 35.16 Block diagram of the circuit that generates the CAN channel communication clock

Table 35.21 Nominal baud rate calculation formula and example CAN communication configurations

Baud rate calculation formula	(DLL clock) (Baud rate prescaler divide-by-N value*1) × (Number of TQs in one bit)		
	80 MHz	**40 MHz**	**125 MHz**
1 Mbps	8 TQ (10) 20 TQ (4)	8 TQ (5) 20 TQ (2)	25 TQ (5)
500 Kbps	8 TQ (20) 20 TQ (8)	8 TQ (10) 20 TQ (4)	25 TQ (10)
250 Kbps	8 TQ (40) 20 TQ (16)	8 TQ (20) 20 TQ (8)	25 TQ (20)
125 Kbps	8 TQ (80) 20 TQ (32)	8 TQ (40) 20 TQ (16)	25 TQ (40)
83.3 Kbps	8 TQ (120) 12 TQ (80) 16 TQ (60) 24 TQ (40)	8 TQ (60) 12 TQ (40) 16 TQ (30) 24 TQ (20)	10 TQ (150) 12 TQ (125) 15 TQ (100) 20 TQ (75)
33.3 Kbps	8 TQ (300) 12 TQ (200) 16 TQ (150) 20 TQ (120) 24 TQ (100)	8 TQ (150) 12 TQ (100) 16 TQ (75) 20 TQ (60) 24 TQ (50)	10 TQ (375) 15 TQ (250) 25 TQ (150)

Note: Shown in ( ) are the baud rate prescaler divided-by-N values.
Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 to 1023), P: value selected by the BRP bits in the Channel Configuration Registers.

Table 35.22 Baud rate calculation example for nominal and data bit rate CAN communication configurations (1 of 2)

Baud rate calculation formula	(DLL clock) (Baud rate prescaler divide-by-N value*1) × (Number of TQs in one bit)		
	80 MHz	**40 MHz**	**125 MHz**
Nominal 1 Mbps Data 8 Mbps	80 TQ (1)	40 TQ (1)	125 TQ (1)
	10 TQ (1)	5 TQ (1)	Not possible

Table 35.22 Baud rate calculation example for nominal and data bit rate CAN communication configurations (2 of 2)

Baud rate calculation formula	(DLL clock) (Baud rate prescaler divide-by-N value*1) × (Number of TQs in one bit)		
	80 MHz	40 MHz	125 MHz
Nominal 1 Mbps Data 5 Mbps	80 TQ (1)	40 TQ (1)	125 TQ (1)
	16 TQ (1)	8 TQ (1)	25 TQ (1)
Nominal 500 Kbps Data 2 Mbps	160 TQ (1)	80 TQ (1)	250 TQ (1)
	40 TQ (1)	20 TQ (1)	Not possible

Note: Shown in ( ) are the baud rate prescaler divided-by-N values.
Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 to 1023), P: value selected by the BRP bits in the Channel Configuration Registers.

For optimum clock tolerance in networks using the FD frame format, the length of the time quantum should be the same in nominal bit time and in data bit time. This means CFDCnNCFG.NBRP = CFDCnDCFG.DBRP.

Additionally, if transceiver delay compensation is used, do not program the CFDCnDCFG.DBRP[7:0] bits to be greater than 1, as 1 means divide by 2.

35.5.1.4 Setting of CAN Clock, Bit Timing and Baud Rate

Figure 35.17 shows the procedure for setting the CAN clock and the baud rate for each channel.

These settings should be performed during Channel Reset mode (Configuration mode) for the CAN channels.

Before going to channel communication state, the baud rate must be configured, otherwise the mode does not switch correctly.

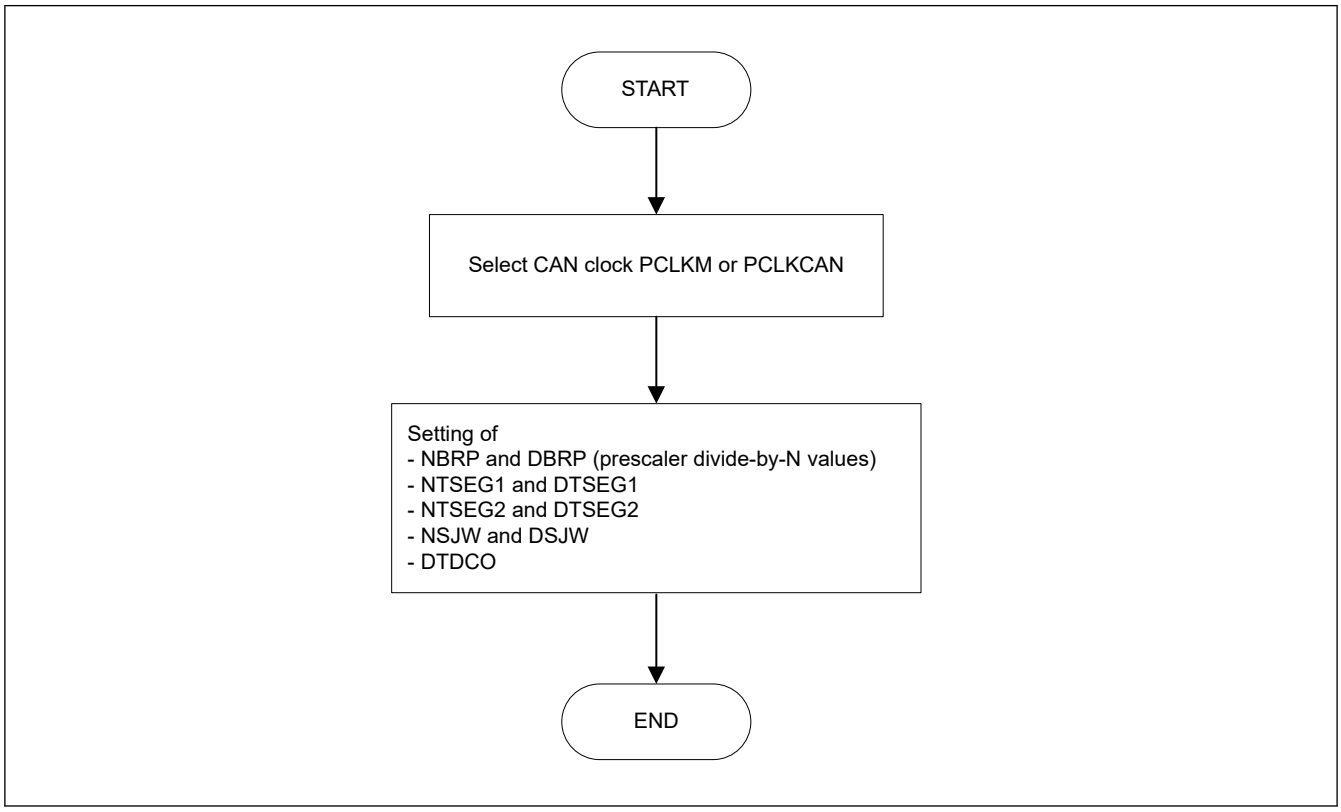

Figure 35.17 Procedure for setting the CAN bit timing and baud rate

35.5.1.5 Transmitter Delay Compensation

When a high baud rate is used such as 5 to 8 Mbps for the data phase, the transmitter delay can become greater than TSEG1. In this case, the transmitter always detects a bit-error in the data phase of the CAN-FD frame. The TDC compensates for the inability of the transmitter to receive its own transmitted bit at the sample point of that bit.

There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the data phase of CAN-FD frames. This is derived from the Transceiver Delay Compensation Result bit (CFDCnFDSTS.TDCR) as shown in Figure 35.18.

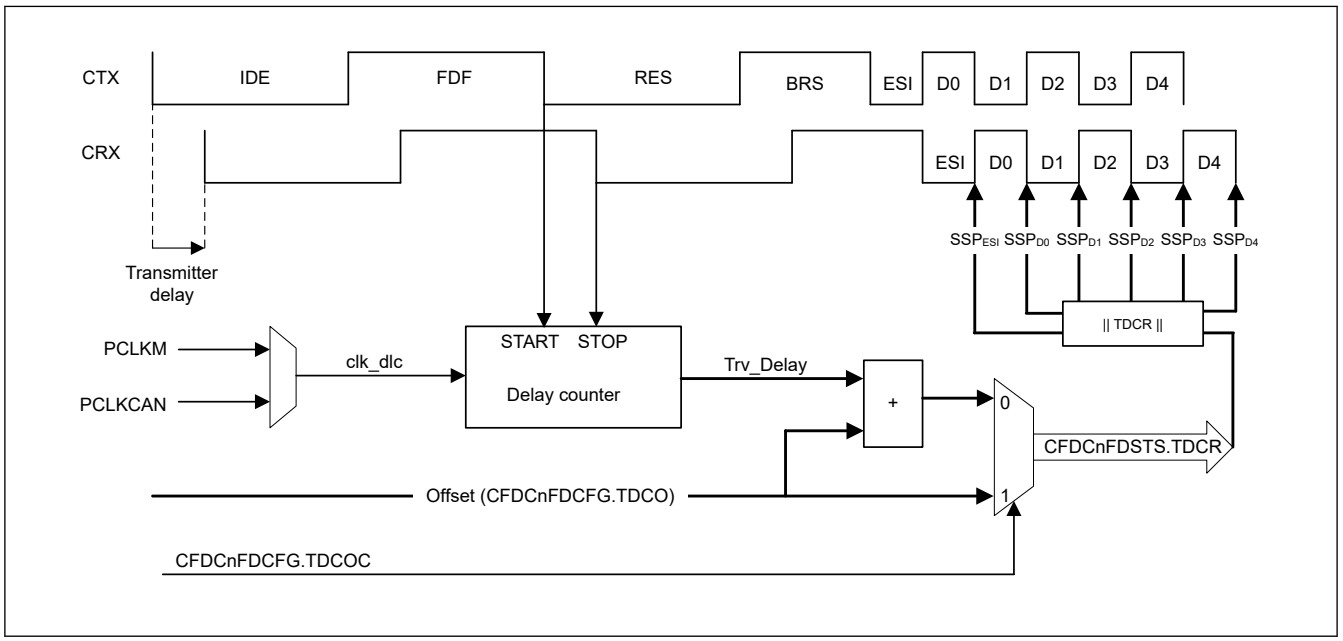

Figure 35.18 Transmitter delay compensation

The measured Trv_Delay is based on the number of clk_dlc clock cycles. The delay is counted up by 1 for each started clock until the dominant value is seen on CAN_RX. Figure 35.19 shows the measured result. Trv_Delay counted to maximum 127 with a clk_dlc clock.

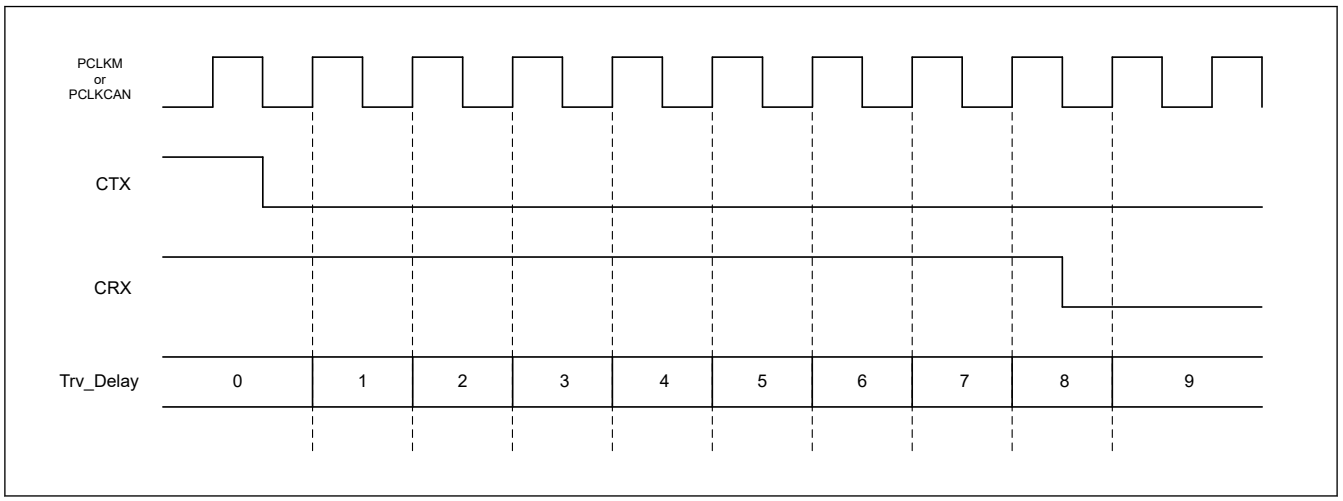

Figure 35.19 Trv_Delay measurement example

The SSP is calculated by taking the result from CFDCnFDSTS.TDCR and rounding the value down to the nearest integer number of data time quanta.

Figure 35.20 shows the positioning of the secondary sample point. When CFDCnFDCFG.TDCOC is equal to 0, the SSP is equal to the Trv_Delay (measured delay) + CFDCnFDCFG.TDCO, rounded down to the nearest integer number of time quanta. Usually, the TDCO value should have the size of (Sync Segment data + TSEG1 data) to position the SSP to a theoretical location of the sample point.

If the CFDCnFDCFG.TDCOC is equal to 1, the SSP is defined by CFDCnFDCFG.TDCO. If CFDCnDCFG.DBRP[7:0] is greater than 0, the value is also rounded down to the nearest integer number of time quanta.

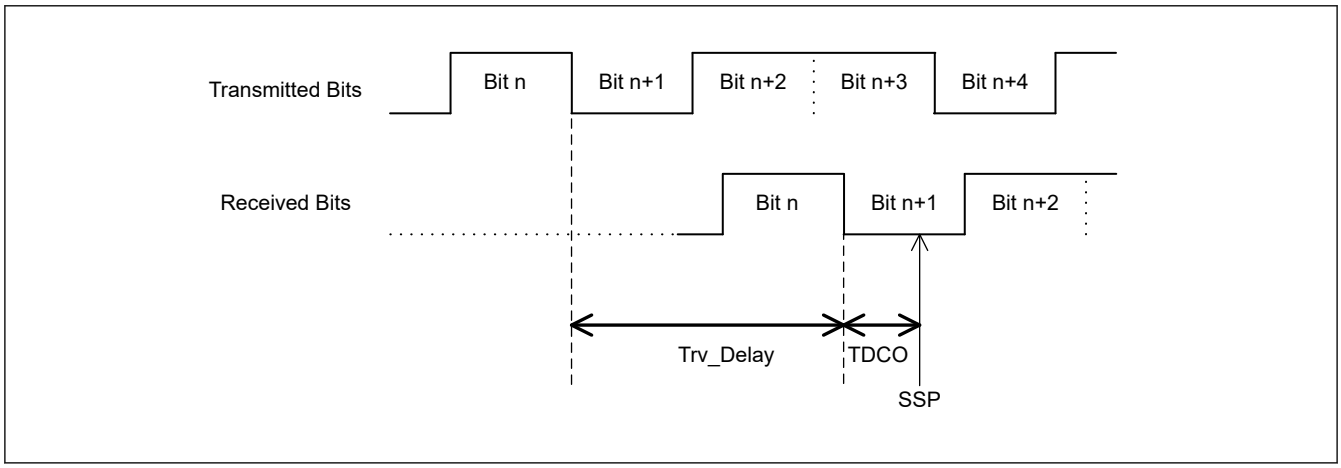

Figure 35.20 Position of the secondary sample point

The maximum delay (Trv_Delay + TDCO) which can be compensated by the CAN-FD module is (6 data bits - 2clk_dlc).

The ISO 11898-1 allows you to set different values for BRP_data and BRP_nom.

If different values are used for CFDCnNCFG.NBRP and CFDCnDCFG.DBRP, then two CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after sample point of the BRS bit. This condition is shown in Figure 35.21.

The length of the time quantum should be the same in the nominal bit time and in the data bit time. This means CFDCnNCFG.NBRP = CFDCnDCFG.DBRP.

Different bit rates can be achieved by selecting different configuration values for the Time Segments. The nominal bit rate can be configured from 8 to 385 TQs and the data bit rate from 5 to 49 TQs.

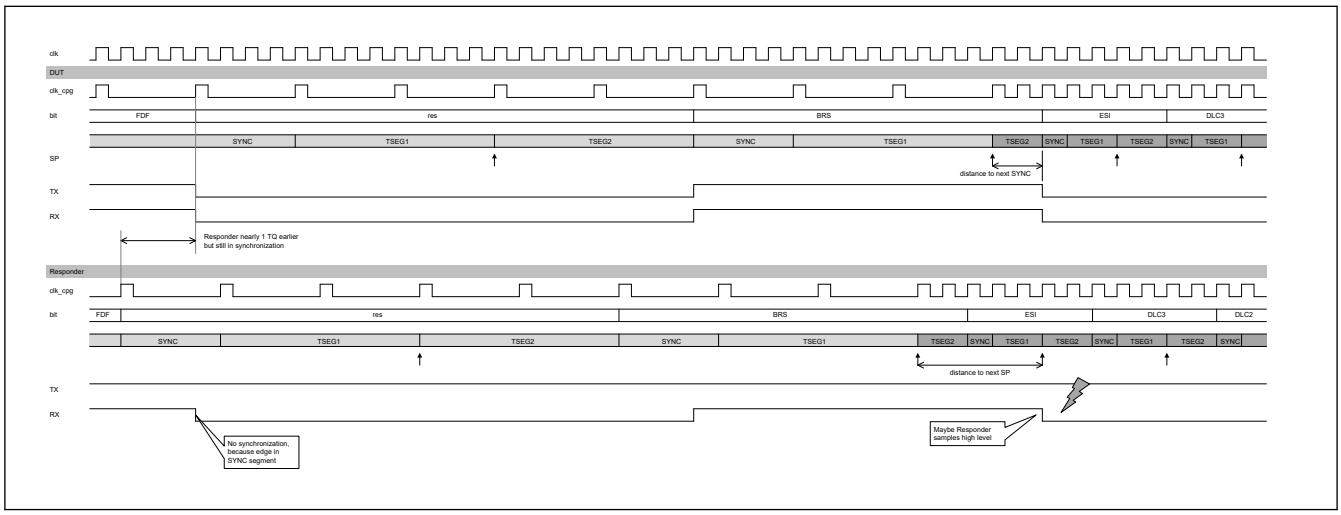

Figure 35.21 Loss of synchronization between 2 CAN nodes

The transmitter delay compensation measurement result is updated at the falling edge from FDF bit to RES bit when configured accordingly (CFDCnFDCFG.TDCE = 1, CFDCnFDCFG.TDCOC = 0).

Figure 35.22 shows the read flow to get the measured transmitter delay compensation result.

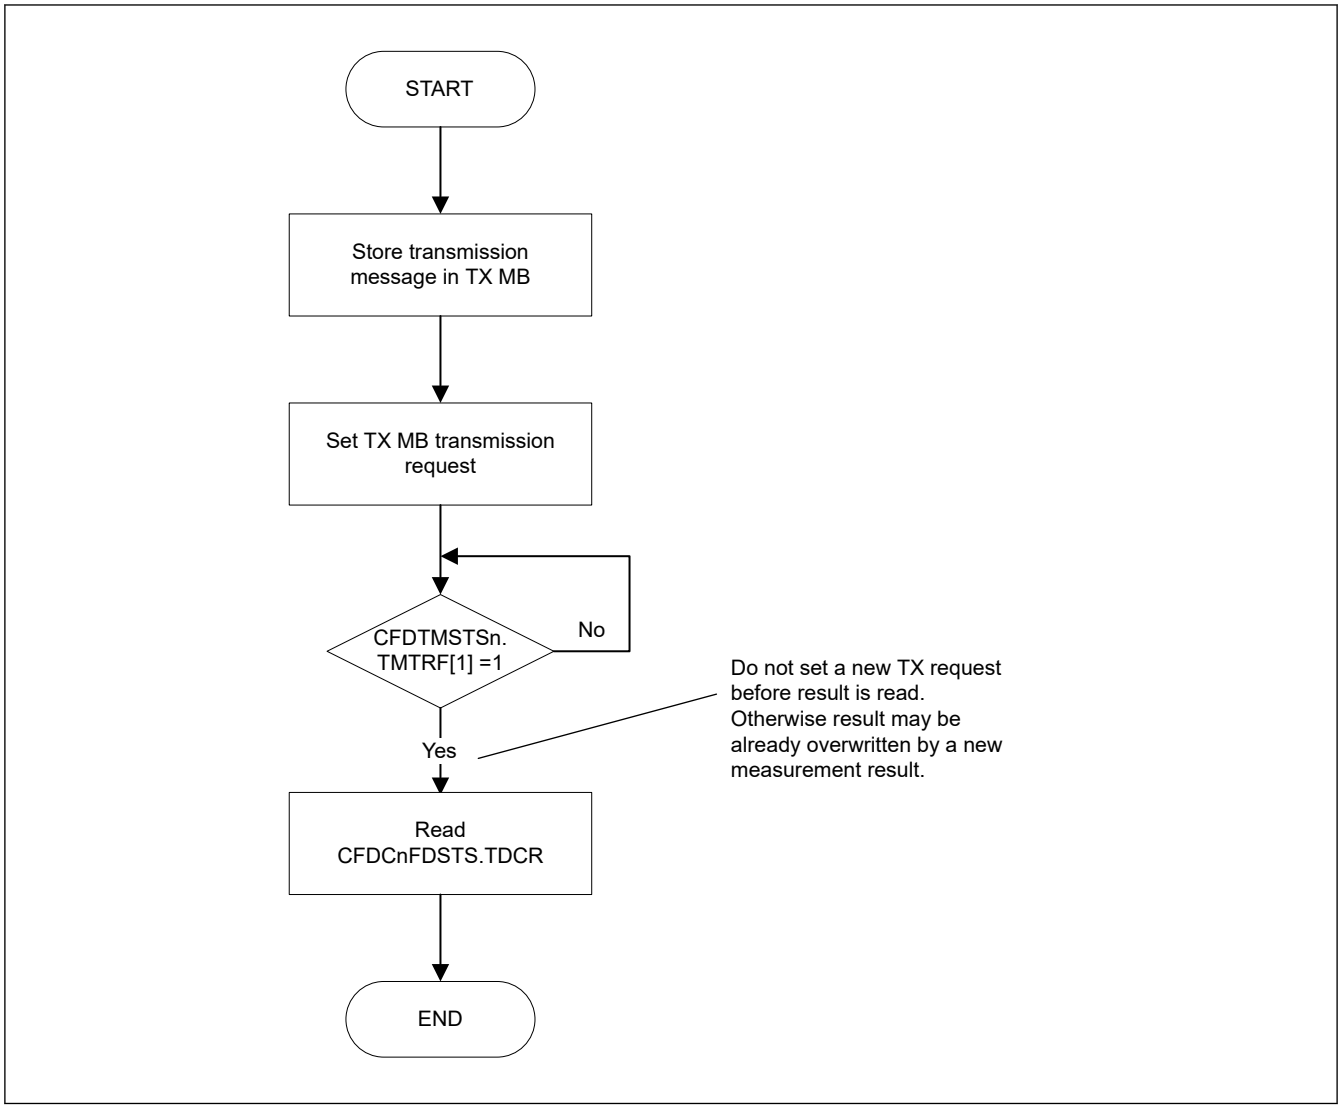

Figure 35.22 TDC result read flow

35.5.2 CAN Module Configuration after Hardware Reset

After a hardware reset (power on reset) or after setting and clearing the CFDGRSTC.SRST bit, the CAN-FD module enters Global Sleep mode automatically.

To enable configuration of the CAN-FD module, you must exit Sleep mode by clearing the Global Sleep Request bit CFDGCTR.GSLPR to 0.

After a hardware reset, the module starts RAM initialization, the CFDGSTS.GRAMINIT bit in the Global Status Register is set automatically to indicate that the CAN-FD logic is initializing the RAM.

After RAM initialization is complete, this bit is cleared automatically.

Do not access registers of the CAN-FD in either read or write until RAM initialization is complete and the CFDGSTS.GRAMINIT bit is cleared.

Before going to communication mode, the Global Acceptance Filter List and message FIFO buffers must be configured. In addition, each required CAN channel must be configured such as CAN bit timing. For this configuration, all required CAN channels must be released from Channel Sleep mode and must be configured for communication in Channel Reset mode (Configuration mode).

For this, all required CAN channels must be released from Channel Sleep mode and must be configured for communication in Channel Reset mode (Configuration mode).

Figure 35.23 shows the configuration procedure. For details about each step, see section 35.6. Acceptance Filtering Function using Global Acceptance Filter List (AFL), section 35.7. FIFO Buffers and Normal Message Buffer Configuration, section 35.8. Interrupt and DMA, and section 35.5.1.3. Baud Rate.

The CAN-FD module does not perform RAM initialization sequence after executing a software reset by setting CFDGRSTC.SRST.

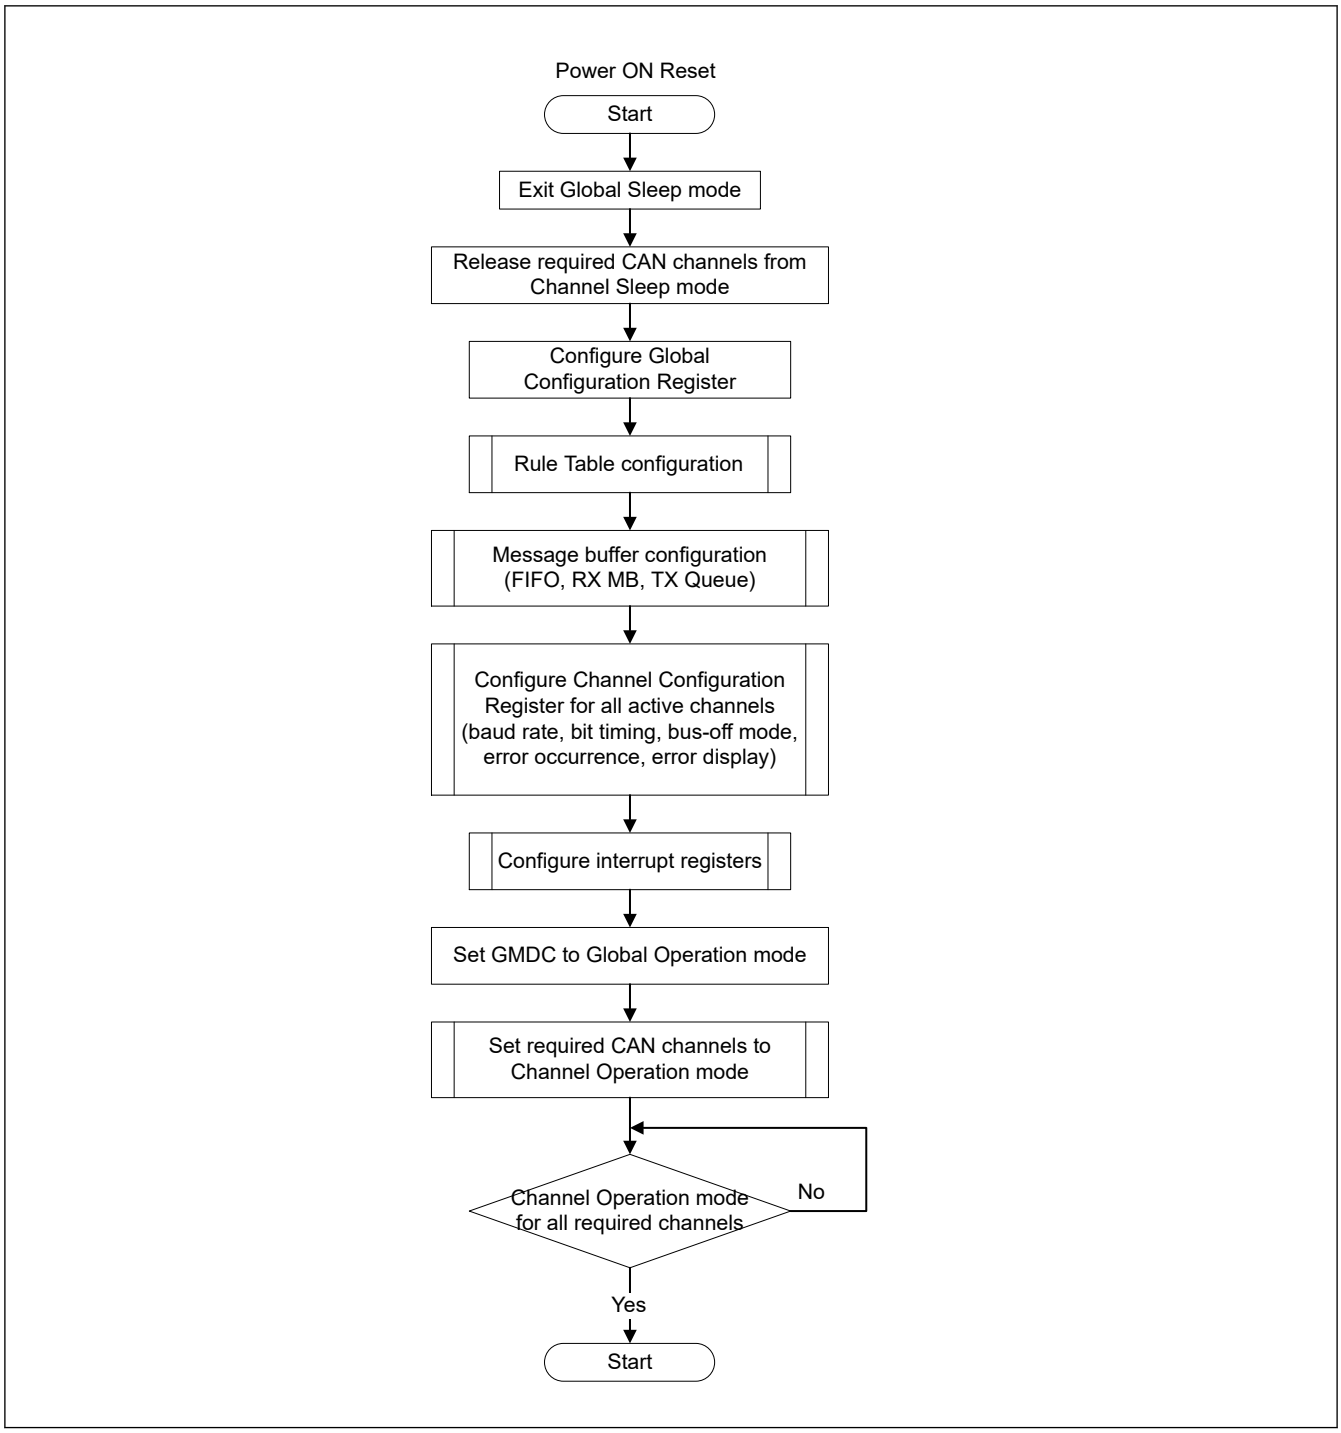

Figure 35.23 Configuration procedure after a hardware reset

35.6 Acceptance Filtering Function using Global Acceptance Filter List (AFL)

35.6.1 Overview

The CAN-FD module can handle message acceptance filtering for all channels with a global Acceptance Filter List (AFL). Each element of the AFL defines a filter rule for messages received on a specific channel.

The following actions are performed based on the AFL entries:

- Acceptance filtering based on received CAN identifier and masking
- DLC filtering based on received DLC value
- Message data payload according to the CFDGCFG.CMPOC bit
- Storage of accepted messages in the message buffer objects defined in the related AFL entry
- Attaching a 16-bit pointer to the stored messages defined in the related AFL entry, for example to support AUTOSAR applications
- Attaching a 2-bit information label to the stored messages defined in the related AFL entry

The 2-channel CAN-FD module allows a maximum of 256 AFL entries across all channels with a maximum of 128 AFL entries per channel.

During the acceptance filtering process, each AFL entry in a channel is checked against the received message by the acceptance filter unit. The check starts from the lowest AFL entry number for this channel.

The AFL search stops when a match of the received identifier with a configured identifier/mask combination occurs or when the received identifier has been compared against all AFL entries defined for the related channel. If no match occurs, then the received message is rejected. No notification is given to the application in this case.

Additionally, an automatic DLC filtering is performed for each accepted message if DLC check is globally enabled. If the DLC value of the received message is equal to or higher than the configured DLC value in the matching AFL entry, the DLC check is passed.

If DLC replacement (CFDGCFG.DRE bit) is enabled, DLC value configured in the matching AFL entry is greater than 0x0 and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination RXMB or FIFO Buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received on the CAN bus are not stored in the destination RXMB or FIFO Buffer. These additional data bytes are stored as 0x00 in the destination RXMB or FIFO Buffer.

If DLC replacement is enabled and DLC value of matching AFL entry is 0x0, then the received value of DLC is stored in the destination RX MB or FIFO Buffer.

If DLC replacement (the CFDGCFG.DRE bit) is disabled and DLC check passes, then the received value of DLC on the CAN bus is stored in the destination RXMB or FIFO buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received from the CAN bus are also stored in the destination RXMB or FIFO buffer.

If DLC value of the received message is less than the configured DLC value in the matching AFL entry, then DLC check fails. In this case, the received message is rejected and is not stored in any RXMB or FIFO buffer.

Additionally, DLC check failure is flagged by the DLC Error Flag in the Global Error Flag Register. If configured, an error interrupt is also generated. The DLC replacement configuration has no impact if the DLC check fails.

If a message has passed both acceptance filtering and DLC filtering, it is stored in a single reception message buffer and/or in FIFO buffers configured for reception or gateway function.

This message storage target information is also defined in the same AFL entry. Do not set a target at the AFL entry which is not configured.

Each accepted received message can be stored into a maximum of 8 different target destinations (single reception message buffer and/or FIFO buffers).

The programming of more than eight target destinations is not allowed. When more destinations are programmed then internal timing, a race condition can occur and received message may not be stored to the message RAM. Correct configuration of the numbers of target destination is the responsibility of the application.

Additional protection mechanism is made for the case when a received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS[2:0], CFDRFCCn.RFPLS[2:0] or CFDCFCCn.CFPLS[2:0]).

If CFDGCFG.CMPOC = 0, the message is completely rejected and is stored in the target destination. When CFDGCFG.CMPOC = 0 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS[2:0], CFDRFCCn.RFPLS[2:0] or CFDCFCCn.CFPLS[2:0]), the corresponding CFDFMSTS.RFXMLT[7:0] or CFDFMSTS.CFXMLT[5:0] bits are not set to 1, respectively.

When CFDGCFG.CMPOC = 1, the received data bytes greater than CFDRMNB.RMPLS is rejected. When CFDGCFG.CMPOC = 1 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS[2:0], CFDRFCCn.RFPLS[2:0] or CFDCFCCn.CFPLS[2:0]), the corresponding CFDFMSTS.RFXMLT[7:0] or CFDFMSTS.CFXMLT[5:0] bits are set to 1, respectively.

Depending on the CFDGCFG.DRE bit, the original received DLC or the DLC value configured at the AFL entry is stored.

Regardless of the CFDGCFG.CMPOC bit setting, CFDGERFL.CMPOF is set to 1 if a payload overflow condition is detected.

The DLC filtering is performed before the payload overflow function. So for one reception frame, only one flag can be set at the same time with CFDGERFL.DEF or CFDGERFL.CMPOF.

35.6.2 Allocation of AFL Entries to each CAN Channel

The number of AFL entries per channel can be configured using the dedicated field in the related Global Acceptance Filter Configuration Registers (see Figure 35.24).

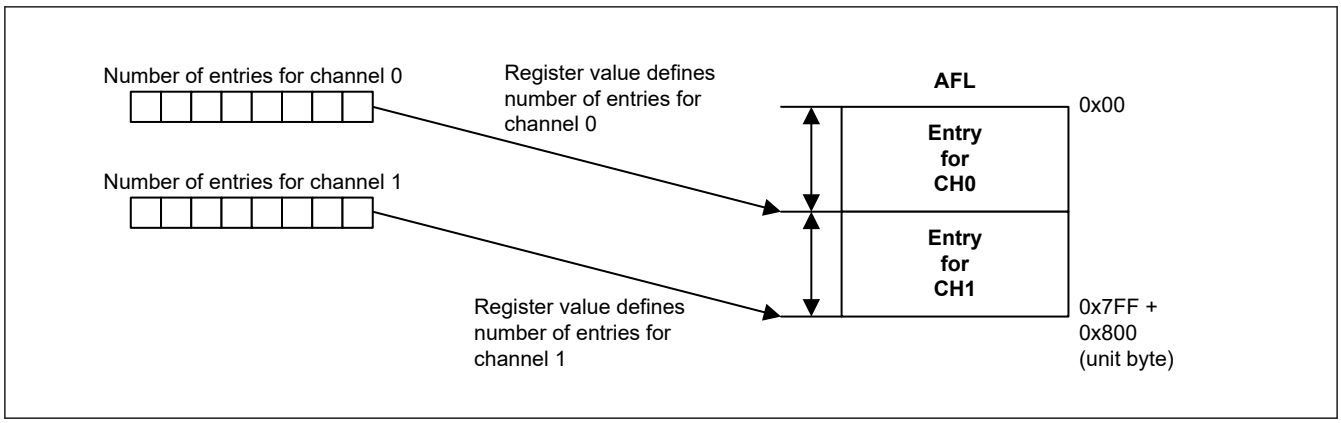

Figure 35.24 Configuration of AFL for each channel

The minimum number of entries for one channel is 0 (no entries defined for the channel) and the maximum number of entries for one channel is 128. The total number of entries for all channels should not exceed the maximum limit of (n + 1) × 128.

All entries are unique for a channel and overlapping or sharing of entries is not supported. Correct configuration of the AFL is the responsibility of the application.

The CAN-FD module does not flag errors related to the configuration of the AFL.

35.6.3 AFL Entry Description

Each AFL entry consists of 16 bytes. The fields in all entries are identical.

Each entry contains the following information for acceptance filtering and DLC filtering:

- Identifier (11 bits for Standard Frame format, 29 bits for Extended Frame format):
  Acceptance filter unit checks the identifier field of the received message against the identifier field of each AFL entry (full 29 bits masking of identifier bits is possible, see information that follows).
- IDE bit:
  Acceptance filter unit checks the IDE bit of the received message against this bit and selects the relevant part of the identifier field for acceptance filtering (masking of IDE bit is possible, see the information that follows).

- RTR bit:
  Acceptance filter unit only accepts data frames (RTR = 0) or remote frames (RTR = 1) according to the setting of this bit (masking of RTR bit is possible, see the information that follows).
- Loopback Configuration bit:
  This bit can enable or disable the AFL entry depending on the Loopback Configuration or Mirror mode condition.
- Mask for Identifier bits (29 bits):
  Each bit in the identifier mask can mask the corresponding identifier bit in the AFL entry during acceptance filtering, see Figure 35.25.
- Mask for IDE bit:
  If this Mask bit masks the IDE bit of the AFL entry in both Standard Identifier and Extended Identifier format, messages can be accepted by this AFL entry. The identifier of the received message is compared against the Standard Identifier part of the AFL entry for Standard Identifier format messages and against the Extended Identifier part of the AFL entry for Extended Identifier format messages.
- Mask for RTR bit:
  If this Mask bit masks the RTR bit of the AFL entry in both frame formats, data frame and remote frame formats are accepted by this AFL entry.
- Pointer information (16 bits):
  This 16-bit pointer is attached to a received message accepted by the related AFL entry. The pointer is added during message storage in the message buffer area and can be used by application as support function. The pointer information can be used for example to support PDU identifier allocation for the received message in AUTOSAR systems.
- Information label (2 bits):
  This 2-bit label is attached to a received message accepted by the related AFL entry. The label is added during message storage in the message buffer area and can be used by application as support function.
- DLC value for automatic DLC filtering:
  If the DLC value of the received message is equal or higher than the configured DLC value, the DLC check is passed. If the DLC value in this AFL entry is configured to 0, DLC filtering is effectively disabled for this entry (all accepted messages pass DLC filtering).

Each AFL entry contains the following information for the handling of received messages:

- Message buffer number of one single reception message buffer as target for received message storage
- Single reception message buffer enable bit to configure the single reception message buffer number to be valid or invalid, as target for received message storage
- FIFO direction pointer - each bit of the FIFO direction pointer configures a dedicated FIFO as possible target for a received message

Note: A message received on channel A can be routed to Common FIFO buffer of another channel. If this Common FIFO buffer is configured in Gateway mode, then the message stored in this Common FIFO Buffer is transmitted on that channel because Common FIFO buffer is associated with channel.

There is no hardware protection against such storage of message. Therefore, the FIFO direction pointer must be configured carefully.

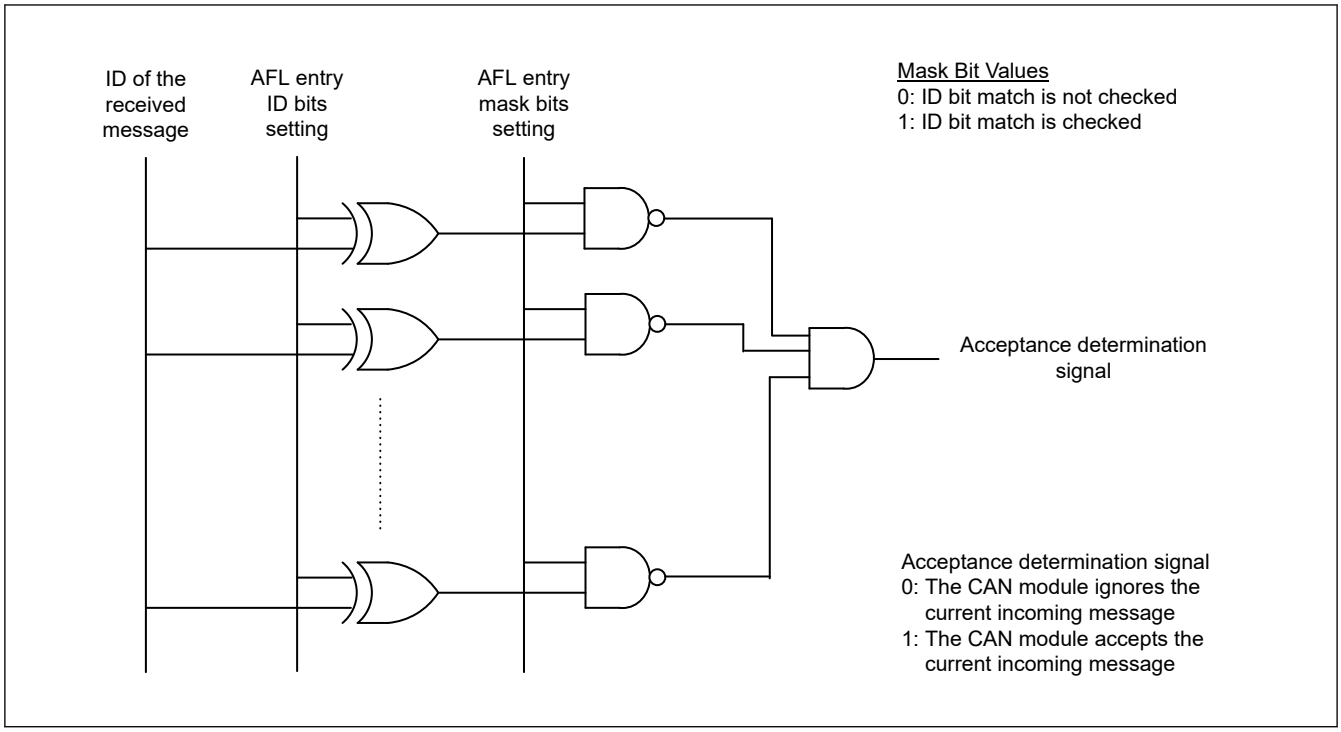

Figure 35.25 Acceptance function

35.6.4 Entering Entries in the AFL

Application software can enter one full entry into the AFL using the following registers:

- Global AFL ID Entry Register: Part 1 of the AFL entry
- Global AFL Mask Entry Register: Part 2 of the AFL entry
- Global AFL Pointer 0 Entry Register: Part 3 of the AFL entry
- Global AFL Pointer 1 Entry Register: Part 4 of the AFL entry

16 sets of these registers form a group of AFL entries. Each group can be accessed through a page mechanism. For the CAN-FD module, 2-channel version, 16 of these pages exist to allow access to the whole AFL range. The AFL should only be configured in CH_RESET or CH_HALT mode. Pages are linked to the AFL entries in the following way:

Table 35.23 Mapping between pages and AFL entries (1 of 2)

Page 0	Entry 0 – 15
Page 1	Entry 16 – 31
Page 2	Entry 32 – 47
Page 3	Entry 48 – 63
Page 4	Entry 64 – 79
Page 5	Entry 78 – 95
Page 6	Entry 96 – 111
Page 7	Entry 112 – 127
Page 8	Entry 128 – 143
Page 9	Entry 144 – 159
Page 10	Entry 160 – 175
Page 11	Entry 176 – 191
Page 12	Entry 192 – 207
Page 13	Entry 208 – 223

Table 35.23 Mapping between pages and AFL entries (2 of 2)

Page 14	Entry 224 – 239
Page 15	Entry 240 – 255

The selection of the AFL access page is done using the Global Acceptance Filter List Entry Control Register (CFDGAFLECTR) (see Figure 35.26). This register has the following fields:

- 4 bits to select the AFL page number
- 1 bit to enable or disable the AFL data access to prevent unwanted write access to the AFL

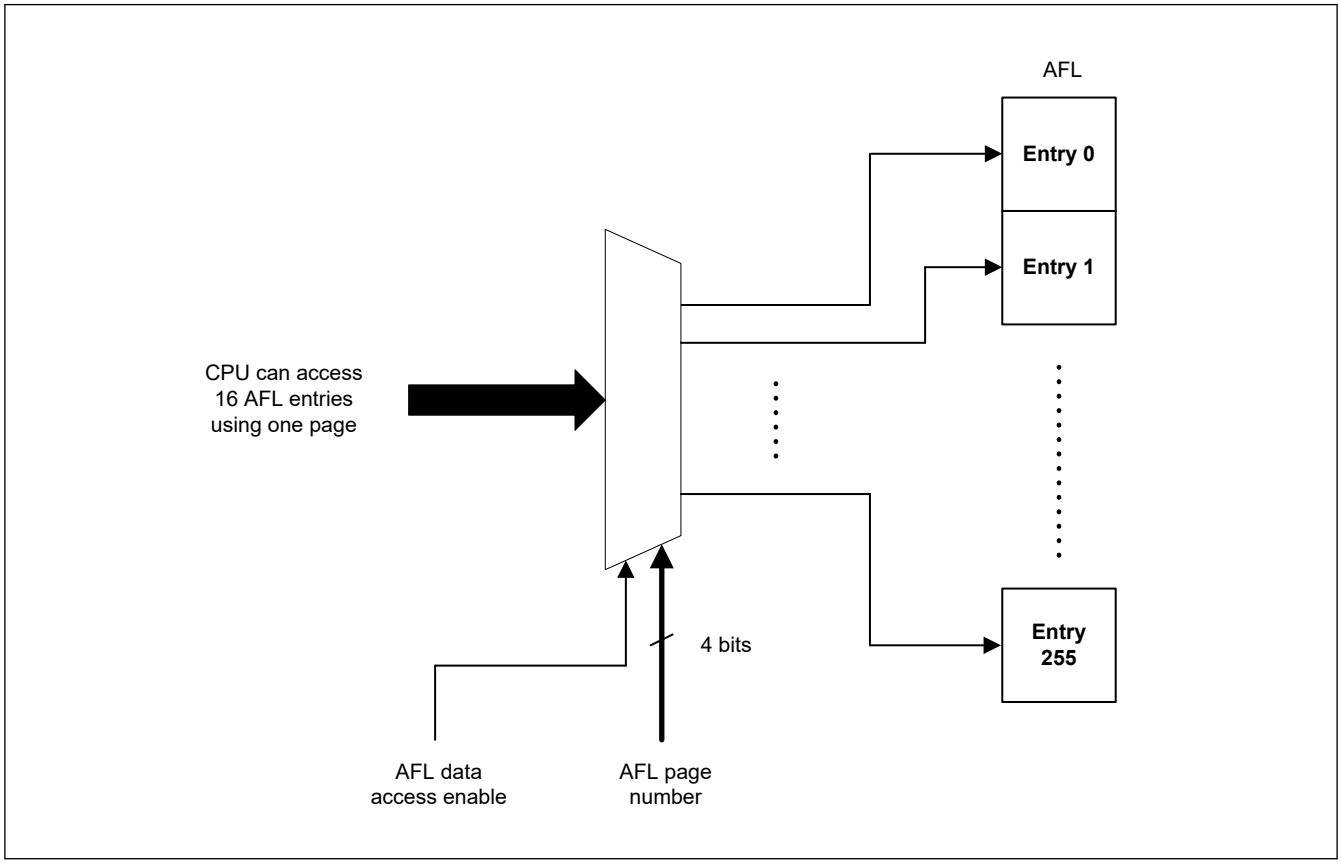

Figure 35.26 AFL page access

Application software should not write numbers higher than 0xF for the AFL page number.

Follow the configuration shown in Figure 35.27 to program the AFL.

After entering all entries in Configuration mode, locking of the AFL access should be performed to protect unwanted write access to the AFL.

Write protection is active during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION) if the lock bit is set.

Read access to AFL is still possible during all Global modes even when AFL data access is disabled (consistency check of AFL contents is possible during run time).

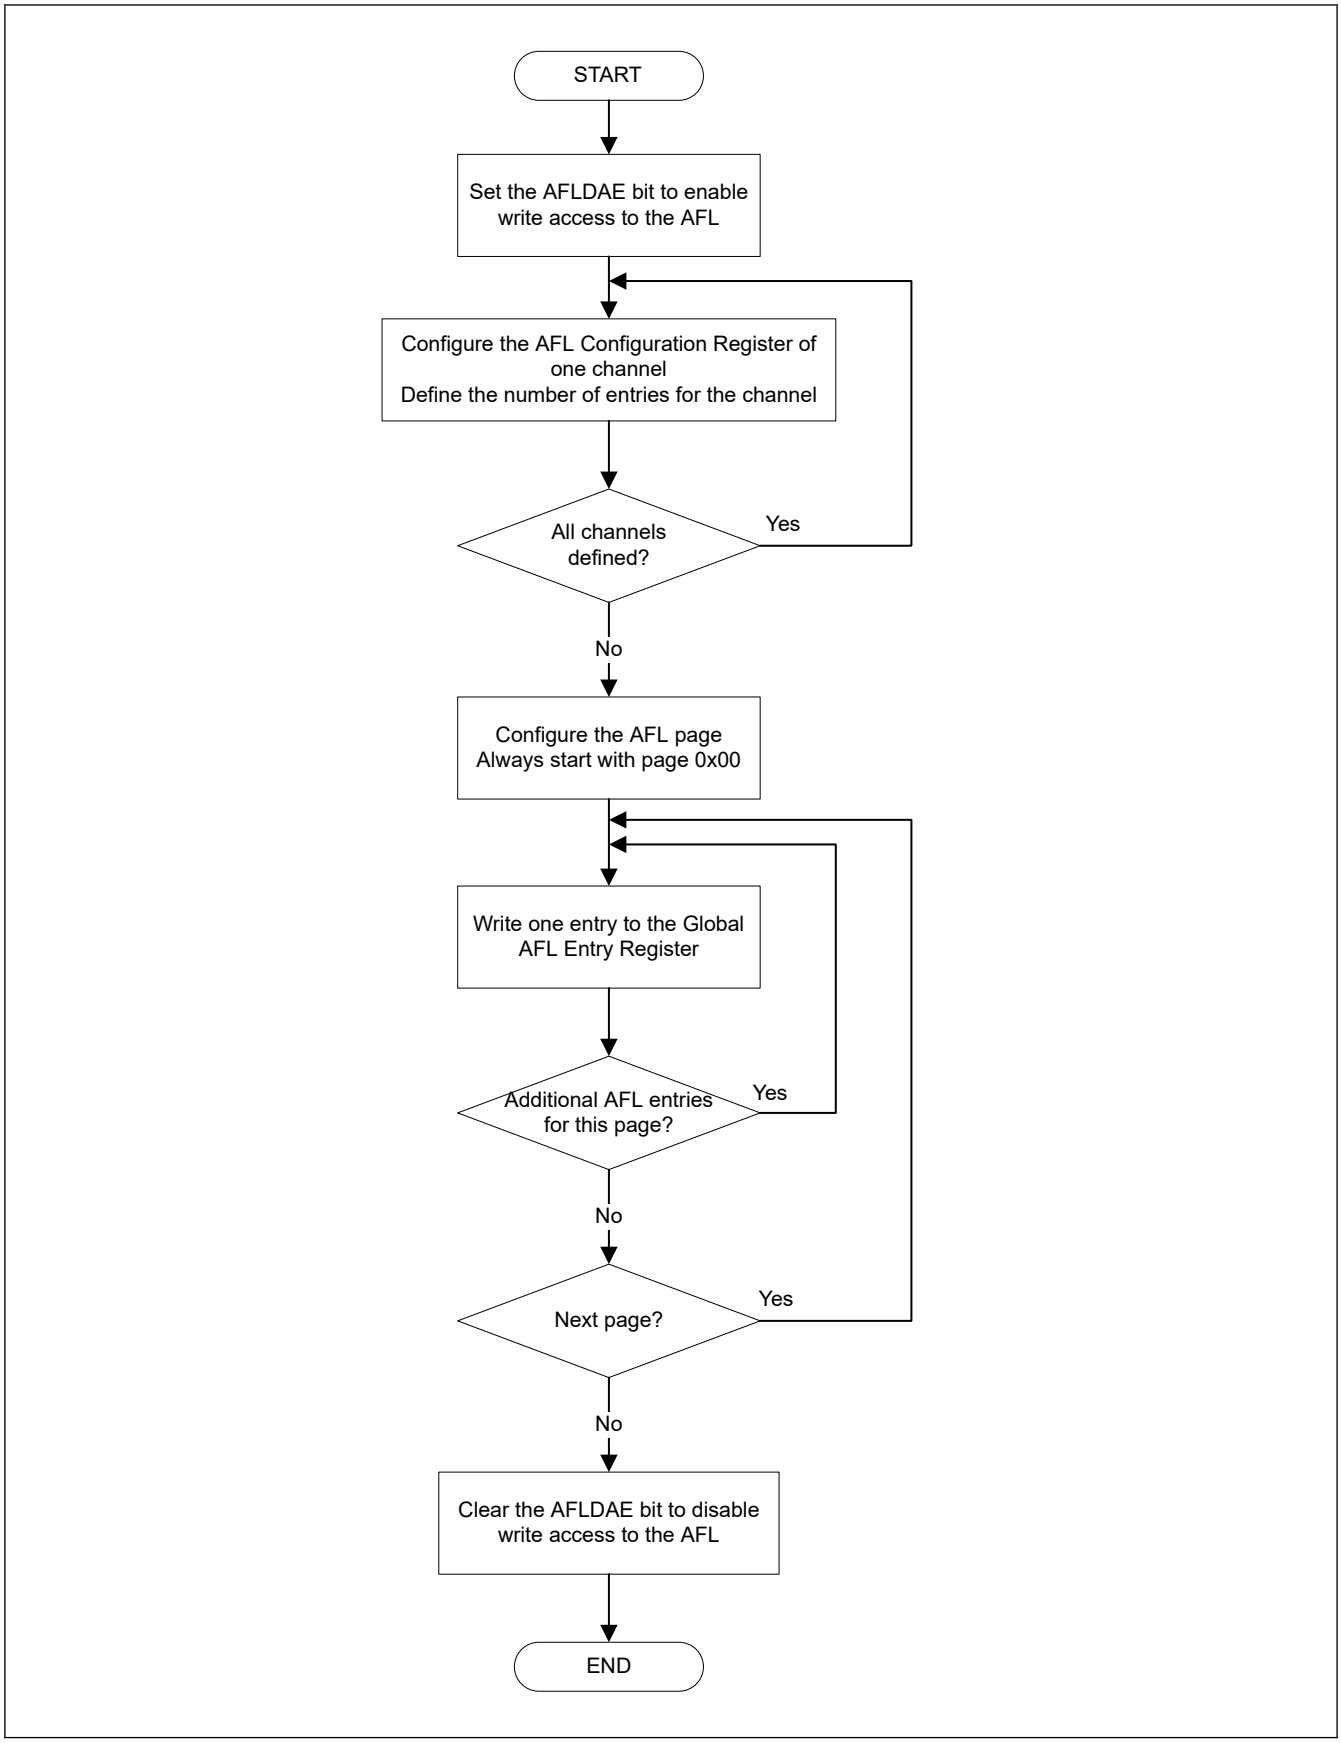

Figure 35.27 AFL configuration flow

35.6.5 Loopback Modes

If the Loopback Configuration bit is set, the AFL entry is only valid in loopback test mode (Self test mode 0 or Self test mode 1) or in mirror mode when receiving messages that were transmitted by the respective CAN channel itself.

The AFL entry is not valid for received messages in loopback mode transmitted by other CAN nodes on the bus. The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID respectively.

If the Loopback Configuration bit is 0, the AFL entry is only valid for:

- Received messages transmitted by other CAN nodes on the bus in normal (non-loopback mode) and mirror modes
- Received messages transmitted by other CAN nodes or the CAN channel itself in loopback test mode.

The mirror mode can be enabled with the CFDGCFG.MME bit in the Global Configuration Register. If CFDGCFG.MME bit is set, then a successfully transmitted message can be stored back in an RX message buffer or FIFO buffer if a matching entry is configured in the AFL for that channel.

The Loopback Configuration bit in the matching AFL entry must be set to store this frame.

If mirror mode and loopback test mode are configured at the same time, the loopback test mode behavior applies.

Table 35.24 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 35.24 Behavior of acceptance filter based on the loopback configuration setting in AFL entry

Mirror mode enable (MME Configuration bit)	Loopback in Test mode (Self test mode 0 or Self test mode 1)	Channel mode	Loopback Configuration bit in AFL entry	AFL entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

35.6.6 IDE Masking

When the GAFLIDEM bit is 0 in an AFL entry, the IDE bit configured in the AFL entry is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is based on the received IDE bit.

Consider the following example:

- The ID and Mask fields of an AFL entry x is configured as follows:
  - CFDGAFLID [x] = 0xC0553A20 → IDE = 1, RTR = 1, LLB = 0, ID[10:0] = 0x220 / ID[28:0] = 0x0553A20
  - CFDGAFLMn = 0x0000FFFF → IDEM = 0, RTRM = 0, IDM[10:0] = 0x7FF / IDM[28:0] = 0x0000FFFF
- The comparison result for the four different received IDs with AFL entry x is described as follows:

– If a frame with IDE = 0 and ID = 0x220 is received, this is considered as a match
– If a frame with IDE = 0 and ID = 0x320 is received, this is not a match
– If a frame with IDE = 1 and ID = 0x1FFF3A20 is received, this is considered as a match
– If a frame with IDE = 1 and ID = 0x08803220 is received, this is not a match.

35.7 FIFO Buffers and Normal Message Buffer Configuration

This section describes the process for configuring the number of RX message buffers, the FIFO buffers, and the flat TX message buffers in the CAN-FD module. The message buffers are mapped as shown in Figure 35.28.

The RX message buffers can be accessed with the RX Message Buffer Registers.

The RX FIFO buffers and the common FIFO buffers configured in RX mode, TX mode, or GW mode can only be accessed with the FIFO Access Registers.

If the common FIFO is configured in TX mode, you can only write data into the FIFO buffer using the FIFO Access registers.

If the common FIFO is configured in GW mode or RX mode, you can only read data from the FIFO Access Registers.

The TX message buffers can be accessed with the TX Message Buffer Registers.

If unused message buffer locations are read, the message buffer locations are read as unknown values.

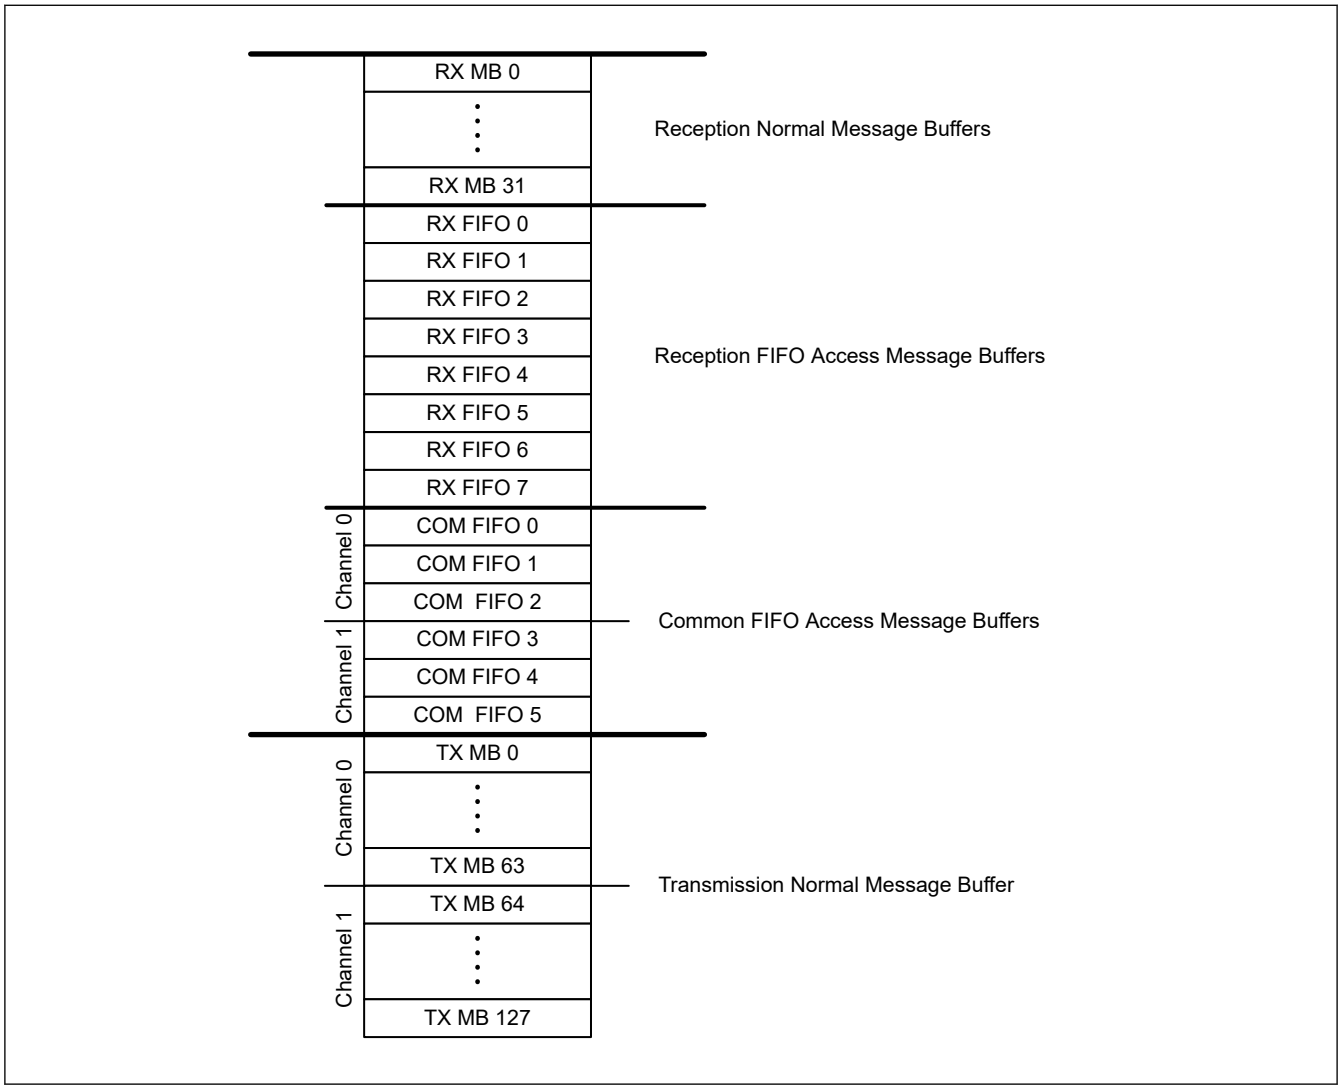

Figure 35.28 Message buffer configuration

35.7.1 Normal RX Message Buffers

In CAN-FD module, the frames received by various channels can be stored in normal RX message buffers based on the configuration of the AFL entries.

Additionally, the number of normal RX message buffers required in the system can be chosen up to a fixed maximum limit.

35.7.1.1 Normal RX Message Buffer Configuration

In CAN-FD module, the number of normal RX message buffers can be configured by writing to the RX Message Buffer Number Register.

The limiting values for the configuration of number of message buffers are:

- Minimum value = 0x00 (no normal RX MB)
- Maximum value = (16 × number of CAN channels) = 16 × 2 = 32 = 0x20 (32 flat RX MBs for 2 channels)

Do not use values outside these limits.

The AFL entries for routing the received messages to normal RX message buffers must be configured to match the requirements of the system.

The AFL entries must also be configured properly, and an AFL entry for normal RX message buffers should not exceed the number of message buffers configured in the RX Message Buffer Number Register.

Note: There is no internal check procedure provided in CAN-FD module against incorrect configuration of the AFL.

The data field size of the RX message buffer can be configured with the CFDRMNB.RMPLS[2:0] bits. The default size is 8 bytes and the maximum data payload size is 64 bytes.

When the receiving frame exceeds the data field size, then the acceptance depends on the configuration of CFDGCFG.CMPOC (message rejecting or data payload cut).

35.7.2 FIFO Buffer

The CAN-FD module provides a fixed number of FIFO buffers to support storage of frames for reception, transmission and gateway functions for various CAN channels.

The number of reception-only FIFO buffers is fixed to 8. However, 3 common FIFO buffers per channel can be configured to store messages for transmission, reception, or gateway function.

These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- Size
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the TX FIFO or GW FIFO

When the receiving frame exceeds the data field size, the acceptance depends on the configuration of the CFDGCFG.CMPOC bit (message rejecting or data payload cut).

35.7.2.1 FIFO Buffers Configuration

In CAN-FD module, the FIFO buffers can be configured to match the system requirements.

The total number of FIFO buffers = 8 RX FIFO buffers + 6 common FIFO buffers = 14 FIFO buffers for 2 channels and message overwrite mechanism.

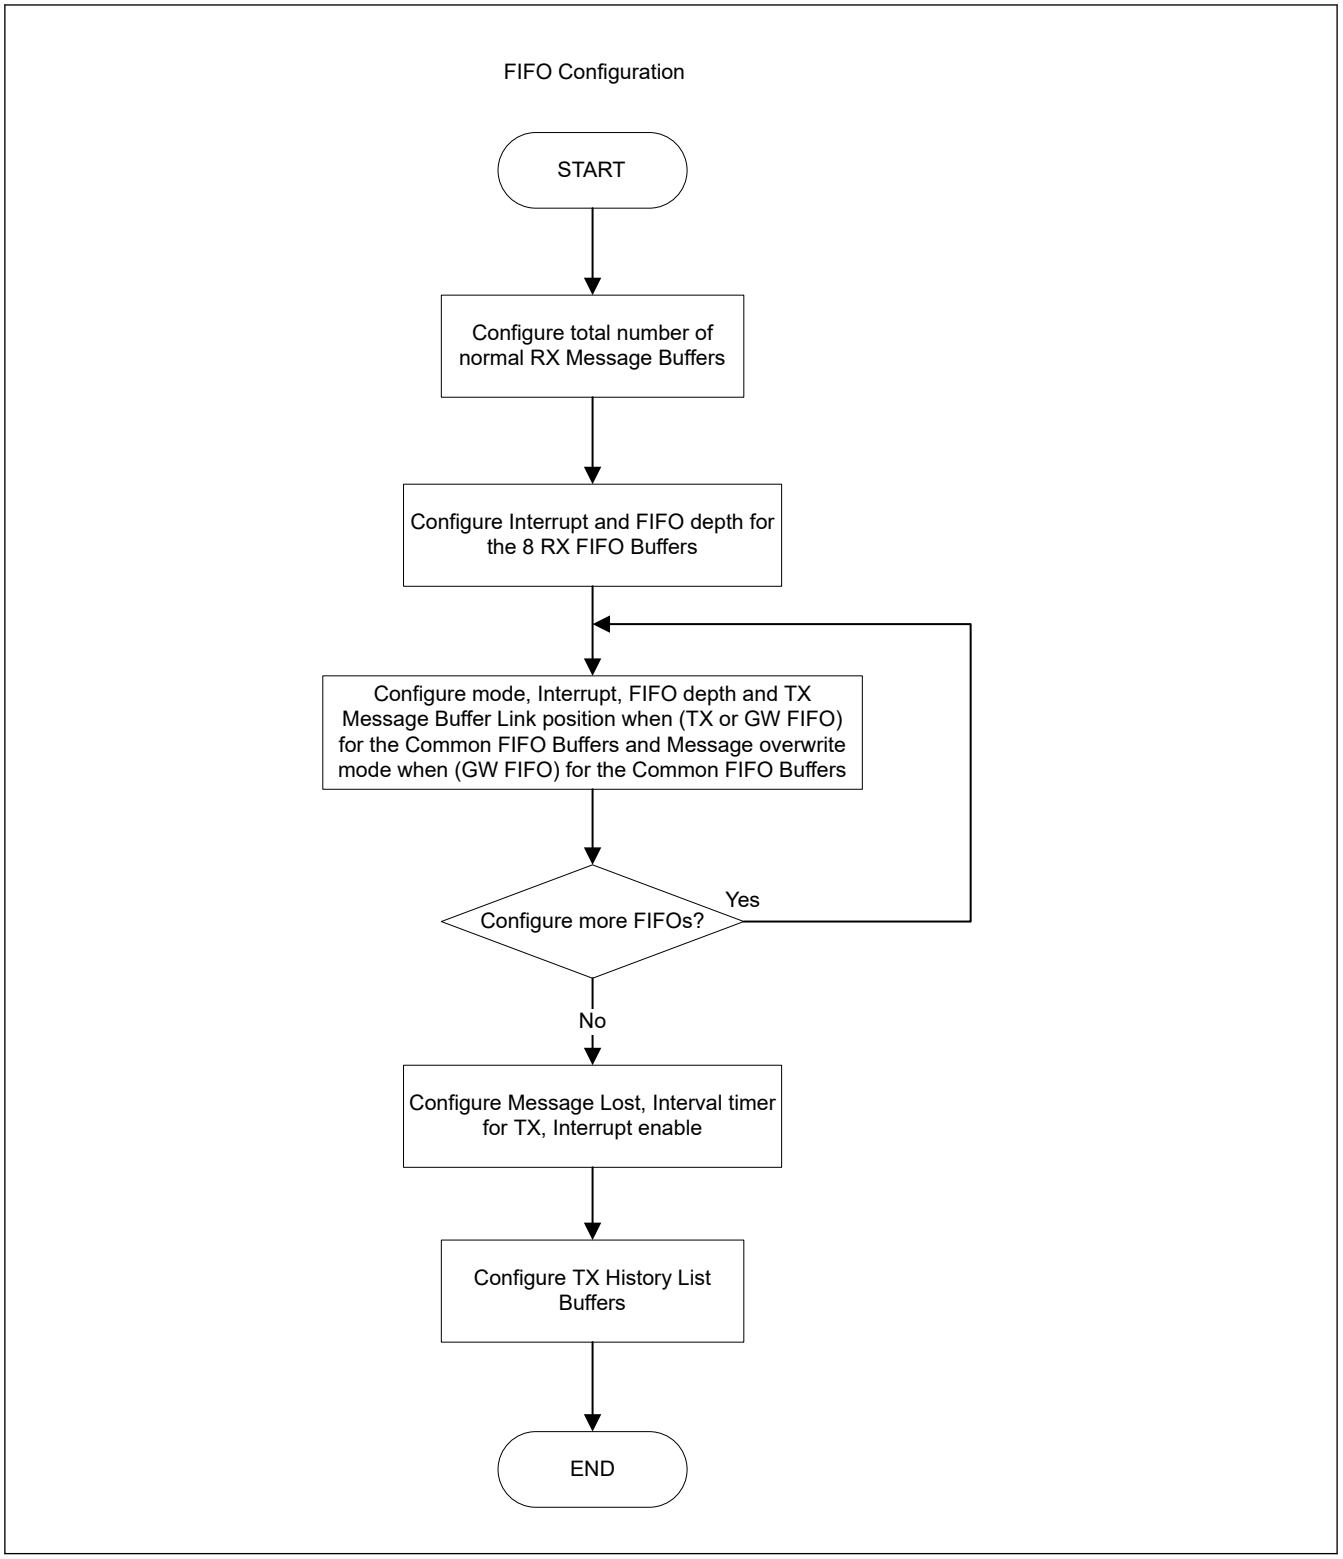

Figure 35.29 FIFO buffer configuration flow in CAN-FD module

As shown in Figure 35.29, the various FIFO buffers can be configured by writing to the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

For the 8 RX FIFO buffers, the following parameters can be configured:

- Interrupts
- FIFO depth
- FIFO payload data size

For the common FIFO buffers, the following parameters can be configured:

- Mode
- Interrupts FIFO depth
- FIFO payload data size
- FIFO TX link position

(1) FIFO Mode Configuration of Common FIFO Buffers

The mode of the common FIFO buffers can be configured by writing to the CFDCFCCn.CFM[1:0] bits in the Common FIFO Configuration/Control Registers. The possible modes of configuration for Common FIFO buffers are:

- 00b: RX mode (default mode after hardware reset)
- 01b: TX mode
- 10b: GW mode
- 11b: Reserved (do not write this value to the register bits)

Messages can only be read from the RX FIFO buffers and the Common FIFO buffers configured in RX mode. Messages are stored by the CAN module in these FIFO buffers based on the AFL entries.

Messages can be read and written into the Common FIFO buffers configured in TX mode. These messages are transmitted on the appropriate CAN channel.

Messages can only be read from the Common FIFO buffers configured in GW mode. However, the CPU read access has no impact on the read or write pointers. The pointers can only be incremented when a new message is stored in the FIFO buffer and decremented when a message is transmitted on the corresponding CAN channel by the CAN-FD module.

After a hardware reset, all the Common FIFO buffers are configured in RX mode by default. Only enable the FIFO buffers after configuring the Common FIFO buffers in the required modes.

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting the CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded, and CFDCFSTSn.CFMLT bit is set to 1.
- When CFDCFCCEn.CFMOWM = 1:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message. The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message. The CFDCFSTSn.CFMOW bit is then set to 1, which notifies that the oldest message has been overwritten with the received message.
  In addition, when a CAN bus error or arbitration-lost for the transmitting message occurs in the transmit/receive FIFO buffer full, the transmitting message is lost and retransmission for the message is not performed. The read point is then moves to the next message automatically. Do not write to this bit when the CFDCFCCn.CFE bit is 1.

(2) FIFO TX Message Buffer Link Configuration

When the common FIFO is configured as TX or GW FIFO, the FIFO buffer must be linked to a normal TX message buffer to participate in the transmission scan of a CAN channel.

The link to a normal TX message buffer must be unique, for example the same TX message buffer cannot be shared between 2 or more common FIFO buffers.

Do not write data into a TX message buffer that is linked to a Common FIFO buffer. Also, the TX message buffer linked to a Common FIFO buffer should not be a part of the TX Queue.

The TX message buffer link of each Common FIFO buffer can be configured by writing to the CFDCFCCn.CFTML[4:0] bits in the Common FIFO Configuration/Control Registers. Available options for TX message buffer link configuration are:

- 0x00: TX Message Buffer 32
- 0x01: TX Message Buffer 33
  ⋮

- 0x1F: TX Message Buffer 63

(3) FIFO Depth Configuration

The depth of each FIFO buffer can be configured by writing to the CFDRFCCn.RFDC[2:0] bits and CFDCFCCn.CFDC[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/ Control Registers. The 8 available options for depth configuration are:

- 000b: 0 Messages (FIFO buffer cannot be enabled)
- 001b: 4 Messages
- 010b: 8 Messages
- 011b: 16 Messages
- 100b: 32 Messages
- 101b: 48 Messages
- 110b: 64 Messages
- 111b: 128 Messages

The RAM allocation for RX message buffers along with FIFO buffers is limited to (n + 1) × 256 messages. Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CAN-FD module logic does not check the validity of the configuration.

Note:
- If the FIFO depth of a common FIFO is 4 messages or more (CFDCFCCn.CFDC[2:0] > 000b), then the Common FIFO TX message buffer link is valid when the FIFO is disabled or enabled.
- If FIFO depth is 0 messages, then the Common FIFO TX message buffer link is not valid when the FIFO is disabled or enabled.

(4) FIFO Payload Size Configuration

The data size of each FIFO buffer can be configured by writing to the CFDRFCCn.RFPLS[2:0] bits and CFDCFCCn.CFPLS[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/ Control Registers. The eight available options for depth configuration are:

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes

(5) FIFO Interrupt Configuration

The interrupt generation conditions for the FIFO buffers can be configured by writing to the CFDRFCCn.RFIM bit and the CFDCFCCn.CFIM bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The two available options are:

- 0:
  - RX FIFO mode: Interrupt generated when the Common FIFO counter reaches CFDRFCCn.RFIGCV/ CFDCFCCn.CFIGCV value
  - TX FIFO mode: Interrupt generated when the Common FIFO transmits the last message successfully
  - GW FIFO mode
    Frame RX: Interrupt generated when message counter increments and reaches the interrupt threshold value
    Frame TX: Interrupt generated when the last message is transmitted successfully from FIFO
- 1:

– RX FIFO mode: Interrupt generated at the end of storage of every received message
– TX FIFO mode: Interrupt generated for every successfully transmitted message
– GW FIFO mode
Frame RX: Interrupt generated when message is stored in the FIFO
Frame TX: Interrupt generated when message is successfully transmitted from the FIFO

If the Interrupt Mode bit is 0 for a RX FIFO, then interrupt is generated based on the configuration of the CFDRFCCn.RFIGCV[2:0] bits.

Similarly, if the Interrupt Mode bit is 0 for a Common FIFO configured in RX mode, then interrupt is generated based on the configuration of CFDCFCCn.CFIGCV[2:0] bits.

The eight available options for configuring the FIFO counter value for generation of an interrupt are:

- 000b: Interrupt generated when FIFO is 1/8th Full
- 001b: Interrupt generated when FIFO is 1/4th Full
- 010b: Interrupt generated when FIFO is 3/8th Full
- 011b: Interrupt generated when FIFO is 1/2 Full
- 100b: Interrupt generated when FIFO is 5/8th Full
- 101b: Interrupt generated when FIFO is 3/4th Full
- 110b: Interrupt generated when FIFO is 7/8th Full
- 111b: Interrupt generated when FIFO is Full

In this case, an interrupt is generated when the message count matches the configured value.

However, there are some limitations on the configuration of the CFDRFCCn.RFIGCV[2:0] and CFDCFCCn.CFIGCV[2:0] bits depending on the FDC[2:0] bits (FIFO Depth Configuration), see Table 35.25.

Table 35.25 FIFO interrupt generation counter and FIFO depth configuration

RFDC[2:0] (FDC[2:0])	RFIGCV[2:0] (CFGCV[2:0])							
	111b	110b	101b	100b	011b	010b	001b	000b
000b	Don't care (FIFO cannot be enabled)							
001b	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed
010b	Allowed							
011b	Allowed							
100b	Allowed							
101b	Allowed							
110b	Allowed							
111b	Allowed							

Common FIFO buffer can set an interrupt output at the completion time of transmitting one frame, or the completion of reception. In addition, Common FIFO and RX FIFO can set an interrupt output, when stored to the setup number (CFDC/RFDC) of FIFO stages.

35.7.2.2 FIFO Buffers Control

The FIFO interrupt must be enabled by setting any one of the following bits in the RX FIFO Configuration/Control Registers:

- CFDRFCCn.RFIE
- CFDRFCCn.RFFIE

In addition, the FIFO interrupt must be enabled by setting any one of the following bits in the Common FIFO Configuration/Control Registers:

- CFDCFCCn.CFRXIE

- CFDCFCCn.CFTXIE
- CFDCFCCEn.CFFIE
- CFDCFCCEn.CFOFRXIE
- CFDCFCCEn.CFOFTXIE

After configuration is complete, each FIFO can be enabled by setting the CFDRFCCn.RFE and CFDCFCCn.CFE bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers to allow transmission and reception of messages.

When CFDCFCCEn.CFBME = 1, it becomes FIFO buffering mode, send data is stored in the Common FIFO, and transmission is stopped. Transmission starts when CFDCFCCEn.CFBME = 0.

Do not write 1 from 0 for this bit when the CFDCFCCn.CFE bit is 1.

35.8 Interrupt and DMA

35.8.1 Interrupts

The CAN-FD module generates several interrupts. The interrupt output, which is connected to the Interrupt Controller Unit (ICU), can be controlled by the corresponding interrupt enable bit.

The status flag is set independent from this enable bit.

The channel transmission interrupt has an additional Status Flag register. These status bits are only set when the corresponding interrupt enables are set.

The Status Flag register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.

The interrupts in the CAN-FD module can be classified into 2 groups, global interrupts and channel interrupts:

- Global interrupts:
  The CAN-FD module can generate 2 global interrupts:
  1. One Global interrupt for successful reception into the 8 RX FIFO buffers
  2. One Global error interrupt
- Channel interrupts:
  Each channel of the CAN-FD module can generate 3 channel interrupts:
  1. Channel transmission
     Transmission completion from channel
     Transmission abort from channel
     Transmission from TX Queue for a channel
     Channel THL Interrupt
     Successful transmission from a Common FIFO in TX or GW mode for a channel
  2. Channel error interrupt
  3. Successful reception in a Common FIFO in RX or GW mode for a channel or successful routing in a TXQ

The interrupts are cleared when the corresponding flag bits are cleared or interrupt enable bits are cleared.

Table 35.26 provides an overview of interrupt.

Table 35.26 Overview of interrupt source

Parameter	Interrupt	Interrupt source	Interrupt clearing
Global Interrupts	Successful reception into at least one RX FIFO	Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the interrupt flag of corresponding RX FIFO buffer for which interrupt is enabled
	FIFO full into at least one RX FIFO	FIFO Full Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the FIFO Full Interrupt flags of corresponding RX FIFO buffer for which interrupt is enabled
	Global error	Any of the following: • DLC Error flag • Message Lost Status bit • Message Overwrite Status bit • TXQ Message Lost Status bit • TXQ Message Overwrite Status bit • TX History Entry Lost Status bit • CAN-FD Message Payload overflow flag	Clear all of: • DLC Error flag • Message Lost flags in all of the FIFO Status Registers • Message Overwrite flags in all of the Common FIFO Status Registers • Message Lost flags in all of the TXQ Status Registers • Message Overwrite Flags in all of the TXQ Status Registers • TX History List Entry Lost flag • CAN-FD Message Payload Overflow flag
Channel Transmission Interrupts	Channel n successful transmission	Any channel related TX MB Successful flag when interrupt is enabled Separate interrupts are provided for common FIFO buffers and TX Queue*1	Clear all channel related TX MB Result Status bits for which the interrupt is enabled
	Channel n abort	Any channel related TX MB Abort flag when interrupt is enabled Separate interrupts are provided for common FIFO buffers and TX Queue*1	Clear all channel related TX MB Result Status bits for which the interrupt is enabled globally
	Channel n transmission from TX Queue	Related channel TX Queue Interrupt flag	Clear related channel TX Queue Interrupt flag
	Channel n THL Interrupt	Channel n THL Interrupt Status flag	Clear the relevant THL Interrupt Status flag
	Channel n COM FIFO TX Interrupt	Interrupt flag for Common FIFOs in TX or GW mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in TX or GW mode belonging to the related channel
	Channel n COM FIFO One Frame TX Interrupt	One Frame Transmission Interrupt flag for Common FIFOs belonging to the related channel	Clear the One Frame Transmission Interrupt flags of Common FIFOs belonging to the related channel
	Channel n TXQ One Frame TX Interrupt	One Frame Transmission Interrupt flag for TXQs belonging to the related channel	Clear the One Frame Transmission Interrupt flags of TXQs belonging to the related channel
Channel COM RX FIFO Interrupt	Channel n COM FIFO RX Interrupt	Interrupt flag for Common FIFOs in RX or GW mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in RX or GW mode belonging to the related channel
	Channel n COM FIFO One Frame RX Interrupt	One Frame Reception Interrupt flag for Common FIFOs belonging to the related channel	Clear the One Frame Reception Interrupt flags of Common FIFOs belonging to the related channel
	Channel n COM FIFO Full Interrupt	FIFO Full Interrupt flag for Common FIFOs in RX or GW mode belonging to the related channel	Clear the FIFO Full Interrupt flags of Common FIFOs in RX or GW mode belonging to the related channel
	Channel n TXQ One Frame Routing Interrupt	One Frame Routing Interrupt flag for TXQs in GW mode belonging to the related channel	Clear the One Frame Routing Interrupt flags of TXQs in GW mode belonging to the related channel
	Channel n TXQ Full Interrupt	TXQ Full Interrupt flag for TXQs in GW mode belonging to the related channel	Clear the FIFO Full Interrupt flags of TXQs in GW mode belonging to the related channel
Channel Error Interrupt	Channel n Error	Any channel related error flag in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register	Clear all channel related error flags in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register

Note 1. These interrupts are only set for TX Message Buffers that do not belong to an enabled TX Queue and are not pointing to a common FIFO.

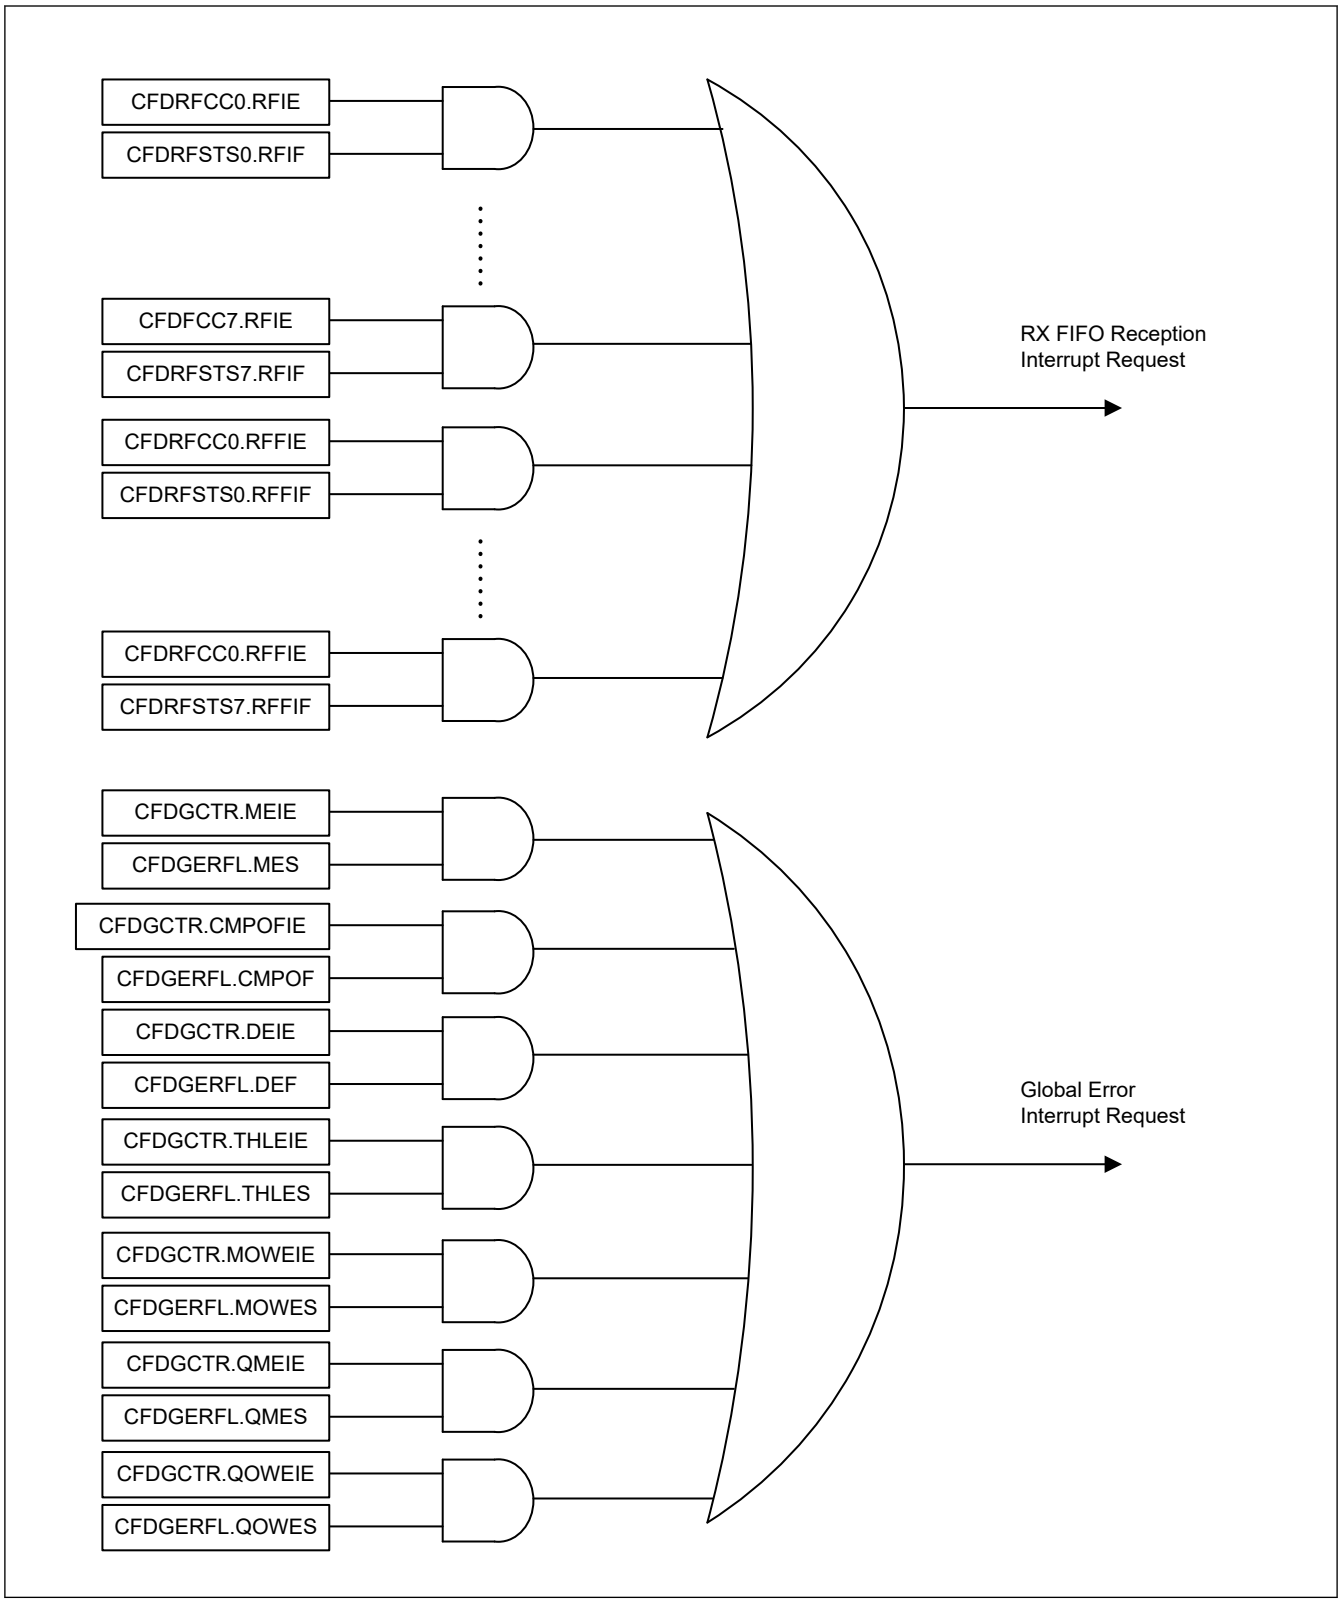

Figure 35.30 Block diagram of Global interrupt

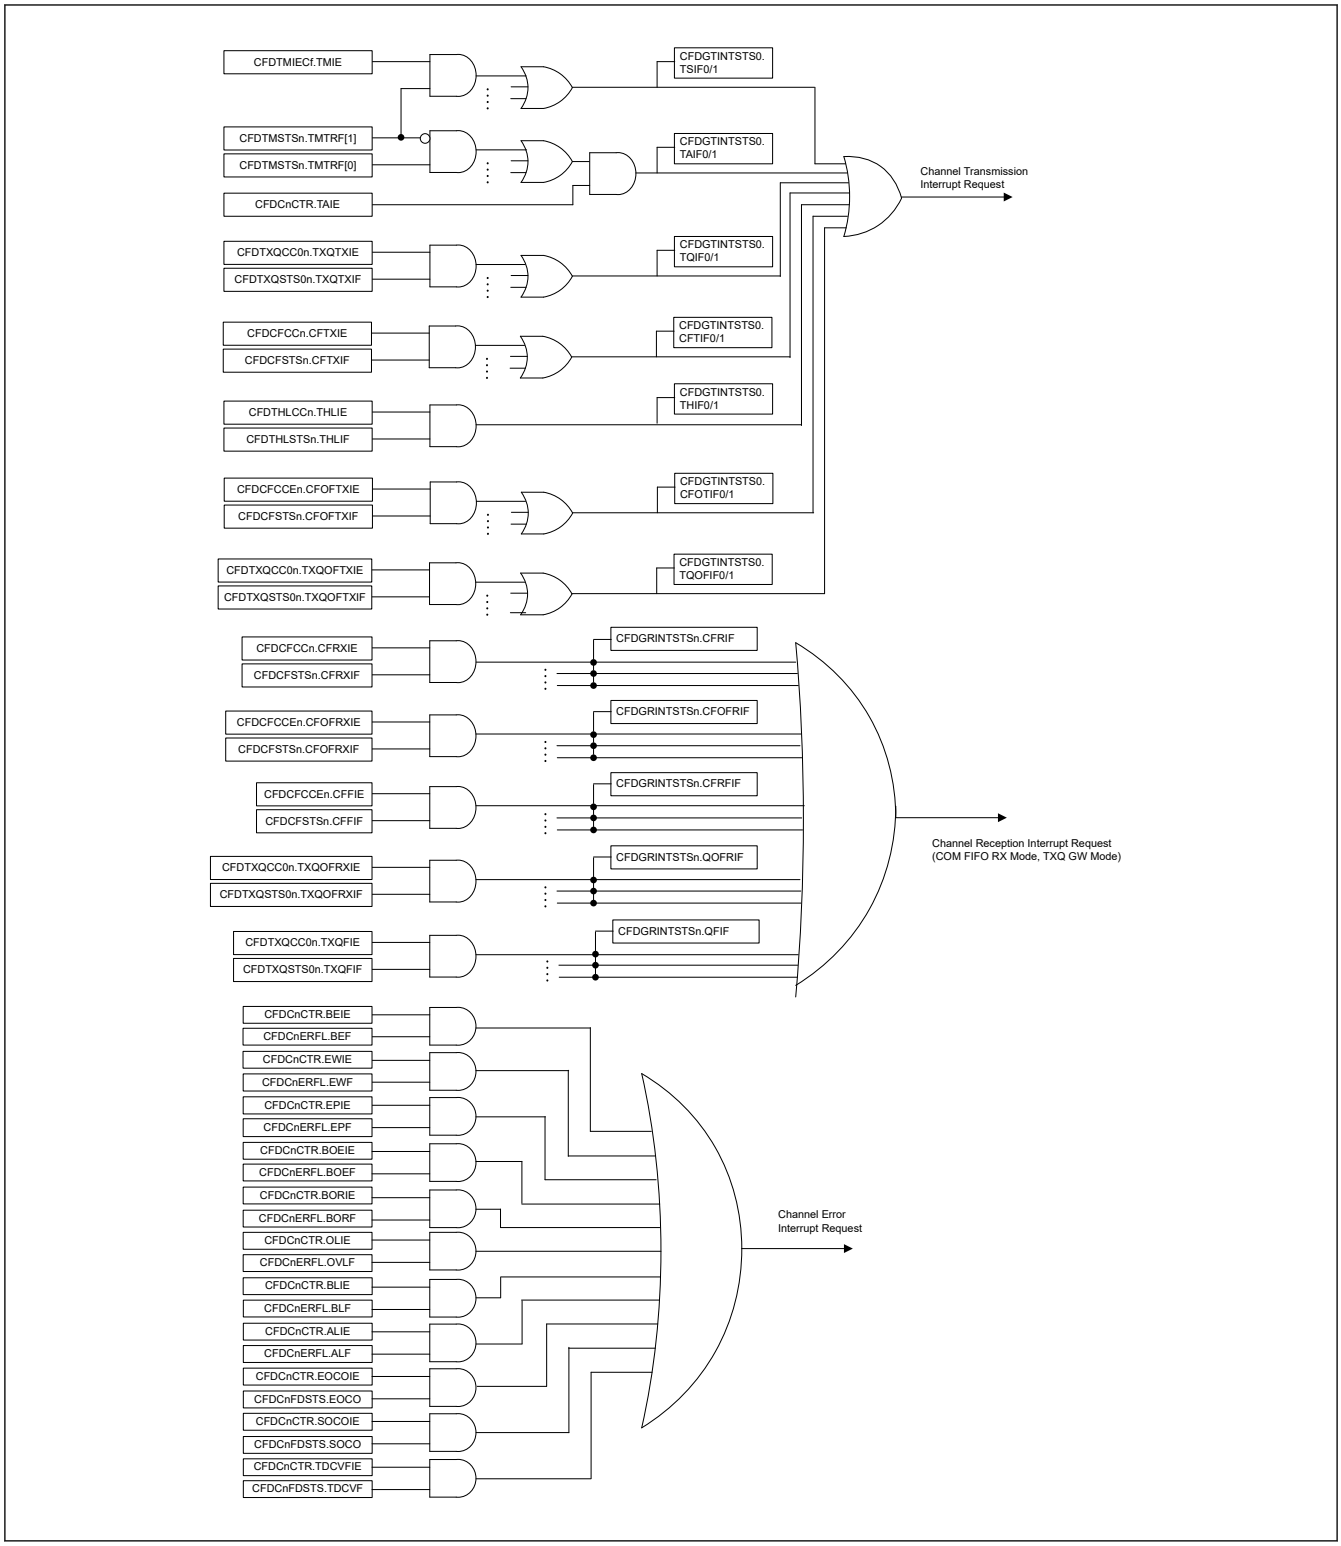

Figure 35.31 Block diagram of Channel interrupt

35.8.2 DMA Transfer

The CAN-FD module has some message buffer which can be associated with a DMA channel:

- Reception DMA
  - 8 RX FIFO Message Buffers
  - 2 Common FIFO Message Buffers

- Transmission DMA
  - 16 TXQ Message Buffers (TXQ0, TXQ3)
  - 2 Common FIFO Message Buffer

Figure 35.32 shows the potential DMA channels.

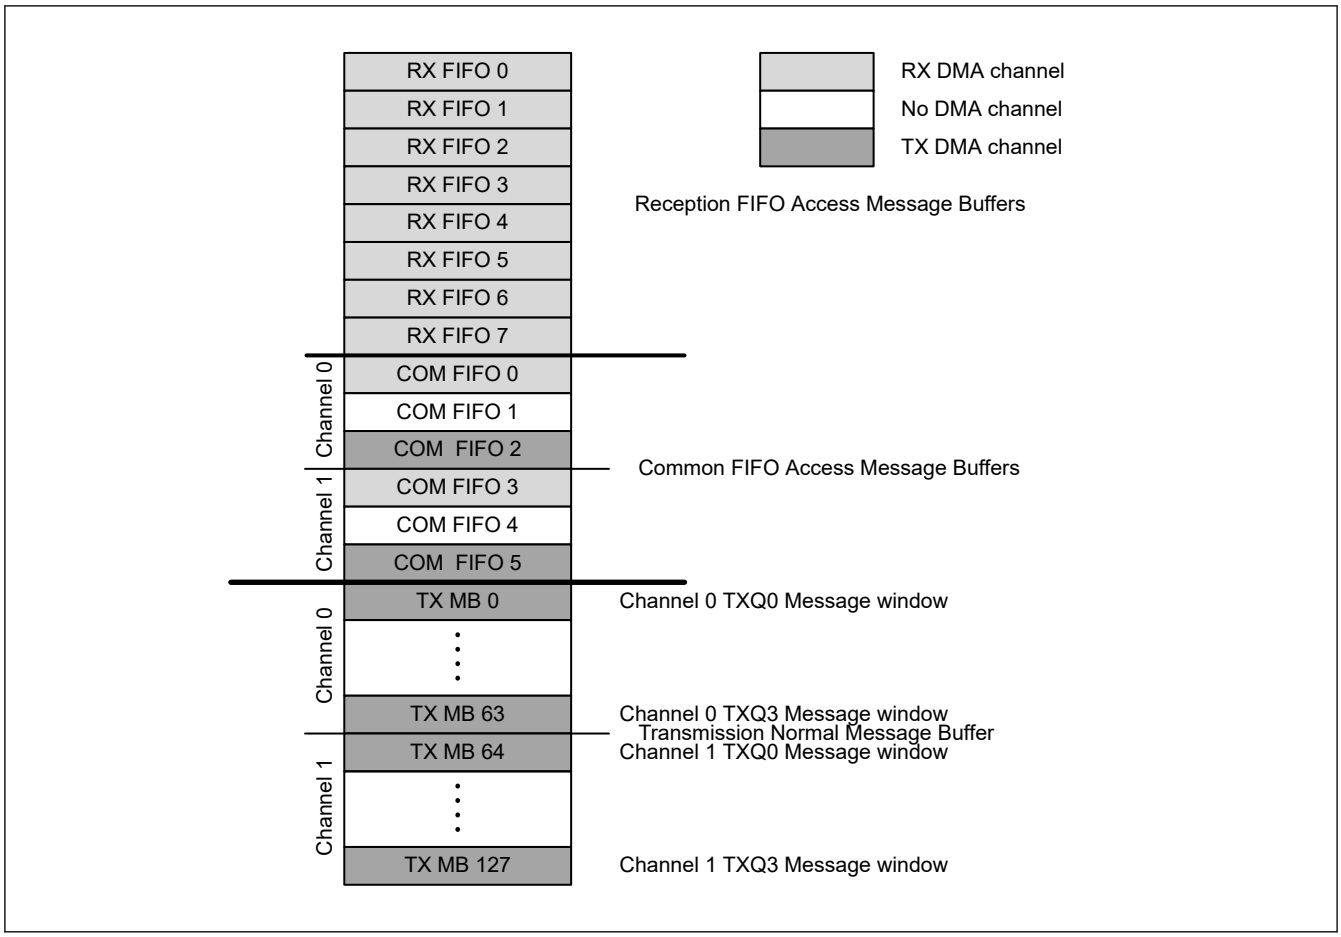

Figure 35.32 Message buffer connectable to DMA channel

A DMA channel transfer request is generated for each FIFO entry to the DMAC when the related CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE is set to 1 and the belonging FIFO is not empty.

Reception FIFO interrupt should be disabled for this particular FIFO (CFDRFCCn.RFIE or CFDCFCCn.CFRXIE).

Use the regular start address for the DMA access window address and add 0x8000 to the regular start address for the debugger access window. See Table 35.27.

Table 35.27 DMA channel access window address (1 of 2)

b = Message buffer component.index	MBCP	Register	p	Start address n = 0, 1
0 to number_of_RFMBCPs - 1	RFMBCPb	RFID	x	0x6000 + b × 0x0080
		RFPTR	x	0x6004 + b × 0x0080
		RFFDSTS	x	0x6008 + b × 0x0080
		RFDFp	0 to 15	0x600C + p × 0x0004 + b × 0x0080

Table 35.27 DMA channel access window address (2 of 2)

b = Message buffer component.index	MBCP	Register	p	Start address n = 0, 1
0 to number_of_CFMBCPs_per_channel - 1	CFMBCPb	CFID	x	0x6400 + b × 0x0080 + n × 0x0180
		CFPTR	x	0x6404 + b × 0x0080 + n × 0x0180
		CFFDCSTS	x	0x6408 + b × 0x0080 + n × 0x0180
		CFDFp	0 to 15	0x640C + p × 0x0004 + b × 0x0080 + n × 0x0180

DMA FIFO pointer decrement is done automatically by reading the last configured data payload byte (CFDRFCCn.RFPLS or CFDCFCCn.CFPLS).

Note: The DMA must read the exact length of the configured data payload size (CFDRFCCn.RFPLS or CFDCFCCn.CFPLS).

The software debugger must access outside of the regular SFR address range from 0xE000 to 0xEFFF.

Do not write to the FIFO and TXQ control registers when DMA is enabled.

The DMA enable of the particular DMA FIFO (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE) can be set at any time, the procedure in this section is a configuration flow for an initial setup.

When CFDCDTTCT.TQ0DMAE or CFDCDTTCT.TQ3DMAE or CFDCDTTCT.CFDMAE is set, the messages of the corresponding TXQ or Common FIFO can be handled by DMA controller.

Use the following procedure when the TXQ or the Common FIFO can be handled by DMA controller.

1. CPU checks the TXQ or the Common FIFO is not full.
2. When transmit data can be used, CPU sets this data to Common FIFO or TXQ.
   When using Common FIFO, transmit data is write in CFDCFID, CFDCFPTR, CFDCFFDCSTS, and CFDTMBCPb[i] registers.
   When using TXQ, transmit data is write in CFDTMID, CFDTMPTR, CFDTMFDCTR, and CFDTMDFp registers.
3. For Common FIFO, the common FIFO pointer is incremented automatically when DMA controller writes the last data payload byte configured by CFDCFCCn.CFPLS.
   For TXQ, if the data of 64 data payload is written, a TXQ pointer increases automatically. When payload data is less than 64 bytes, dummy data must be written in and 64 data payload size must be done.

   Note: Only 32-bit write-access can be possible on the DMA message handling.

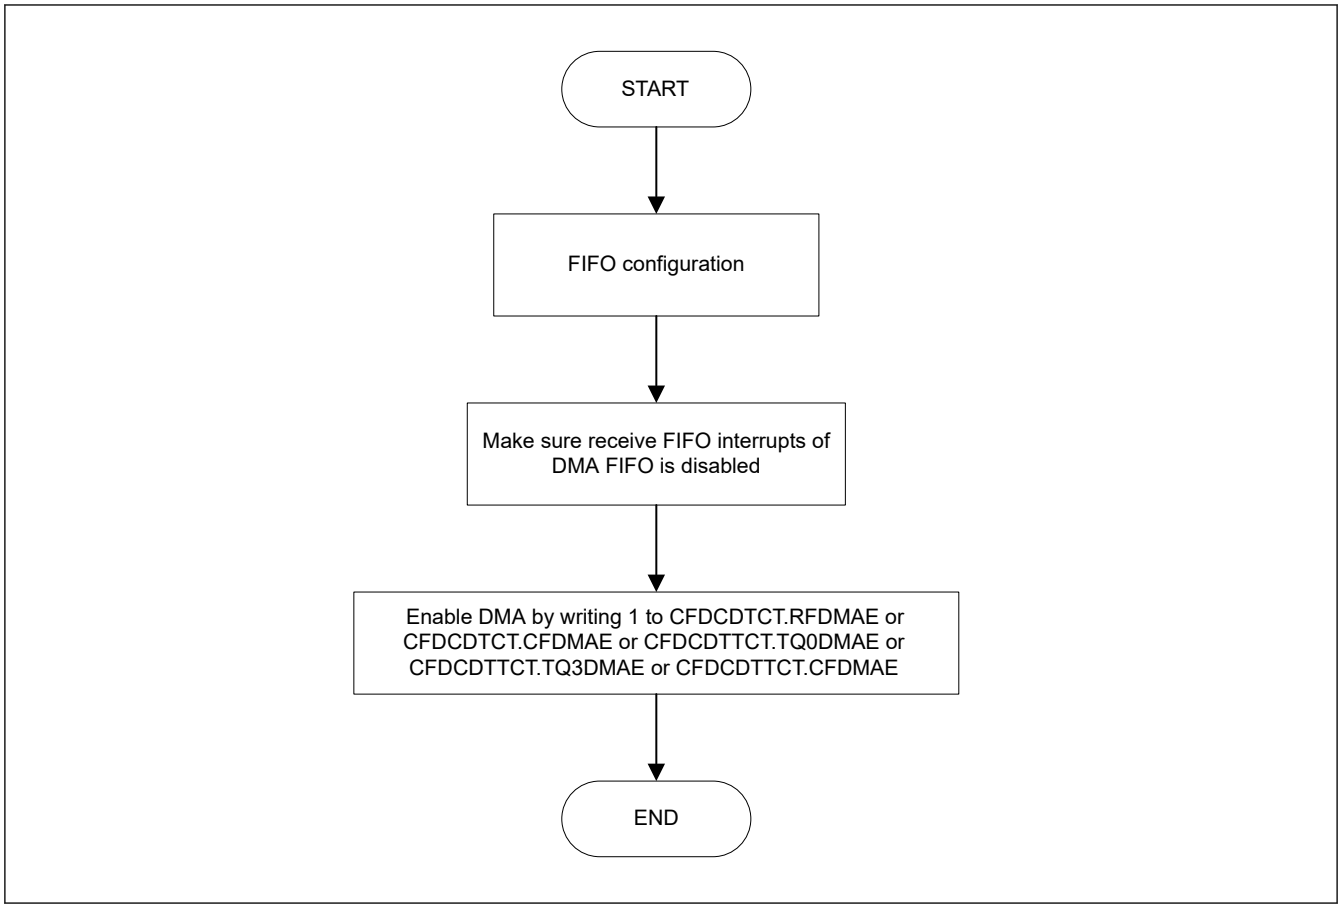

Figure 35.33 DMA enable flow

To disable a DMA transfer requested, disable the particular DMA enable bit (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE). If the disable is made during an ongoing transfer, then this must be completed first before further action can be taken. The transfer status can be identified by the CFDCDTSTS.RFDMASTS or CFDCDTSTS.CFDMASTS. For reference, see the flow in Figure 35.34. When the DMA is disabled, then consider what to do with the remaining or new incoming messages to this particular FIFO reception.

When the FIFO is not disabled, reception to the FIFO continues.

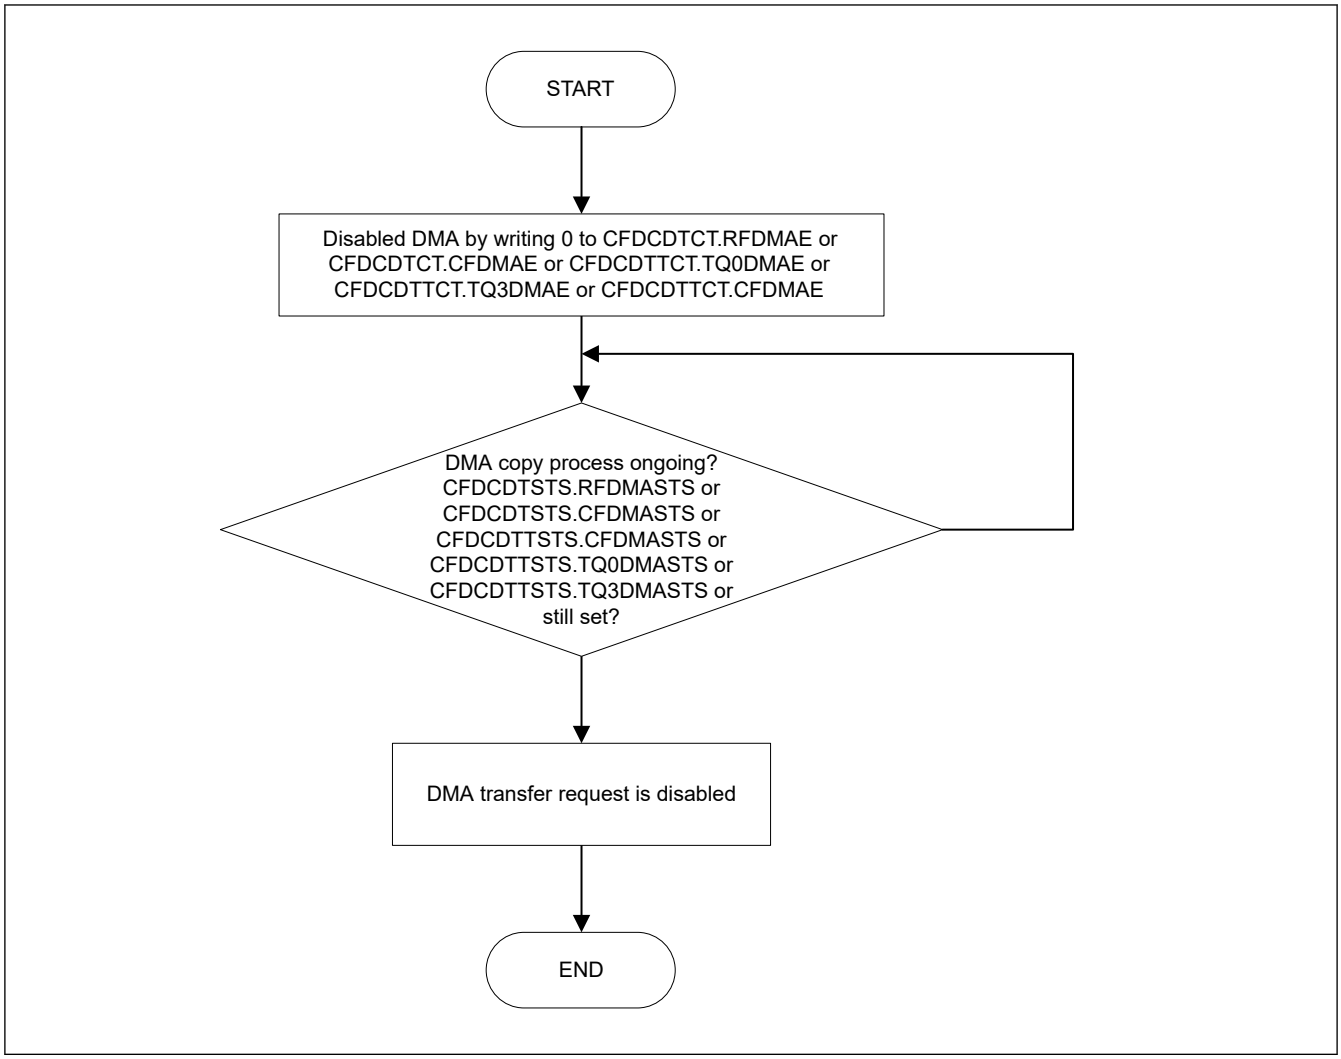

Figure 35.34 DMA disable flow

35.9 Reception and Transmission

35.9.1 Reception

FIFO buffers or Common FIFO buffers configured in RX mode or GW mode depending on the Acceptance Filter List entries are as follows:

- Up to 32 RX Message Buffers can be configured
- 8 RX FIFO buffers available
- Up to 6 Common FIFO buffers can be configured in RX mode or GW mode
- Up to 4 TX Queues can be configured in GW mode

35.9.1.1 Message Storage in RX Message Buffers

When a message is successfully received and stored in a RX Message Buffer, the corresponding New Data flag is set in the RX Message Buffer New Data Register.

The CAN message can be read from the corresponding RX Message Buffer.

If a new message is stored into a RX Message Buffer before the previous message in this message buffer can be read, then the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the RX Message Buffer. If such a loss of messages is not acceptable, then RX FIFO should be used to store related messages.

Note:
- Interrupts are not provided for the RX Message Buffers in the CAN-FD module and so the RX Message Buffer New Data Register should be accessed periodically to check if a new message has been stored in the RX Message Buffers.
- Unused data bytes are filled with 0x00 depending on the DLC value.

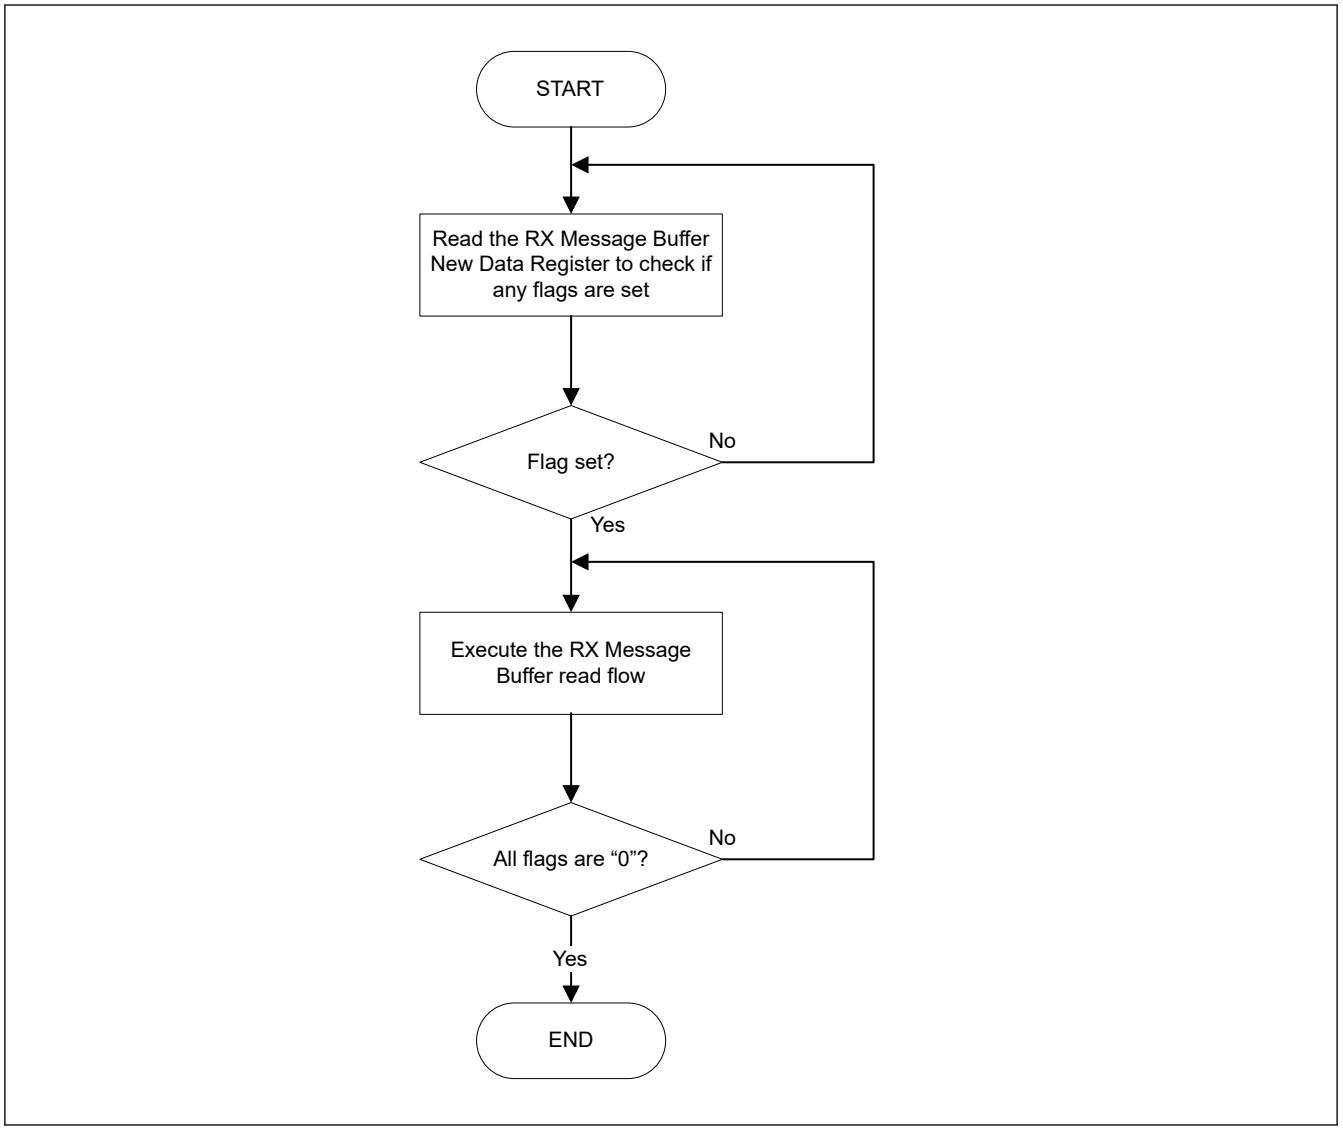

Figure 35.35 RX Message Buffer message access flow

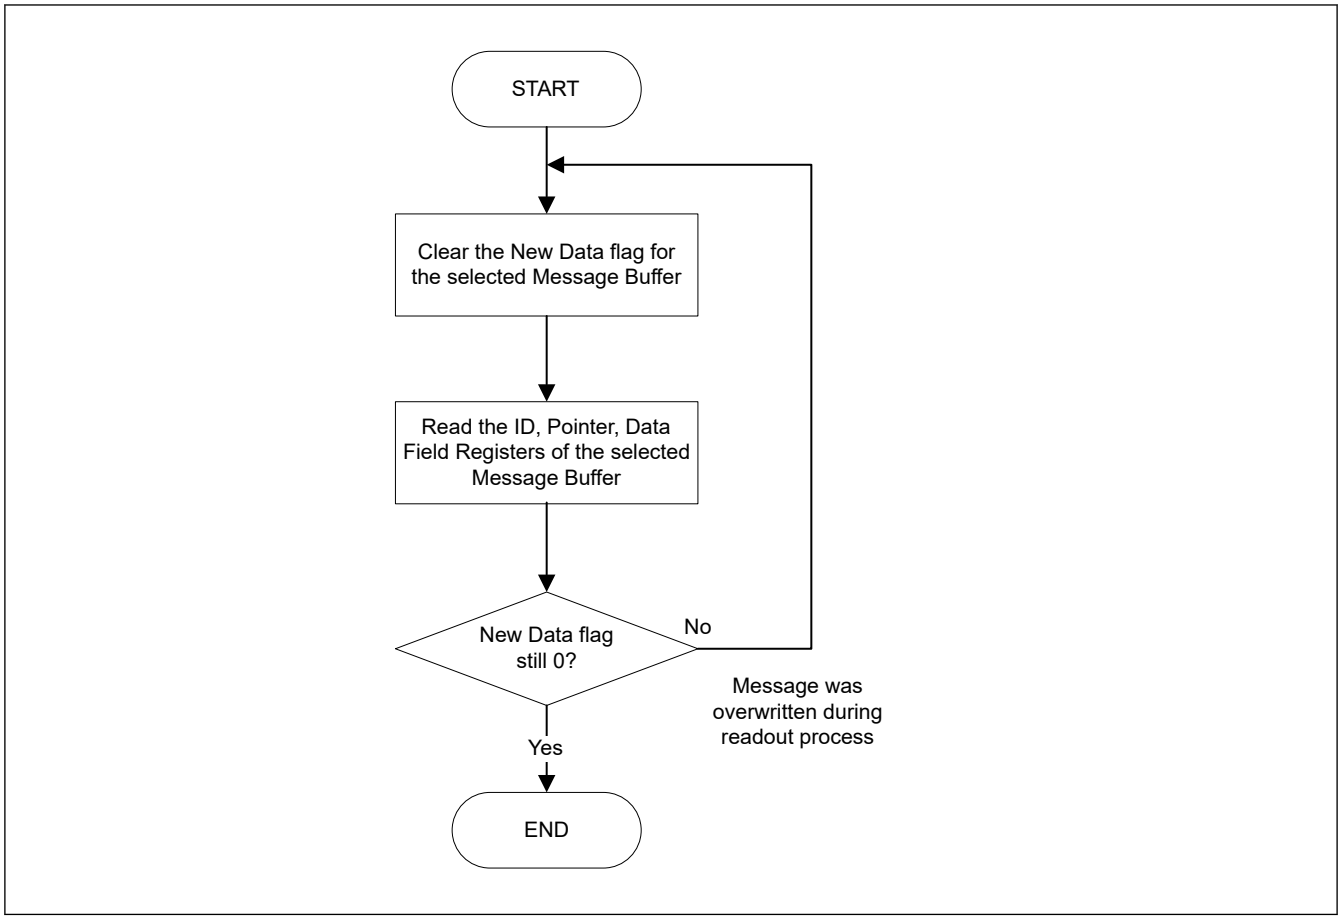

Figure 35.36 RX Message Buffer read flow

35.9.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to RX FIFO buffers or Common FIFO buffers configured in RX or GW mode should be configured based on system requirements.

The CFDGAFLP1n.GAFLFDP[31:0] field in the matching AFL entry selects the FIFO buffers to which the related reception message is stored.

When the received message is stored in one or more RX FIFO buffers or Common FIFO buffers configured in RX mode or GW mode, the message counter value is incremented in the corresponding RX FIFO Status Registers or Common FIFO Status Registers.

Depending on the configuration of the FIFO buffers, an interrupt may also be generated.

The message can be read from the corresponding FIFO Access registers.

Note: Because many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, the FIFO Full flag is set.

When the value 0xFF is written to the corresponding FIFO Pointer Control Register, the message count is decremented by 1.

Only write 0xFF to the FIFO Pointer Control register after reading the complete message from the FIFO Access registers of the corresponding FIFO.

When all the messages stored in the FIFO are read, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO Full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

An appropriate value can be configured as warning level to generate an interrupt before the FIFO full condition occurs to avoid loss of a message due to overrun condition.

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded and CFDCFSTSn.CFMLT bit is set to 1.
- When CFDCFCCEn.CFMOWM = 1:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message.
  The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message.
  The CFDCFSTSn.CFMOW bit is then set to 1, which notifies that the oldest message has been overwritten with the received message.
  In addition, if a CAN bus error or arbitration-lost for the transmitting message occurs in the transmit/receive FIFO buffer full, the transmitting message is lost and retransmission of the message is not performed. The read point moves to the next message automatically.

Do not write change for this bit when the CFDCFCCn.CFE bit is 1.

Common FIFO can set interrupt when:

- CAN frame reception is completed
- FIFO is in full status in RX mode or GW mode

Note:
- The message lost can be set only in RX or GW mode by CAN, the flag is not set when the CPU is overloading the FIFO buffers.
- When CFDGAFLP0n.GAFLSRDi (i = 0 to 2) is set and CFDTXQCCin.TXQGWE (i = 0 to 2, n = 0, 1) is also set, a receiving frame is stored in the target TXQ as send data by routing.

The RX FIFO Buffers and the Common FIFO Buffers configured in RX or GW mode can be disabled at any time by clearing the CFDRFCCn.RFE or CFDCFCCn.CFE bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

When the CFDRFCCn.RFE or CFDCFCCn.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO Buffers are lost and no further messages can be stored into the FIFO.

When the RX FIFO Buffers or Common FIFO Buffers configured in RX mode are assigned as DMA channel, software should not access the FIFO Access Register of this FIFO buffer or write 0xFF to the FIFO Pointer Control Register (CFDCFPCTRn.CFPC or CFDRFPCTRn.RFPC), because this could lead to unintended FIFO message decrement. The DMA channel controls the FIFO decrement automatically.

Note: If the interrupt flag is set for a FIFO Buffer and then the FIFO is disabled, the interrupt flag is not automatically cleared. The interrupt flag should be cleared before disabling the FIFO.

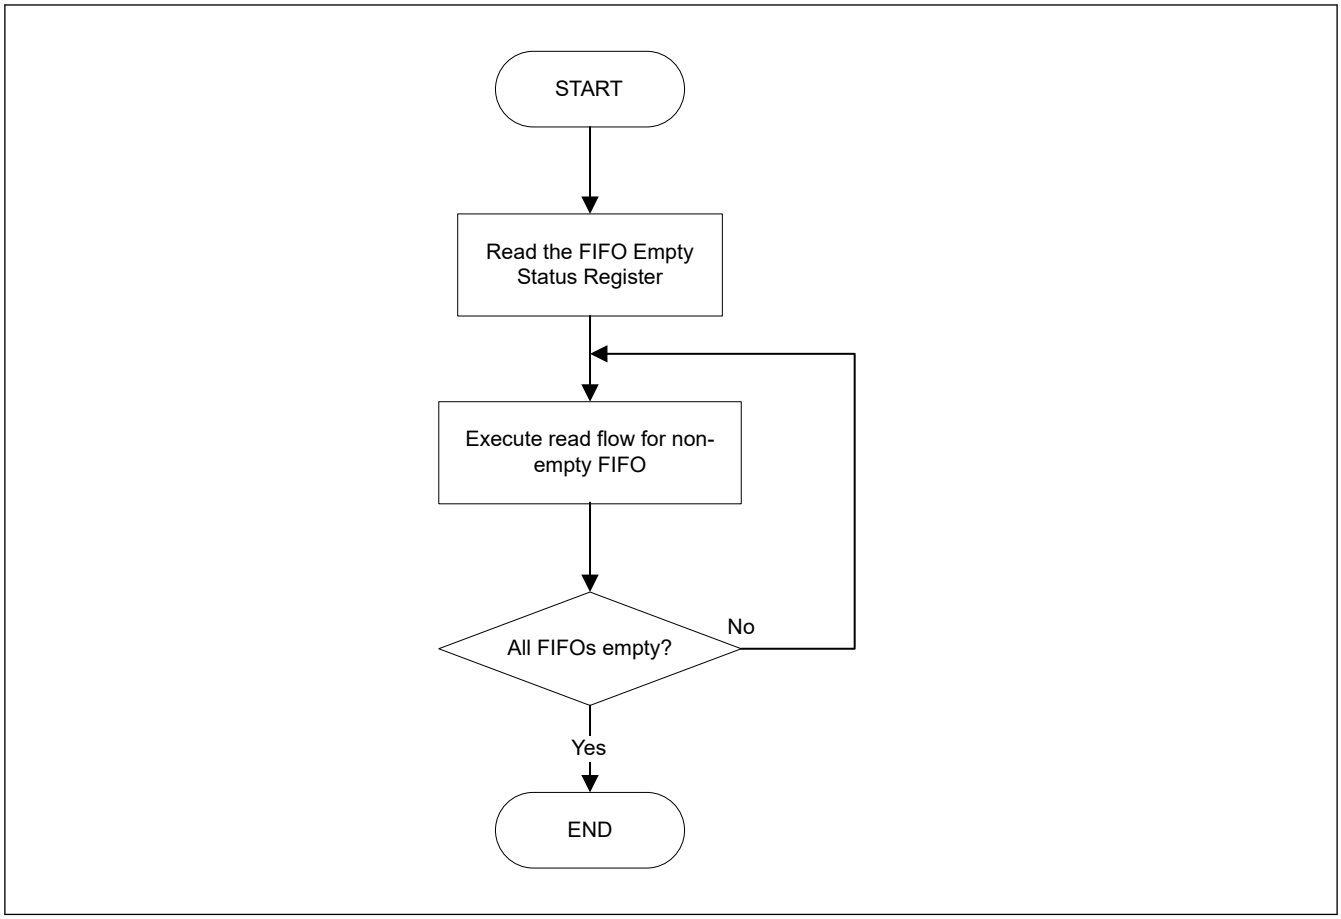

Figure 35.37 FIFO buffer message access flow (example for polling case)

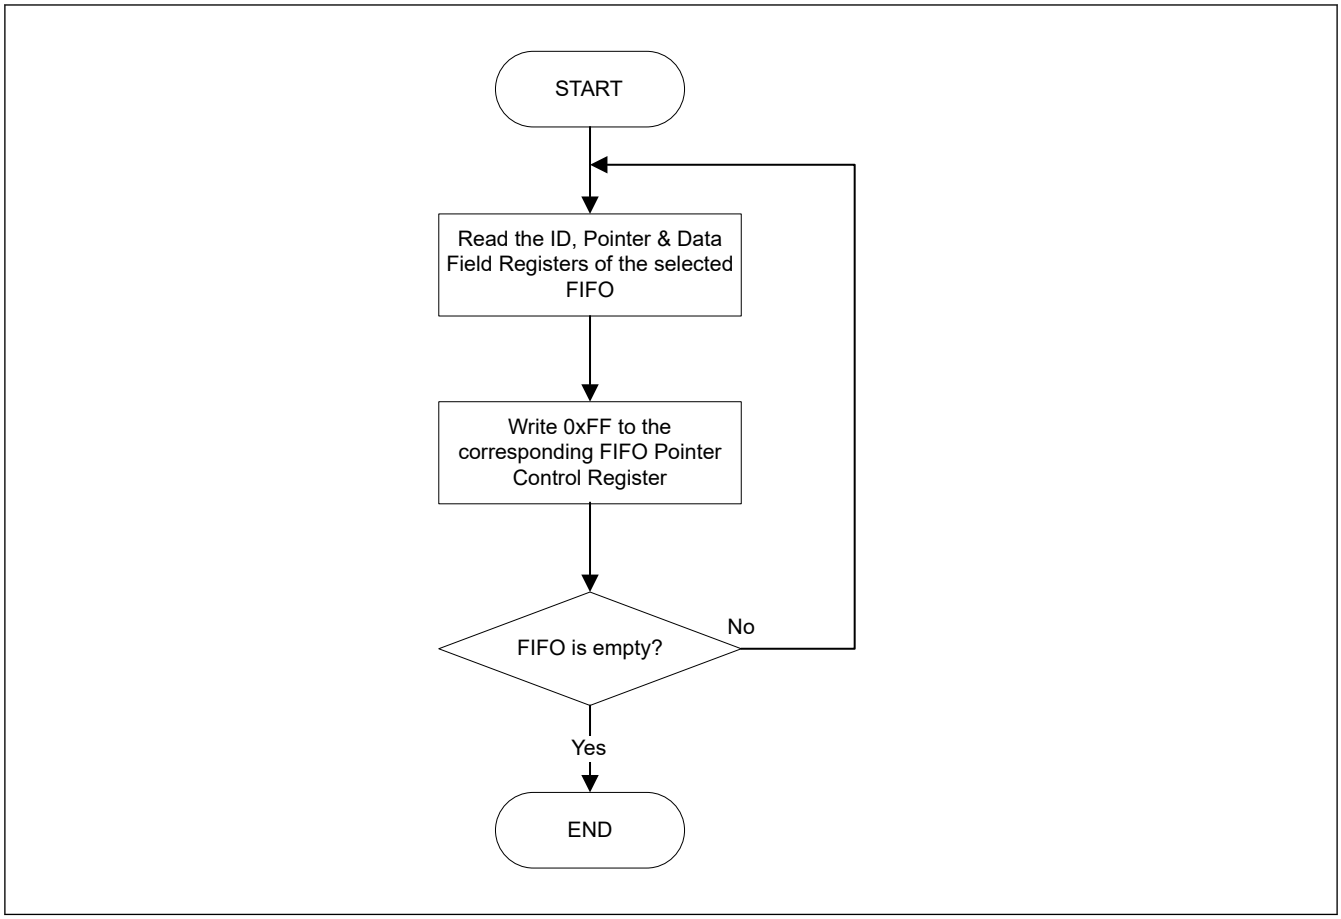

Figure 35.38 RX FIFO buffer read flow (example for polling case)

Note: When the next frame is received before clearing the completion interrupt flag of reception, the completion interrupt of reception is not set again.

Even if it clears an interruption flag after the completion processing of reception, the already received interrupt flag is not set.

It is necessary to perform the completion processing of reception even before the next completion of frame reception, and to clear an interruption flag.

When processing does not meet the deadline, after checking that receiving data is empty, interrupt flag is cleared and it checks that receiving data is empty again.

35.9.1.3 Timestamp

The Timestamp counter is a free-running counter that can be used to check reception time of an incoming message or transmission time of successful transmitted messages. The Timestamp counter value is captured based on the CFDGFDCFG.TSCCFG[1:0] configuration (at the sample point of start of frame, point in time when the frame is valid, or for CAN-FD frames also at the sample point of the RES bit). For reception, it is stored together with the message ID and Data into the target RX Message Buffer or RX/GW FIFO.

For transmit message, the Timestamp counter value is stored as part of the TX History List entry.

The counter can be clocked with the peripheral clock or with the CAN channel bit timing clock. The counter source clock can be configured with the CFDGCFG.TSSS bit of the Global Configuration Register. If it is 0, the peripheral clock is used. If it is 1, the selected CAN channel bit time clock is used.

The channel selection is done with the CFDGCFG.TSBTCS bit of the Global Configuration Register.

Care must be taken when using selected CAN channel bit time clock as the clock source. When entering Channel Halt mode or Channel Reset mode for this channel, the Timestamp counter is stopped. Therefore, for other CAN channels, the Timestamp counter value is also not updated.

If peripheral clock is selected as the Timestamp counter clock source, Channel modes do not influence the Timestamp counter function.

The source clock for the Timestamp counter can be divided by a factor defined by the CFDGCFG.TSP bits (Timestamp Prescaler) in the Global Configuration Register.

The Timestamp counter can be reset to 0x0000 with the CFDGCTR.TSRST bit (Timestamp Reset).

35.9.2 Transmission

There are several possible transmission configurations for each channel:

- Normal transmission
- FIFO transmission
- Gateway transmission
- TX Queue transmission
  A fixed number of transmission message buffers (64 TX message buffers) are dedicated for each channel. These message buffers are only used for transmission and cannot be configured for reception.
  Additionally transmission from TX Queue and/or Common FIFO in TX or GW mode can be configured in the following way (see Figure 35.39):
  - TX Queue: Up to 32 transmission message buffers for one channel can be grouped to form a TX Queue with a common access window.
    Upper transmission message buffers are used to form the TXQ1 or TXQ3.
    Lower transmission message buffers are used to form the TXQ0 or TXQ2.
    Transmission control and status registers of these transmission message buffers should not be used.
    One channel has four TX Queues. Each TXQ has an access window:
    - TXQ0 is transmission Message Buffer 0 of each channel
    - TXQ1 is transmission Message Buffer 31 of each channel
    - TXQ2 is transmission Message Buffer 32 of each channel
    - TXQ3 is transmission Message Buffer 63 of each channel

    When using TXQ1 and TXQ0 simultaneously, the sum of the depths of TXQ1 and TXQ0 should not exceed 32.
    When using TXQ3 and TXQ2 simultaneously, the sum of the depths of TXQ3 and TXQ2 should not exceed 32.
- Common FIFO (TX/GW mode): Each Common FIFO in TX or GW mode is linked to a dedicated channel.
  Each channel has a fixed number of three Common FIFOs assigned to it. Within the channel, a Common FIFO configured in TX or GW mode, can be freely linked (assigned) between 32 and 39 transmission message buffers (only one FIFO to one transmission message buffer).
  The Common FIFO buffer then replaces the transmission message buffer linked to it.
  Transmission control and status registers of these transmission message buffers should not be used.

See Figure 35.28 for information on Common FIFO buffer assignment to related channels.

Note: Common FIFO buffers should not be linked to TX message buffers that are already part of a TX Queue.

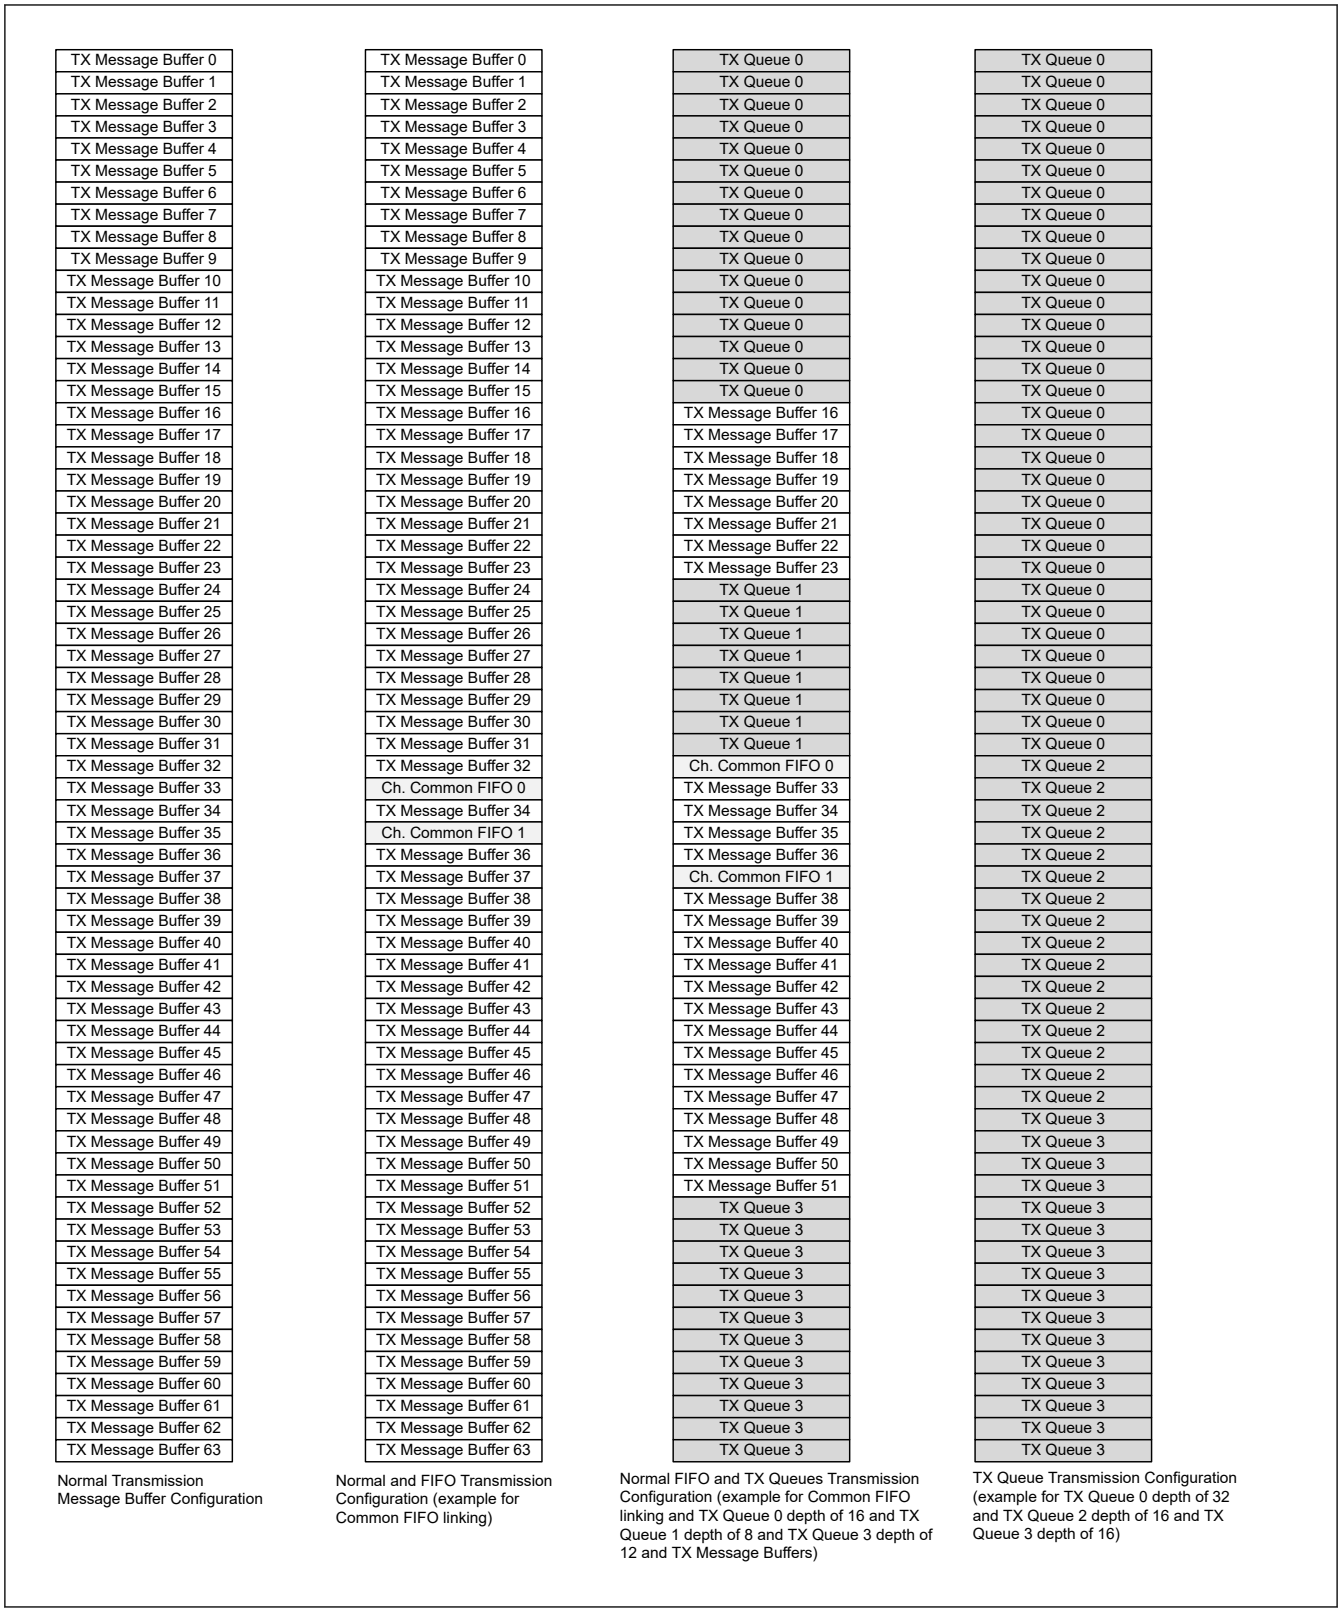

Figure 35.39 Channel transmission message buffer configuration

35.9.2.1 Transmission Priority

If two or more transmission message buffers of a channel are configured for transmission, the transmission priority in the CAN-FD module can be selected from the following two modes:

- CAN ID priority

- Message buffer number priority

The transmission priority mode is common for all message buffers and all CAN channels. It can be configured with the CFDGCFG.TPRI bit in the Global Configuration Register.

For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the TX message buffers linked to the Common FIFO buffers configured in TX mode or GW mode.

However, message buffer number priority should not be used if TX Queue is enabled.

For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All TX message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the TX message buffers linked to the Common FIFO buffers configured in TX mode or GW mode and includes the TX Queue message buffers.

If the ID of two or more message buffers is the same, the smaller message buffer number has higher priority for transmission.

Note: For Common FIFO buffers configured in TX mode or GW mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.

If the message is being transmitted from the FIFO, the next pending message within the same FIFO will be considered in the transmission arbitration.

In contrast to this, all transmission message buffers of a TX Queue participate in internal transmission arbitration.

Figure 35.40 shows the transmission configuration flow.

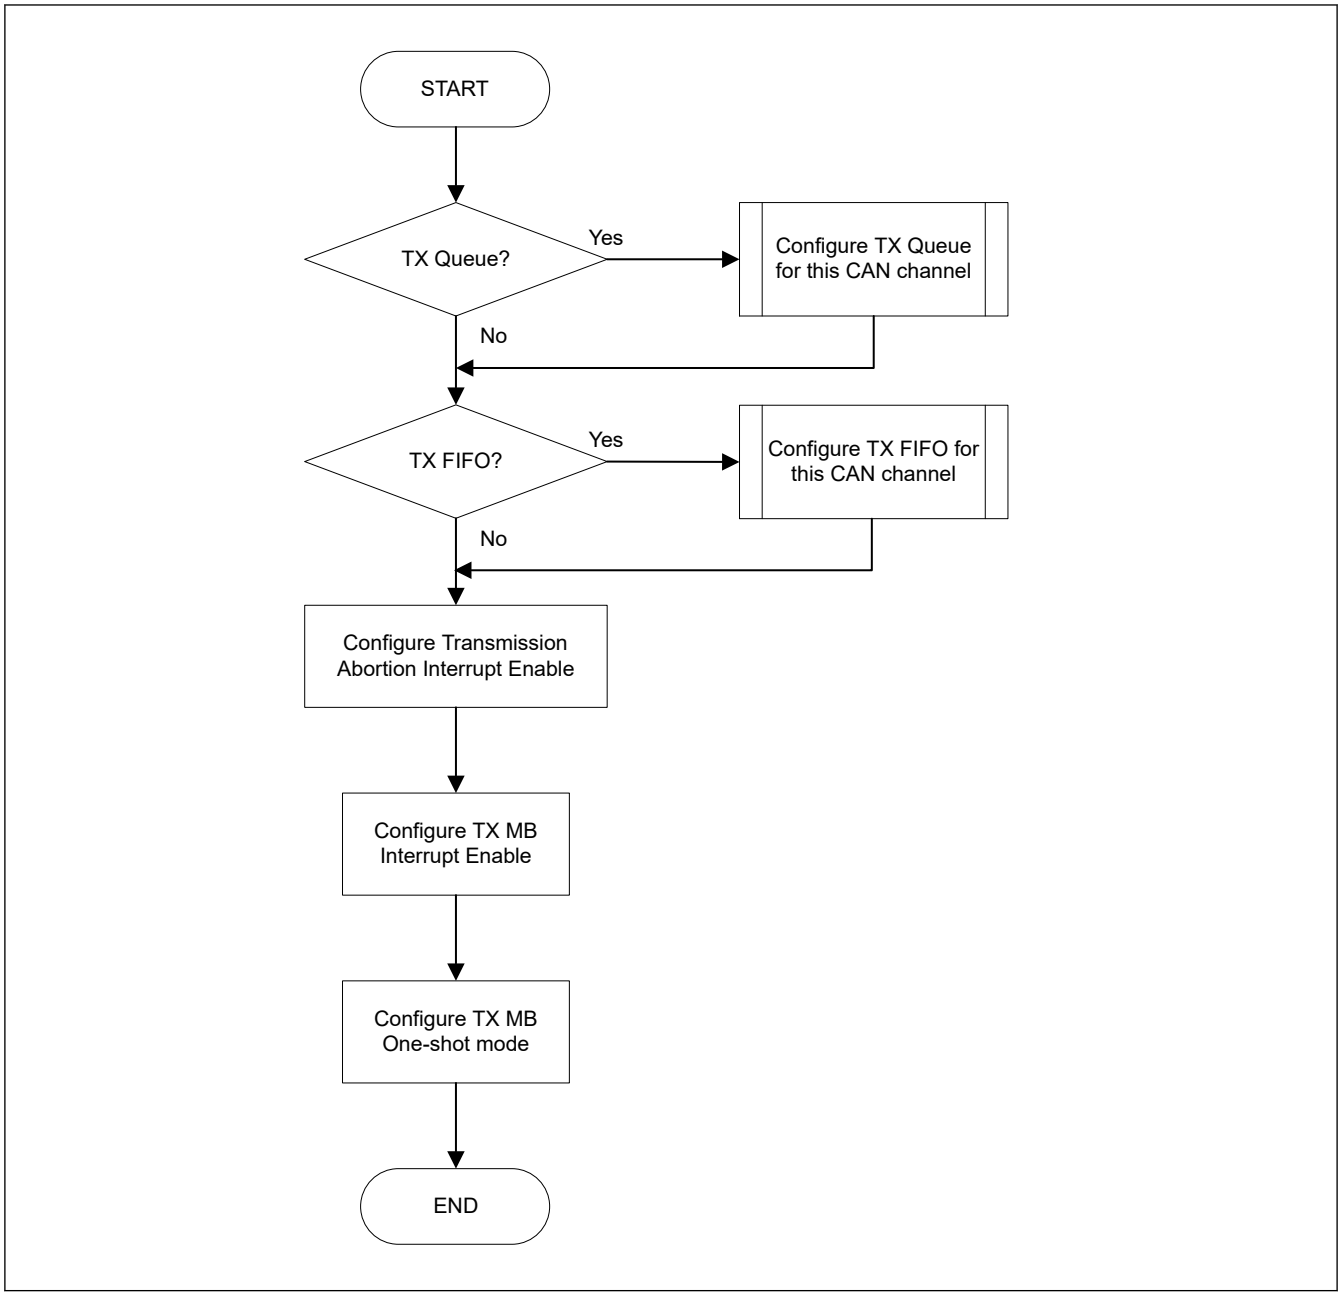

Figure 35.40 Transmission configuration flow

35.9.2.2 Normal Transmission

Each transmission message buffer has two modes of message transmission:

- Regular transmission mode
  If the message buffer is placed in regular transmission mode, the data frame or remote frame set in that message buffer can be transmitted.
  Completion of regular transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSn.TMTRF[1:0]) in the TX Message Buffer Status Registers. These bits are set to 10b or 11b when the regular transmission is successful.
  When arbitration is lost or an error occurs, message transmission will be attempted further if no transmission abort request is set for this transmission message buffer.
  New internal transmission arbitration for this channel is performed for all message buffers with transmission request.
- One-shot transmission mode
  When the CFDTMCn.TMOM bit of the TX Message Buffer Control Registers is set for a transmission message buffer, then the message buffer is placed in one-shot transmission mode and attempts to transmit a message only once.

Completion of one-shot transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSn.TMTRF[1:0]) in the TX Message Buffer Status Registers. The CFDTMSTSn.TMTRF[1:0] bits are set to 10b or 11b when the one-shot transmission is successful.
The CFDTMSTSn.TMTRF[1:0] bits are set to 01b when arbitration is lost or an error occurs during the transmission of the related message buffer.
Additional message transmission will not be attempted in this case.

The regular transmission request procedure after a configuration is shown in Figure 35.41.

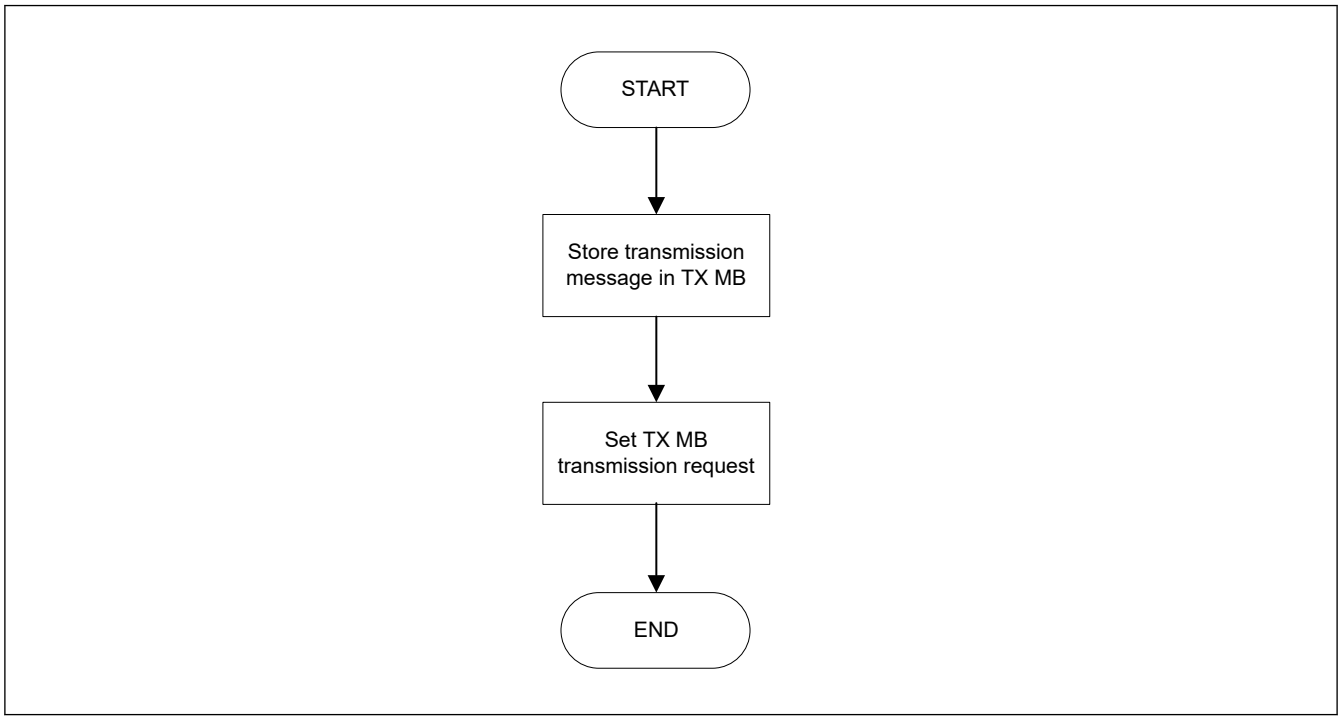

Figure 35.41 Transmission request procedure using normal TX message buffer mode

(1) TX Message Buffer Control Register Setting

Table 35.28 shows configuration of the normal CAN transmission mode.

Table 35.28 Configuration of CAN transmission mode

Transmission request CFDTMCn.TMTR	Transmission abortion request CFDTMCn.TMTAR	One Shot Enable CFDTMCn.TMOM	Communication activity
0	0	0	Message buffer is disabled
0	0	1	Message buffer is disabled
1	0	0	Configured as a transmission message buffer for a data frame or a remote frame
1	0	1	Configured as a one shot transmission message buffer for a data frame or a remote frame
1	1	0	Transmission abortion is requested
1	1	1	One shot transmission abortion is requested

The configuration bits can be configured in the TX Message Buffer Control Registers.

Figure 35.42 shows timings for successful transmission for two message buffers of one channel.

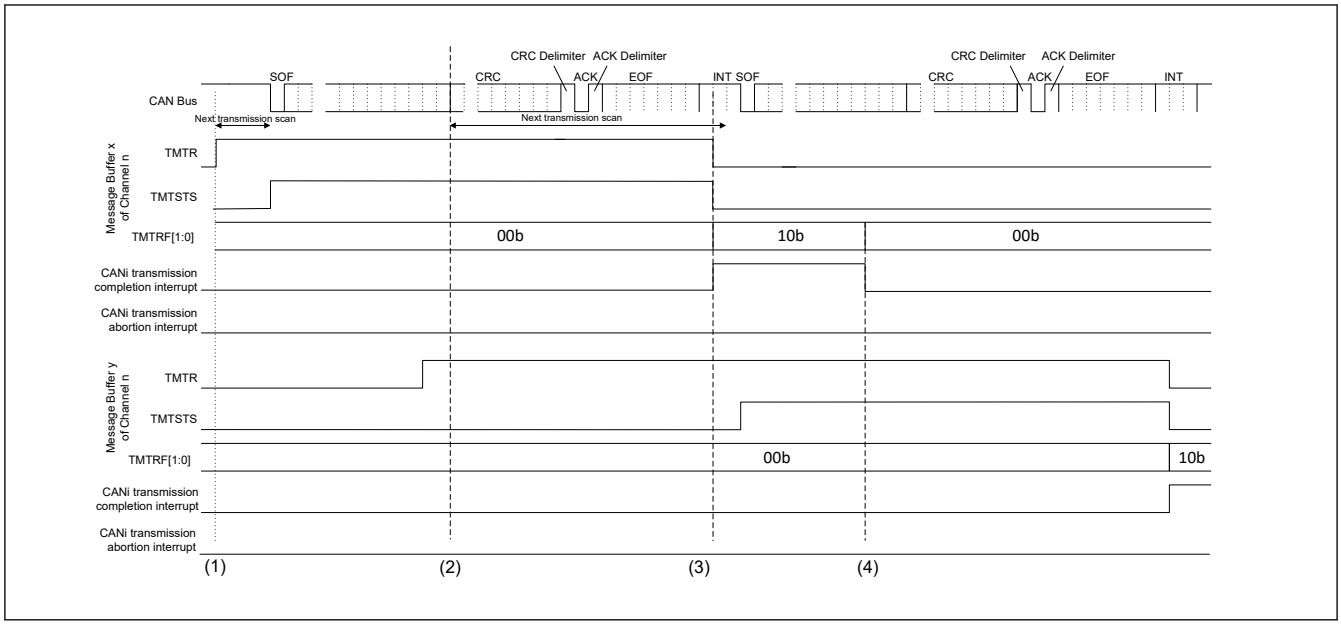

Figure 35.42 Timing of request and flag bits for successful transmission

1. If the CFDTMCn.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, message buffer scanning procedure starts to determine the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSn.TMTSTS bit in the related TX Message Buffer Status Registers is set (Transmitting/Transmitter), and CAN channel starts the transmission[*1].
2. On the first bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.
   The scan time can be delayed due to other transmission scan on other channels, but it will be finished before Intermission 3 to be able to continue transmission without any gaps.
3. If the message is successfully transmitted, the CFDTMSTSn.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 10b and CFDTMSTSn.TMTSTS and the CFDTMCn.TMTR bits are cleared.
   When the TMIE bits in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line the CFDTMSTSn.TMTRF flag bits must be cleared.
4. Before starting the next transmission, clear the CFDTMSTSn.TMTRF[1:0] bits. Load the next message in the transmission message buffer and set the CFDTMCn.TMTR bit again. CFDTMCn.TMTR bit cannot be set again before CFDTMSTSn.TMTRF[1:0] bits are cleared.

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs either during the transmission or following the loss of arbitration, then during Error Frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

Note: The setting point of CFDTMSTSn.TMTSTS is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID due to the synchronization logic implemented for the PLL bypass.

Figure 35.43 shows timings for transmission abort for two message buffers of one channel.

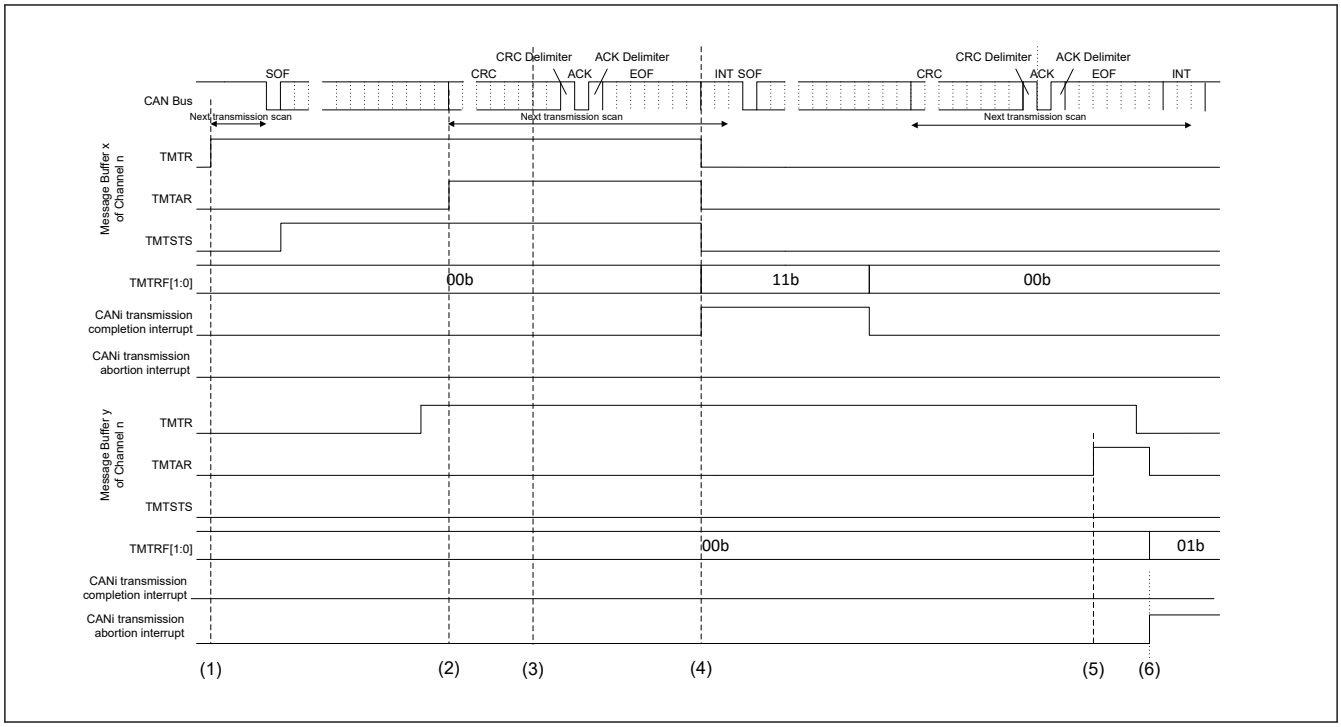

Figure 35.43 Timing of request and flag bits for transmission abort

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSn.TMTSTS bit is cleared.

1. If the CFDTMCn.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, message buffer scanning procedure starts to determine the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSn.TMTSTS bit in the TX Message Buffer Status Registers is set (Transmitting/Transmitter), and CAN channel starts the transmission[*1].
2. If the CFDTMCn.TMTAR bit is set when the related message buffer is already selected for transmission or currently transmitting, the message is not aborted, if no error occurs or arbitration is lost.
3. On the first CRC bit, the transmission scanning procedure starts for the next transmission. In this example timing diagram, message buffer y is not selected as the next transmission message buffer.
   The scan time can be delayed due to other transmission scan on other channels, but it will be finished before Intermission 3 to be able to continue transmission without any gaps.
4. If the message is successfully transmitted, the CFDTMSTSn.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 11b and CFDTMSTSn.TMTSTS and the CFDTMCn.TMTR bits are cleared.
   When the TMIE bits in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSn.TMTRF[1:0] bits.
5. Another CAN node is transmitting on the CAN bus (CFDTMSTSn.TMTSTS not set). If the CFDTMCn.TMTAR bit is set when the related channel is under transmission scan, the transmission request cannot be cleared.
6. After internal processing time, the transmission is aborted and the CFDTMSTSn.TMTRF[1:0] bits are set to 01b. If the message buffer is not transmitting or selected as the next transmission message buffer or under transmit scan, then the abort is immediately accepted and the corresponding CFDTMSTSn.TMTRF[1:0] bits in the TX Message Buffer Status Registers are set to 01b.
   In addition, CFDTMCn.TMTR, and CFDTMCn.TMTAR bits are cleared automatically.
   When the transmission abort interrupt enable TAIE bit of the related Channel Control Register is set, an interrupt is generated for successful transmission abort.
   To clear the related interrupt line, clear the CFDTMSTSn.TMTRF[1:0] bits.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSn.TMTSTS is cleared. The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit. If an error occurs, either during the transmission, or following the loss of arbitration, then during Error Frame, the transmission scanning procedure is performed again to search for the highest priority transmission Message Buffer.

35.9.2.3 TX FIFO or GW FIFO Transmission

Three common FIFO buffers are assigned to each channel. The three FIFO buffers can be linked to any normal TX Message Buffer position for this channel by the CFDCFCCn.CFTML[4:0] bits in the Common FIFO Configuration/Control Register if configured in TX or GW mode.

When the transmission scan starts and the FIFO buffer corresponding to this TX Message Buffer is enabled, the relevant message in the FIFO buffer participates in the transmission scan.

Configuration of a TX Message Buffer linked to a FIFO buffer configured in TX or GW mode should not be done.

(1) TX FIFO Operation

CAN messages can be written into the TX FIFO by writing to the corresponding FIFO Access registers.

When the value 0xFF is written into the corresponding FIFO Pointer Control Register, the message count of the related FIFO is incremented by 1.

Only write to the FIFO Pointer Control register after writing the complete message to the corresponding FIFO Access registers.

If the message count matches the FIFO Depth, the FIFO Full flag is set.

The oldest message in the TX FIFO is included in the scan for transmission by the corresponding CAN-FD module channel logic.

When a message is successfully transmitted from the TX FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the FIFO Empty flag is set.

The interrupt generation conditions for the TX FIFO buffers can be configured by configuring the CFDCFCCn.CFIM bit in the corresponding Common FIFO Configuration/Control Registers.

If CFDCFCCn.CFIM bit is 0, an interrupt is generated when the last message is successfully transmitted from the TX FIFO buffer.

If CFDCFCCn.CFIM bit is 1, an interrupt is generated for every successfully transmitted message from the TX FIFO buffer.

Common FIFO can set interrupt, when CAN frame transmitted is completed.

The Common FIFO buffers configured in TX mode can be disabled by clearing the CFDCFCCn.CFE bit in the Common FIFO Configuration/Control Registers. If this bit is cleared to 0, the FIFO Empty flag is set as follows:

- Immediately if the message from the TX FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX FIFO is already scheduled for transmission or already in transmission.

Note: The Common FIFO buffer is considered as disabled after clearing the CFDCFCCn.CFE bit only when the Empty flag is set for the corresponding Common FIFO Buffer.

Other possible messages pending from the TX FIFO are lost and their transmission must be requested again. Before CFDCFCCn.CFE is set again, ensure that CFDCFSTSn.CFEMP bit is set and that there is no pending abort from the TX FIFO.

When the CFDCFCCn.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after configuration is shown in Figure 35.44.

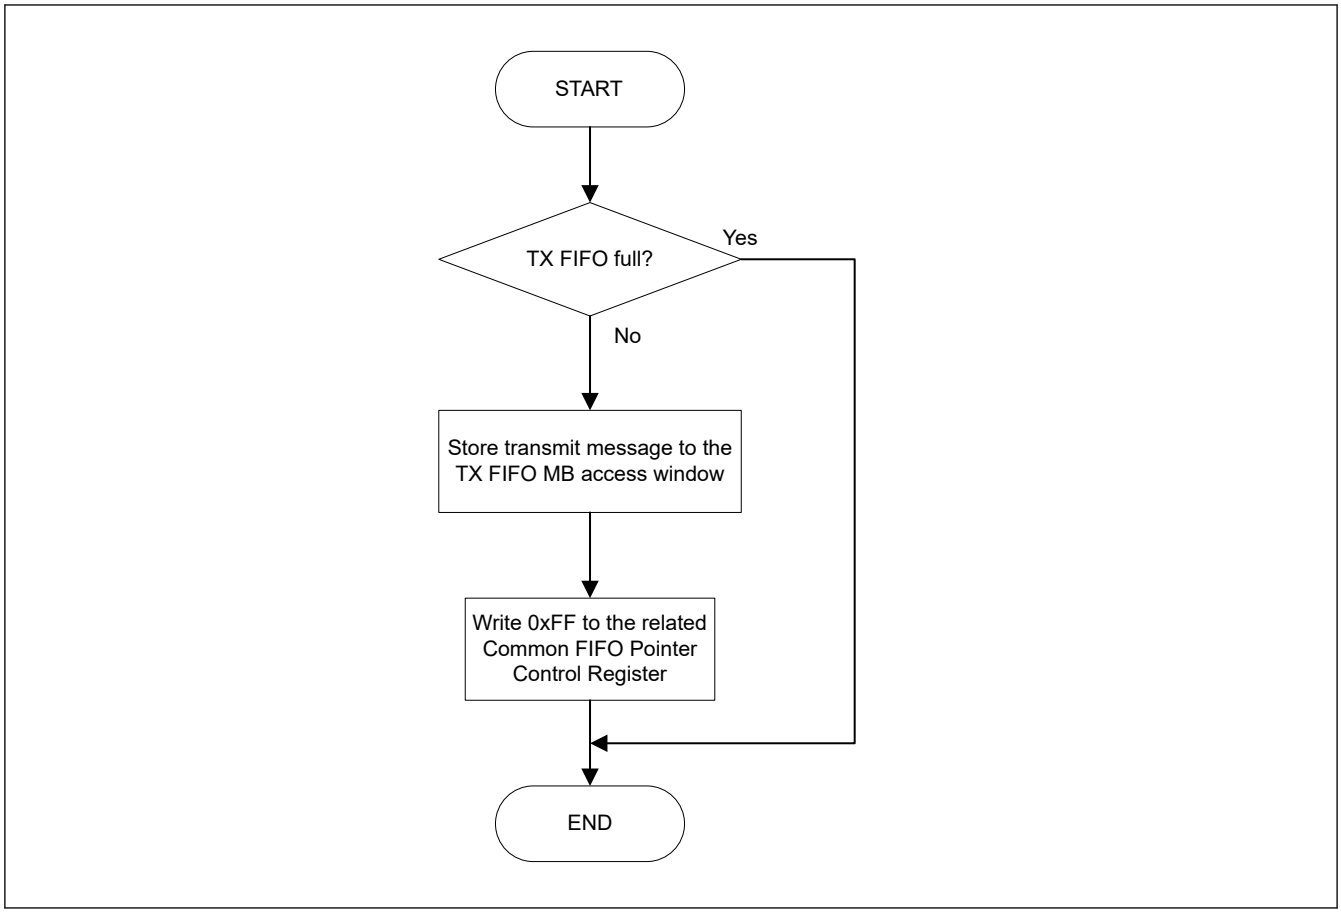

Figure 35.44 TX FIFO transmission request procedure

(2) GW FIFO Operation

The AFL entries for routing the received messages to GW FIFO buffers should be configured based on the requirements of the system. The matching AFL entry selects the GW FIFO buffer for storage of a received message on any of the CAN channels.

When a message is successfully received and stored in a GW FIFO buffer, the FIFO message count in the corresponding FIFO Status Register is incremented by 1.

If the message count matches the FIFO depth, then the FIFO Full flag is set.

The oldest message in the GW FIFO is included in the scan for transmission by the corresponding CAN-FD module channel logic.

When a message is successfully transmitted from the GW FIFO, the message count value is decremented by 1. When all the messages from the GW FIFO are transmitted, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded and CFDCFSTSn.CFMLT bit is set to 1.
- When CFDCFCCEn.CFMOWM = 1:
  When writing of data is required due to reception of a new message while a transmit/receive.
  FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message.
  The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message.

The CFDCFSTSn.CFMOW bit is then set to 1, which notifies that the oldest message is overwritten with the received message.
In addition, when a CAN bus error or arbitration-lost for the transmitting message occurs in transmit/receive FIFO buffer full, the transmitting message is lost and retransmission for the message is not performed. The read point moves to the next message automatically.

The interrupt generation conditions for the GW FIFO buffers can be configured by configuring the CFDCFCCn.CFIM bit in the corresponding Common FIFO Configuration/Control Registers.

If CFDCFCCn.CFIM bit is 0, then RX interrupt flag is set when FIFO counter increments and reaches value configured by CFDCFCCn.CFIGCV and the TX interrupt flag is set when FIFO transmits the last message successfully.

If CFDCFCCn.CFIM bit is 1, then RX interrupt flag is set at the end of storage of every received message and TX interrupt flag is set if a message is successfully transmitted from the FIFO.

Common FIFO can set interrupt when:

- CAN frame transmitted is completed
- CAN frame reception is completed
- FIFO is in full status in RX mode or GW mode

When CFDCFCCEn.CFBME = 1, it becomes FIFO buffering mode, send data is stored in Common FIFO, and transmission is stopped. Transmission will be started if it is set as CFDCFCCEn.CFBME = 0.

The Common FIFO buffers configured in GW mode can be disabled by clearing the CFDCFCCn.CFE bit in the Common FIFO Configuration/Control Register. If this bit is cleared, the GW FIFO becomes empty as follows:

- Immediately if the message from the GW FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the GW FIFO is already scheduled for transmission or already in transmission

Other possible messages pending from the GW FIFO are lost.

Before CFDCFCCn.CFE is set again, ensure that the CFDCFSTSn.CFEMP bit is set and that there is no pending abort from the GW FIFO.

When the CFDCFCCn.CFE bit is cleared and the CFDCFSTSn.CFEMP bit is set, the message read and write pointers of the GW FIFO are cleared and are no longer active. Therefore, all messages in the GW FIFO buffers are lost and no further message can be stored into the GW FIFO.

In applications intended to be used as CAN-to-CAN gateways, it is useful if the Error State Indication (ESI) information of the routing messages is not replaced by the sending node Error State Indication. For this, each channel has the control function register CFDCnFDCFG.ESIC to replace their own ESI information by the routing ESI information.

Note: If the sending node is error passive, the ESI bit is sent anyway as error passive (ESI = 1).

(3) Interval Timer for FIFO Transmission

For each Common FIFO in TX or GW mode, it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFDCFCCn.CFE bit is set.

When the Common FIFO in TX or GW mode is enabled, the first message is transmitted without considering this interval time.

The interval timer stops counting when:

- FIFO is disabled by clearing the CFDCFCCn.CFE bit
- CAN channel is in CH_RESET mode

The interval time is specified by the CFDCFCCn.CFITT value in the Common FIFO Configuration/Control Register and can be specified from 0 to 255 timer units.

The timer unit can be defined based on two different source clocks for the interval timer. To disable the interval timer for FIFO transmission, a value of 0 should be selected.

The timer source can be selected by the configuration bit CFITSS in the Common FIFO Configuration/Control Register. For the timer source the CAN bit timing clock of the FIFO related channel or a global reference clock can be selected.

If CAN channel bit time clock is configured as clock source and the CAN channel enters CH_HALT or CH_RESET or CH_SLEEP mode, the interval timer is stopped for that channel.

If peripheral clock is selected as interval timer clock source, then the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.

The reference clock can be used to configure the interval time in fixed time units. It is based on the peripheral clock. The reference clock prescaler value CFDGCFG.ITRCP in the Global Configuration Register defines the relation between the peripheral clock frequency/period and the reference clock period.

See Table 35.29 for CFDGCFG.ITRCP configuration values to achieve different reference clock periods based on the peripheral clock frequency/period.

Table 35.29 Configuration example for the FIFO interval timer reference clock

Peripheral clock (PCLKM)	Reference clock		
	1 µs	100 µs	500 µs
125 MHz / 8 ns	125	12500	62500

Additionally, the reference clock resolution can be specified by the interval timer reference clock resolution value CFDCFCCn.CFITR in the Common FIFO Configuration/Control Register.

The interval time is based on the reference clock period multiplied by the configured value (× 1 or × 10).

The reference clock based interval timer can be used to follow the requirements of the ISO 15765-2 Separation Time. The whole range for the separation time from 100 µs to 127 ms can be covered.

The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).

When the interval time has elapsed, the next transmission request is raised by the related TX/GW FIFO. Therefore, the interval time defines the minimum time between two messages transmitted from one FIFO.

The next message is sent at earliest after this interval time.

Figure 35.45 shows an example timing of the internal processing.

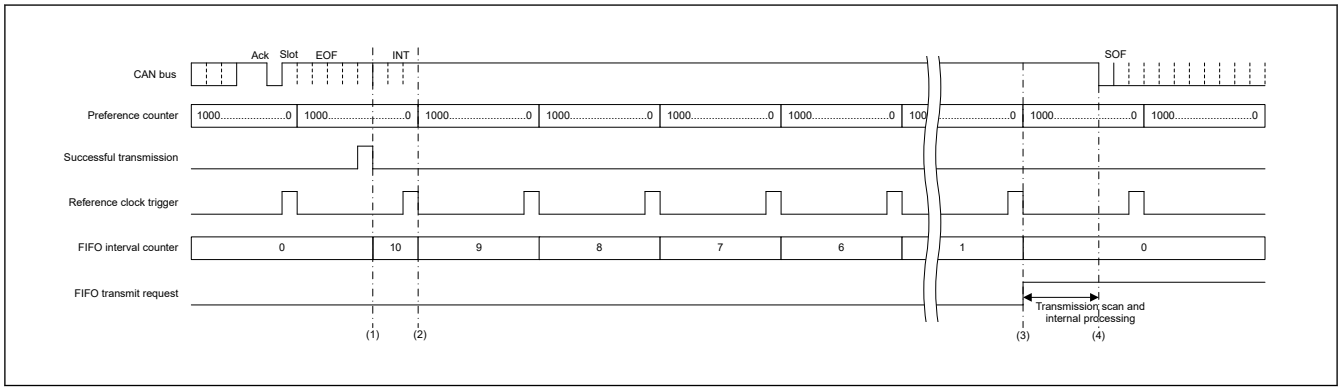

Figure 35.45 Example for interval processing time

The configuration for the above timing is as follows:

- Peripheral clock frequency = 125 MHz
- Interval timer reference clock (CFDGCFG.ITRCP) = 1250 times
- Reference clock due to the above settings = 10 µs
- Common FIFO interval timer source selection (CFDCFCCn.CFITSS) = 0
- Common FIFO interval timer resolution (CFDCFCCn.CFITR) = 0
- Common FIFO interval transmission time (CFDCFCCn.CFITT) = 10 times
- Theoretical message separation interval = 100 µs

1. Internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore, the first interval is counting less or equal to one reference clock interval.
2. With the next reference clock trigger, the FIFO interval timer is decremented.
3. When the FIFO interval timer reached the value 0 the FIFO transmit request is set.
4. When the FIFO is selected for transmission, the transmission starts. Due to internal processing this usually takes less than 3 CAN bit time, between internal FIFO transmit request set 3 and actual transmission.

In the worst case when multi events such as reception scan, internal message routing, transmit scan on all channels occur, then it can take up to 432 peripheral clock cycles.

As shown in Figure 35.45, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure CFDCFCCn.CFITT to the required minimum value + 1.

If additional TX message buffers or TX/GW FIFOs are configured for transmission for the same channel, the real delay between two messages transmitted from a TX FIFO can be much longer than specified by the interval time due to higher priority message transmission from these TX message buffers or TX/GW FIFOs.

Figure 35.46 shows a block diagram of the FIFO interval time generation circuit.

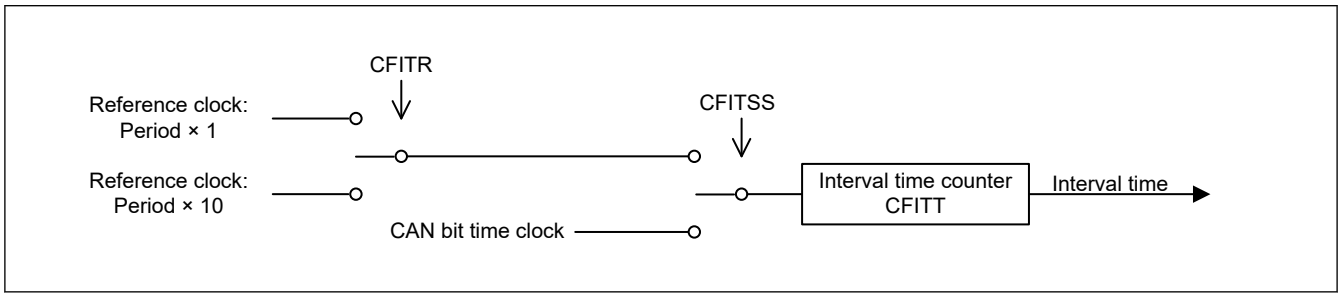

Figure 35.46 Block diagram of FIFO interval timer

35.9.2.4 TX Queue

Each enabled TX Queue for a specific channel consists of 3 to 32 TX message buffers, which are accessed by one access window. One channel has 4 TX Queues. One TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 0 as access window (referred to as TXQ0). The second TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 31 as access window (referred to as TXQ1). The third TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 32 as access window (referred to as TXQ2). The fourth TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 63 as access window (referred to as TXQ3).

All TXQ0, TXQ1, TXQ2, and TXQ3 messages enter the priority comparison for the transmission, which should be only ID Priority (CFDGCFG.TPRI = 0).

The registers for TXQ0 are CFDTXQCC0n, CFDTXQSTS0n, and CFDTXQPCTR0n.

The registers for TXQ1 are CFDTXQCC1n, CFDTXQSTS1n, and CFDTXQPCTR1n.

The registers for TXQ2 are CFDTXQCC2n, CFDTXQSTS2n, and CFDTXQPCTR2n.

The registers for TXQ3 are CFDTXQCC3n, CFDTXQSTS3n, and CFDTXQPCTR3n.

When access window TX Message Buffer No.63 (TXQ3) or TX Message Buffer No.32 (TXQ2) or TX Message Buffer No.31 (TXQ1) or TX Message Buffer No.0 (TXQ0) is used, refer to the related access registers TX Message Buffer ID Registers (CFDTMIDn), TX Message Buffer Pointer Registers (CFDTMPTRn), TX Message Buffer Data Field 0 Registers (CFDTMDF0_n), and TX Message Buffer Data Field 1 Registers (CFDTMDF1_n).

The depth of each TXQ0 buffer can be configured by writing to the CFDTXQCC0n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ0 can set from TXMB0 to TXMB31 as a queue buffer at the maximum.

The 31 available options for depth configuration are:

- 0x00: TX Queue disabled

- 0x01: Reserved
- 0x02: 3 messages
- ⋮
- 0x1D: 30 messages
- 0x1E: 31 messages
- 0x1F: 32 messages

The depth of each TXQ1 buffer can be configured by writing to the CFDTXQCC1n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ1 can set from TXMB31 to TXMB0 as a queue buffer at the maximum.

The 31 available options for depth configuration are:

- 0x00: TX Queue disabled
- 0x01: Reserved
- 0x02: 3 messages
- ⋮
- 0x1D: 30 messages
- 0x1E: 31 messages
- 0x1F: 32 messages

The depth of each TXQ2 buffer can be configured by writing to the CFDTXQCC2n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ2 can set from TXMB32 to TXMB63 as a queue buffer at the maximum.

The 31 available options for depth configuration are:

- 0x00: TX Queue disabled
- 0x01: Reserved
- 0x02: 3 messages
- ⋮
- 0x1D: 30 messages
- 0x1E: 31 messages
- 0x1F: 32 messages

The depth of each TXQ3 buffer can be configured by writing to the CFDTXQCC3n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ3 can set from TXMB63 to TXMB32 as a queue buffer at the maximum.

The 31 available options for depth configuration are:

- 0x00: TX Queue disabled
- 0x01: Reserved
- 0x02: 3 messages
- ⋮
- 0x1D: 30 messages
- 0x1E: 31 messages
- 0x1F: 32 messages

When using TXQ1 and TXQ0 simultaneously, the depth of TXQ is 32 or less in total.

When using TXQ3 and TXQ2 simultaneously, the depth of TXQ is 32 or less in total.

Do not access all the TX message buffers forming the TX Queue directly (except TX Message Buffer No. 63, TX Message Buffer No. 32, TX Message Buffer No. 31 and TX Message Buffer No. 0, which acts as TX Queue access window).

When CFDGAFLP0n.GAFLSRD i (i = 0 to 2) is set and the CFDTXQCCin.TXQGWE (i = 0 to 2, n = 0, 1) is also set, a receiving frame is stored in the target TXQ as send data by routing.

When CFDTXQCCn.TXQOWE bit is 1, the TX Queue is in TX Queue overwrite mode. If the message of the same ID is stored in TX Queue when a frame is received and it is stored in TX Queue, an old message is overwritten by a new message. Therefore, an old message is not transmitted. When the old message of the same ID is transmitting and a CAN bus error and an arbitration-lost occur, the message of old ID is not resent.

When using the function in GW mode and TX Queue overwrite mode, the depth of TXQ (CFDTXQCC0n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3. If it accesses by routing in gateway mode when a TXQ buffer is full, CFDTXQSTS.TXQMLT is set and send data is thrown away.

The function is valid for the standard ID frame and is invalid for the extended ID frame.

Explanation of operation of the TX Queue with same ID over-writing function in GW mode is shown in Figure 35.47.

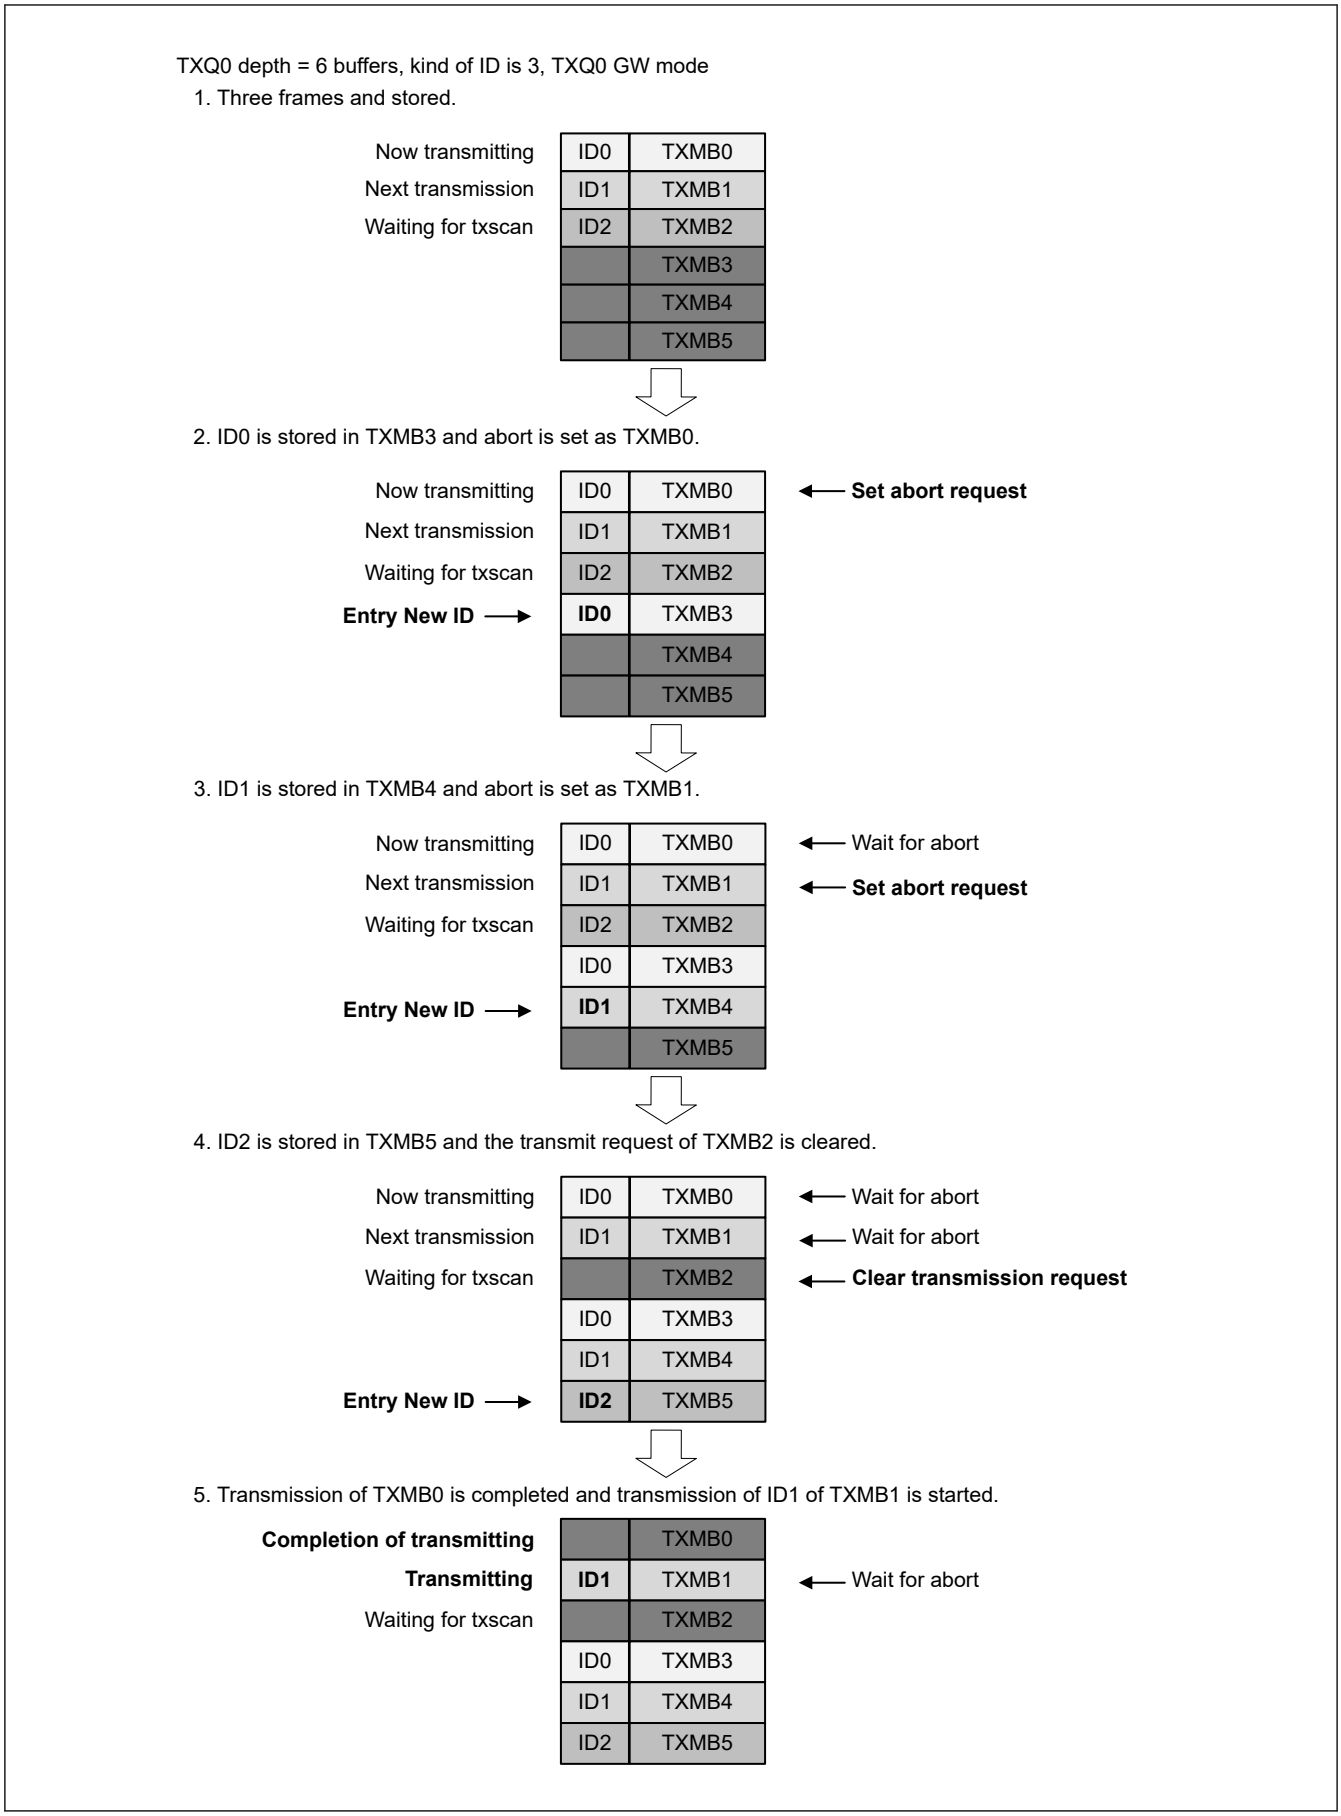

Figure 35.47 Operation of TXQ0 in Gateway mode

When a system writes in TXQ, a system should write in send data, after checking the state of TXQ.

Do not access or configure the related TX Message Buffer Control Registers.

The messages stored to the TX Queue access window are internally stored to a free buffer of the TX Queue.

When the buffer is full then no further access should be done to the queue, until it is no longer full. If it accesses by software writing in when the buffer of TXQ is full, send data is overwritten.

The TX Queue can be disabled by clearing the TXQE bit in the TX Queue Configuration/Control Register. If this bit is cleared, the TX Queue Empty flag is set as follows:

- Immediately if the message from the TX Queue is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX Queue is already scheduled for transmission or already in transmission.

Note: The TX Queue is disabled only when the Empty flag is set after clearing the TXQE bit for the corresponding TX Queue.

Other possible messages pending from the TX Queue are lost and their transmission must be requested again.

Before TXQE is set again, ensure that the CFDTXQSTSn.TXQEMP bit is set and that there is no pending abort from the TX Queue.

When the TXQE bit is cleared, all messages in the TX Queue buffers are lost and no further message should be stored into the TX Queue.

When a message has been stored to the TX Queue, 0xFF must be written into the TX Queue Pointer Control Register. This sets the transmit request automatically and changes the internal message buffer pointer to the next free message buffer location of the TX Queue.

Note: If two messages with the same identifier are stored in the TX Queue, then the order of transmission of these messages can be different from the order in which they were stored in the TX Queue.

To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same identifier is stored in the TX Queue. Or if TX queue overwrite mode is used, the frame of the same ID is rewritten on a new frame.

For the TX Queue a dedicated interrupt can be enabled by setting the TXQIE bit of the TX Queue Configuration/Control Register.

The interrupt mode can be configured with the CFDTXQCCn.TXQIM bit of the same register either to generate an interrupt for every transmitted message or for the last transmitted message.

The TX Queue transmission request procedure after configuration is shown in Figure 35.48.

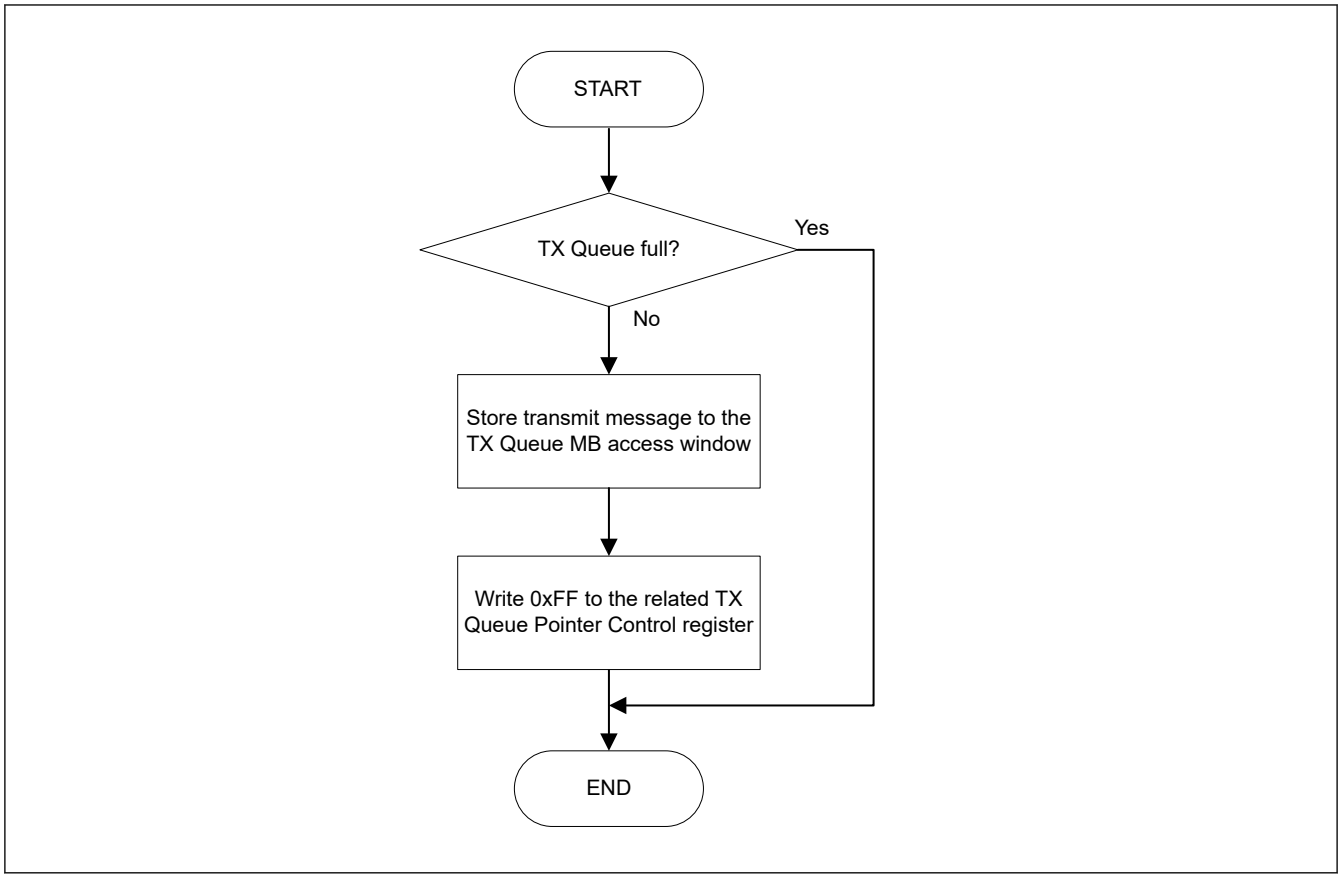

Figure 35.48 TX Queue transmission request

TXQ name	Access window	Range width	Direction	Hardware routing access point	CPU access point	DMA access point	Note
TXQ0	TXMB0	0, 3-32	TXMB0 → TXMB31	Yes	Yes	Yes	When using both TXQ0/1, the total number of stages is 32 or less
TXQ1	TXMB31	0, 3-32	TXMB31 → TXMB0	Yes	Yes	No	
TXQ2	TXMB32	0, 3-32	TXMB32 → TXMB63	Yes	Yes	No	When using both TXQ2/3, the total number of stages is 32 or less
TXQ3	TXMB63	0, 3-32	TXMB63 → TXMB32	No	Yes	Yes	

TXQ0 can use hardware routing, CPU access, and DMA access.

Hardware routing access, CPU access, and DMA access should not be used simultaneously. Choose one access method.

35.9.2.5 TX History List

The TX History List function records the information of the successfully transmitted message in the TX History List buffers for each CAN channel. Two TX History List buffers are provided for each CAN channel and each TX History List buffer can store up to 16 TX History List entries for a CAN channel.

The CFDTHLCCn.THLDTE bit of the TX History List Configuration/Control Register can be used to configure if only message information from TX FIFOs/TX Queue is stored or if all transmit message information from TX Queue, TX FIFO or normal TX message buffers should be stored in the TX History List for a CAN channel.

When a CFDTHLCCn.THLDGE bit is set up, the information on all the frames transmitted in GW mode is stored in TX History List.

Each transmit message can be individually configured for acceptance to the TX History List by the CFDCFID.THLEN bit in the Message Buffer Pointer Register.

The message information is stored to the TX History List Buffer of a CAN channel after the message is successfully transmitted on that CAN channel.

Storing to the List is not synchronized with the status of CFDTMSTSn.TMTRF[1:0] bits in the TX Message Buffer Status Register.

Due to internal processing, the storage to the List can happen with a delay after the successful transmission indication.

Storing the TX History List data can be recognized by the condition that the THLIF bit is set to 1 when the THLIE is configured to 1 or when the TX History List counter CFDTHLSTSn.THLMC[5:0] is increased.

The delay time is dependent on the number of channels due to internal processing.

- Maximum delay time from setting the CFDTMSTSn.TMTRF to storing the TX History List data is 224 peripheral bus clock cycles.

The History list records the following information of the transmitted message:

- Buffer type:
  - 001b: TX Message Buffer
  - 010b: TX FIFO
  - 100b: TX Queue
- Buffer number:
  TX Message Buffer, TX Queue Message Buffer or TX Message Buffer Link for the Common FIFO Buffer from which the transmission occurred. The number depends on the buffer type, see Table 35.30.
- Transmission ID:
  Transmission pointer stored in the transmission message
- Transmit timestamp:
  Message timestamp captured at the capture point as configured by CFDGFDCFG.TSCCFG.
- Transmission information label:
  Transmission information label stored in the transmission message.
- Transmit gateway buffer indication:
  For data transmitted from the gateway, CFDTHLACC0n.TGW bit is set to 1.

Table 35.30 TX History List buffer number entry

CFDTHLACC0n.BT[2:0] buffer type		
001b	**101b**	**100b**
TX Message Buffer	**TX FIFO**	**TX Queue**
TXMB0	Number shown corresponds to the common FIFO. TX Message Buffer Link CFTML of the related Common FIFO Configuration	Number shown corresponds to the message buffer belonging to the TX Queue for which the frame was transmitted.
TXMB1		
TXMB2		
TXMB3

TXMB30		
TXMB31		
TXMB32		
TXMB33		
TXMB34		
⋮		
TXMB61		
TXMB62		
TXMB63		

The Transmission ID entry is used to identify which message of a TX FIFO or TX Queue has been successfully transmitted because the TX FIFO or TX Queue number alone is not sufficient.

Therefore, a unique number can be attached to each transmission message stored in a TX FIFO or TX Queue. This unique identification number should be written to the CFDCFFDCSTSn.CFPTR[15:0] part of the Common FIFO Access Pointer Register for a TX FIFO or to the CFDTMFDCTRn.TMPTR[15:0] part of the TX Message Buffer Pointer Register of the TX Queue access window message buffer.

When the message is successfully transmitted, the identification number is then stored together with the other message related information to the TX History List and can be read with the Transmission ID (TID) of the TX History List Access Register.

Also for normal TX message buffers, the CFDTMFDCTRn.TMPTR[15:0] part of the TX Message Buffer Pointer Register is stored in the Transmission History List. Information label is the same.

Figure 35.49 shows a transmission preparation flow when TX History List is used.

Read access to the TX History List Access Register is done for every single entry.

After reading one entry, 0xFF must be written to the corresponding TX History List Pointer Control Register to be able to access the next entry until TX History List is empty.

Figure 35.50 shows an example flow for processing the TX History List information.

The TX History Lists have dedicated interrupts, which can be configured with the CFDTHLCCn.THLIM bit of the corresponding TX History List Configuration/Control Registers and enabled with the CFDTHLCCn.THLIE bit of the same registers, either to generate an interrupt when the history list reached a filling level of 75% or for every new TX History List entry.

An entry lost indication is flagged by the CFDTHLSTSn.THLELT bit in the TX History List Status Register.

Status of this bit is also shown by the THLES bit in the Global Error Flag Register.

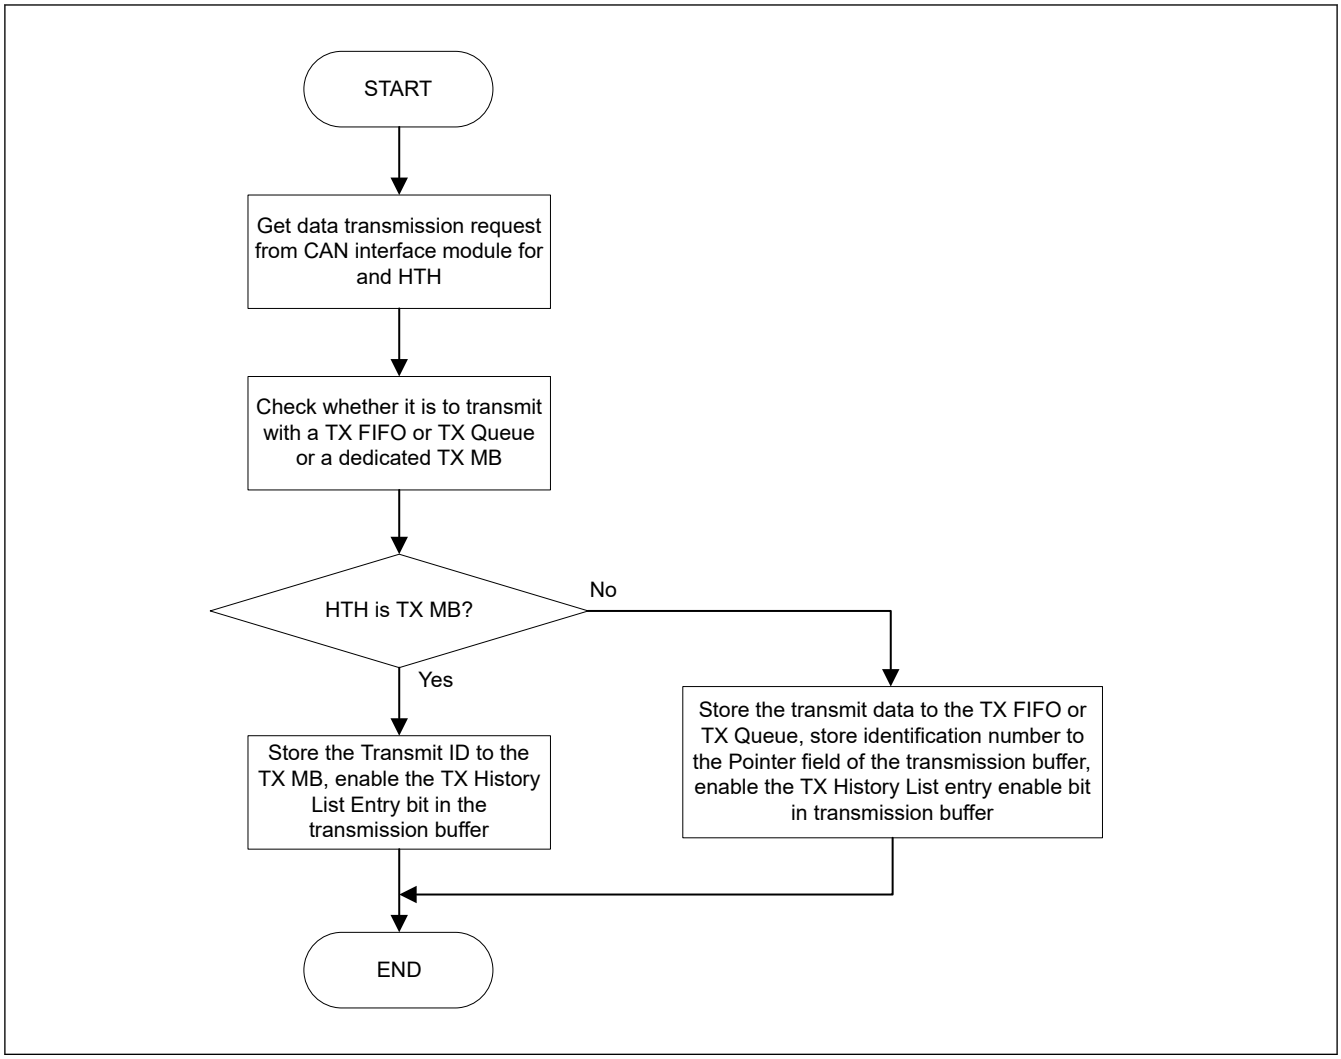

Figure 35.49 Transmission preparation flow when TX History List is used

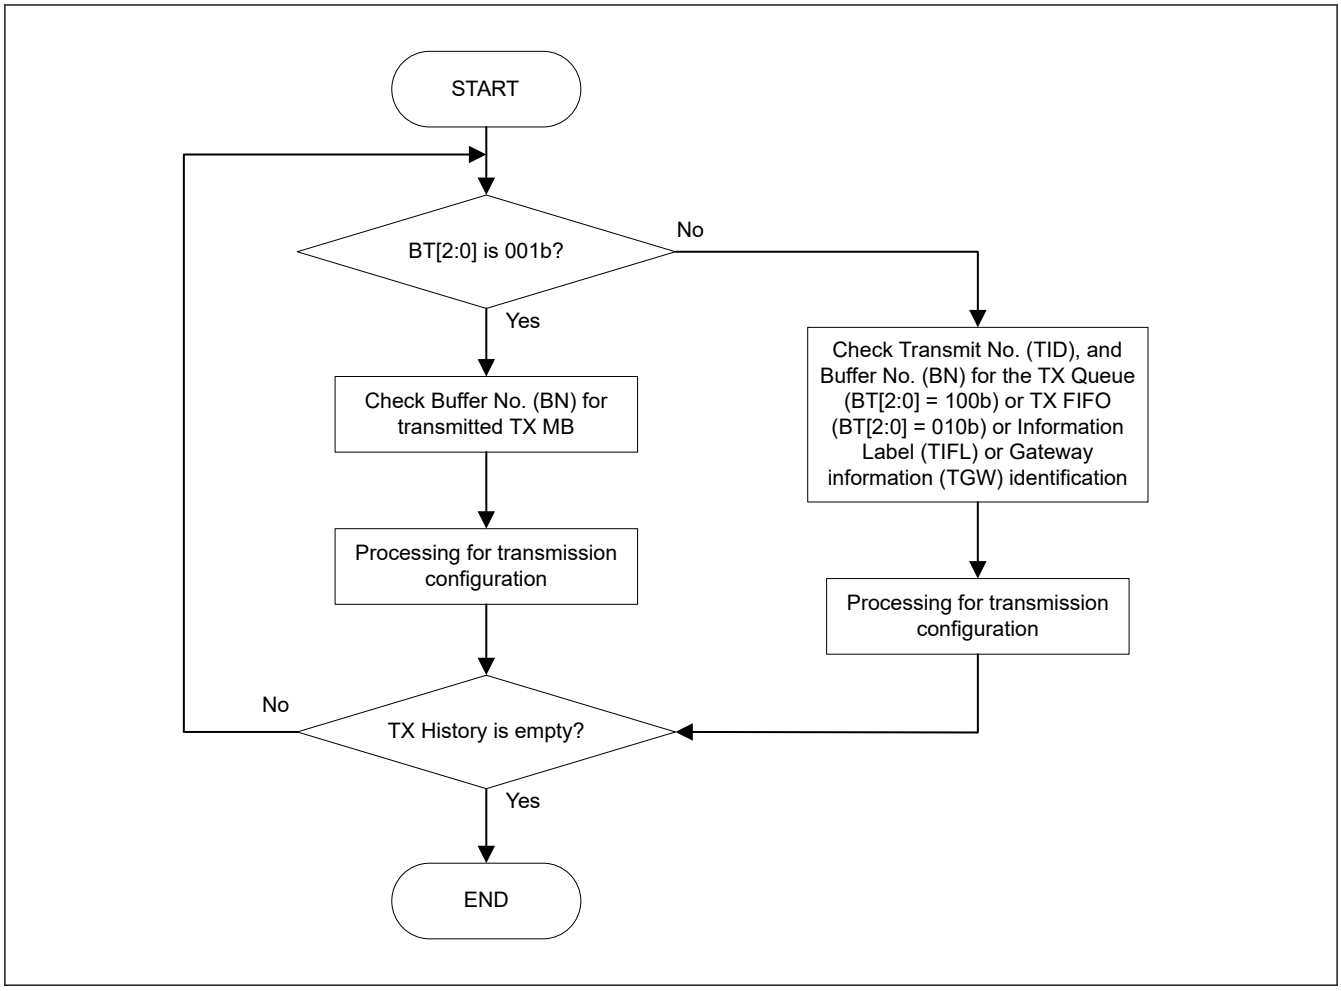

Figure 35.50 Example flow for processing TX History List information

35.9.2.6 TX Data Padding

If the data length code (DLC) of the transmitting message has a higher number of data bytes than the buffer size, then the data bytes beyond the restricted range are replaced by bytes with the value of CC HEX.

This can happen for Common FIFOs configured as (TX or GW) when the transmit message DLC is higher than CFDCFCCn.CFPLS.

This can also happen in FD-only mode, if a Classical Frame is configured with a DLC larger than 8.

35.10 Test Mode

The CAN-FD module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CAN-FD module in test modes.

All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combinations of the various test modes specified in this section.

The test modes can be broadly split into 2 groups:

- Channel specific test modes
- Global test modes

35.10.1 Channel Specific Test Modes

Each CAN channel can be configured into the following test modes:

- Basic test mode

- Listen-only mode
- Self-test mode 0 (External Loop Back mode)
- Self-test mode 1 (Internal Loop Back mode)
- Restricted operation mode

35.10.1.1 Basic Test Mode

The Basic test mode should be used when a particular test setting must be enabled other than when in Listen-Only and Self-test modes.

35.10.1.2 Listen-Only Mode

The ISO 11898-1 recommends an optional Bus-monitoring mode. In this mode, the CAN channel is able to receive valid data frames and valid remote frames. However, it sends only recessive bits on the CAN bus and is not allowed to transmit.

If the CAN engine is required to send a dominant bit (ACK bit, Overload flag, Active Error flag), the bit is routed internally so that the CAN engine monitors this as dominant. The external TX pin remains in recessive state.

This mode can be used for baud rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.

In this mode, it is not permitted to request transmission from any normal TX Message Buffer or TX-/GW-FIFO of this channel.

Note: If a message is stored in GW FIFO or Routing TXQ, ensure that the transmitting channel is not in Listen-only mode so that transmission is not requested for this channel from the GW FIFO or Routing TXQ.

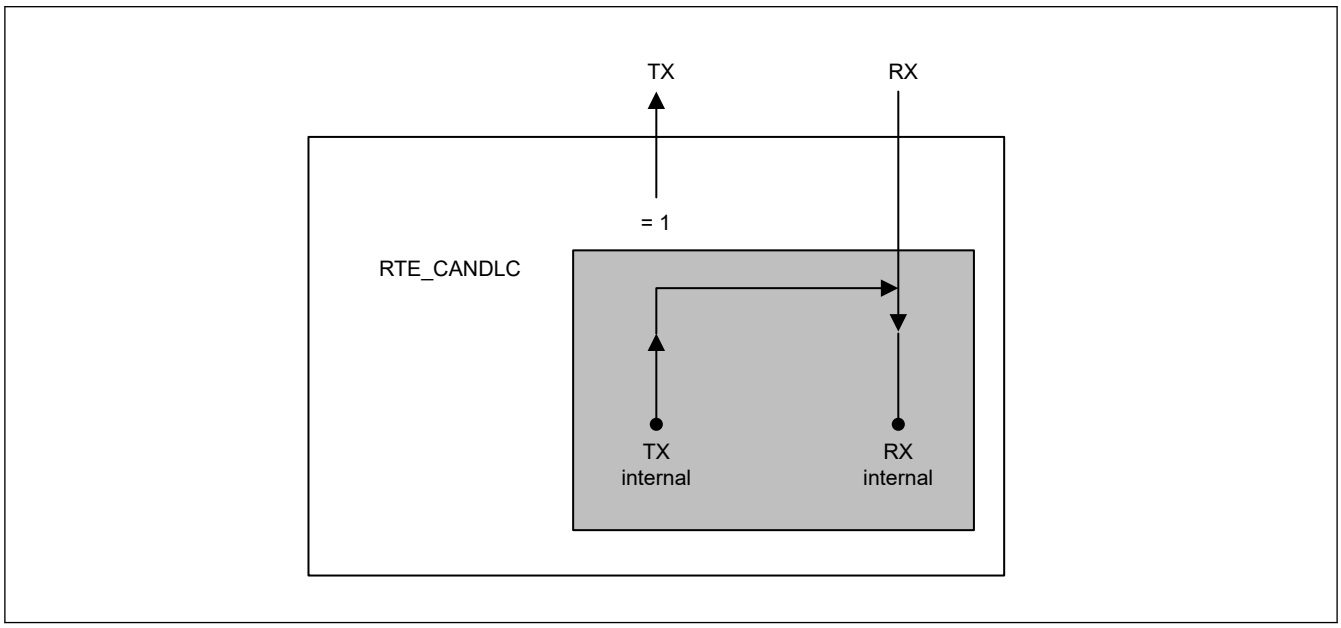

Figure 35.51 Listen-only mode

35.10.1.3 Self-Test Mode 0 (External Loop Back Mode)

In Self-test mode 0, the CAN engine treats its own transmitted messages as received messages through the CAN transceiver and can store them into its receive message buffers.

To be independent from external stimulation, the engine generates its own Acknowledge bit.

This test can be used for CAN transceiver tests.

The RX/TX pins should be connected to the transceiver.

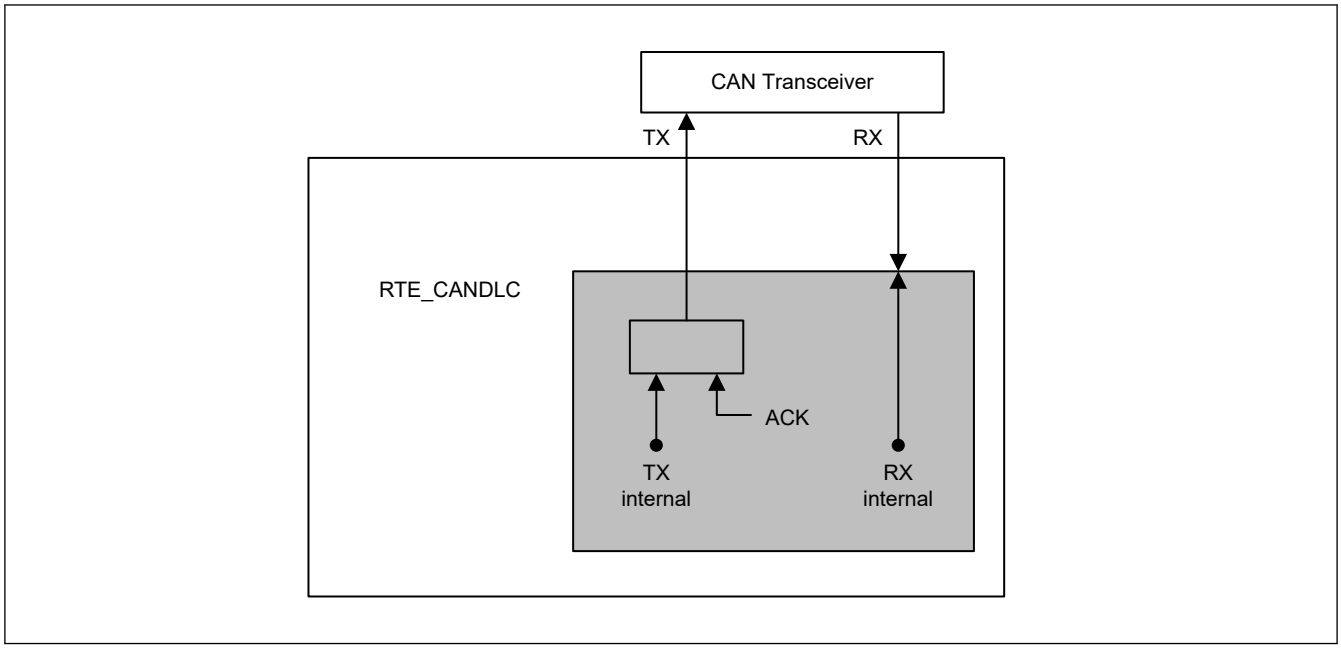

Figure 35.52 Self-test mode 0 (External Loop Back mode)

35.10.1.4 Self-Test Mode 1 (Internal Loop Back Mode)

In Self-test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent from external stimulation, the CAN engine generates its own Acknowledge bit. In this mode the CAN engine performs an internal feedback from TX internal to RX internal. The actual value of the external RX input is disregarded by the CAN engine.

The external TX pin outputs only recessive bits.

The RX/TX pins do not need to be connected to the CAN bus or any external device.

Note: The channel pins are also disconnected from the internal CAN bus communication line.

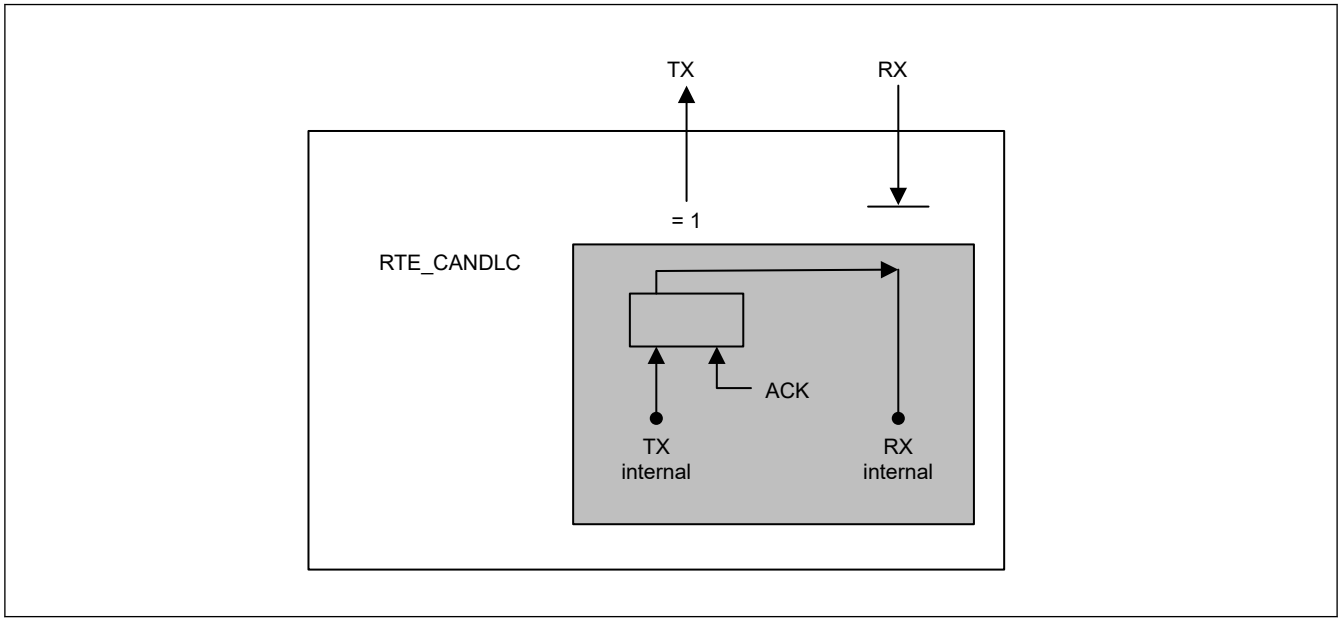

Figure 35.53 Self-test mode 1 (Internal Loop Back mode)

35.10.1.5 Restricted Operation Mode

In Restricted operation mode, the CAN node is able to receive valid data and remote frames that generates the Acknowledge bit.

Active error and overload frames cannot be transmitted, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.

Additionally, the Receive and Transmit Error Counter (REC and TEC) are frozen independently from the occurrence of errors.

The mode is specified as in ISO 11898-1. However, it is permitted to set any requested transmit.

35.10.2 Global Test Modes

The CAN-FD module can be configured into the following test modes:

- RAM test mode
- Internal CAN bus communication mode
- CRC error test

These test modes are protected by a special software procedure to enable the mode. This software procedure enables write access to the test mode by a specific unlock key, the related unlock key can be seen in the following table.

Test mode	Unlock key 1	Unlock key 2
RAM test mode	0x7575	0x8A8A

If the software sequence of the two consecutive unlock key write accesses (half-word or word accesses) is interrupted by any other write access to the SFR or if incorrect data is written to the Global Unlock Key Register then the corresponding test mode cannot be set and the sequence must be restarted.

After the two unlock key write accesses, the next write access should be to set the corresponding Test Mode Enable bit. If this is not followed, the unlock mechanism resets and the Test Mode Enable bit cannot be set. At this time, the unlock sequence must be restarted.

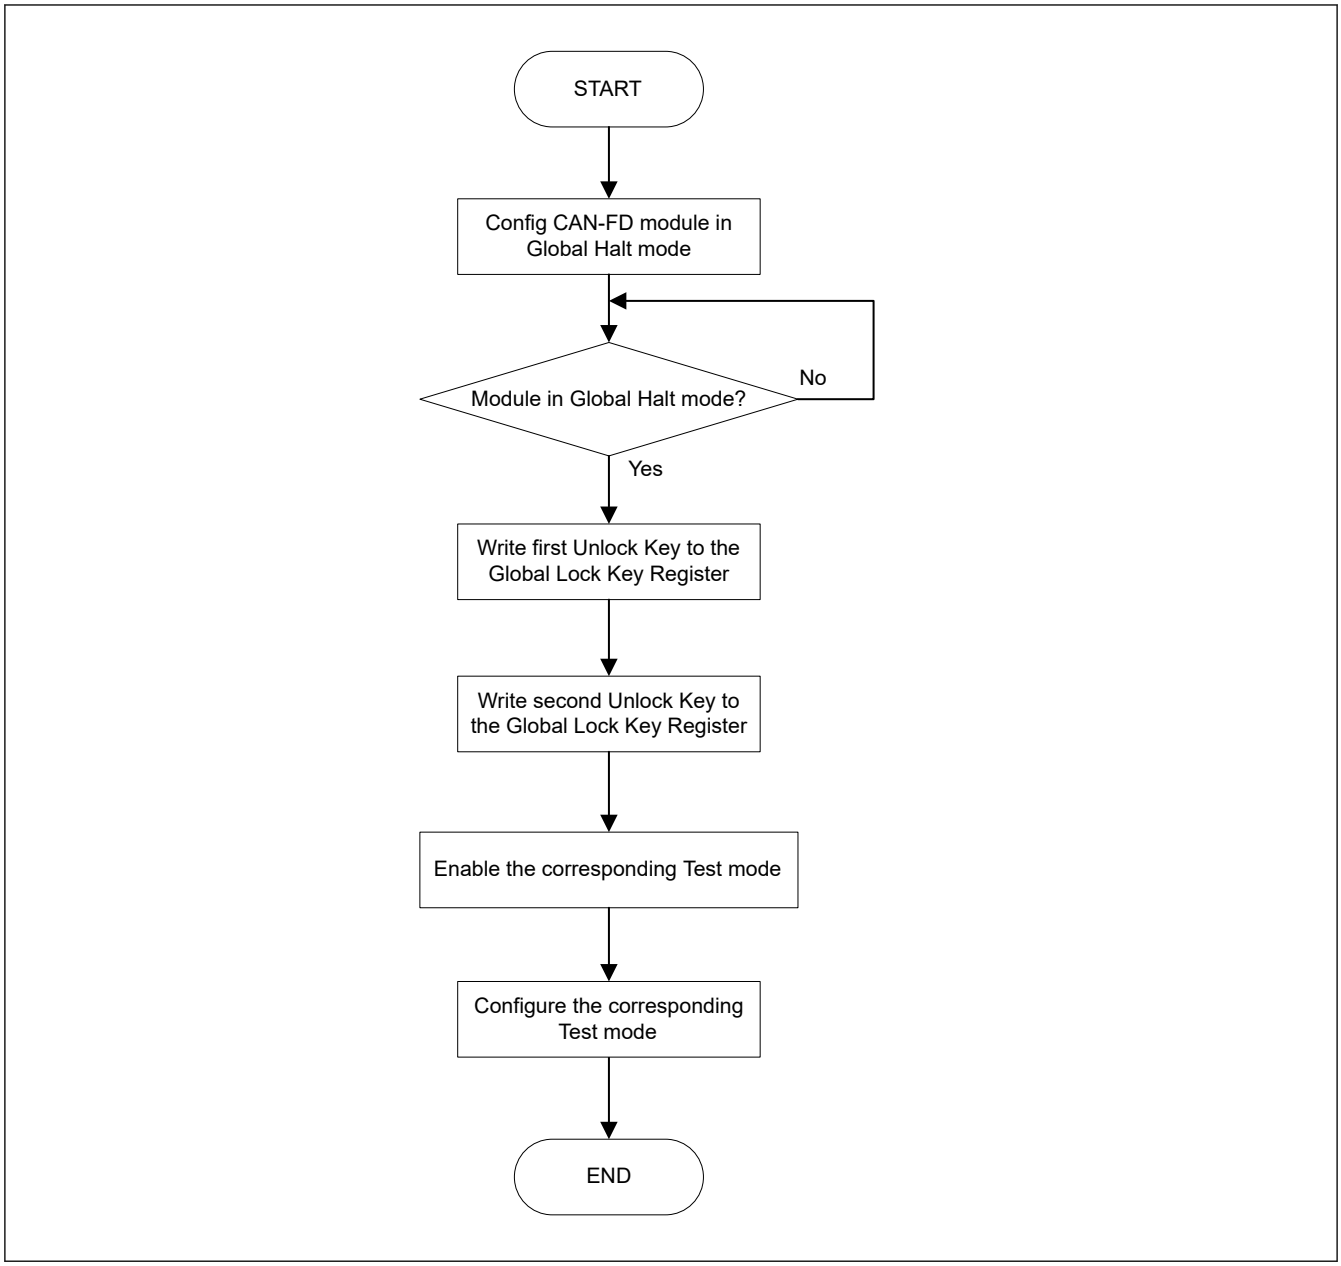

Figure 35.54 Unlock software protection routine

35.10.2.1 RAM Test Mode

The CAN-FD module can be configured in RAM test mode by setting the CFDGTSTCTR.RTME bit in the Global Test Control Register when the corresponding lock key is previously written. This is a special test mode, in which, the complete RAM area can be accessed.

In this mode, the RAM area is split into number of pages (pn) of 256 bytes each. Which can be accessed with the CFDRPGACCn register.

The page should be selected for read/write access by writing to the CFDGTSTCFG.RTMPS[9:0] bits in the Global Test Control Register. Data can then be read from or written into the RAM Test Page Access Registers.

Figure 35.55 shows the structure of the pages in the RAM when performing a RAM test mode.

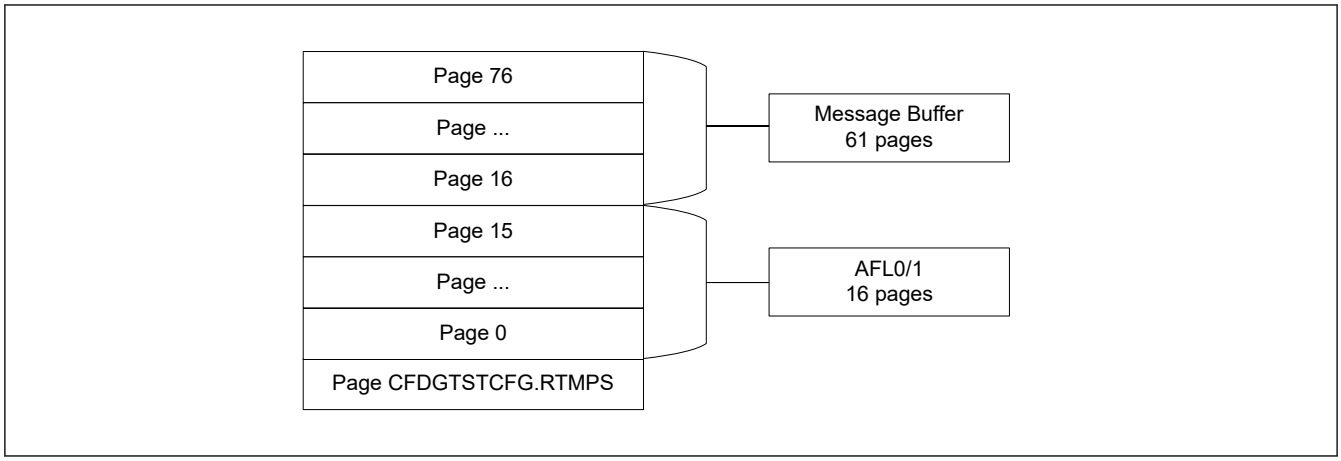

Figure 35.55 RAM page structure

The total available RAM size for a 2-CAN channel version is 4096 bytes for the AFL RAM and 15424 bytes for the Message Buffer RAM.

AFL RAM0/1 can treat RAM test mode as one RAM.

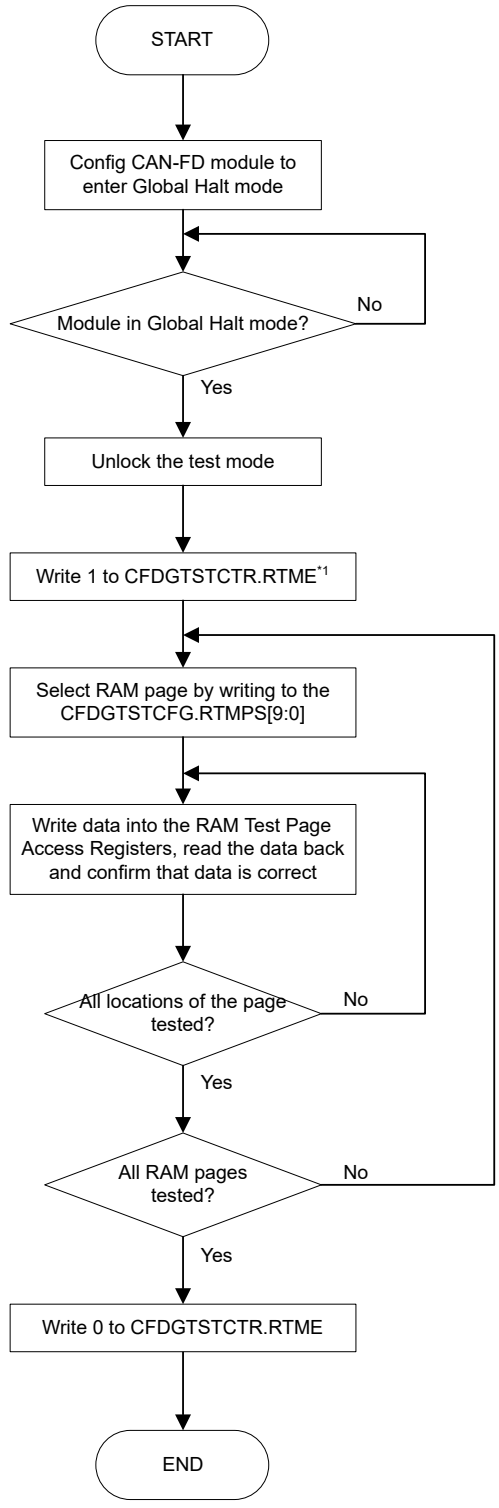
The number of pages (pn) and CFDGTSTCFG.RTMPS[9:0] values for the AFL and MB RAMs are calculated in the following way:

pn = ceil (total RAM size in bytes / number of bytes per page)

- AFL RAM:
  pn = ceil (4096 / 256) = 16 pages
  CFDGTSTCFG.RTMPS[9:0] = 0 to 15 (0x00F) inclusive
- MB RAM:
  pn = ceil (15424 / 256) = 61 pages
  CFDGTSTCFG.RTMPS[9:0] = 16 to 76 (0x04C) inclusive

Do not access more than 64 bytes of RAM on the last page (RTMPS[9:0] = 0x04C).

Figure 35.56 shows the software flow for RAM test mode.



Note 1: Change into the following status before changing to RAMTEST.

- Cancel of a request of transmission
- Disable of all the FIFO and TXQ
- Clear of the receiving flag of a receiving buffer

Figure 35.56 Software flow of RAM test mode

To exit this test mode, clear the CFDGTSTCTR.RTME bit. The CFDGTSTCTR.RTME bit is cleared by writing 0 to it.

The CFDGTSTCTR.RTME bit is cleared automatically when the CAN-FD module enters Global Reset mode from the test mode.

35.10.2.2 Internal CAN Bus Communication Mode

The CAN-FD module can be configured in Internal CAN bus communication test mode by setting the CFDGTSTCTR.ICBCTME bit in the Global Test Control Register. This is a special test mode, in which the CAN channels can be connected together internally to generate a CAN cluster within the CAN-FD module.

Only use the following sequence to enter Internal CAN bus communication test mode:

1. Configure all channels in Halt mode and check that all channels have entered Global Halt mode.
2. Write data into the Global Test Configuration Register to select the channels participating in the Internal CAN bus communication test.
3. Set the CFDGTSTCTR.ICBCTME bit of the Global Test Control Register.
4. Check that CFDGTSTCTR.ICBCTME bit is set in the Global Test Control Register.

In this mode, the TXD outputs of the channels participating (configured) in Internal CAN bus communication mode are connected together using AND gate. The output of the AND gate is connected to the RXD inputs of all participating channels to create a CAN cluster within the CAN-FD module. The channels are isolated from the external CAN bus while the CAN-FD module is in this test mode.

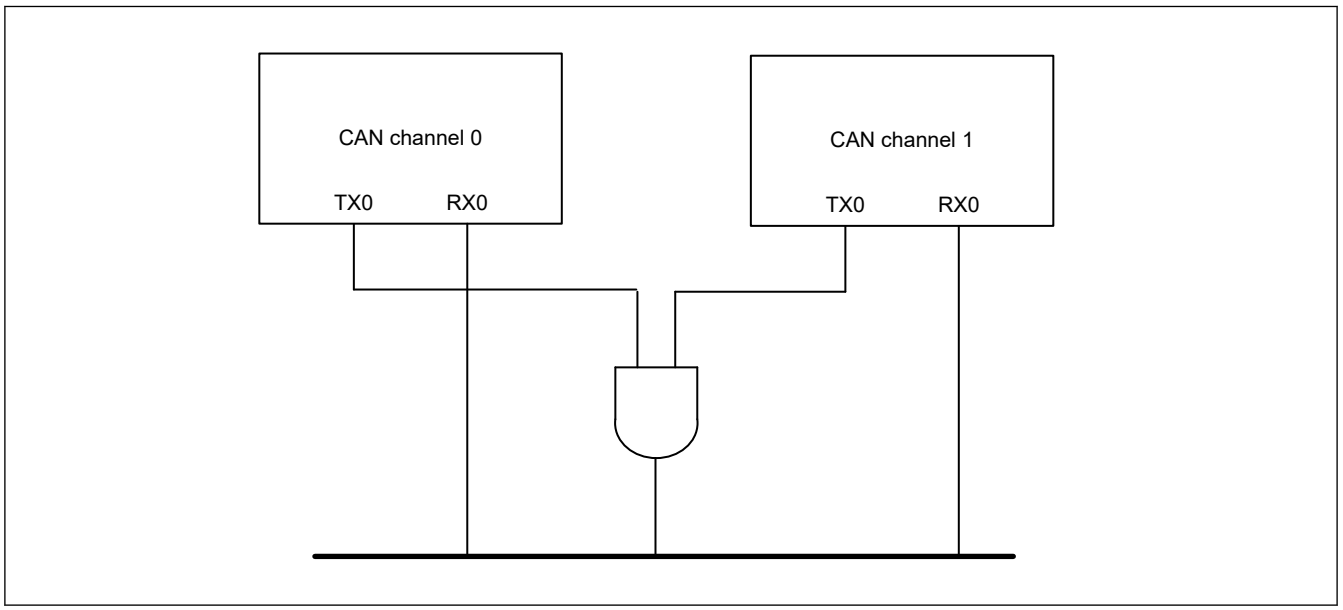


Figure 35.57 Internal CAN bus connections

The AFL, Flat RX message buffers, FIFO buffers, Flat TX message buffers, and various registers can now be configured as normal to start communication between channels.

The channels not participating in Internal CAN bus should only be configured in Halt mode.

35.10.2.3 CRC Error Test

After the CAN-FD module has been configured in Internal CAN bus communication test mode, use the following sequence to perform CRC error testing. In the following sequence, channel x is the reference transmitter CAN-FD module and channel y is the receiver CAN-FD module where (x, y = [0,…, n] and $x \neq y$):

1. Configure channel x node to transmit one reference message.
2. Set the CFDCyCTR.CRCT bit to 1, in order to invert the first bit of the incoming bit stream from channel x.
3. Set the CFDTMCx.TMTR.
4. Read either CFDCyERFL.CRCREG or CFDCyFDCRC.CRCREG (depending on the received frame type: Classical or FD). The value should be different from the received CRC value of the reference message from channel x.

5. Check that CFDCyERFL.CERR is 1.

As the CRC generator logic is shared for RX and TX there is no need to create a separate TX CRC error test.

35.11 Bus Traffic Measurement

The idle time of the CAN bus can be measured using PCLKM or PCLKCAN. Bus traffic can be calculated based on the measurement results.

35.11.1 How to count the CAN Bus Idle Time

Figure 35.58 shows the concept of measuring the idle time of the CAN bus.

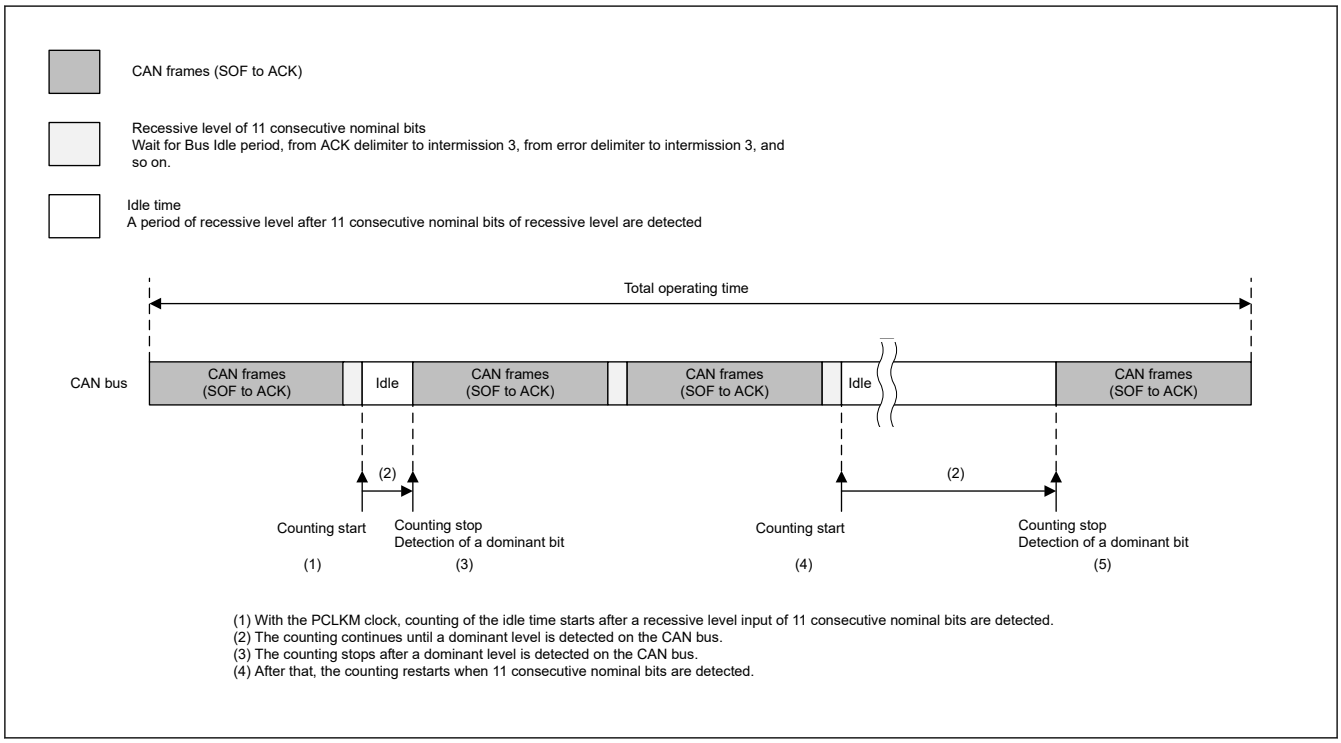

Figure 35.58 How to measure idle time of the CAN bus

35.11.2 Operations and Measurement Procedure

The following procedure is for measuring the idle time of the CAN bus.

1. The channel to be measured transits to operation mode.
2. Write 1 to CFDCnBLCT.BLCE bit to set the measuring counter to operating mode.
3. Write 1 to CFDCnBLCT.BLCLD bit to clear the counter register.
4. Detect a recessive level input of 11 consecutive nominal bits.
5. Start counting the bus idle time.
6. Detect a dominant level.
7. The counting stops.
8. Detect a recessive level input of 11 consecutive nominal bits.
9. The counting starts.
10. Write 1 to CFDCnBLCT.BLCLD bit to clear the counter register and simultaneously load the counter value to CFDCnBLSTS.
11. Read the value of CFDCnBLSTS.

To stop the measurement counter, write 0 to CFDCnBLCT.BLCE bit.

To initialize the counter, write 1 to CFDCnBLCT.BLCLD bit.

This measurement is enabled when the channel to be measured is in Operation mode.

When the relevant channels are in reset mode, the counter does not operate.

Also, accurate measurements are not available in test mode.

Write 1 to CFDCnBLCT.BLCLD bit to clear the counter register and simultaneously load the value of the counter to CFDCnBLSTS.

The lower 3 bits of CFDCnBLSTS are fixed to 0.

Based on the values of the counter, software can calculate the CAN bus traffic according to the following formulas:

$$\frac{(\text{Total operating time} - \text{Total idle time})}{\text{Total operating time}} = \frac{\text{Bus operating time}}{\text{Total operating time}} = \text{Bus usage ratio}$$

- Total idle time: a value read from CFDCnBLSTS × a clock cycle of PCLKM
- Total operating time: a setting interval of CFDCnBLCT.BLCLD bit

Example: Below is a calculation example under the following conditions:

- Conditions: nominal bit rate = 1 Mbps
- PCLKCAN clock = 40 MHz (= 25 ns)
- A setting interval of CFDCnBLCT.BLCLD bit = cycle of 1 ms
- A read value of CFDCnBLSTS register = 0x4E20

$$\frac{(\text{Total operating time} - \text{Total idle time})}{\text{Total operating time}} = \frac{(1000000\ \text{ns} - 20000 \times 25\ \text{ns})}{1000000\ \text{ns}} = 50\%$$

35.12 Flexible CAN Mode

This is a mode in which it is possible to connect the CAN modules of 2 channels to a single CAN driver.

The pair of Channel in flexible CAN mode is as follows:

When CFDGFCMC.FLXC0 bit is set, Channel 0 and Channel 1 of a CAN-FD module are Flexible CAN mode.

The Channel 1 uses TX/RX terminal of Channel 0, and the TX/RX terminal of Channel 1 cannot use.

In Flexible CAN mode, each channel performs communication processing independently. However, when one of the channels transmits, the other channel will not return an acknowledge bit.

Note: When operating in Flexible CAN mode, the error counters (TEC/REC) of the two CAN nodes are not synchronized with each other.

Flexible transmission buffer assignment configured in CFDGFTBAC register and Flexible CAN mode configured in CFDGFCMC register should not be used simultaneously.

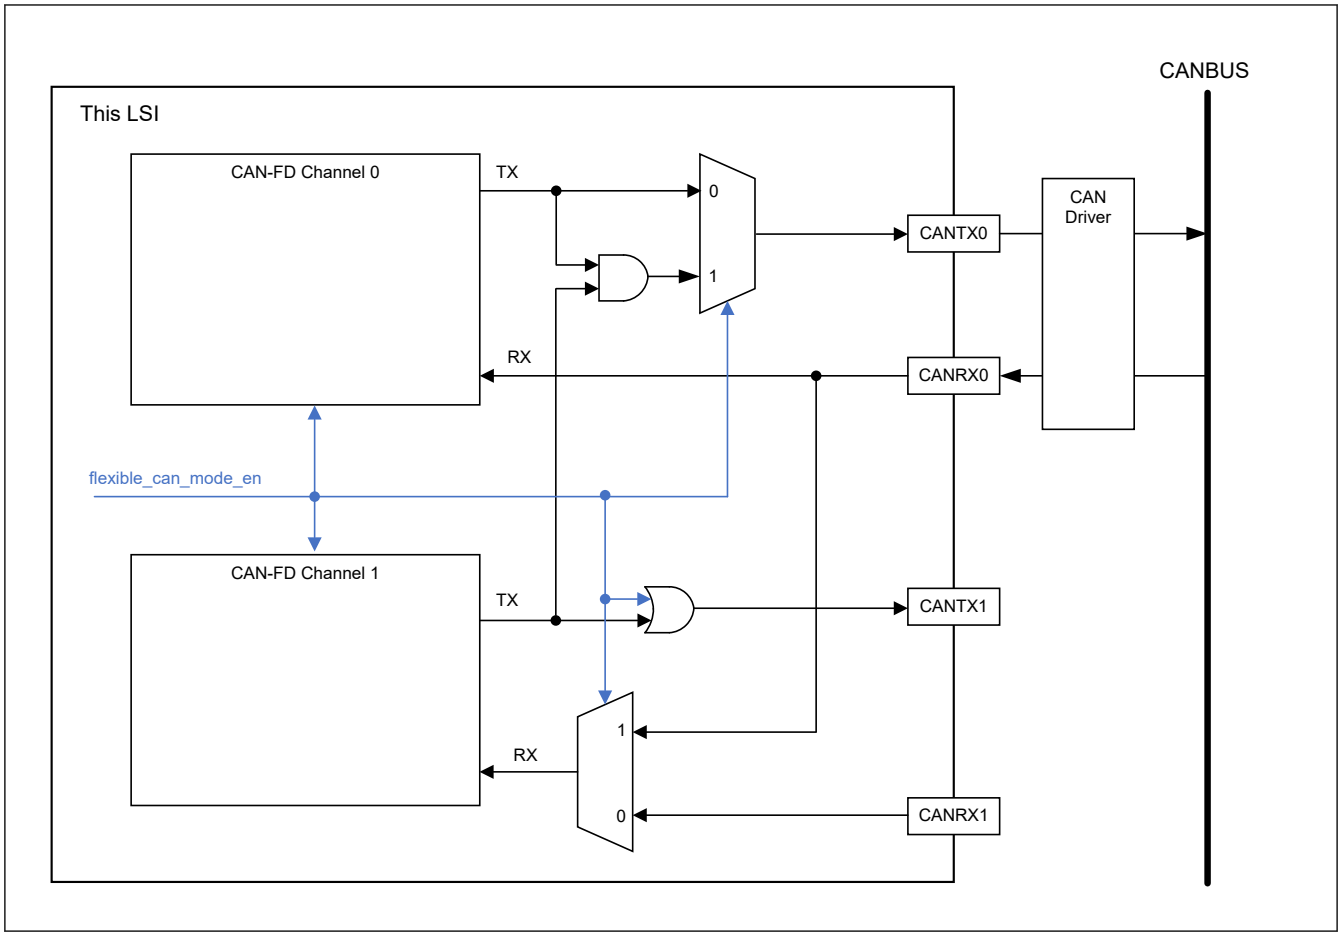

Figure 35.59 Diagram of the Flexible CAN

35.13 Flexible Transmission Buffer Assignment

Each Channel has 64 transmit buffers by exclusive use.

In order to correspond to an insufficient case by a TXMB, this Channel can rent a maximum of 32 TXBMs from the next Channel.

The buffer which can be rented becomes every four units by 4 to 32 buffers.

When CFDGFTBAC.FLXMB0 bit is set, flexible transmission buffer assignment is performed between Channel 0 and Channel 1.

Flexible transmission buffer assignment configured in CFDGFTBAC register and Flexible CAN mode configured in CFDGFCMC register should not be used simultaneously.

Interrupt of the rented buffer is output to interrupt of the rented channel.

When using TXQ by the rented buffer, TXQ should only set within the rented range.

The TXMB lent out operates in the mode of the channel to be used. For example, when the channel 1 is in a reset mode, using rented TXMB and transmission of the channel 0 is possible. Moreover, the rented TXMB is affected by the transmitting status, TX SCAN PROCESS, or transmitting abortion of the rented channel.

In the case of message buffer number priority mode, the priority of TXMB0 is high and the priority of TXMB95 (case which rented 32 buffers) becomes low. Priority of rented TXMB becomes low.

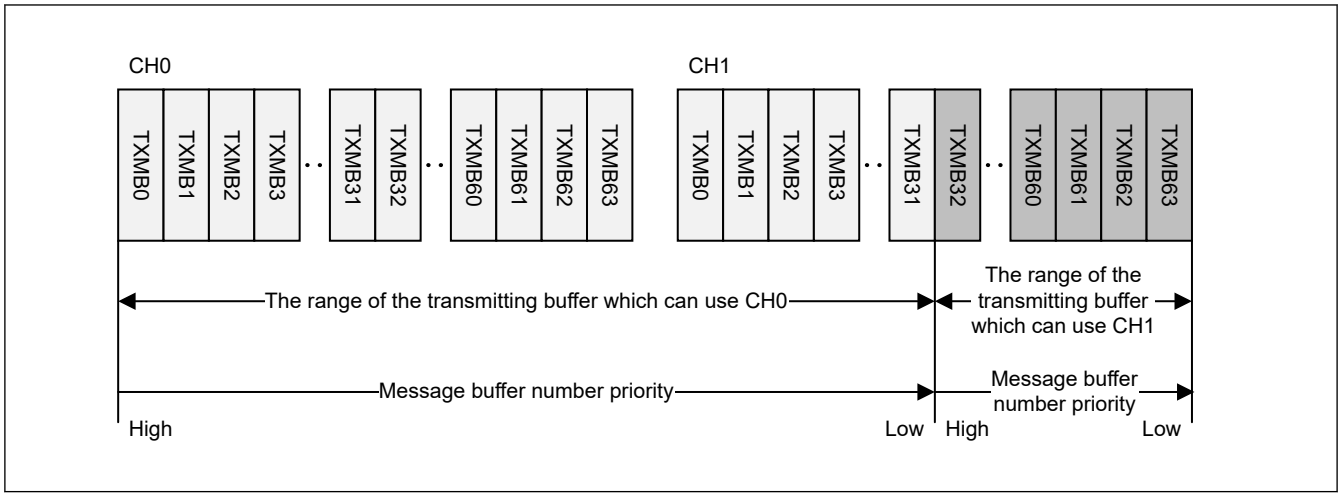

Figure 35.60 The priority of message buffer number priority mode (Example of CH0: 96 buffers, CH1: 32 buffers)

The example of a rental between channel 0 and channel 1 is shown below.

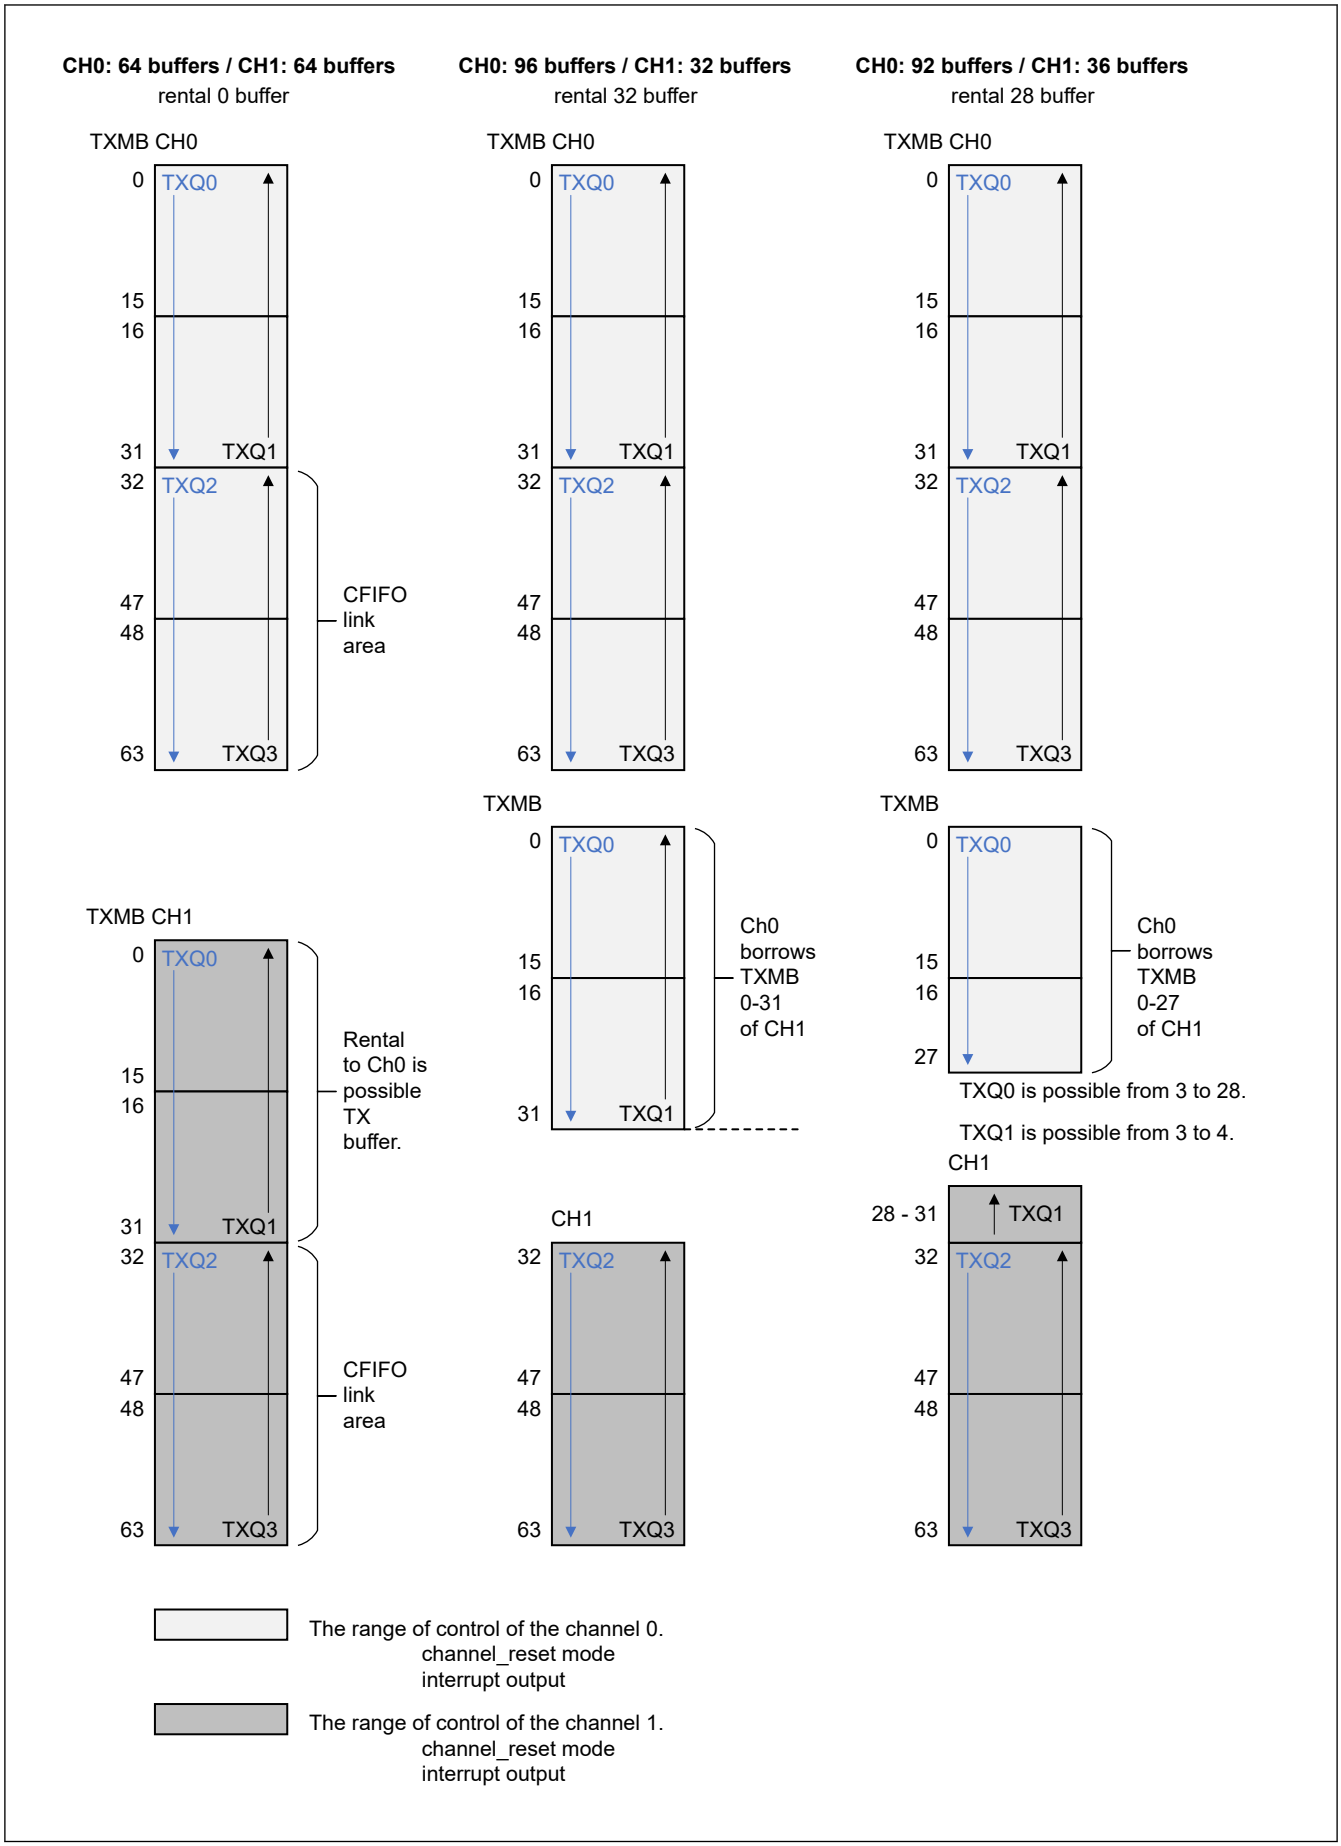

Figure 35.61 Flexible transmission buffer assignment (0, 32, 28 TXMB rental)

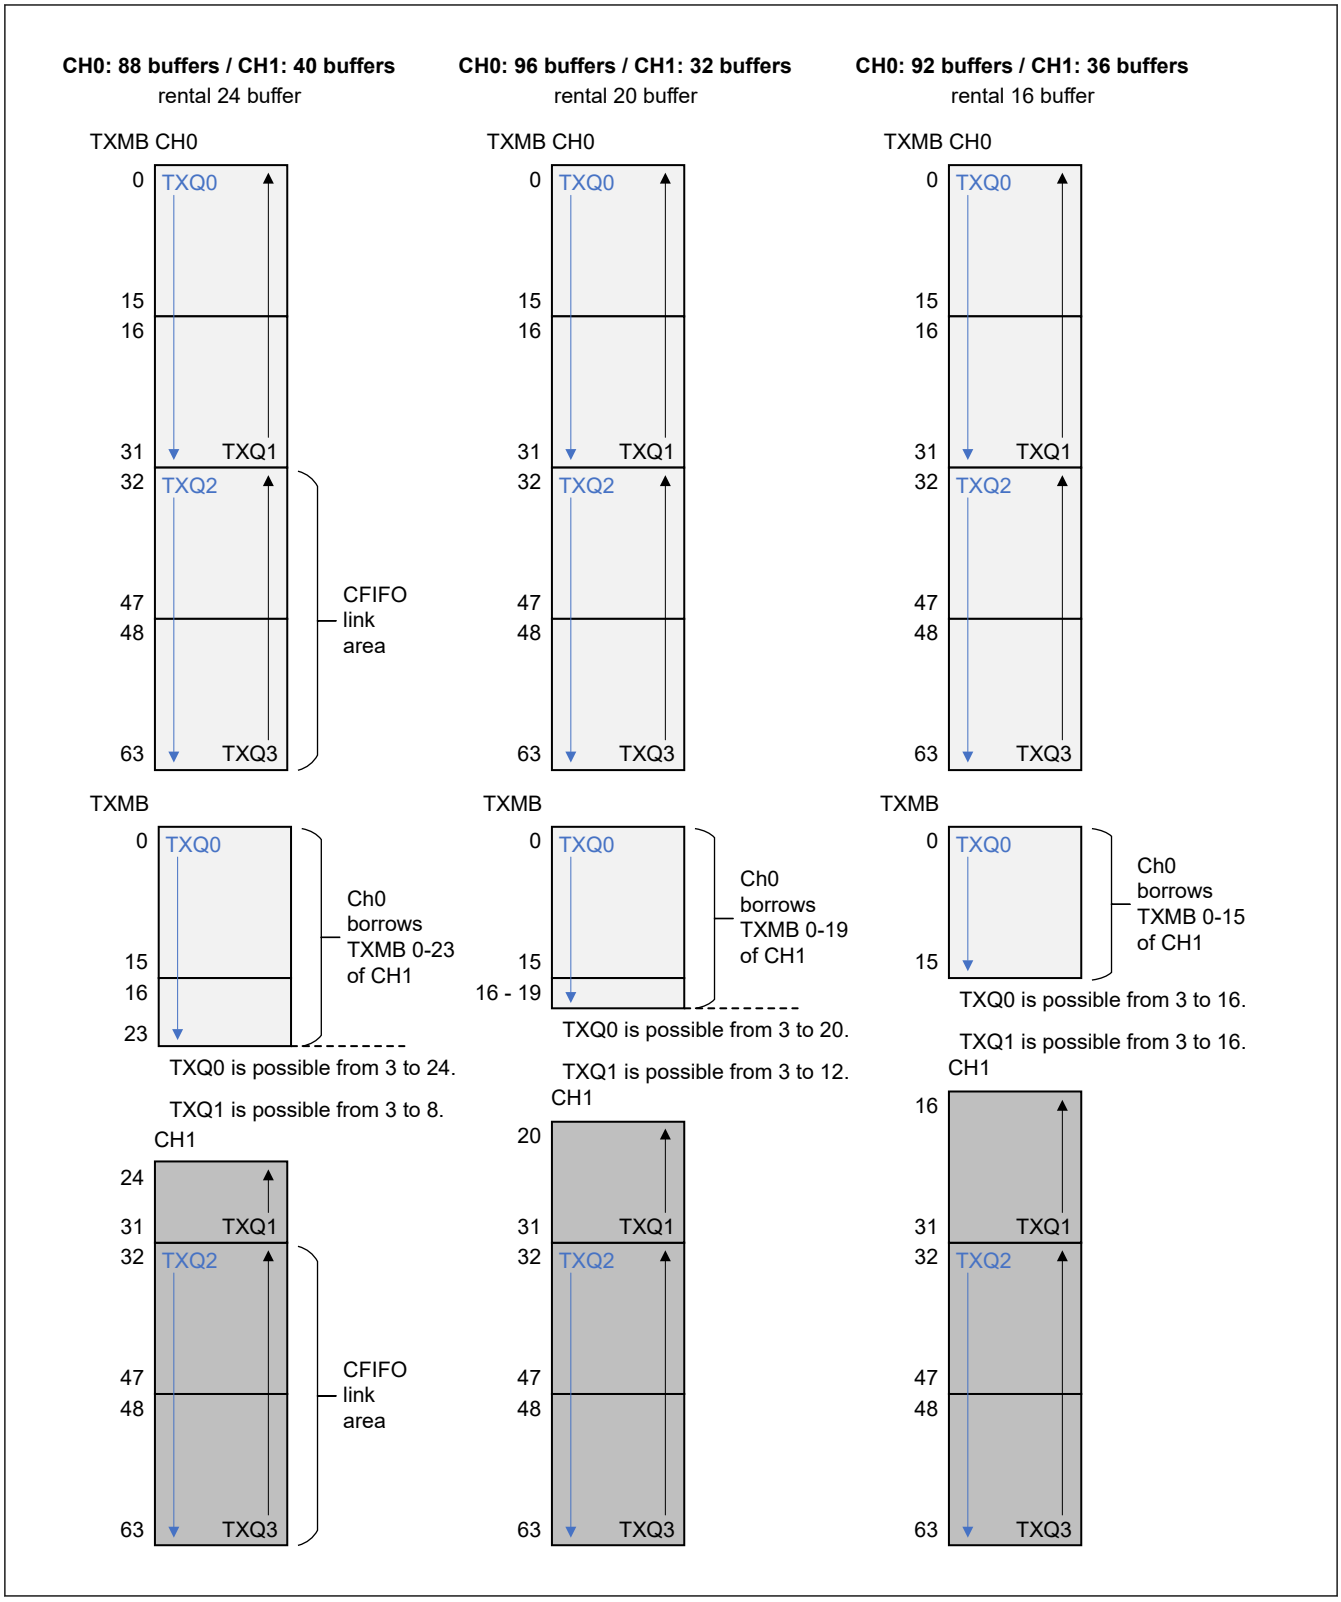

Figure 35.62 Flexible transmission buffer assignment (24, 20, 16 TXMB rental)

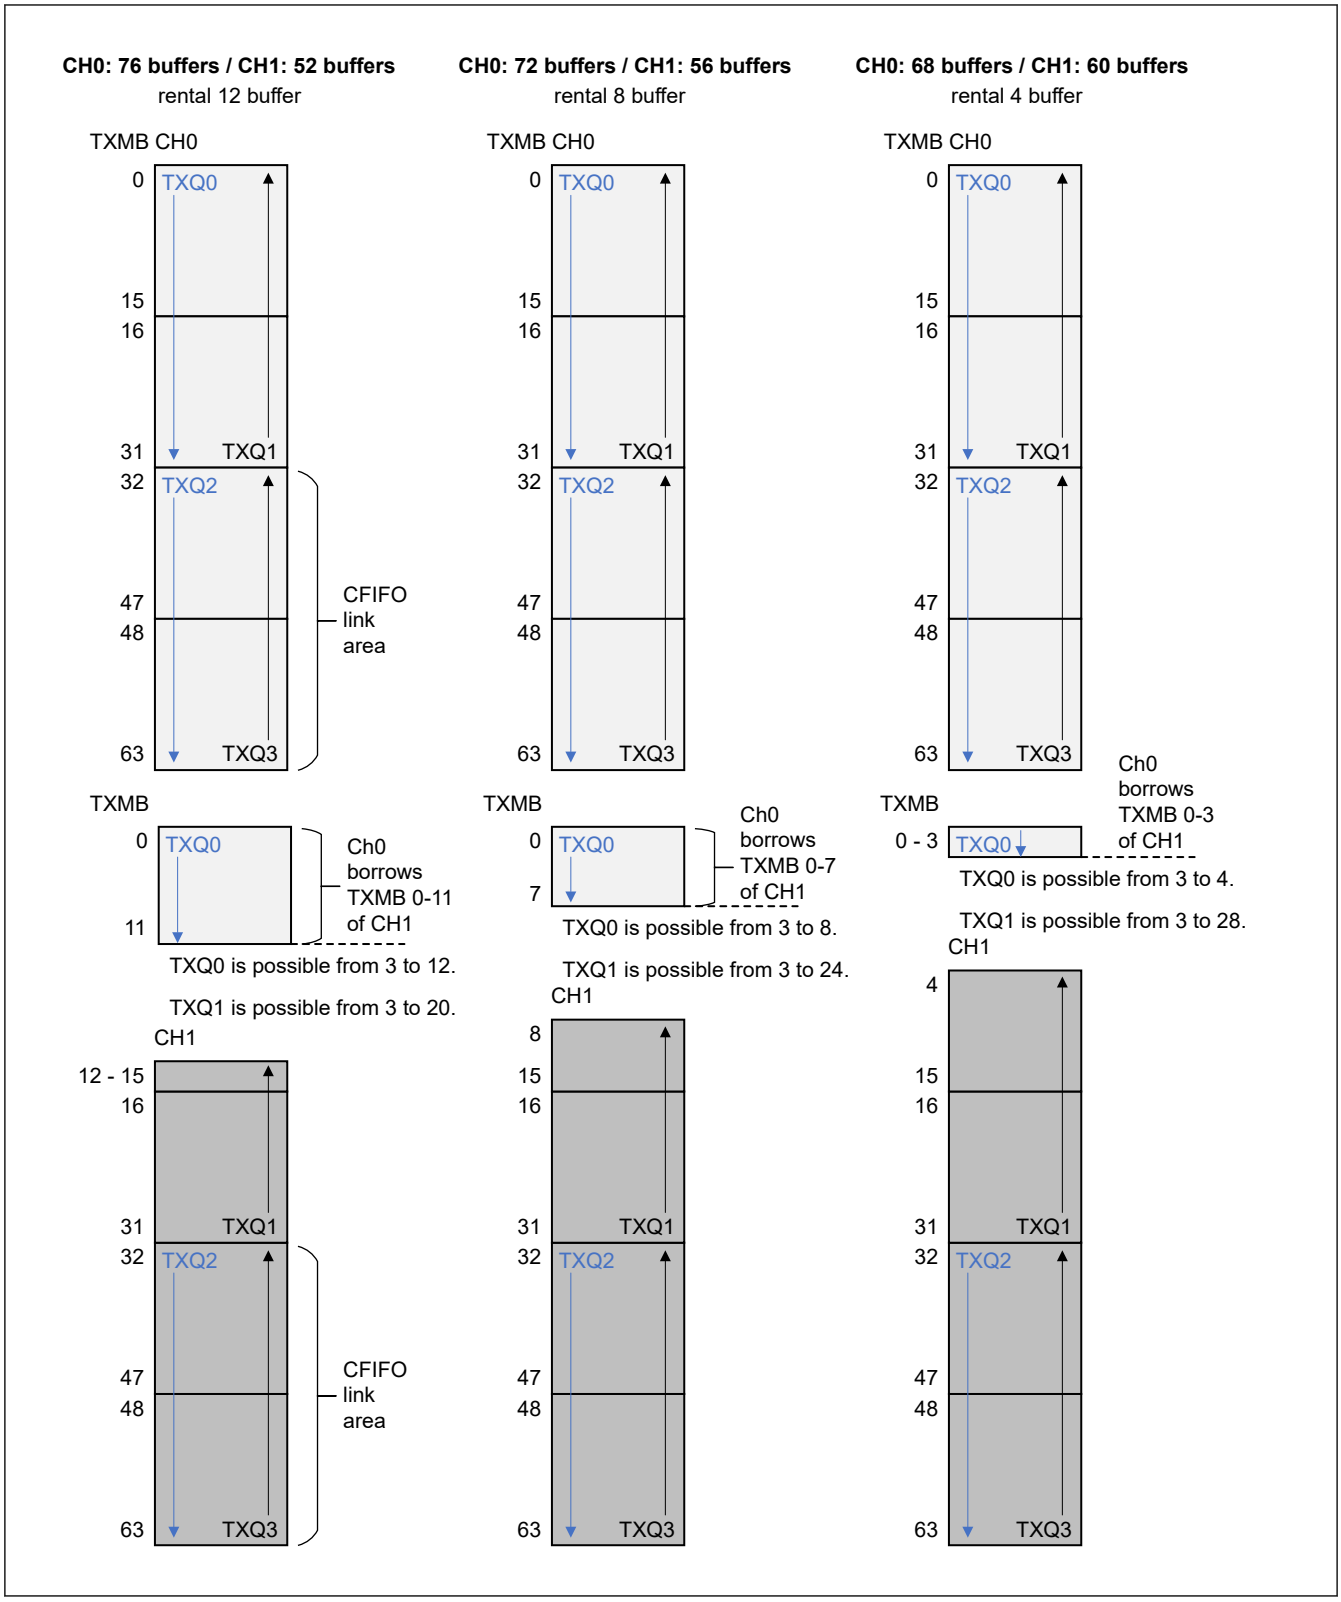

Figure 35.63 Flexible transmission buffer assignment (12, 8, 4 TXMB rental)

36. Serial Peripheral Interface (SPI)

36.1 Overview

The SPI supports serial communications for transmit-receive, transmit only, and receive only. The SPI is provided with a function for high-speed serial communication with multiple processors and peripheral devices.

36.1.1 Features

Table 36.1 lists the specifications of the SPI, and Figure 36.1 shows a block diagram of the SPI.

Table 36.1 SPI specifications (1 of 2)

Item	Description
Number of channels	4 channels (ch0 to ch2 in NON-SAFETY and ch3 in SAFETY)
Transfer functions	• SPI serial communication (4-wire) and clock synchronous (3-wire) serial communication are possible by using the MOSI (Master Out Slave In), MISO (Master In Slave Out), SSL (Slave Select), and RSPCK (SPI Clock) signals. • Transmit-only operation is available • Receive-only operation is available • Serial communication is possible in master mode and slave mode • RSPCK polarity switching • RSPCK phase switching
Data format	• MSB first or LSB first selectable. • Transfer bit length selectable from 4 to 32 bits • 32 bit x 4 stage FIFO transmit and receive buffers • Up to four frames transferable in one round of transmission or reception (each frame consisting of up to 32 bits) • Byte swap operating function • Transmit/receive data inversion
Bit rate	• In master mode, the on-chip baud rate generator divides the PCLKSPIn to generate RSPCK. A division ratio of 2 to 4096 is settable. • In slave mode, an external input clock is used as a serial clock. The maximum frequency = PCLKSPIn/2 (High width: 1 PCLKSPIn cycles, low width: 1 PCLKSPIn cycles)
Buffer configuration	• Transmit buffer and receive buffer are configured independently.
Error detection	• Mode fault error detection • Underrun error detection • Overrun error detection • Parity error detection

Table 36.1 SPI specifications (2 of 2)

Item	Description
SSL control function	[Motorola SPI mode] ● Four SSL pins (SSLn0 to SSLn3) each channel ● In single master mode, SSLn0 to SSLn3 pins are output. ● In multi-master mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins either for output or unused ● In slave mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins unused ● Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) ● Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) ● Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) ● Configurable delay between frames in burst transfer ● Function for changing SSL polarity [TI SSP mode] ● Four SSL pins (SSL0 to SSL3) each channel ● In single master mode, SSLn0 to SSLn3 pins are output. ● In multi-master mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins either for output or unused ● In slave mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins unused ● Controllable delay from SSL output assertion to SSL output negation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) ● Controllable delay from RSPCK stop to Output disable (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) ● Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) ● Configurable delay between frames in burst transfer ● Function for changing SSL polarity
Communication Protocol	● Motorola SPI ● TI SSP (Synchronous Serial Protocol)
Synchronization bypass function	● Synchronization circuit can be bypassed using bus clock (PCLKM) as operation clock (PCLKSPIn)
Control in master transfer	[Motorola SPI mode] ● Transfers of up to eight commands each can be executed sequentially in looped execution ● For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, LSB first/MSB first, burst, RSPCK delay, SSL negation delay, next-access delay ● Transfers can be initiated by writing to the transmit buffer ● MOSI signal value specifiable in SSL negation ● RSPCK auto-stop function [TI SSP mode] ● Transfers of up to eight commands each can be executed sequentially in looped execution ● For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, LSB first/MSB first, burst, RSPCK delay, SSL negation delay (Output disable delay), next-access delay ● Transfers can be initiated by writing to the transmit buffer ● MOSI signal value specifiable in SSL negation ● RSPCK auto-stop function
Interrupt sources	● Maskable Interrupt sources SPI receive buffer full / Receive data ready interrupt SPI transmit buffer empty interrupt SPI communication end interrupt SPI error interrupt (mode fault, overrun, parity error, receive data ready) SPI idle interrupt (SPI idle)
Others	● Switching between CMOS output and open-drain output ● SPI disable (initialization) function ● Loopback mode function
Module-stop function	Module-stop state can be set to reduce power consumption*1

Note 1. Module stop condition: It depends on the setting higher than this module. This module is not reset, and the clock stops on module stop condition. It contributes to low power consumption, because the clock stops.

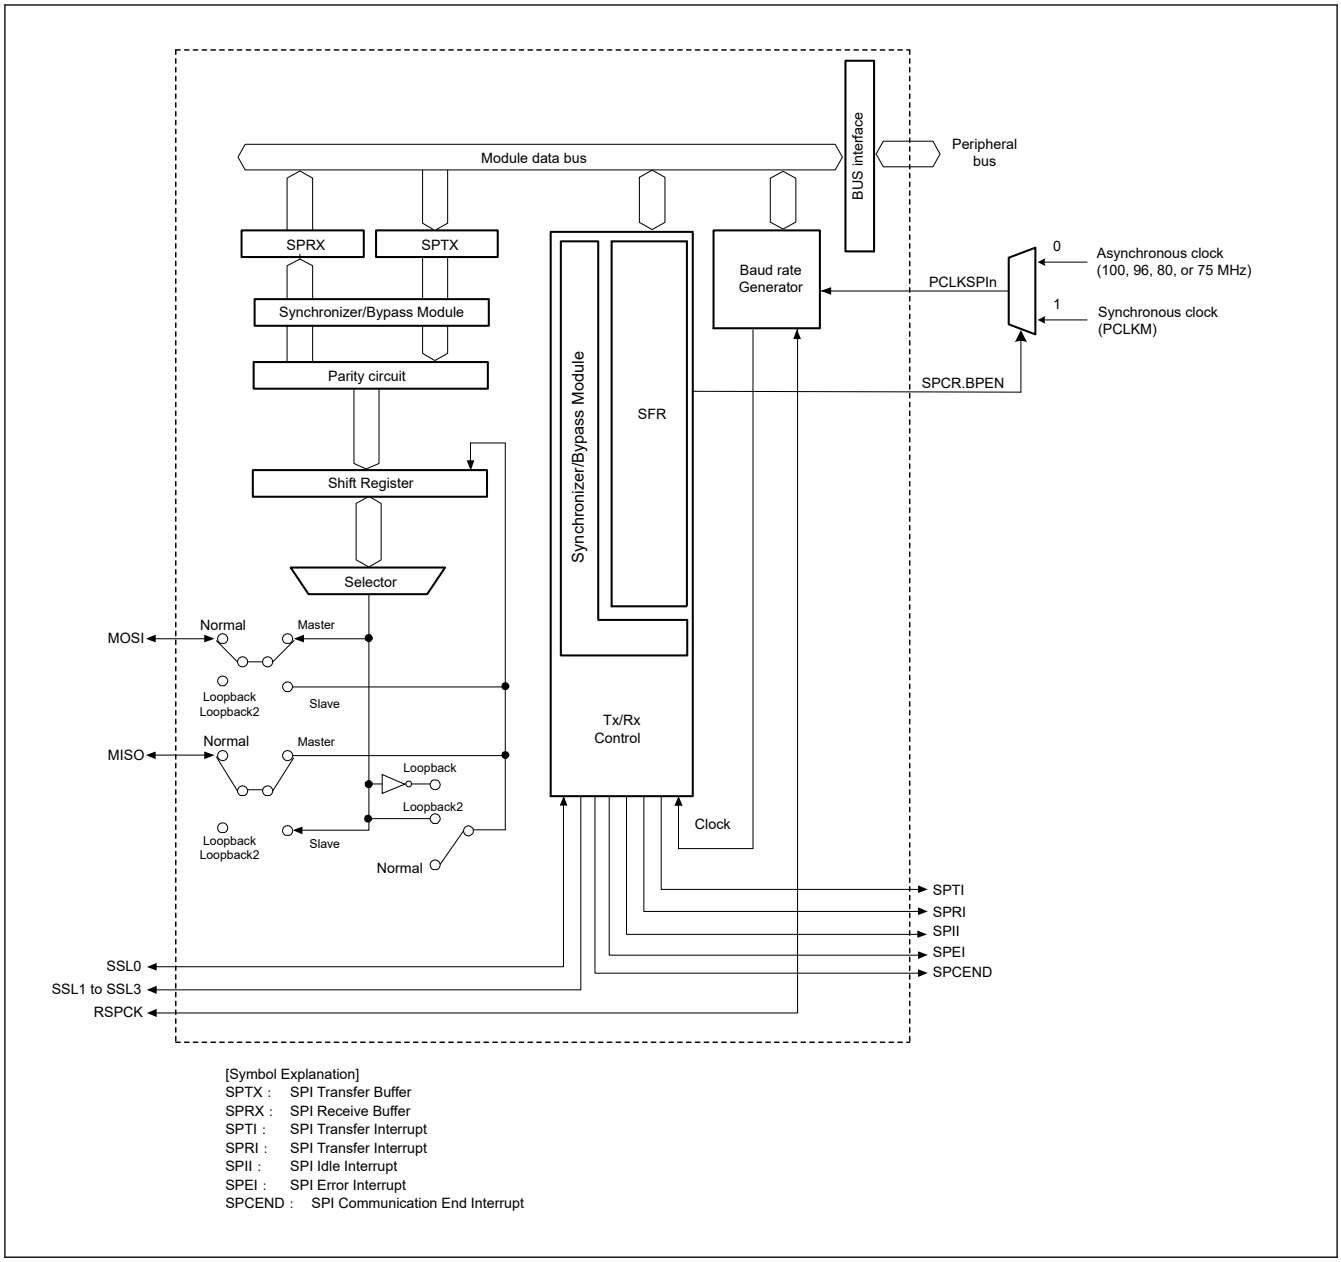

Figure 36.1 SPI block diagram

The SPI automatically switches the SSL0 pin input and output directions. The SSL0 pin is switched to output when single master is set, and it is switched to input when multi-master or slave is set. Furthermore, the SPI automatically switches the input and output directions of pins RSPCK, MOSI, MISO, SSL1 to SSL3 according to the master/slave setting and SPI operation (4-wire)/clock synchronous operation (3-wire) SSL0 input level. (See section 36.4.2. SPI Pin Control.)

Table 36.2 lists the I/O pins used in the SPI.

Table 36.2 SPI pin configuration

Channel	Pin name	I/O	Function
SPIn (n = 0 to 3)	SPI_RSPCKn	I/O	Clock I/O
	SPI_MOSIn	I/O	Master transmit data I/O
	SPI_MISOn	I/O	Slave transmit data I/O
	SPI_SSLn0	I/O	Slave selection signal I/O
	SPI_SSLn1	Output	Slave selection signal output
	SPI_SSLn2	Output	Slave selection signal output
	SPI_SSLn3	Output	Slave selection signal output

Note: For convention, pin names within this chapter are written without "SPI_" notation except this table.

36.2 Register Map

36.3 Register Descriptions

36.3.1 SPDR/SPDR_HA/SPDR_BY : SPI Data Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

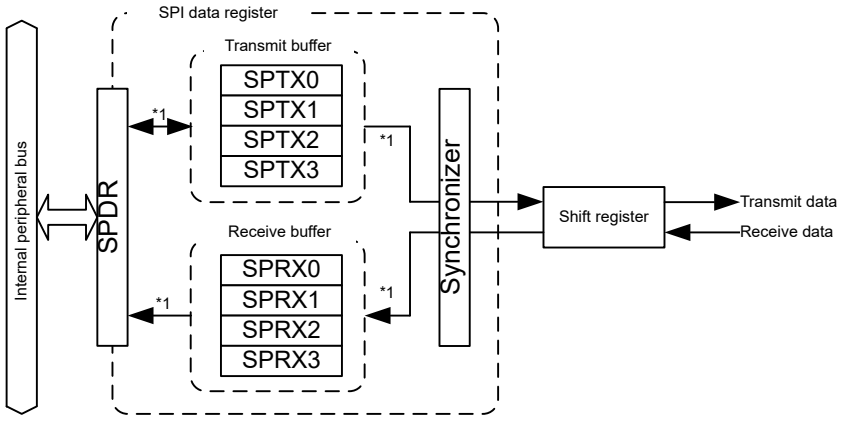
Offset address: 0x00

Bit position:	31																													0
Bit field:	SPD[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SPD[31:0]	The SPI data register (SPDR) is used to store SPI's transmit data and receive data. Transmit buffers and receive buffers independently function.	R/W

SPDR is the interface with the buffers that hold data for transmission and reception by the SPI.

Figure 36.2 shows the structure of SPDR.



Note 1. The destination buffer and stage for access is automatically switched by hardware.

Figure 36.2 Structure of SPDR

32 bit × 4 stage transmit FIFO and 32 bit × 4 receive FIFO are provided. These 8 stage FIFO are mapped to one address in the SPDR. Transmit buffers (SPTXn, n = 0 to 3) can be written by writing data to SPDR to transmit written data.

Upon completion of receiving data, receive buffers store received data. When an overrun error occurs, data in the receive buffer is not updated.

Bus Interface

The SPI data register has 32 bit × 4 stage transmit FIFO and 32 bit × 4 receive FIFO (32 bytes in total). These 32 bytes are mapped to the 4-byte space of SPDR. Write transmit data from the LSB. Received data is stored from the LSB.

SPDR register write operation and read operation are described below.

(a) Write

A transmit buffer write pointer is provided for transmit buffers. When data is written to SPDR, the pointer automatically switches to the next buffer. The following illustrates the structure of the transmit buffer bus interface (write).

Figure 36.3 shows the configuration of the bus interface with the transmission buffer in the case of writing to SPDR.

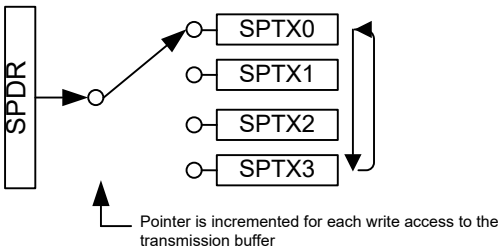


Figure 36.3 Structure of SPDR (write)

The transmit buffer (SPTX0 to SPTX3) switching order:

SPTX0→SPTX1→SPTX2→SPTX3→SPTX0→SPTX1→…

When writing transmit data to transmit buffers (SPTXn), write transmit data of frames +1 specified by the Transmission FIFO threshold setting bits of SPI data control register 2 (SPDCR2.TTRG[1:0]) while an SPI transmit buffer empty interrupt is present (SPSR.SPTEF flag = 1). Writing to the transmit buffer (SPTXn, n = 0 to 3) in the state where there is no empty stage in the transmit FIFO does not update the buffer value.

(b) Read

Values can be read from receive buffers (SPRXn, n = 0 to 3) or transmit buffers (SPTXn, n = 0 to 3) by reading the SPDR register. Reading a receive buffer or reading a transmit buffer can be selected by the SPI receive data or transmit data select bit (SPDCR.SPRDTD).

The SPDR register is read according to the independent receive buffer read pointer and the transmit buffer read pointer.

The following illustrates the structure of the receive buffer and transmit buffer bus interface (read).

Figure 36.4 shows the configuration of the bus interface with the receive and transmission buffers in the case of reading from SPDR.

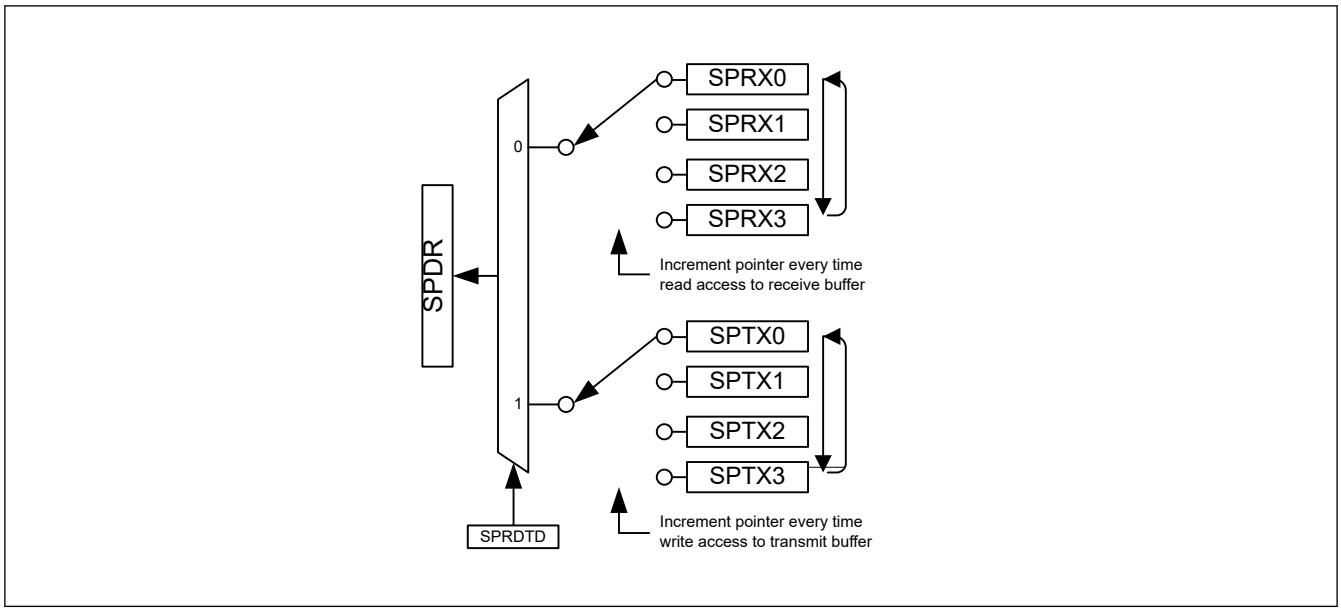

Figure 36.4 Structure of SPDR (read)

When a receive buffer is read, the receive buffer read pointer automatically switches to the next buffer. The receive buffer read pointer switches in the same order as the transmit buffer write pointer.

The transmit buffer read pointer is updated during the SPDR write access, but it is not updated during the transmit buffer read access. When a transmit buffer is read, the value written to SPDR last can be read.

36.3.2 SPCKD : SPI Clock Delay Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SCKDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SCKDL[2:0]	RSPCK Delay Setting 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

[In the Motorola-SPI case]

The SPCKD register is used to set the period (RSPCK delay) from SSL signal assertion start until RSPCK oscillates while SPCMD.SCKDEN = 1. If SPCKD is modified while SPCR.MSTR = 1 and SPCR.SPE = 1, subsequent operation is not guaranteed.

[In the TI-SSP case]

The SPCKD register is used to set the period (RSPCK delay) from SSL signal assertion start until RSPCK oscillates while SPCMD.SCKDEN = 1. Also that is used to set the period until the SSL signal is negated. If SPCKD is modified while SPCR.MSTR = 1 and SPCR.SPE = 1, subsequent operation is not guaranteed.

SCKDL[2:0] bits (RSPCK Delay Setting)

These bits are used to set the RSPCK delay value when SPCMD.SCKDEN = 1.

To use the SPI in slave mode, set SCKDL[2:0] bits to 000b.

36.3.3 SSLND : SPI Slave Select Negation Delay Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SLNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SLNDL[2:0]	SSL Negation Delay Bits This is the synchronization delay for replacing the RSPCK input with PCLKSPIn. RSPCK Delay Setting 0 0 0: 1 RSPCK [Master mode] 1 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 0 0 1: 2 RSPCK [Master mode] 2 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 0 1 0: 3 RSPCK [Master mode] 3 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 0 1 1: 4 RSPCK [Master mode] 4 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 1 0 0: 5 RSPCK [Master mode] 5 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 1 0 1: 6 RSPCK [Master mode] 6 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 1 1 0: 7 RSPCK [Master mode] 7 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode] 1 1 1: 8 RSPCK [Master mode] 8 PCLKSPIn + (2~3 PCLKSPIn (Synchronization delay)) [TI-SSP case in Slave Mode]	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

[In the Motorola-SPI case]

The SSLND register is used to set the period (SSL negation delay) after the SPI in master mode sends the final RSPCK edge during serial transfer until it negates the SSL signal while SPCMD.SCKDEN = 1. If SSLND is modified while SPCR.MSTR = 1 and SPCR.SPE = 1, subsequent operation is not guaranteed.

[In the TI-SSP case]

The SSLND register is used to set the period (Output disable delay) after the SPI in master mode sends the final RSPCK edge during serial transfer until it negates the Output enable signal while SPCMD.SCKDEN = 1. Also, that is used to set the period from when the SPI in slave mode detects the last RSPCK edge of serial transfer to when the Output enable signal is negated. If SSLND is modified while the SPE bit in SPCR.SPE = 1, subsequent operation is not guaranteed.

SLNDL[2:0] bits (SSL Negation Delay Bits)

[In the Motorola-SPI case]

These bits are used to set the SSL negation delay value when SPCMD.SLNDEN = 1.

To use the SPI in slave mode except TI-SSP, set SLNDL[2:0] bits to 000b.

[In the TI-SSP case]

These bits are used to set the Output disable delay value when SPCMD.SLNDEN = 1.

36.3.4 SPND : SPI Next-Access Delay Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SPNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SPNDL[2:0]	SPI Next-Access Delay Bits RSPCK Delay Setting 0 0 0: 1 RSPCK + 5 PCLKSPIn 0 0 1: 2 RSPCK + 5 PCLKSPIn 0 1 0: 3 RSPCK + 5 PCLKSPIn 0 1 1: 4 RSPCK + 5 PCLKSPIn 1 0 0: 5 RSPCK + 5 PCLKSPIn 1 0 1: 6 RSPCK+ 5 PCLKSPIn 1 1 0: 7 RSPCK + 5 PCLKSPIn 1 1 1: 8 RSPCK + 5 PCLKSPIn	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

The SPND register is used to set the SSL signal inactive period (next-access delay) after completion of serial transfer while SPCMD.SCKDEN = 1. If SPND is modified while SPCR.MSTR = 1 and SPCR.SPE = 1, subsequent operation is not guaranteed.

SPNDL[2:0] bits (SPI Next-Access Delay Bits)

These bits are used to set the next-access delay value when SPCMD.SCKDEN = 1. To use the SPI in slave mode, set SPNDL[2:0] bits to 000b.

36.3.5 MRCKD : SPI ClocK Digital control Register for Master Receive

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x07

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	ARST[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	ARST[2:0]	Receive Sampling Timing Adjustment Bits The sampling of the serial data (MISO) input in master mode can be adjusted by delaying 0 to 7 PCLKSPIn from the center of the bit. 0 0 0: 0 PCLKSPIn delay 0 0 1: 1 PCLKSPIn delay 0 1 0: 2 PCLKSPIn delay 0 1 1: 3 PCLKSPIn delay 1 0 0: 4 PCLKSPIn delay 1 0 1: 5 PCLKSPIn delay 1 1 0: 6 PCLKSPIn delay 1 1 1: 7 PCLKSPIn delay	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

The MRCKD register is a register for adjusting the reception sampling timing in master mode. If the ARST[2:0] bits are rewritten while SPCR.SPE = 1, subsequent operations are not guaranteed.

ARST[2:0] bits (Receive Sampling Timing Adjustment Bits)

These bits are used to select the amount of reception sampling timing adjustment. The sampling timing can be adjusted by delaying 0 to 7 PCLKSPIn from the center of the bit.

Delay setting exceeding the dividing ratio is prohibited.

This bit setting is valid only when the loopback function is not used (when SPPCR.SPLP = 0, when MRCLK is selected (SPCR.SPSCKSEL = 1), and SPPCR.SPLP2 = 0) and in master mode. For details, see SPSCKSEL bit of section 36.3.6. SPCR : SPI Control Register.

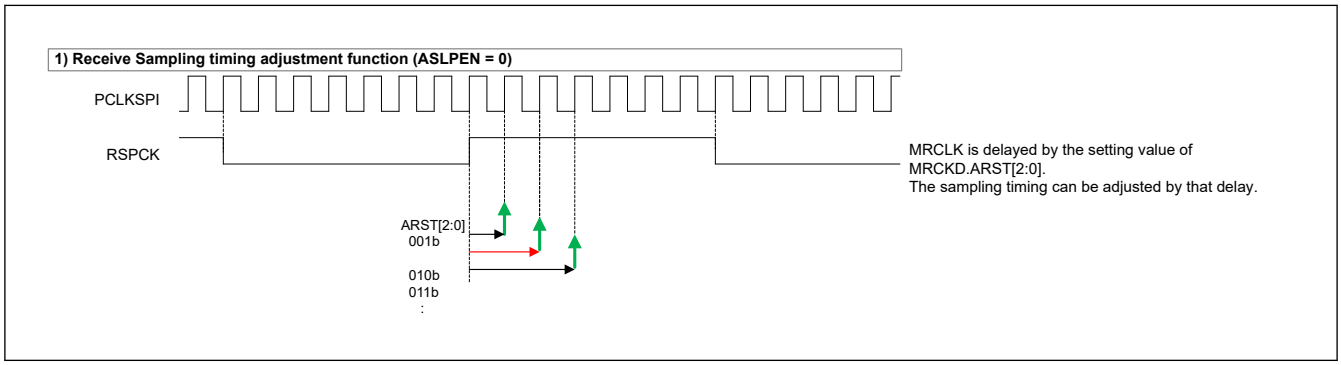

Figure 36.5 Description about receive sampling timing adjustment function

36.3.6 SPCR : SPI Control Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BPEN	MSTR	TXMD[1:0]		—	—	SPFRF	SPMS	—	—	CENDIE	SPTIE	SPDRES	SPIIE	SPRIE	SPEIE

21	CENDIE	SPI Communication End Interrupt Enable 0: Communication end interrupt request is disabled. 1: Communication end interrupt request is enabled.	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
24	SPMS	SPI Function Enable 0: SPI operation (4-wire) 1: Clock synchronous operation (3-wire)	R/W
25	SPFRF	SPI Frame Format Select When SPMS = 1 (clock synchronous operation (3-wire)), this bit setting is invalid. 0: Motorola-SPI 1: TI-SSP	R/W

Bit	Symbol	Function	R/W
27:26	—	These bits are read as 0. The write value should be 0.	R/W
29:28	TXMD[1:0]	Communication Mode Select 0 0: Transmit-Receive 0 1: Transmit only 1 x: Receive only	R/W
30	MSTR	SPI Master/Slave Mode Select 0: Slave mode 1: Master mode	R/W
31	BPEN	Synchronization Circuit Bypass Enable 0: Non-Bypass 1: Bypass	R/W

The SPCR register is used to set operating mode of the SPI. If the set MSTR, TXMD[1:0], SPFRF, SPMS, MODFEN, BFDS, SCKASE, PTE, SPOE, SPPE, SPSCKSEL, and BPEN bit value is modified while SPCR.SPE = 1, subsequent operation is not guaranteed.

SPE bit (SPI Function Enable)

The SPE bit is used to enable or disable SPI functions. Setting this bit to 1 enables SPI functions. When SPSR.MODF = 1, the SPCR.SPE bit is cleared to 0 and the SPCR.SPE bit cannot be set to 1 until the MODF flag is cleared to 0. (See section 36.4.10. Error Detection.) Setting the SPE bit to 0 disables SPI functions and initializes a part of module functions. (See section 36.4.12. SPI Initialization.)

SPSCKSEL bit (SPI Master Receive Clock Select)

The SPSCKSEL bit selects the clock used to sample the received data in master mode. By setting this bit, the sampling timing of the MISO can be adjusted. This bit setting is valid only when the loopback function is not used (when SPPCR.SPLP = 0 and SPPCR.SPLP2 = 0) and in master mode.

Figure 36.6 shows a Master Receive Clock Delay configuration. By selecting this bit, you can select MRIOCLK (adjust with analog delay (SPCR2.SPSCKDL)) or MRCLK (adjust with digital delay (MRCKD.ARST)).

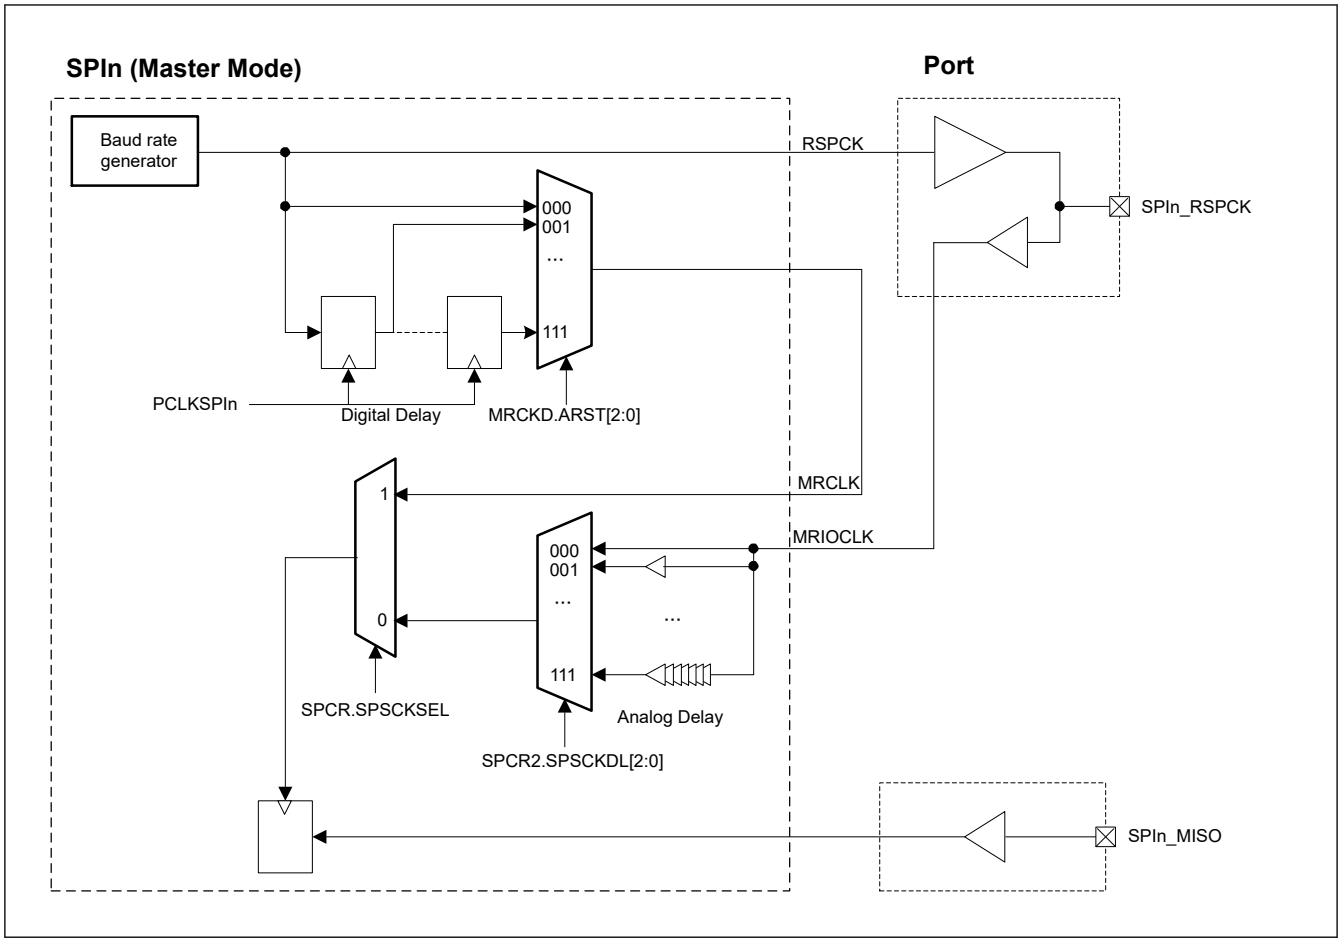

Figure 36.6 Master receive clock delay configuration (Master mode)

SPPE bit (Parity Enable)

The SPPE bit is used to enable or disable the parity function.

SPOE bit (Parity Mode)

The SPOE bit is used to specify even parity or odd parity.

In even parity mode, the parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an even number. In the same way, in odd parity mode, a parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an odd number. The SPOE bit is valid only when the SPCR.SPPE is set to 1.

PTE bit (Parity Self-Diagnosis Enable)

The PTE bit is used to enable or disable self-diagnosis of the parity circuit to confirm that the parity function is normal.

SCKASE bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit is used to enable or disable the RSPCK auto-stop function. When this function is enabled, the RSPCK clock stops immediately before an overrun error occurs during data reception in master mode. For details, see section 36.4.10.1. Overrun Error.

BFDS bit (Between Burst Transfer Frames Delay Select)

The BFDS bit controls whether insert the delay time between the burst transfer frames.

Valid in the master mode (SPCR.MSTR = 1) for frames with the SPCMDm.SSLKP bit set to 1.

This bit shold be set to 0 in slave mode. The usage of SSL delay control between transfer frames is shown as below.

For details, see (4) Burst Transfer in section 36.4.13.2. Slave Mode Operation.

(1) Non-burst transmits

(2) Burst transmit with delay between frames

(2-1) From the 1st frame to the last previous frame

(2-2) The last frame

(3) Burst transmit with no delay between frames

(3-1) From the 1st frame to the last previous frame

(3-2) The last frame

Table 36.5 Usage of SSL delay control between transfer frames (master mode)

	SPCMDm SSLKP bit	SPCR BFDS bit	SSL delay control register*1 (RSPCK clock delay, SSL negation delay, next access delay)
(1)	0	0	Any given value. You can control each delay value according to setting for RSPCK clock delay, SSL negation delay, and next access delay.
(2-1)	1	0	
(2-2)	0	0	
(3-1)	1	1	Any given value. But delay is inserted only below. • RSPCK clock delay of the 1st frame • SSL negation delay and next access delay of the last frame
(3-2)	0	1	

Note 1. Whether the setting value of following bits are valid or not depends on the setting value of the SPCMD.SPNDEN bit. (See section 36.3.14. SPCMDm : SPI Command Register m (m = 0 to 7).)
The SPCKD.SCKDL[2:0] bits: RSPCK delay
The SSLND.SLNDL[2:0] bits: SSL negate delay
The SPND.SPNDL[2:0] bits: Next access delay

< Setting / operation example > (Motorola SPI, BFDS = 1 Case)

SPCMD0.SSLKP = 1 → Burst transfer / no interframe delay between 0 and 1 (SSL keep active)

SPCMD1.SSLKP = 1 → Burst transfer / no interframe delay between 1 and 2 (SSL keep active)

SPCMD2.SSLKP = 1 → Burst transfer / no interframe delay between 2 and 3 (SSL keep active)

SPCMD3.SSLKP = 1 → Burst transfer / no interframe delay between 3 and 4 (SSL keep active)

SPCMD4.SSLKP = 0 → do not Burst Transfer, and once in-activate SSL.

(BFDS setting is invalid because it does not Burst Transfer.)

SPCMD5.SSLKP = 1 → Burst transfer / no interframe delay between 5 and 6 (SSL keep active)

SPCMD6.SSLKP = 1 → Burst transfer / no interframe delay between 6 and 7 (SSL keep active)

SPCMD7.SSLKP = 0 → do not Burst Transfer, and once in-activate SSL.

(BFDS setting is invalid because it does not Burst Transfer.)

MODFEN bit (Mode Fault Error Detection Enable)

The MODFEN bit is used to enable or disable detection of a mode fault error. (See section 36.4.10. Error Detection.) The SPI determines SSL0 pin input or output direction according to the combination of the MODFEN and MSTR bits. (See section 36.4.2. SPI Pin Control.)

SPEIE bit (SPI Error Interrupt Enable)

The SPEIE bit is used to enable or disable an SPI error interrupt request when the SPI detects a mode fault error or an underrun error and sets the MODF flag in the SPI status register (SPSR) to 1, when the SPI detects an overrun error and sets the OVRF flag in SPSR to 1, or when the SPI detects a parity error and sets the PERF flag in SPSR to 1. (See section 36.4.10. Error Detection.)

SPRIE bit (SPI Receive Buffer Full Interrupt Enable)

The SPRIE bit is used to enable or disable a receive buffer full interrupt request of the SPI.

SPIIE bit (SPI Idle Interrupt Enable)

The SPIIE bit is used to enable or disable an idle interrupt request of the SPI after the SPI detects the idle state and sets the IDLNF flag in the SPI status register (SPSR) to 0.

SPDRES bit (SPI Receive Data Ready Error Select)

When a receive data ready is detected (SPSR.SPDRF = 1), select whether to use SPRI interrupt request or SPEI interrupt request.

SPTIE bit (SPI Transmit Buffer Empty Interrupt Enable)

The SPTIE bit is used to enable or disable a transmit buffer empty interrupt request of the SPI.

A transmit buffer empty interrupt request at the beginning of transmission is generated by setting the SPE bit to 1 simultaneously when or after the SPTIE bit is set to 1. Note that a transmit buffer empty interrupt is generated while the SPTIE bit is 1 even though SPI functions are disabled (SPE bit = 0).

CENDIE bit (SPI Communication End Interrupt Enable)

The CENDIE bit controls generation of a communication end interrupt request.

SPMS bit (SPI Function Enable)

The SPMS bit is used to select SPI operation (4-wire) or clock synchronous operation (3-wire).

For clock synchronous operation, the SSL pin is not used but three pins RSPCK, MOSI, and MISO are used for communication. When SPMS = 1 (clock synchronous operation (3-wire)), the setting of the SPFRF bit is invalid.

To perform clock synchronous operation in master mode (SPCR.MSTR = 1), the SPCMD.CPHA bit can be set to 0 or 1. To perform clock synchronous operation in slave mode (SPCR.MSTR = 0), set the CPHA bit to 1. If this bit is set to 0 for clock synchronous operation in slave mode (SPCR.MSTR = 0), subsequent operation is not guaranteed.

The communication status according to the settings of SPCR.MSTR, SPCR.TXMD[1:0], SPCR.SPFRF, and SPCR.SPMS as follows.

Table 36.6 SPI communication status

SPCR MSTR	SPCR TXMD[1]	SPCR TXMD[0]	SPCR SPFRF	SPCR SPMS	Communication Status	Communication Status No.
1	0	0	0	0	Transmit-Receive Master / Motorola SPI / SPI operation (4-wire)	1-(1)
1	0	0	1	0	Transmit-Receive Master / TI-SSP / SPI operation (4-wire)	1-(2)
1	0	0	—	1	Transmit-Receive Master / Clock synchronous operation (3-wire)	1-(3)
1	0	1	0	0	Transmit only Master / Motorola SPI / SPI operation (4-wire)	1-(4)
1	0	1	1	0	Transmit only Master / TI-SSP / SPI operation (4-wire)	1-(5)
1	0	1	—	1	Transmit only Master / Clock synchronous operation (3-wire)	1-(6)
1	1	—	0	0	Receive only Master / Motorola SPI / SPI operation (4-wire)	1-(7)
1	1	—	1	0	Receive only Master / TI-SSP / SPI operation (4-wire)	1-(8)
1	1	—	—	1	Receive only Master / Clock synchronous operation (3-wire)	1-(9)
0	0	0	0	0	Transmit-Receive Slave / Motorola SPI / SPI operation (4-wire) (default)	0-(1)
0	0	0	1	0	Transmit-Receive Slave / TI-SSP / SPI operation (4-wire)	0-(2)
0	0	0	—	1	Transmit-Receive Slave / Clock synchronous operation (3-wire)	0-(3)
0	0	1	0	0	Transmit only Slave / Motorola SPI / SPI operation (4-wire)	0-(4)
0	0	1	1	0	Transmit only Slave / TI-SSP / SPI operation (4-wire)	0-(5)
0	0	1	—	1	Transmit only Slave / Clock synchronous operation (3-wire)	0-(6)
0	1	—	0	0	Receive only Slave / Motorola SPI / SPI operation (4-wire)	0-(7)
0	1	—	1	0	Receive only Slave / TI-SSP / SPI operation (4-wire)	0-(8)
0	1	—	—	1	Receive only Slave / Clock synchronous operation (3-wire)	0-(9)

SPFRF bit (SPI Frame Format Select)

The SPFRF bit selects the communication protocol.

The format of the SPI terminal (RSPCK, SSL0 to 3) can be set according to the set communication protocol.

When SPMS = 1 (clock synchronous operation (3-wire)), this bit is invalid because SSL is not used.

TXMD[1:0] bits (Communication Mode Select)

The TXMD[1:0] bits are used to select the transmit-receive, transmit-only, and receive-only serial communication.

TXMD[1:0] = 01b

→ Transmit-only is performed without reception.

→ Receive buffer full interrupt request cannot be used.

TXMD[1] = 1b

→ Receive-only is performed without transmission.

→ Transmit buffer empty interrupt request cannot be used.

For details, see section 36.4.6. Communications Operating Mode.

MSTR bit (SPI Master/Slave Mode Select)

The MSTR bit is used to select master mode or slave mode of the SPI. The SPI determines input/output directions of pins RSPCK, MOSI, MISO, and SSL1 to SSL3 according to the MSTR bit setting.

BPEN bit (Synchronization Circuit Bypass Enable)

When BPEN = 1, bus clock (PCLKM) is used as operation clock (PCLKSPIn) and synchronization circuit is bypassed.

36.3.7 SPCRRM : SPI Control Register for Master Receive only

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RMSTTG	RMEDTG	—	RMFM[4:0]				
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	RMFM[4:0]	Frame processing count setting in Master Receive only 0x00: This function is not used.*1 0x01: Automatically stop communication after processing 1 received frame. ⋮ 0x1F: Automatically stop communication after processing 31 received frames.	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
6	RMEDTG	1: Receive End (writable only when in Master Receive) Reading value is always 0.	W
7	RMSTTG	1: Receive Start (writable only when in Master Receive) Reading value is always 0.	W

Note 1. See (9) Software Processing Flow in section 36.4.13.1. Master Mode Operation.

The SPCRRM register controls the start and completion of communication for master mode reception only operation. If the RMFM[4:0] bits are rewritten while SPCR.SPE = 1, subsequent operations are not guaranteed.

RMFM[4:0] bits (Frame processing count setting in Master Receive only)

The number of received frames can be adjusted when operating in master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication operation mode select bits (SPCR.TXMD[1:0]) are 10b.

Only the start bit in master mode reception automatically stops communication after "starts frame processing according to the value set in this bit" after reception starts.

RMEDTG bit (1: Receive End (writable only when in Master Receive))

This bit is used to end reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.TXMD[1:0]) are 10b.

RMSTTG bit (1: Receive Start (writable only when in Master Receive))

This bit is used to start reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.TXMD[1:0]) are 10b.

Writing 1 to this bit during reception is not accepted. Write again after reception is completed.

36.3.8 SPDRCR : SPI Control Register for Received Data Ready Detection

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x0D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SPDRC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SPDRC[7:0]	SPI Receive Data Ready Detect Adjustment 0x00: Disable receive data ready detection function 0x01: Performs reception data ready judgment after 1 PCLKSPIn ⋮ 0xFF: Performs reception data ready judgment after 255 PCLKSPIn	R/W

The SPDRCR register is used to set the SPI receive data ready detection function. If the set value is changed while SPCR.SPE = 1, subsequent operations are not guaranteed.

SPDRC[7:0] bits (SPI Receive Data Ready Detect Adjustment)

The receive data ready detection function can be disabled or, if used, the period until detection can be set from 1 to 255 PCLKSPIn.

The value set in the SPDRC[7:0] bits is used to 1 set the SPDRF flag. For details, see the description of SPDRF in section 36.3.18. SPSR : SPI Status Register.

36.3.9 SPPCR : SPI Pin Control Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x0E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MOIFE	MOIFV	—	SPOM	SPLP2	SPLP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPLP	SPI Loopback 0: Normal mode 1: Loopback mode (data is inverted for transmission)	R/W

Bit	Symbol	Function	R/W
1	SPLP2	SPI Loopback 2 0: Normal mode 1: Loopback mode (data is not inverted for transmission)	R/W
2	SPOM	SPI Output Pin Mode 0: CMOS output 1: Open-drain output	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	MOIFV	MOSI Idle Fixed Value 0: The fixed value of MOSI idle = 0. 1: The fixed value of MOSI idle = 1.	R/W
5	MOIFE	MOSI Idle Value Fixing Enable 0: The MOSI output value is the last data of previous transfer. 1: The MOSI output value is the set MOIFV bit value.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

The SPPCR register is used to set pin mode of the SPI. If SPPCR is modified with the SPCR.SPE bit = 1, subsequent operation is not guaranteed.

SPLP bit (SPI Loopback)

When the SPLP bit is set to 1, the SPI shuts down the route between the MISO pin and the shift register (when SPCR.MSTR = 1) or shuts down the route between the MOSI pin and the shift register, inverts the input route value in the shift register, and then connects the route to the output route (when SPCR.MSTR = 0) (loopback mode).

SPLP2 bit (SPI Loopback 2)

When the SPLP2 bit is set to 1, the SPI shuts down the route between the MISO pin and the shift register (when SPCR.MSTR = 1) or shuts down the route between MOSI pin and the shift register and then connects the route to the output route without inverting the input route value in the shift register (when SPCR.MSTR = 0) (loopback mode). If this bit is set to 1 together with the SPLP bit, setting this bit takes precedence.

SPOM bit (SPI Output Pin Mode)

This bit is used to select CMOS output pin or open drain output pin as SPI's output pins.

MOIFV bit (MOSI Idle Fixed Value)

This bit is used to select the MOSI pin output value during the SSL negation period (including SSL retention period in burst transfer) when SPCR.MOIFE = 1 in master mode.

MOIFE bit (MOSI Idle Value Fixing Enable)

This bit is used for the SPI in master mode to fix the MOSI output value during the SSL negation period (including SSL retention period in burst transfer). When SPCR.MOIFE = 0, the SPI outputs the last data of the previous serial transfer to MOSI during the SSL negation period. When SPCR.MOIFE = 1, the SPI outputs the fixed MOIFV bit value to MOSI.

36.3.10 SPCR2 : SPI Control Register 2

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x0F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SPSCKDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SPSCKDL[2:0]	SPI Master Receive Clock Analog Delay Valid only in master mode 0 0 0: No delay 0 0 1: 1.1 ns (max) 0 1 0: 2.2 ns (max) 0 1 1: 3.3 ns (max) 1 0 0: 4.4 ns (max) 1 0 1: 5.5 ns (max) 1 1 0: 6.6 ns (max) 1 1 1: 7.7 ns (max)	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

The SPCR2 register is used to set the analog delay of the master receive clock. If the value set in this register is changed while SPCR.SPE = 1, subsequent operations are not guaranteed.

SPSCKDL[2:0] bits (SPI Master Receive Clock Analog Delay)

These bits set the analog delay for MRIOCLK input to SPI in master mode. By setting these bits, the sampling timing of the received data can be adjusted. For details, see the SPSCKSEL bit of section 36.3.6. SPCR : SPI Control Register.

36.3.11 SSLP : SPI Slave Select Polarity Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	SSL3P	SSL2P	SSL1P	SSL0P
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SSL0P	SSL0 Signal Polarity Setting 0: In the Motorola-SPI case, the SSL0 signal is active low (0). In the TI-SSP case, the SSL0 signal is active high (1). 1: In the Motorola-SPI case, the SSL0 signal is active high (1). In the TI-SSP case, the SSL0 signal is active low (0).	R/W
1	SSL1P	SSL1 Signal Polarity Setting 0: In the Motorola-SPI case, the SSL1 signal is active low (0). In the TI-SSP case, the SSL1 signal is active high (1). 1: In the Motorola-SPI case, the SSL1 signal is active high (1). In the TI-SSP case, the SSL1 signal is active low (0).	R/W
2	SSL2P	SSL2 Signal Polarity Setting 0: In the Motorola-SPI case, the SSL2 signal is active low (0). In the TI-SSP case, the SSL2 signal is active high (1). 1: In the Motorola-SPI case, the SSL2 signal is active high (1). In the TI-SSP case, the SSL2 signal is active low (0).	R/W
3	SSL3P	SSL3 Signal Polarity Setting 0: In the Motorola-SPI case, the SSL3 signal is active low (0). In the TI-SSP case, the SSL3 signal is active high (1). 1: In the Motorola-SPI case, the SSL3 signal is active high (1). In the TI-SSP case, the SSL3 signal is active low (0).	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

The SSLP register is used to set the polarity of SSL0 to SSL3 signals of the SPI. If any of these SSLP bits is modified with the SPCR.SPE bit = 1, subsequent operation is not guaranteed.

SSLnP bits (SSLn Signal Polarity Setting)

These bits are used to specify the polarity of SSL signals. The set SSLnP bit (n = 3 to 0) values indicate the active polarity of SSLn signals.

SSL0 is different from SSL1, SSL2, and SSL3. In slave or multi-master mode, it functions as an input.

For details, see section 36.4.3.2. Single Master/Single Slave (This LSI = Slave) and section 36.4.3.5. Multi-Master/Multi-Slave (with This LSI Acting as Master) .

36.3.12 SPBR : SPI Bit Rate Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x11

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SPR[7:0]							
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	SPR[7:0]	The SPBR register is used to set the bit rate in master mode. If SPBR is modified while SPCR.MSTR = 1 and SPCR.SPE = 1, subsequent operation is not guaranteed.	R/W

When the SPI is used in slave mode, the bit rate depends on the input clock bit rate regardless of the SPBR.BRDV setting. (Specify a bit rate that meets electrical characteristics.)

The bit rate is determined by a combination of the set SPBR and BRDV[1:0] in the SPCMDm register (SPCMD0 to SPCMD7).

The bit rate is calculated by the following expression, where "n" is the set SPBR value (0 to 255) and "N" is the set BRDV[1:0] bits value (0 to 3).

$$\text{Bit rate} = \frac{f(\text{PCLKSPIn})}{2 \times (n+1) \times 2^{N}}$$

Table 36.7 shows an example of correspondence between bit rates and set values of SPBR and BRDV[1:0].

Table 36.7 Corresponding between bit rates and set values (examples)

SPBR (n)	BRDV[1:0] bits (N)	Division ratio	Bit rate				
			PCLKSPIn = 75 MHz	PCLKSPIn = 80 MHz	PCLKSPIn = 96 MHz	PCLKSPIn = 100 MHz	PCLKSPIn = 125 MHz
0	0	2	37.5 Mbps	40.00 Mbps	48.00 Mbps	50.00 Mbps	No support
1	0	4	18.75 Mbps	20.00 Mbps	24.00 Mbps	25.00 Mbps	31.25 Mbps
2	0	6	12.5 Mbps	13.33 Mbps	16.00 Mbps	16.67 Mbps	20.83 Mbps
3	0	8	9.38 Mbps	10.00 Mbps	12.00 Mbps	12.50 Mbps	15.63 Mbps
4	0	10	7.50 Mbps	8.00 Mbps	9.60 Mbps	10.00 Mbps	12.50 Mbps
5	0	12	6.25 Mbps	6.67 Mbps	8.00 Mbps	8.33 Mbps	10.42 Mbps
5	1	24	3.13 Mbps	3.33 Mbps	4.00 Mbps	4.17 Mbps	5.21 Mbps
5	2	48	1.56 Mbps	1.67 Mbps	2.00 Mbps	2.08 Mbps	2.60 Mbps
5	3	96	781 kbps	833 kbps	1.00 Mbps	1.04 Mbps	1.30 Mbps
255	3	4096	18.3 kbps	19.5 kbps	23.4 kbps	24.4 kbps	30.5 kbps

36.3.13 SPSCR : SPI Sequence Control Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x13

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SPSLN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SPSLN[2:0]	SPI Sequence Length Specification The order in which the SPCMD0 to SPCMD07 registers are to be referenced is changed in accordance with the sequence length that is set in these bits. The relationship among the setting of these bits, the sequence length, and the SPCMD0 to SPCMD7 register numbers referenced by SPI is as follows. However, the SPI in slave mode always refers to SPCMD0. 0 0 0: Sequence Length = 1 (0→0→⋯) 0 0 1: Sequence Length = 2 (0→1→0→⋯) 0 1 0: Sequence Length = 3 (0→1→2→0→⋯) 0 1 1: Sequence Length = 4 (0→1→2→3→0→⋯) 1 0 0: Sequence Length = 5 (0→1→2→3→4→0→⋯) 1 0 1: Sequence Length = 6 (0→1→2→3→4→5→0→⋯) 1 1 0: Sequence Length = 7 (0→1→2→3→4→5→6→0→⋯) 1 1 1: Sequence Length = 8 (0→1→2→3→4→5→6→7→0→⋯)	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

The SPSCR register is used to set the sequence length for the SPI to perform master operation.

Before modifying the SPSLN[2:0] bits in SPSCR while SPCR.MSTR = 1 and SPCR.SPE = 1, confirm that SPSR.IDLNF = 0.

SPSLN[2:0] bits (SPI Sequence Length Specification)

These bits are used to set the sequence length for the SPI in master mode to perform sequence operation.

According to the sequence length specified by SPSLN[2:0] bits, the SPI in master mode changes the SPCMDm registers (SPCMD0 to SPCMD7) to be referenced and the reference sequence. For details, see (3) Sequence Control.

The SPI in slave mode always references SPCMD0.

36.3.14 SPCMDm : SPI Command Register m (m = 0 to 7)

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x14 + 0x04 × m

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	SSLA[1:0]		—	—	—	SPB[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SCKDEN	SLNDEN	SPNDEN	LSBF	—	—	—	—	SSLKP	—	—	—	BRDV[1:0]		CPOL	CPHA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CPHA	RSPCK Phase This register is valid only for Motorola-SPI cases. (In the TI-SSP case, it is fixed at 1). 0: Data is sampled at an odd edge and changes at an even edge. 1: Data changes at an odd edge and is sampled at an even edge.	R/W
1	CPOL	RSPCK Polarity 0: RSPCK in idle state is 0. 1: RSPCK in idle state is 1.	R/W
3:2	BRDV[1:0]	Bit Rate Division 0 0: The base bit rate is selected. 0 1: Two-divided base bit rate is selected. 1 0: Four-divided base bit rate is selected. 1 1: Eight-divided base bit rate is selected.	R/W
6:4	—	These bits are read as 0. The write value should be 0.	R/W
7	SSLKP	SSL Signal Level Hold 0: All SSL signals are negated at the end of transfer. 1: SSL signal level is held after the transfer ends until the next access starts.	R/W
11:8	—	These bits are read as 0. The write value should be 0.	R/W
12	LSBF	SPI LSB First 0: MSB first 1: LSB first	R/W
13	SPNDEN	SPI Next-Access Delay Enable 0: Next-access delay is 1 RSPCK + 5 PCLKSPIn 1: Next-access delay is the set value of the SPI next-access delay register (SPND).	R/W
14	SLNDEN	SSL Negation Delay Setting Enable 0: [Master] SSL negation delay is 1 RSPCK. [Slave in the TI-SSP] SSL negation delay is 1 PCLKSPIn + 2~3 PCLKSPIn (Synchronization delay) 1: SSL negation delay is the set value of the slave select negation delay register (SSLND).	R/W
15	SCKDEN	RSPCK Delay Setting Enable 0: RSPCK delay is 1 RSPCK. [In the Motorola-SPI case] RSPCK delay is 0 RSPCK. [In the TI-SSP case] 1: RSPCK delay is the set value of the RSPCK delay register (SPCKD).	R/W
20:16	SPB[4:0]	SPI Data Length 0x00: Setting prohibited 0x01: Setting prohibited 0x02: Setting prohibited 0x03: 4 bits 0x04: 5 bits 0x05: 6 bits ⋮ 0x1E: 31 bits 0x1F: 32 bits	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
25:24	SSLA[1:0]	SSL Signal Assertion 0 0: SSL0 0 1: SSL1 1 0: SSL2 1 1: SSL3	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

The SPI has eight SPI command registers (SPCMD0 to SPCMD7) that are used to set the transfer format of the SPI in master mode. Furthermore, some bits in SPCMD0 are used to set the transfer format of the SPI in slave mode.

The SPI in master mode sequentially references SPCMD0 to SPCMD7 according to the setting of SPSCR.SPSLN[2:0], and then performs serial transfer specified in the referenced SPCMD.

SPCMD should be set while the transmit buffer is empty (next-transfer data is not set) and data which refers to SPCMD has not been written.

The SPCMD referenced by the SPI in master mode is indicated by SPCP[2:0] in the SPSSR register. If SPCMD0 is modified while the SPI in slave mode is enabled (SPCR.SPE = 1), subsequent operation is not guaranteed.

CPHA bit (RSPCK Phase)

This bit is used to set the RSPCK phase of the SPI in master mode or slave mode. To perform data communication between SPI modules, the same RSPCK phase must be set for both modules.

When SPCR.SPMS = 0 and SPCR.SPFRF = 1 (in TI SSP mode), setting CPHA = 0 is invalid.

This register is valid only for Motorola-SPI cases.

CPOL bit (RSPCK Polarity)

This bit is used to set the RSPCK polarity of the SPI in master mode or slave mode. To perform data communication between SPI modules, the same RSPCK polarity must be set for both modules.

BRDV[1:0] bits (Bit Rate Division)

This register is used to determine the bit rate with a combination of the set values of the BRDV[1:0] bits and the SPBR register. The set SPBR value determines the base bit rate. The set BRDV[1:0] bits value is used to select undivided, 2-divided, 4-divided, or 8-divided base bit rate. SPCMD0 to SPCMD7 enable setting of different BRDV[1:0] values. This makes it possible to perform serial transfer with a different bit rate for each command.

SSLKP bit (SSL Signal Level Hold)

This bit is used to set whether to hold or negate the SSL signal level of the current command during a period from the SSL negation timing for the current command to the SSL assertion timing for the next command when the SPI in master mode performs serial transfer. Setting this bit to 1 enables burst transfer in SPI operation master mode. For details, see (4) Burst Transfer in section 36.4.13.1. Master Mode Operation.

To use the SPI in slave mode, set SSLKP bit to 0.

LSBF bit (SPI LSB First)

This bit is used to set the data format of the SPI in master mode or slave mode to MSB first or LSB first.

SPNDEN bit (SPI Next-Access Delay Enable)

This bit is used to set the period from SSL negation to SSL assertion in SPI master mode. When SPNDEN = 0, the SPI sets the next-access delay to 1 RSPCK + 5 PCLKSPIn. When SPNDEN = 1, the SPI inserts the next-access delay in accordance with the SPND register setting.

To use the SPI in slave mode, set SPNDEN bit to 0.

SLNDEN bit (SSL Negation Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period from RSPCK oscillation stop to SSL negation in SPI master mode. When SLNDEN = 0, the SPI sets the SSL negation delay to 1 RSPCK. When SLNDEN = 1, the SPI negates the SSL signal with the RSPCK delay in accordance with the SSLND register setting.

To use the SPI in slave mode, set SLNDEN bit to 0.

[In the TI-SSP case]

This bit is used to set the period from RSPCK oscillation stop to output disable in SPI master mode, or last edge of RSPCK to output disable in slave mode. When the SLNDEN bit is 0, the SSL negate delay is 1 RSPCK in master mode and 1 PCLKSPIn + 2~3 PCLKSPIn (Synchronization delay) in slave mode. When SLNDEN = 1, the SPI negates the SSL signal with the RSPCK delay in accordance with the SSLND register setting.

When using SPI in slave mode except TI SSP setting, set the SLNDEN bit to 0.

SCKDEN bit (RSPCK Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period (RSPCK delay) after the SPI in master mode activates the SSL signal until it oscillates RSPCK. When SCKDEN = 0, the SPI sets the RSPCK delay to 1 RSPCK. When SCKDEN = 1, the SPI starts RSPCK oscillation with the RSPCK delay in accordance with the SPCKD register setting.

To use the SPI in slave mode, set SCKDEN bit to 0.

[In the TI-SSP case]

This bit is used to set the period from the start of assertion of the SSL signal to the RSPCK oscillation (RSPCK delay) and the period of the SSL signal to negation by the SPI in master mode. When SCKDEN = 0, the SPI does not sets the RSPCK delay. When SCKDEN = 1, the SPI starts RSPCK oscillation with the RSPCK delay in accordance with the SPCKD register setting.

To use the SPI in slave mode, set SCKDEN bit to 0.

SPB[4:0] bits (SPI Data Length)

These bits are used to set the transfer data length of the SPI in master mode or slave mode.

SSLA[1:0] bits (SSL Signal Assertion)

These bits are used to control SSL signal assertion for the SPI in master mode to perform serial transfer. The set SSLA[1:0] bits value controls assertion of the SSL3 to SSL0 signals. The signal polarity when the SSL signal is asserted depends on the set value of the SSLP register. When SSLA[1:0] bits are set to 00b in multi-master mode, serial transfer is performed with all SSL signals negated (because SSL0 is input).

To use the SPI in slave mode, set SSLA[1:0] bits to 00b.

36.3.15 SPDCR : SPI Data Control Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x40

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SPFC[1:0]		—	—	—	SINV	SPRDTD	SLSEL[1:0]		BYSW
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BYSW	Byte Swap Operating Mode Select 0: Byte swap is disabled 1: Byte swap is enabled	R/W
2:1	SLSEL[1:0]	SSL Pin Output Select See Table 36.8.	R/W
3	SPRDTD	SPI Receive Data or Transmit Data Selection 0: The SPDR reads the receive buffer 1: The SPDR reads the transmit buffer	R/W
4	SINV	Serial data invert 0: Not invert serial data 1: Invert serial data	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
9:8	SPFC[1:0]	Frame Count Number of Frames Specification 0 0: 1 frame 0 1: 2 frames 1 0: 3 frames 1 1: 4 frames	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

The SPDCR register controls the data format.

If the value set in this register is changed while SPCR.SPE = 1, subsequent operations are not guaranteed.

BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. A data after byte swap is different by a data length (setting of SPCMD.SPB[4:0]).

When byte swap, A data length (setting of SPB[4:0]) must be set to 32 bits or 16 bits. Other case of data length (for example, 4 to 15, 17 to 31 bit length), byte swap is not guaranteed. For the arrangement of data before and after swapping data lengths of 32 bits and 16 bits, see section 36.4.4. Data Format and section 36.4.4.5. Byte swap reception.

When the parity function set to valid, the behavior is not guaranteed.

SLSEL[1:0] bits (SSL Pin Output Select)

The SLSEL[1:0] bits are used to select SSL output or I/O as an SSL pin function in master mode.

Table 36.8 SSL pin output selection

SSLn pin	SLSEL[1:0] = 00b	SLSEL[1:0] = 01b	SLSEL[1:0] = 10b	SLSEL[1:0] = 11b
SSL0	Output/Input	Output/Input	Output/Input	Setting prohibited
SSL1	Output	I/O	Output	
SSL2, SSL3	Output	I/O	I/O	

Note: Input or output of SSL0 is determined by the SPCR.MODFEN bit. For details, see Table 36.9.

SPRDTD bit (SPI Receive Data or Transmit Data Selection)

The SPRDTD bit is used to select receive buffer or transmit buffer from which the SPI data register (SPDR) value is read.

When the transmit buffer is read, the value written to SPDR the last time is read.

SINV bit (Serial data invert)

The SINV bit is used to invert transmit data and receive data.

When the SINV bit is set to 1, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/reception data.

SPFC[1:0] bits (Frame Count)

The SPFC[1:0] bits are used for the condition to set the CENDF flag in slave receive only mode. For details on the CENDF flag setting conditions, see section 36.3.18. SPSR : SPI Status Register.

The SPFC[1:0] bits are invalid except in the slave receive only mode.

36.3.16 SPDCR2 : SPI Data Control Register 2

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x44

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TTRG[1:0]		—	—	—	—	—	—	RTRG[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RTRG[1:0]	Receive FIFO threshold setting When using DMA, set the threshold to 0 for RTRG and TTRG bits. 0 0: Threshold 0 0 1: Threshold 1 1 0: Threshold 2 1 1: Threshold 3	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
9:8	TTRG[1:0]	Transmission FIFO threshold setting When using DMA, set the threshold to 0 for RTRG and TTRG bits. 0 0: Threshold 0 0 1: Threshold 1 1 0: Threshold 2 1 1: Threshold 3	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

The SPDCR2 register controls the FIFO threshold. If the value set in this register is changed while SPCR.SPE = 1, subsequent operations are not guaranteed.

RTRG[1:0] bits (Receive FIFO threshold setting)

Set the receive FIFO threshold.

When the number of data stored in the receive FIFO > the number of frames set by RTRG[1:0], the receive buffer full flag is set.

TTRG[1:0] bits (Transmission FIFO threshold setting)

Set the transmit FIFO threshold.

When the number of empty stages in the transmit FIFO > the number of frames set in TTRG[1:0], the transmit buffer empty flag is set.

36.3.17 SPSSR : SPI Sequence Status Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x51

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	SPECM[2:0]			—	SPCP[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SPCP[2:0]	SPI Command Pointer 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
3	—	This bit is read as 0.	R
6:4	SPECM[2:0]	SPI Error Command 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
7	—	This bit is read as 0.	R

The SPSSR register indicates the sequence control status when the SPI performs master operation. Write access to SPSSR is ignored.

SPCP[2:0] bits (SPI Command Pointer)

These bits show the SPCMDm registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the current pointer in the SPI sequence control. For details about the SPI sequence control, see section 36.4.13.1. Master Mode Operation.

SPECM[2:0] bits (SPI Error Command)

These bits show the SPCMDm registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the command pointer (SPCP[2:0] bits) when an error was detected in the SPI sequence control. The SPI updates the SPECM[2:0] bits value only when an error is detected. When no error is present (SPSR.OVRF = 0, SPSR.MODF = 0, SPSR.PERF = 0), the SPECM[2:0] bits value has no meaning. For the SPI's error detection function, see section 36.4.10. Error Detection. For the SPI's sequence control, see section 36.4.13.1. Master Mode Operation.

36.3.18 SPSR : SPI Status Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x52

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SPRF	CENDF	SPTEF	UDRF	PERF	MODF	IDLNF	OVRF	SPDRF	—	—	—	—	—	—	—
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0.	R
7	SPDRF	SPI Receive Data Ready Flag 0: Receive data ready not detected 1: Receive data ready detected	R
8	OVRF	Overrun Error Flag 0: No overrun error is present. 1: An overrun error is present.	R
9	IDLNF	SPI Idle Flag 0: The SPI is in the idle state. 1: The SPI is in the transfer state.	R
10	MODF	Mode Fault Error Flag 0: Neither mode fault error nor underrun error is present. 1: A mode fault error or underrun error is present.	R
11	PERF	Parity Error Flag 0: No parity error is present. 1: A parity error is present.	R
12	UDRF	Underrun Error Flag This bit indicates error status in combination with the MODF flag. The UDRF bit is valid when MODF flag is 1. 0: Mode fault error occurred (MODF = 1) 1: Underrun error occurred (MODF = 1)	R
13	SPTEF	SPI Transmit Buffer Empty Flag 0: The number of empty stages in the transmit FIFO ≤ the value set in SPDCR2.TTRG 1: The number of empty stages in the transmit FIFO > the value set in SPDCR2.TTRG	R
14	CENDF	Communication End Flag 0: The SPI is not communicating or communicating. 1: The SPI communication completed.	R
15	SPRF	SPI Receive Buffer Full Flag 0: The number of data stored in the receive FIFO ≤ number of frames set by the SPDCR2.RTRG bit. 1: The number of data stored in the receive FIFO > number of frames set by the SPDCR2.RTRG bit.	R

SPDRF bit (SPI Receive Data Ready Flag)

During communication (SPCR.SPE = 1), a certain period of time has elapsed while the number of data stored in the reception FIFO ≤ the reception FIFO threshold.

This bit is set to 0 when the reception operation is not performed (SPCR.TXMD[1:0] = 01b).

[Setting (to 1) condition]

All the following two conditions are met:

- SPDRCR.SPDRC[7:0] ≠ 0x00
- After the receive FIFO has been written, when the number of data stored in the receive FIFO ≤ the receive FIFO threshold and the value set by SPDRC[7:0] has elapsed

[Clearing (to 0) condition]

- When 1 is written to the SPSRC.SPDRFC bit

OVRF bit (Overrun Error Flag)

This flag indicates whether an overrun error is present. When the RSPCK clock auto-stop function is enabled (SPCR.SCKASE bit = 1) in master mode (SPCR.MSTR bit = 1), no overrun error occurs and, therefore, this flag is not set to 1. For details, see section 36.4.10.1. Overrun Error.

[Setting (to 1) condition]

When serial transfer is completed in one of the following two conditions with data stored in the receive FIFO for the number of FIFO stages.

- The SPCR.TXMD[1:0] bits = 00b. (transmit-receive mode)
- The SPCR.TXMD[1:0] bits = 10b. (receive only)

[Clearing (to 0) condition]

- When 1 is written to the SPSRC.OVRFC bit

IDLNF bit (SPI Idle Flag)

This flag indicates transfer status of the SPI.

[Setting (to 1) condition]

[Transmit-Receive, Transmit-only Master mode]

- None of the [Transmit-Receive, Transmit-only Master mode] in [Clearing (to 0) conditions]

[Receive-only Master mode]

- When 1 is written to SPCRRM.RMSTTG bit

[Slave mode]

- SPCR.SPE = 1 (SPI function enabled)

[Clearing (to 0) conditions]

Communication status: 1-(1) to (6) * For details of communication status, see Table 36.6.

[Transmit-Receive, Transmit-only Master mode]

Any of the following two conditions is met:

- SPCR.SPE = 0 (SPI initialization)
- All the following three conditions are met:
  - The next transfer data is not set in the transmission buffer (SPTXn, n = 0 to 3)
  - SPSSR.SPCP[2:0] = 000b (at the beginning of sequence control)
  - The operation completed until the next access delay (the master main state machine has transitioned to the idle state)

[Receive-only Master mode]

Communication status: 1-(7) to (9)

Any of the following two conditions is met:

- SPCR.SPE = 0 (SPI initialization)
- Any of the following three conditions is met:
  - When RMFM[4:0] = 0x00, after writing 1 to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)
  - When RMFM[4:0] ≠ 0x00, after writing 1 to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)
  - When RMFM[4:0] ≠ 0x00, the operation is completed up to the next access delay after processing is completed for the number of received frames set in RMFM[4:0] (the master main state machine has transitioned to the idle state)

[Slave mode]

Communication status: 0 - (1) to (9)

- SPCR.SPE = 0 (SPI initialization)

MODF bit (Mode Fault Error Flag)

This flag indicates whether a mode fault error or an underrun error is present. The UDRF flag allows you to see which error (mode fault error or underrun error) has occurred.

[Setting (to 1) condition]

[Multi-master mode]

- The SSL0 pin input level becomes active level while the SPCR.MSTR bit = 1 (master mode) and the SPCR.MODFEN bit = 1 (mode fault error detection enabled), and then the SPI has detected a mode fault error.

[Slave, Motorola-SPI mode]

Any of the following two conditions is met:

- The SSL0 pin is negated before the RSPCK cycles necessary for data transfer end while the SPCR.MSTR bit = 0 (slave mode), SPCR.SPFRF bit = 0 (Motorola-SPI) and the SPCR.MODFEN bit = 1 (mode fault error detection enabled), and then the SPI has detected a mode fault error.
- Serial transfer is started before transmit data output becomes ready while the SPCR.SPE bit = 1 (SPI function enabled), and then the SPI has detected an underrun error.

[Slave, TI-SSP mode]

Any of the following two conditions is met:

- The SSL0 pin is asserted before the RSPCK cycles necessary for data transfer end while the SPCR.MSTR bit = 0 (slave mode), SPCR.SPFRF bit = 1 (TI-SSP) and the SPCR.MODFEN bit = 1 (mode fault error detection enabled), and then the SPI has detected a mode fault error.
- Serial transfer is started before transmit data output becomes ready while the SPCR.SPE bit = 1 (SPI function enabled), and then the SPI has detected an underrun error.

The SSL signal active level depends on the SSLP.SSLiP bits (SSL signal polarity bits).

[Clearing (to 0) condition]

- When 1 is written to the SPSRC.MODFC bit

PERF bit (Parity Error Flag)

This flag indicates whether a parity error is present.

[Setting (to 1) condition]

When the serial transfer ends and a parity error is detected with the SPCR.SPPE bit set to 1 under any of the following two conditions:

- The SPCR.TXMD[1:0] bits = 00b (transmit-receive)
- The SPCR.TXMD[1:0] bits = 10b (receive-only)

[Clearing (to 0) condition]

- When 1 is written to the SPSRC.PERFC bit

UDRF bit (Underrun Error Flag)

This flag indicates that a mode fault error or an underrun error is present.

[Setting (to 1) condition]

- Serial transfer is started before transmit data output becomes ready while the SPCR.MSTR bit = 0 (slave mode) and the SPCR.TXMD[1:0] bits = 00b or 01b (transmit-receive or transmit-only) and the SPCR.SPE bit = 1 (SPI function enabled), and then the SPI has detected an underrun error.

[Clearing (to 0) condition]

- When 1 is written to the SPSRC.UDRFC bit

SPTEF bit (SPI Transmit Buffer Empty Flag)

This flag indicates the transmit buffer (SPTX) status in the SPI data register (SPDR).

[Setting (to 1) condition]

Any of the following three conditions is met:

- The SPCR.SPE bit is set to 0 (SPI initialization)
- When the number of empty transmission FIFO stages > SPDCR2.TTRG[1:0]
- When 1 is written to SPFCR.SPFRST

[Clearing (to 0) condition]

Any of the following two conditions is met:

- At the time of final access when transmission data is written to SPDR (SPTXn, n = 0 to 2) in one processing routine using DMAC
- When 1 is written to the SPSRC.SPTEFC bit

Writing a value to the SPDR register is enabled only while the SPTEF flag = 1. If a value is written to the SPDR register while the SPTEF flag = 0, transmit buffer data is not updated.

CENDF bit (Communication End Flag)

This flag indicates communication end status of SPI. It turns 1 at communication end and turns 0 at starting next communication.

[Setting (to 1) condition]

Transmit-Receive / Transmit-only Master mode

Communication status: 1 - (1) to (6). For details of communication status, see Table 36.6.

The following three conditions are met:

- The next transfer data is not set in the transmission buffer (SPTXn, n = 0 to 3)
- The SPSSR.SPCP[2:0] are 000b (it means the head of the sequential control)
- Operation completed until the next access delay (the master main state machine has transitioned to the idle state)

Receive-only Master mode

Communication status: 1 - (7) to (9)

Any of the following three conditions is met:

- When RMFM[4:0] = 0x00, after writing 1 to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)

- When RMFM[4:0] ≠ 0x00, after writing 1 to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)
- When RMFM[4:0] ≠ 0x00, the operation is completed up to the next access delay after processing is completed for the number of received frames set in RMFM[4:0] (the master main state machine has transitioned to the idle state)

Transmit-receive / transmit-only slave, Motorola-SPI mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0).

Communication status: 0 - (1), (4)

The following three conditions are met:

- The next transfer data is not set in the transmission buffer
- The transmission shift register is empty (it means SPI does not do serial transfer)
- SSL0 was negated

Transmit-receive / transmit-only slave, TI-SSP mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0).

Communication status: 0 - (2), (5)

The following three conditions are met:

- The next transfer data is not set in the transmission buffer
- The transmission shift register is empty (it means SPI does not do serial transfer)
- When the SSL negate delay is completed

Transmit-receive / transmit only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1)

Communication status: 0 - (3), (6)

The following three conditions are met:

- The next transfer data is not set in the transmission buffer
- The transmission shift register is empty (it means SPI does not do serial transfer)
- The last even edge of RSPCK of the frame was detected (when the SPCMD.CPHA bit is 1)

Receive only slave, Motorola-SPI mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0).

Communication status: 0 - (7)

The following condition is met:

- SSL0 input was negated after getting frames for SPDCR.SPFC set value in the receive buffer

Receive only slave, TI-SSP mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0).

Communication status: 0 - (8)

The following condition is met:

- SSL0 negate delay is completed after getting frames for SPDCR.SPFC set value in the receive buffer

Receive only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1).

Communication status: 0 - (9)

The following condition is met:

- The last even edge of RSPCK of the last frame received for SPFC set value was detected (when the SPCMD.CPHA bit is 1)

[Clearing (to 0) condition]

Transmit-Receive / Transmit-only Master mode

Communication status: 1 - (1) to (6)

Any of the following two conditions is met:

- The next transmit data was written to the transmit buffer (SPTX)

- When 1 is written to the SPSRC.CENDFC bit

Receive-only Master mode

Communication status: 1 - (7) to (9)

Any of the following two conditions is met:

- When 1 is written to the SPCRRM.RMSTTG bit with SPCR.SPE = 1
- When 1 is written to the SPSRC.CENDFC bit

Transmit-receive / transmit only slave mode

Communication status: 0 - (1) to (6)

Satisfy one of following conditions:

- The next transmit data is written to the transmit buffer (SPTX)
- When 1 is written to the SPSRC.CENDFC bit

Receive-only slave mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0).

Communication status: 0 - (7) to (8)

Satisfy one of following conditions:

- SSL0 assertion of next data is detected
- When 1 is written to the SPSRC.CENDFC bit

Receive-only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1).

Communication status: 0 - (9)

Satisfy one of following conditions:

- The first edge of RSPCK of the next data is detected
- When 1 is written to the SPSRC.CENDFC bit

SPRF bit (SPI Receive Buffer Full Flag)

This flag indicates the receive buffer (SPRX) status in the SPDR register.

[Setting (to 1) condition]

When the number of data stored in the receive FIFO > the number of frames set in the SPDCR2.RTRG[1:0] bits in Transmit-Receive, Receive-only modes. However, the SPRF flag does not change from 0 to 1 while the OVRF flag = 1. (See section 36.4.10. Error Detection.)

[Clearing (to 0) condition]

Any of the following three conditions is met:

- At the last access when read data is read from SPDR (SPRXn, n = 0 to 2) in one processing routine using DMAC
- When 1 is written to the SPSRC.SPRFC bit
- When 1 is written to the SPFCR.SPFRST bit

36.3.19 SPTFSR : SPI Transfer FIFO Status Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x58

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	TFDN[2:0]		
Value after reset:	0	0	0	0	0	1	0	0

Bit	Symbol	Function	R/W
2:0	TFDN[2:0]	Transmit FIFO data empty stage number 0 0 0: Number of empty stages 0 0 0 1: Number of empty stages 1 0 1 0: Number of empty stages 2 0 1 1: Number of empty stages 3 1 0 0: Number of empty stages 4	R
7:3	—	These bits are read as 0.	R

Note: TFDN[2:0] is initialized by SPCR.SPE = 0.

36.3.20 SPRFSR : SPI Receive FIFO Status Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x5C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	RFDN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	RFDN[2:0]	Receive FIFO data store stage number 0 0 0: Number of store stages 0 0 0 1: Number of store stages 1 0 1 0: Number of store stages 2 0 1 1: Number of store stages 3 1 0 0: Number of store stages 4	R
7:3	—	These bits are read as 0.	R

Note: RFDN[2:0] is initialized by SPCR.SPE = 0.

36.3.21 SPPSR : SPI Poling Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x60

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPEPS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPEPS	SPI Polling Status 0: SPCR.SPE is 0 1: SPCR SPE is 1	R
31:1	—	These bits are read as 0.	R

Note: This bit shows a result of SPCR.SPE after synchronization by the operation clock (PCLKSPIn).

36.3.22 SPSRC : SPI Status Clear Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x6A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SPRFC	CENDFC	SPTEFC	UDRFC	PERFC	MODFC	—	OVRFC	SPDRFC	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0.	R
7	SPDRFC	SPI Receive Data Ready Flag Clear The SPI receive data ready flag can be cleared by writing 1. When read, 0 is read.	W
8	OVRFC	Overrun Error Flag Clear By writing 1, the Overrun Error Flag can be cleared. Reading value is always 0.	W
9	—	This bit is read as 0.	R
10	MODFC	Mode Fault Error Flag Clear By writing 1, the Mode Fault Error Flag can be cleared. Reading value is always 0. Before setting MODFC and UDRFC, make sure that SPSR.MODF and UDRF are set to 1.	W
11	PERFC	Parity Error Flag Clear By writing 1, the Parity Error Flag can be cleared. Reading value is always 0.	W
12	UDRFC	Underrun Error Flag Clear By writing 1, the Underrun Error Flag can be cleared. Reading value is always 0. When clearing the UDRF flag, clear the MODF flag at the same time (MODFC = 1).	W
13	SPTEFC	SPI Transmit Buffer Empty Flag Clear By writing 1, the SPI Transmit Buffer Empty Flag can be cleared. Reading value is always 0.	W
14	CENDFC	Communication End Flag Clear By writing 1, the Communication End Flag can be cleared. Reading value is always 0.	W
15	SPRFC	SPI Receive Buffer Full Flag Clear By writing 1, the SPI Receive Buffer Full Flag can be cleared. Reading value is always 0.	W

The SPSRC register clears the status flag (SPSR) that indicates the operating status of SPI.

36.3.23 SPFCR : SPI FIFO Clear Register

Base address: SPIn = 0x8000_7000 + 0x0400 × n (n = 0 to 2)
SPI3 = 0x8100_7000

Offset address: 0x6C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SPFRST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPFRST	SPI FIFO clear By writing 1, the pointer in the FIFO and the stored data are initialized. Reading value is always 0.	W
7:1	—	The write value should be 0.	W

The SPFCR register is used to clear the FIFO.

If SPFCR is rewritten while SPCR.SPE = 1, subsequent operations are not guaranteed.

36.4 Operation

In this section, a word "serial transfer period" is used as a word that means a period from the start of valid data drive to latching of the final valid data.

36.4.1 Overview of SPI Operations

The SPI can transfer data in the following five modes.

- Slave mode (SPI operation)
- Single master mode (SPI operation)
- Multi-master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation)

SPI modes can be set by the MSTR, MODFEN, SPMS and SPFRF bits in the SPCR register.

Table 36.9 lists the relationship between SPI modes and SPCR settings, and outline of each mode.

Table 36.9 Relationship between SPI modes and SPCR settings and description of each mode (1 of 2)

Mode	Slave (SPI operation)	Single-Master (SPI operation)	Multi-Master (SPI operation)	Slave (Clock synchronous operation)	Master (Clock synchronous operation)
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
SPFRF bit setting	valid	valid	valid	In-valid	In-valid
RSPCK signal	Input	Output	Output/Hi-Z	Input	Output
MOSI signal	Input	Output	Output/Hi-Z	Input	Output
MISO signal	Output/Hi-Z	Input	Input	Output	Input
SSL0 signal	Input	Output	Input	Hi-Z (not used)	Hi-Z (not used)
SSL1 to SSL3 signals	Hi-Z (not used)	Output	Output/Hi-Z	Hi-Z (not used)	Hi-Z (not used)
Output pin mode	CMOS/open drain	CMOS/open drain	CMOS/open drain	CMOS/open drain	CMOS/open drain
SSL polarity modification function	Supported	Supported	Supported	—	—
Transfer rate	Up to PCLKSPIn/2	Up to PCLKSPIn/2	Up to PCLKSPIn/2	Up to PCLKSPIn/2	Up to PCLKSPIn/2
Clock source	RSPCK input	On-chip baud rate generator	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	2 types				
Clock phase	2 types*5	2 types*5	2 types*5	One (CPHA = 1)	2 types
First transfer bit	MSB/LSB				
Transfer data length	4 to 32 bits				
Burst transfer	Enabled (CPHA = 1)	Enabled (CPHA = 0, 1)	Enabled (CPHA = 0, 1)	—	—
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported
SSL negation delay control	Not supported*6	Supported	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Supported	Not supported	Supported

Table 36.9 Relationship between SPI modes and SPCR settings and description of each mode (2 of 2)

Mode	Slave (SPI operation)	Single-Master (SPI operation)	Multi-Master (SPI operation)	Slave (Clock synchronous operation)	Master (Clock synchronous operation)
Transfer activation method	SSL input active or RSPCK oscillation	Transmit buffer empty interrupt request or transmit buffer write when SPTEF = 1	Transmit buffer empty interrupt request or transmit buffer write when SPTEF = 1	RSPCK oscillation	Transmit buffer empty interrupt request or transmit buffer write when SPTEF = 1
Sequence control	Not supported	Supported	Supported	Not supported	Supported
Transmission buffer empty detection	Supported*4	Supported	Supported	Supported*4	Supported
Reception buffer full detection	Supported*1				
Overrun error detection	Supported*1	Supported*1 *3	Supported*1 *3	Supported*1	Supported*1 *3
Parity error detection	Supported*1 *2				
Mode fault error detection	Supported (MODFEN = 1)	Not supported	Supported	Not supported	Not supported
Underrun error detection	Supported*4	Not supported	Not supported	Supported*4	Not supported

Note 1. When SPI is transmit-master mode or transmit-slave mode (see Table 36.6), none of receive buffer full error, overrun error, and parity error is detected.
Note 2. When the SPCR.SPPE bit is 0, parity error is not detected.
Note 3. When the SPCR.SCKASE bit is 1, overrun error is not detected.
Note 4. When SPI is receive only slave mode (see Table 36.6), none of transmit buffer empty and underrun error is detected.
Note 5. CPHA = 0 is invalid in TI SSP mode. (Even if it is set, the operation is the same as when CPHA = 1.)
Note 6. Available only in TI SSP mode.

36.4.2 SPI Pin Control

The SPI automatically switches pin directions and output modes according to the settings of the SPCR.MSTR, SPCR.MODFEN and SPCR.SPMS bits and the SPPCR.SPOM bit.

When the SPPCR.SPOM bit is set to 0, each output becomes CMOS output, when the SPOM bit is set to 1, each output becomes open drain output.

Table 36.10 shows the relationship between pin state and set values of each bit.

For details of OE function, see section 36.4.5. Transfer Format (Frame Format).

Table 36.10 Relationship between pin states and set control bit values (1 of 2)

Mode	Pin	Pin State*1	
		SPOM = 0	SPOM = 1
Single-master mode (SPI operation) (MSTR = 1, MODFEN = 0, SPMS = 0)	RSPCK	CMOS output	Open-drain output
	SSL0 to SSL3	CMOS output	Open-drain output
	MOSI	CMOS output	Open-drain output
	MISO	Input	Input
Multi-master mode (SPI operation) (MSTR = 1, MODFEN = 1, SPMS = 0)	RSPCK*2	CMOS output/Hi-Z	Open-drain output/Hi-Z
	SSL0	Input	Input
	SSL1 to SSL3*2	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MOSI*2	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MISO	Input	Input

Table 36.10 Relationship between pin states and set control bit values (2 of 2)

Mode	Pin	Pin State*1	
		SPOM = 0	SPOM = 1
Slave mode (SPI operation) (MSTR = 0, SPMS = 0)	RSPCK	Input	Input
	SSL0	Input	Input
	SSL1 to SSL3*4	Hi-Z (not used)	Hi-Z (not used)
	MOSI	Input	Input
	MISO*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
Master mode (Clock synchronous operation) (MSTR = 1, MODFEN = 0, SPMS = 1)	RSPCK	CMOS output	Open-drain output
	SSL0 to SSL3*4	Hi-Z (not used)	Hi-Z (not used)
	MOSI	CMOS output	Open-drain output
	MISO	Input	Input
Slave mode (Clock synchronous operation) (MSTR = 0, SPMS = 1)	RSPCK	Input	Input
	SSL0 to SSL3*4	Hi-Z (not used)	Hi-Z (not used)
	MOSI	Input	Input
	MISO	CMOS output	Open-drain output

Note 1. The set SPI value is not applied to multi-function pins for which the SPI function is not selected.
Note 2. When SSL0 is at the active level, the pin state is Hi-Z. Motorola-SPI: When SSL0 is active level, the pin state becomes Hi-Z. TI-SSP: The terminal status becomes Hi-Z until SSL0 is asserted after SPCR.SPE = 1 and communication completed.
Note 3. Motorola-SPI: When SSL0 is inactive level or when SPCR.SPE = 0, the pin state becomes Hi-Z. TI-SSP: When SSL0 is except the communication period or when SPCR.SPE = 0 (assertion after SPE = 1 and communication completed), the pin status changes to Hi-Z.
Note 4. These pins are available for use as I/O port pins.

The SPI in single master mode (SPI operation) or multi-master mode (SPI operation) determines the MOSI signal value in the SSL negation period (including the SSL hold period in burst transfer) according to the settings of the SPPCR.MOIFE and SPPCR.MOIFV bits, as listed in Table 36.11.

Table 36.11 Determining the MOSI signal value in the SSL negation period

MOIFE bit	MOIFV bit	MOSI signal value during SSL negation period
0	0, 1	Final data from previous transfer
1	0	Always low
1	1	Always high

36.4.3 SPI System Configuration Examples

This configuration example describes that 0 level of SSL signals is active level. When connecting and using in a multi-slave or multi-master mode, the transfer format of the connected device should be unified to either Motorola-SPI or TISSP.

36.4.3.1 Single Master/Single Slave (This LSI = Master)

Figure 36.7 shows an example of single master/single slave SPI system configuration where this LSI is used as a master. In the single master/single slave configuration, the SSL0 to SSL3 output signals of this LSI (master) are not used.

SSL input signals of the SPI slave are fixed to 0 level to always select the SPI slave. When SPCMD.CPHA = 0, some slave devices cannot fix SSL signals to active level in the relevant transfer format. If the SSL signal level cannot be fixed, connect the SSL output of this LSI to the SSL input of the slave device.

This LSI (master) always drives the RSPCK and MOSI pins. The SPI slave always drives the MISO pin.

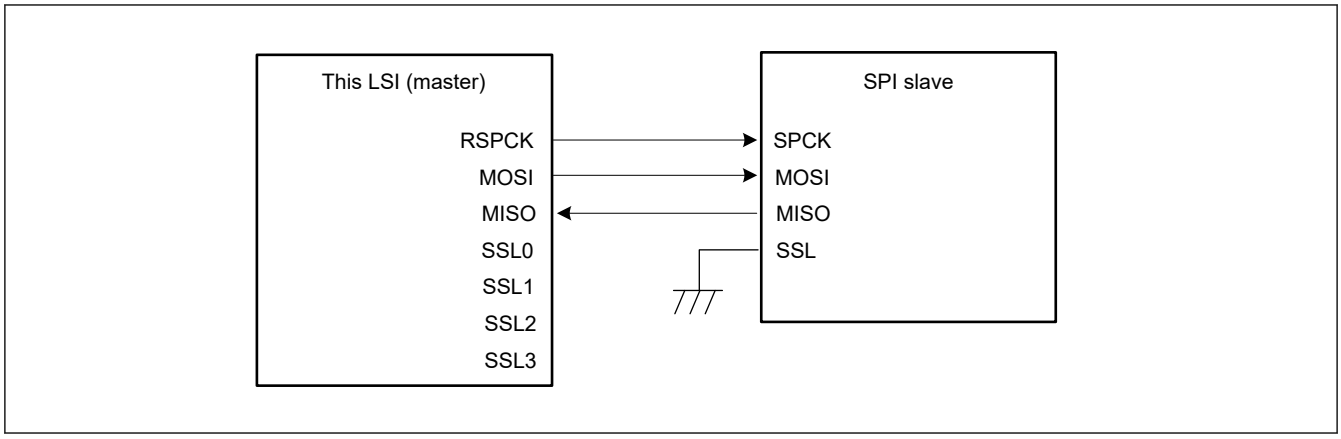

Figure 36.7 Single-master/single-slave configuration example (this LSI = master)

36.4.3.2 Single Master/Single Slave (This LSI = Slave)

Figure 36.8 shows an example of single master/single slave SPI system configuration where this LSI is used as a slave. When this LSI is used as a slave, the SSL0 pin is used as SSL input. The SPI master always drives the RSPCK and MOSI pins. This LSI (slave) always drives the MISO pin. When the SSL0 level is inactive, the pin state becomes Hi-Z.

In the single slave configuration with the SPCMD.CPHA bit set to 1, set the SPCR.SPFRF bit to 0, and set the SPMS bit to 0. There is the SSL0 input level of this LSI (slave) is fixed to 0 so that this LSI (slave) can be always selected and serial transfer can also be performed (Figure 36.9). However, the communication end interrupt does not output when SSL0 input was fixed as Figure 36.9.

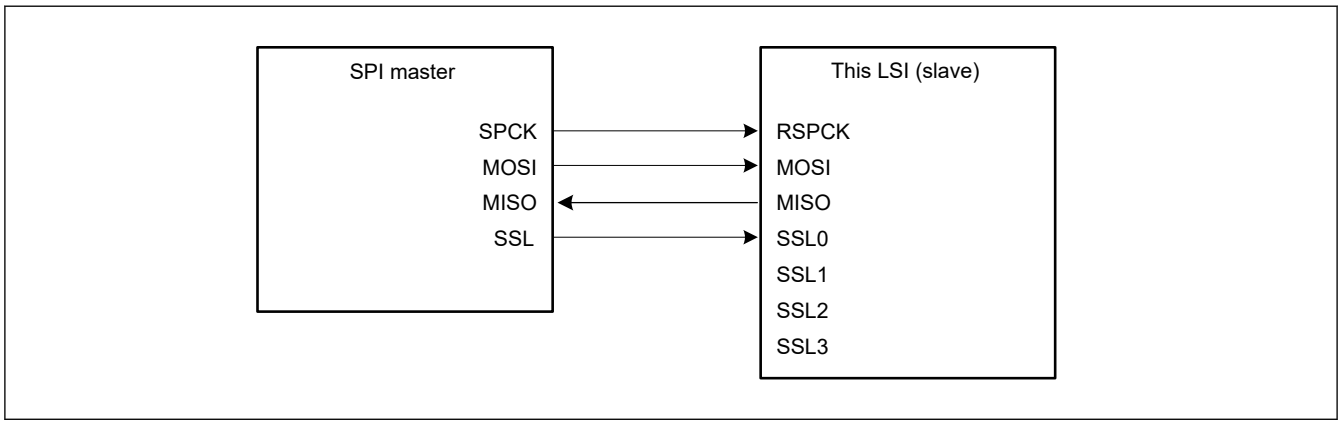

Figure 36.8 Single-master/single-slave configuration example (this LSI = slave, CPHA = 0)

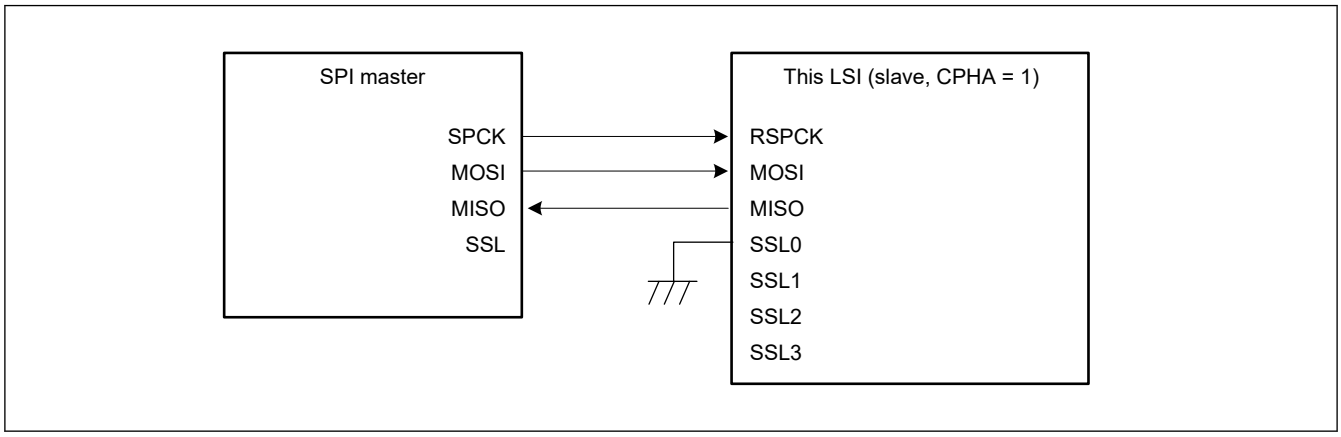

Figure 36.9 Single-master/single-slave configuration example (this LSI = slave, CPHA = 1)

36.4.3.3 Single Master/Multi-Slave (This LSI = Master)

Figure 36.10 shows an example of single master/multi-slave SPI system configuration where this LSI is used as a master. In the example in Figure 36.10, the SPI system is comprised of this LSI (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCK output and MOSI output pins of the master are connected to the RSPCK input and MOSI input pins of SPI slave 0 to SPI slave 3. All of the MISO output pins of SPI slave 0 to SPI slave 3 are connected to the MISO input pin of the master. The SSL0 to SSL3 output pins of this LSI (master) are connected to the SSL input pin of SPI slave 0 to SPI slave 3.

The master always drives RSPCK, MOSI, and SSL0 to SSL3 pins. The slave (out of SPI slave 0 to SPI slave 3) where 0 level is input to SSL input pin drives the MISO pin.

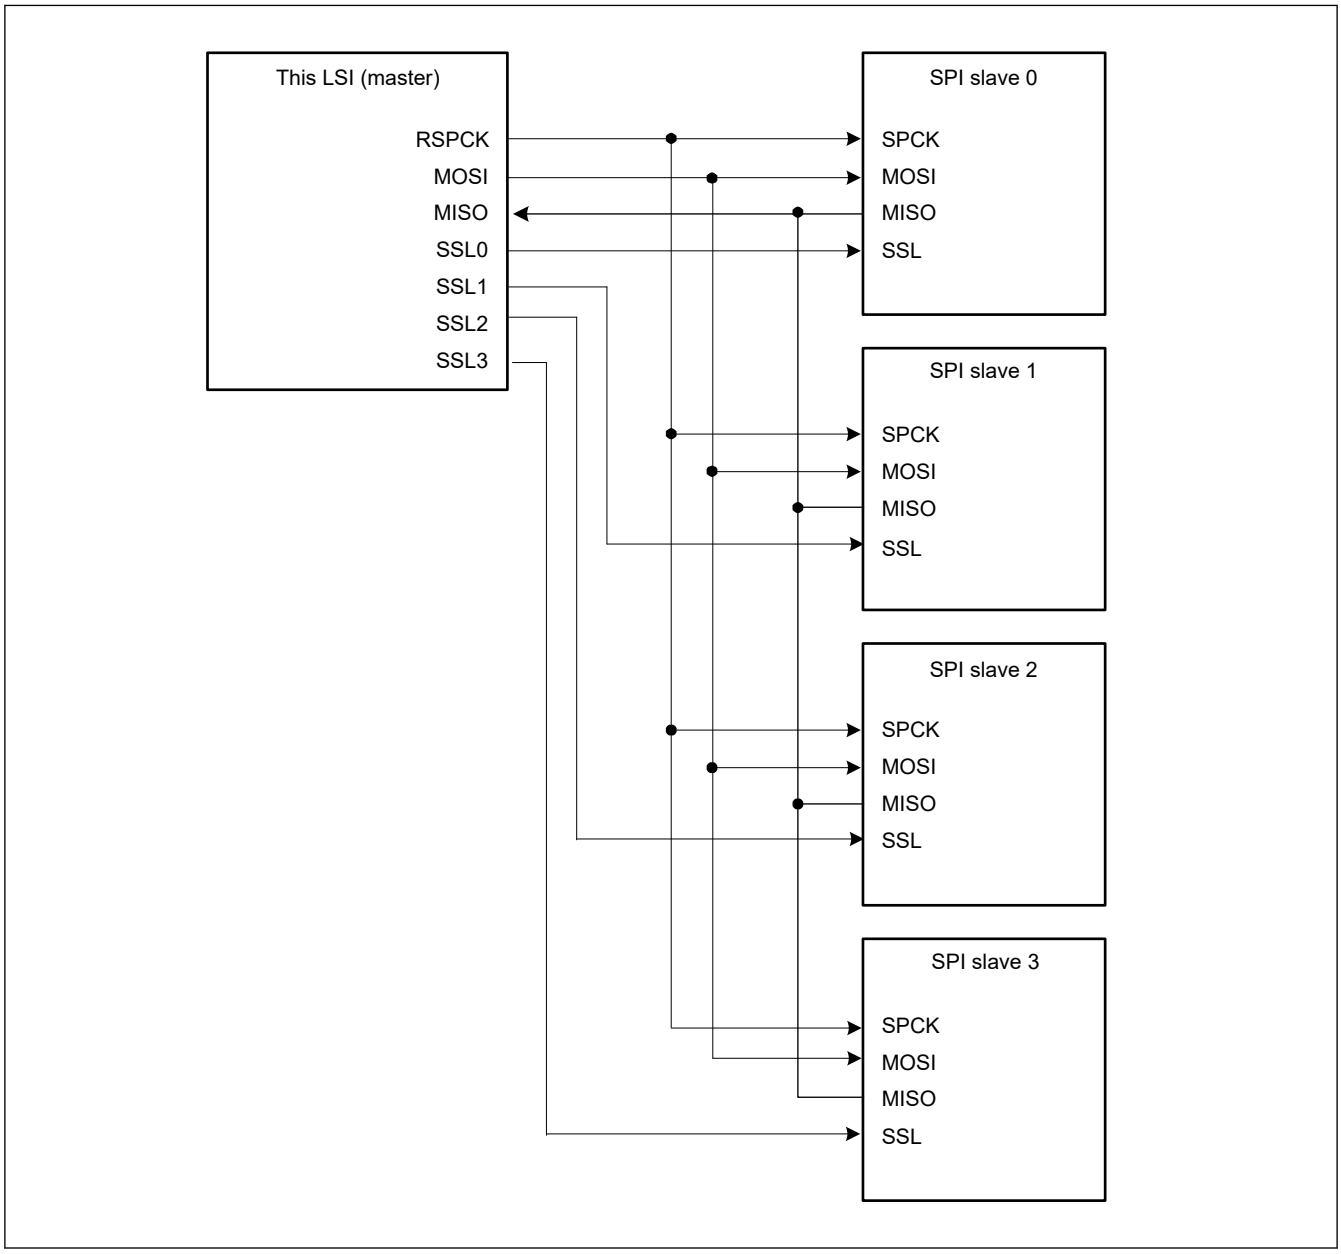

Figure 36.10 Single-master/multi-slave configuration example (this LSI = master)

36.4.3.4 Single Master/Multi-Slave (with This LSI Acting as Slave)

Figure 36.11 shows an example of single master/multi-slave SPI system configuration where this LSI is used as a slave. In the example in Figure 36.11, the SPI system consists of the SPI master and two these LSIs (slave X, slave Y).

The RSPCK output and MOSI output pins of the SPI master are connected to the RSPCK input and MOSI input pins of the LSIs (slave X, slave Y). The MISO output pin of the LSIs (slave X, slave Y) is connected to the MISO input pin of the SPI

master. The SSLX output and SSLY output pins of the SPI master are connected to the SSL0 input pin of the LSIs (slave X, slave Y).

The SPI master always drives the RSPCK, MOSI, SSLX, and SSLY pins. The slave X or slave Y (this LSI) where 0 level is input to the SSL0 input pin drives the MISO pin.

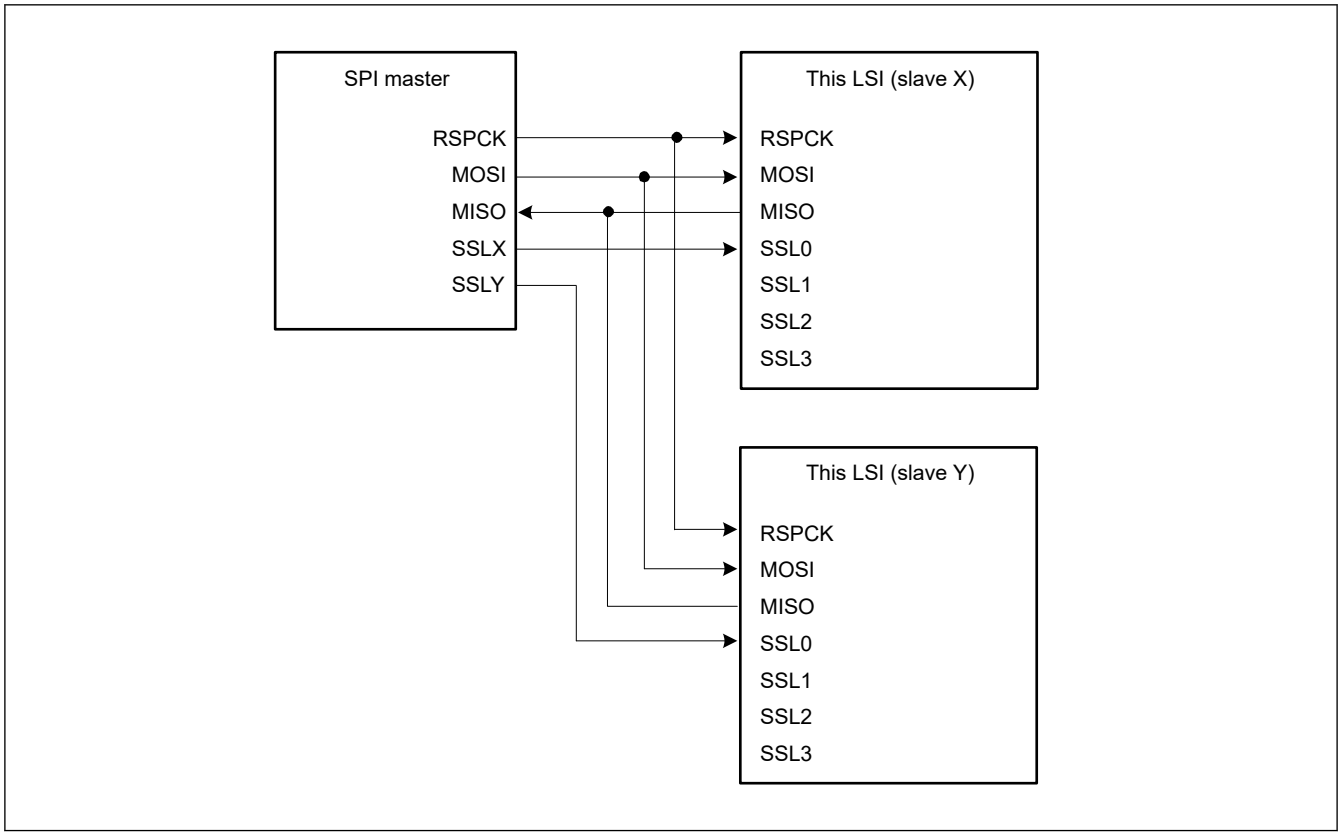

Figure 36.11 Single-master/multi-slave configuration example (this LSI = slave)

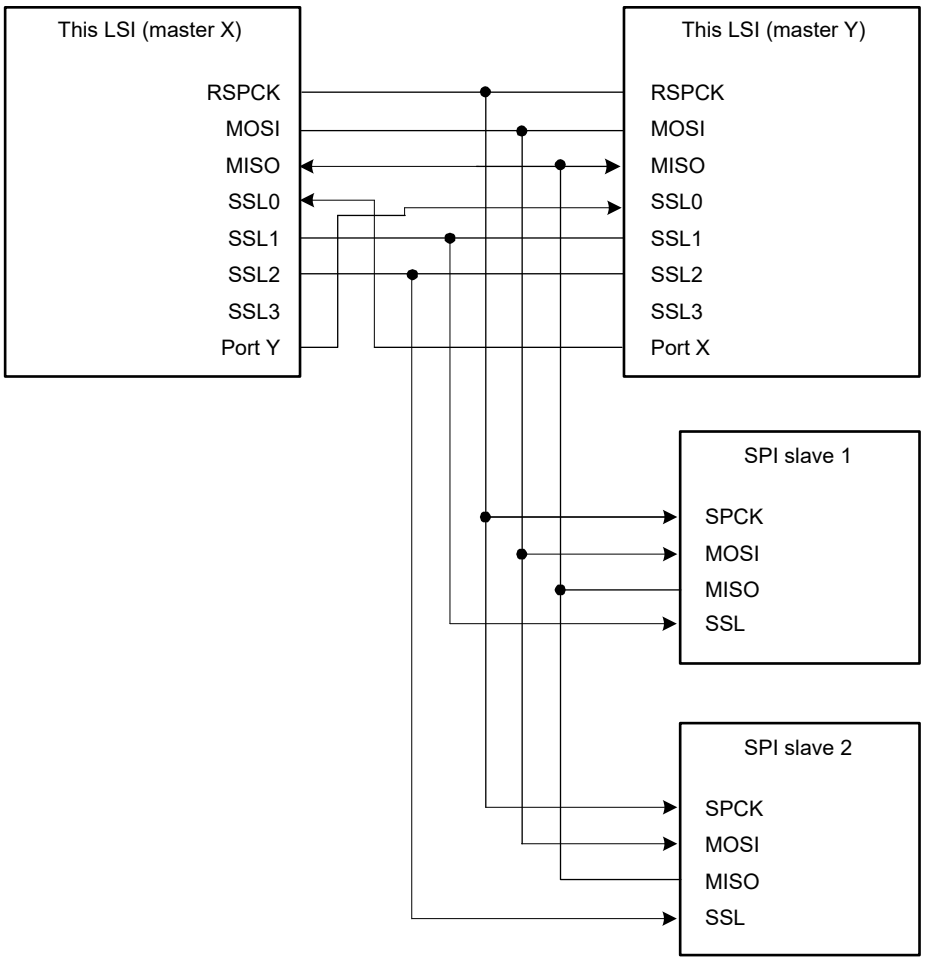
36.4.3.5 Multi-Master/Multi-Slave (with This LSI Acting as Master)

Figure 36.12 shows an example of multi-master/multi-slave SPI system configuration where this LSI is used as a master. In the example in Figure 36.12, the SPI system consists of two these LSIs (master X, master Y) and two SPI slaves (SPI slave 1, SPI slave 2).

The RSPCK output and MOSI output pins of these LSIs (master X, master Y) are connected to the RSPCK input and MOSI input pins of SPI slave 1 and SPI slave 2. The MISO output pin of SPI slave 1 and SPI slave 2 is connected to the MISO input pin of these LSIs (master X, master Y). The Port Y (general port) output pin of this LSI (master X) is connected to the SSL0 input pin of this LSI (master Y). The Port X (general port) output pin of this LSI (master Y) is connected to the SSL0 input pin of this LSI (master X). The SSL1 output and SSL2 output pins of these LSIs (master X, master Y) are connected to the SSL input pin of SPI slave 1 and SPI slave 2. In this configuration example, SSL3 output pins of this LSI are not used because the system can be configured only with SSL0 input pin and SSL1 output and SSL2 output pins for connecting slaves.

While the SSL0 input level is 1, this LSI drives the RSPCK, MOSI, SSL1, and SSL2 pins. While the SSL0 input level is 0, this LSI detects a mode fault error and changes the RSPCK, MOSI, SSL1, SSL2 pin levels to Hi-Z to release the SPI bus mastership for another master. SPI slave 1 or SPI slave 2 where 0 level is input to the SSL input pin drives the MISO pin.



Note: When setting TI SSP, enter the following levels for port X and port Y.
- Start of communication: the value of SSLP.SSL0P of the other master.
- End of communication: the inverted value of SSLP.SSL0P of the other master.

Figure 36.12 Multi-master/multi-slave configuration example (this LSI = master)

36.4.3.6 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (This LSI = Master)

Figure 36.13 shows an example of master (clock synchronous operation)/slave (clock synchronous operation) SPI system configuration where this LSI is used as a master. In this configuration, the SSL0 to SSL3 output pins of this LSI (master) are not used.

This LSI (master) always drives the RSPCK and MOSI pins. The SPI slave always drives the MISO pin.

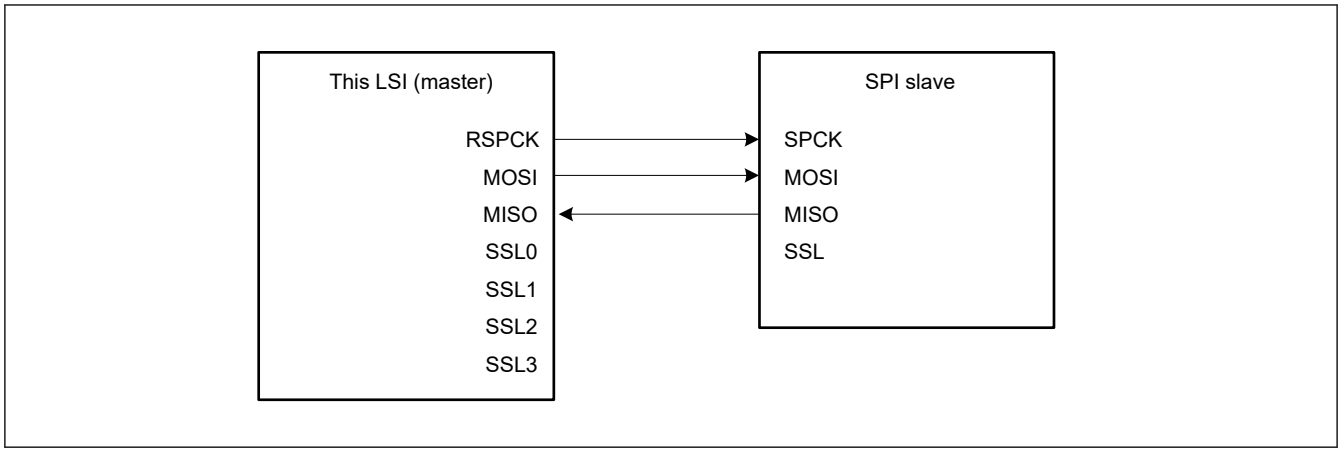


Figure 36.13 Master (clock synchronous operation)/slave (clock synchronous operation) configuration example (this LSI = master)

36.4.3.7 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (This LSI = Slave)

Figure 36.14 shows an example of master (clock synchronous operation)/slave (clock synchronous operation) SPI system configuration where this LSI is used as a slave. When this LSI is used as a slave (clock synchronous operation), this LSI (slave) always drives the MISO pin and the SPI master always drives the RSPCK and MOSI pins.

Only in the single slave configuration with the SPCMD.CPHA bit set to 1, this LSI (slave) can perform serial transfer.

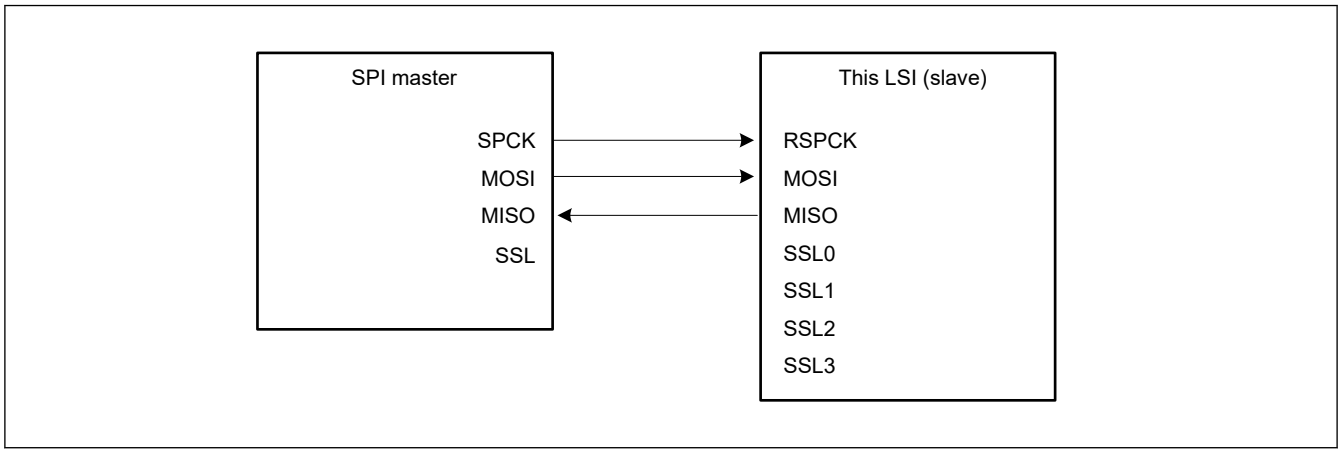

Figure 36.14 Master (clock synchronous operation)/slave (clock synchronous operation) configuration example (this LSI = slave, CPHA = 1)

36.4.4 Data Format

Data format of the SPI depends on the set values of the SPCMD register and the SPCR.SPPE bit. The SPI handles data of the set data length from the LSB in the SPDR register as transfer data regardless of MSB first or LSB first.

36.4.4.1 Data Format of One Frame

The data format of one frame for transmission and reception is shown below.

(1) With Parity Disabled (SPPE=0)

When the parity function is disabled, data of the bit length specified by SPCMDm.SPB[4:0] is transmitted and received.

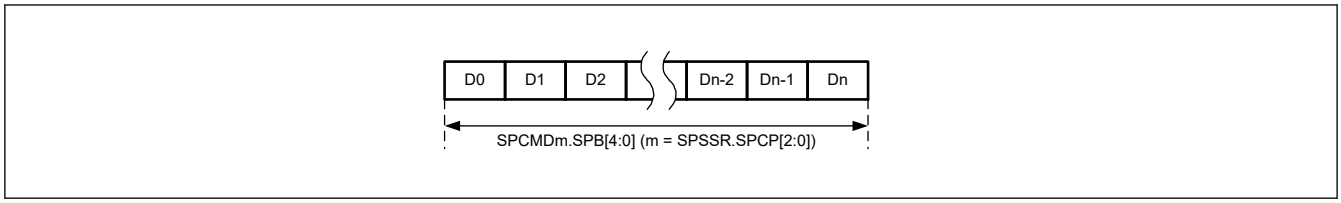

Figure 36.15 Outline of data format (when parity function is disabled)

(2) With Parity Enabled (SPPE = 1)

When the parity function is enabled, data of the bit length specified by SPCMDm.SPB[4:0] is transmitted and received. However, the final bit is used as a parity bit.

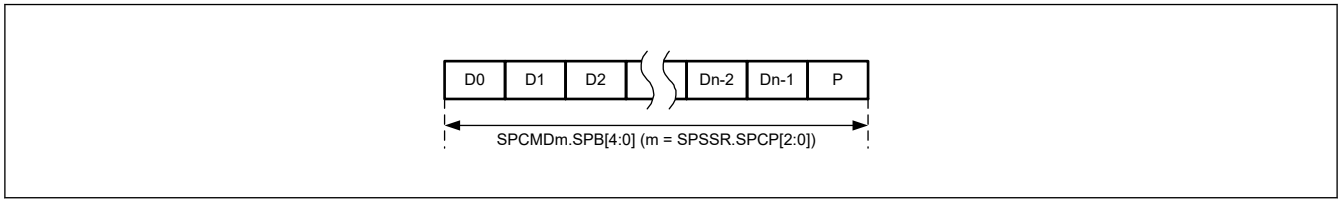

Figure 36.16 Outline of data format (when parity function is enabled)

36.4.4.2 When Parity is Disabled (SPPE = 0)

When the parity function is disabled, transmit buffer data is copied to the shift register without processing it. The following describes the relationship between SPDR, and shift register by using a combination of MSB first/LSB first and bit length.

(1) MSB First Transfer (32-Bit Data)

Figure 36.17 shows operations of the SPDR register and the shift register when the SPI performs 32-bit MSB-first transfer with the parity function disabled.

In transmission, T31 to T00 in the transmit buffer are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → … → T00 as transmit data.

In reception, received data is stored in bit 0 of the shift register, and received data is shifted in units of data. When necessary RSPCK cycles are input and data is stored from R31 to R00, the shift register value is copied to the receive buffer.

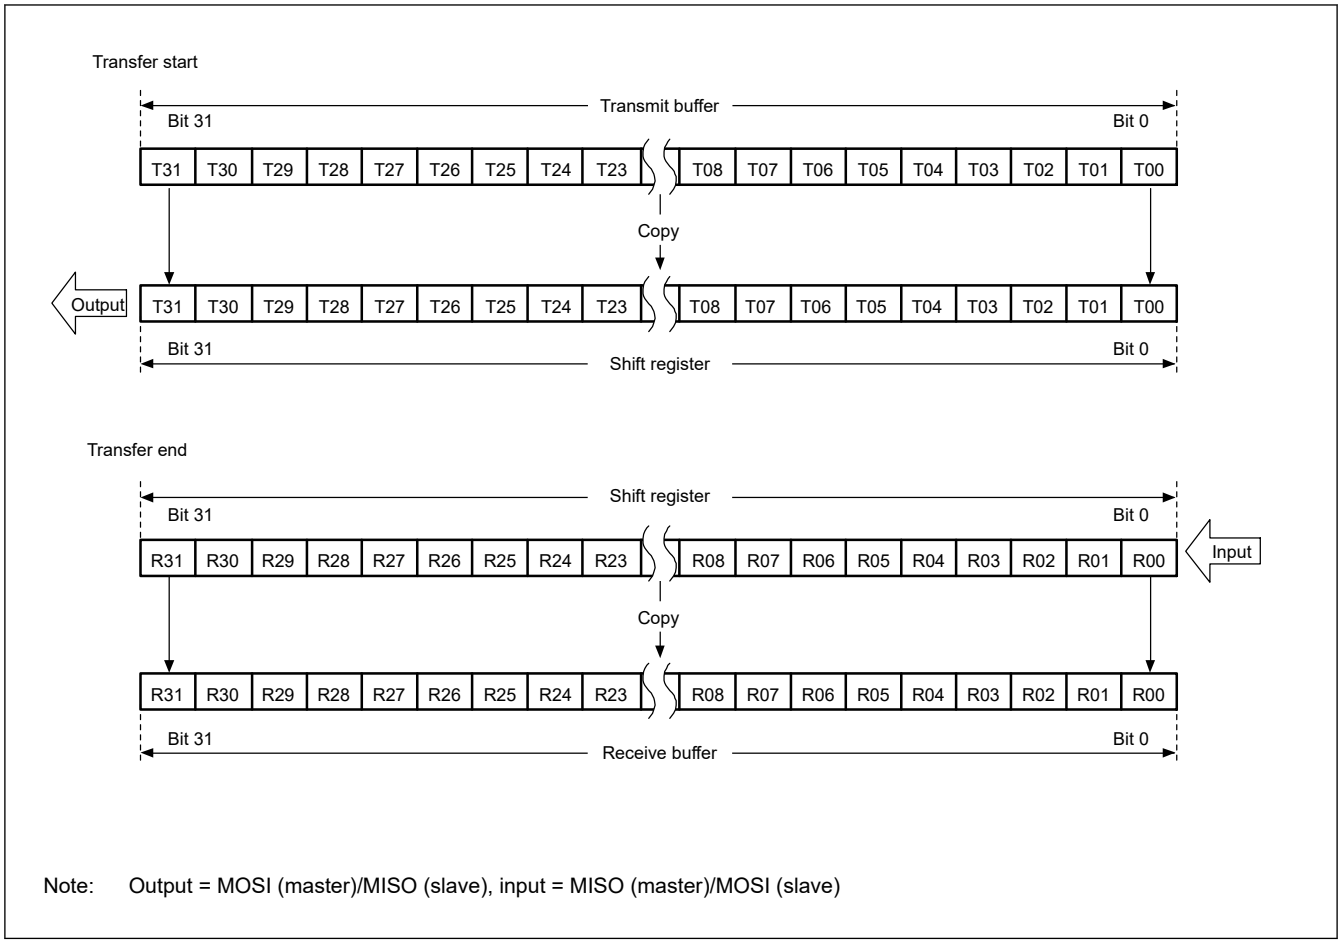

Figure 36.17 MSB first transfer (32-bit data, parity disabled)

(2) MSB First Transfer (24-Bit Data)

As an example of MSB-first transfer of data other than 32 bits with the parity function disabled, Figure 36.18 shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, lower 24 bits (T23 to T00) in the transmit buffer are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T23 → T22 → … → T00 as transmit data.

In reception, received data is stored in bit 0 of the shift register, and received data is shifted in units of data. When necessary RSPCK cycles are input and data is stored from R23 to R00, the shift register value is copied to the receive buffer.

Figure 36.18 MSB first transfer (24-bit data, parity disabled)

(3) LSB First Transfer (32-Bit Data)

Figure 36.19 shows operations of the SPDR register and the shift register when the SPI performs 32-bit LSB-first transfer with the parity function disabled.

In transmission, bit values of the transmit buffer (T31 to T00) are reversed in bit units and are copied to the shift register in the order of T00 to T31. Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T31 as transmit data.

In reception, the first received data is stored in bit 0 of the shift register, and received data is shifted in units of data.

When necessary RSPCK cycles are input and data is stored from R00 to R31, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of R31 to R00.

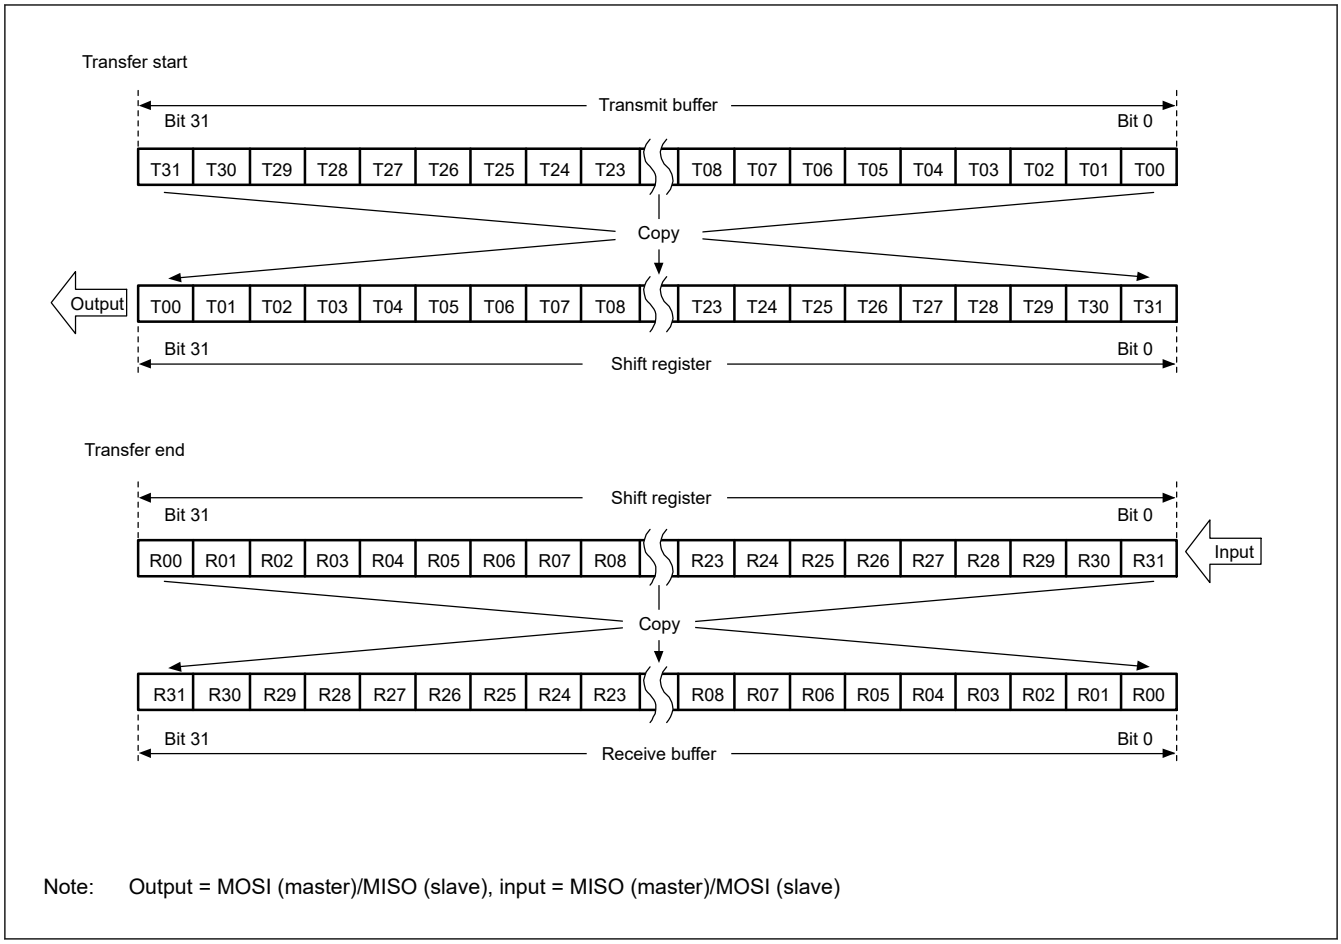

Figure 36.19 LSB first transfer (32-bit data, parity disabled)

(4) LSB First Transfer (24-Bit Data)

As an example of LSB-first transfer of data other than 32 bits with the parity function disabled, Figure 36.20 shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, lower 24-bit values of the transmit buffer (T23 to T00) are reversed to the order from T00 to T23 in bit units and are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T00→ T01 → … → T23 as transmit data.

In reception, received data is stored in bit 8 of the shift register, and received data is shifted in units of data. When necessary RSPCK cycles are input and data is stored from R00 to R23, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of R23 (bit 23) to R00 (bit 0).

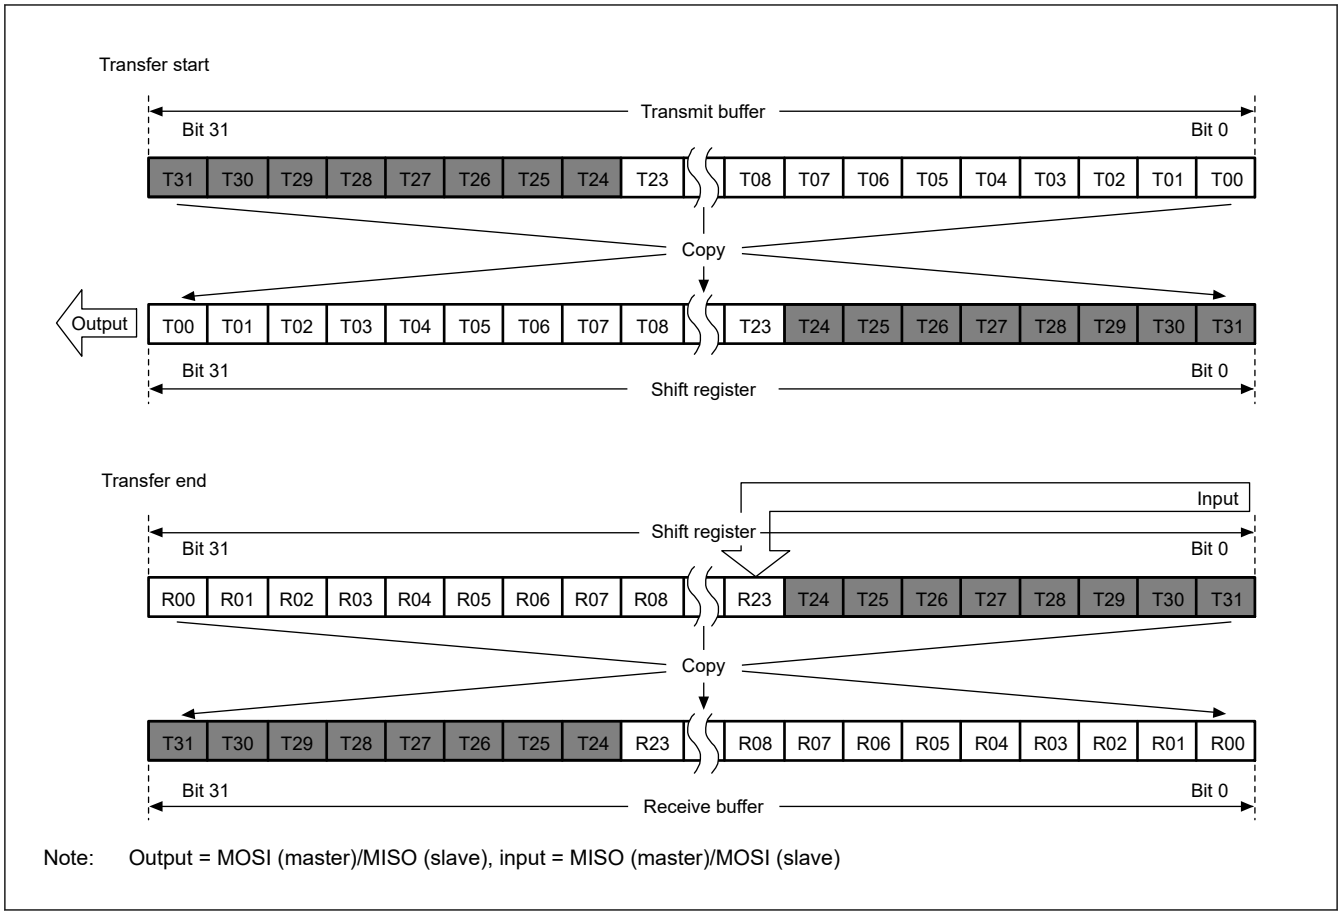

Figure 36.20 LSB first transfer (24-bit data, parity disabled)

36.4.4.3 When Parity is Enabled (SPPE = 1)

When the parity function is enabled, the LSB of transmit data or received data is converted to a parity bit. The parity bit value is calculated and converted by the hardware.

(1) MSB First Transfer (32-Bit Data)

Figure 36.21 shows operations of the SPDR register and the shift register when the SPI performs 32-bit MSB-first transfer with the parity function enabled.

In transmission, the parity bit (P) value is calculated first from the data value T31 to T01, then the final bit T00 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T31 → T30 → … → T01 → P.

In reception, received data is stored in bit 0 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R31 to P, the shift register value is copied to the receive buffer, and at the same time, R31 to P data is checked to determine whether a parity error is present.

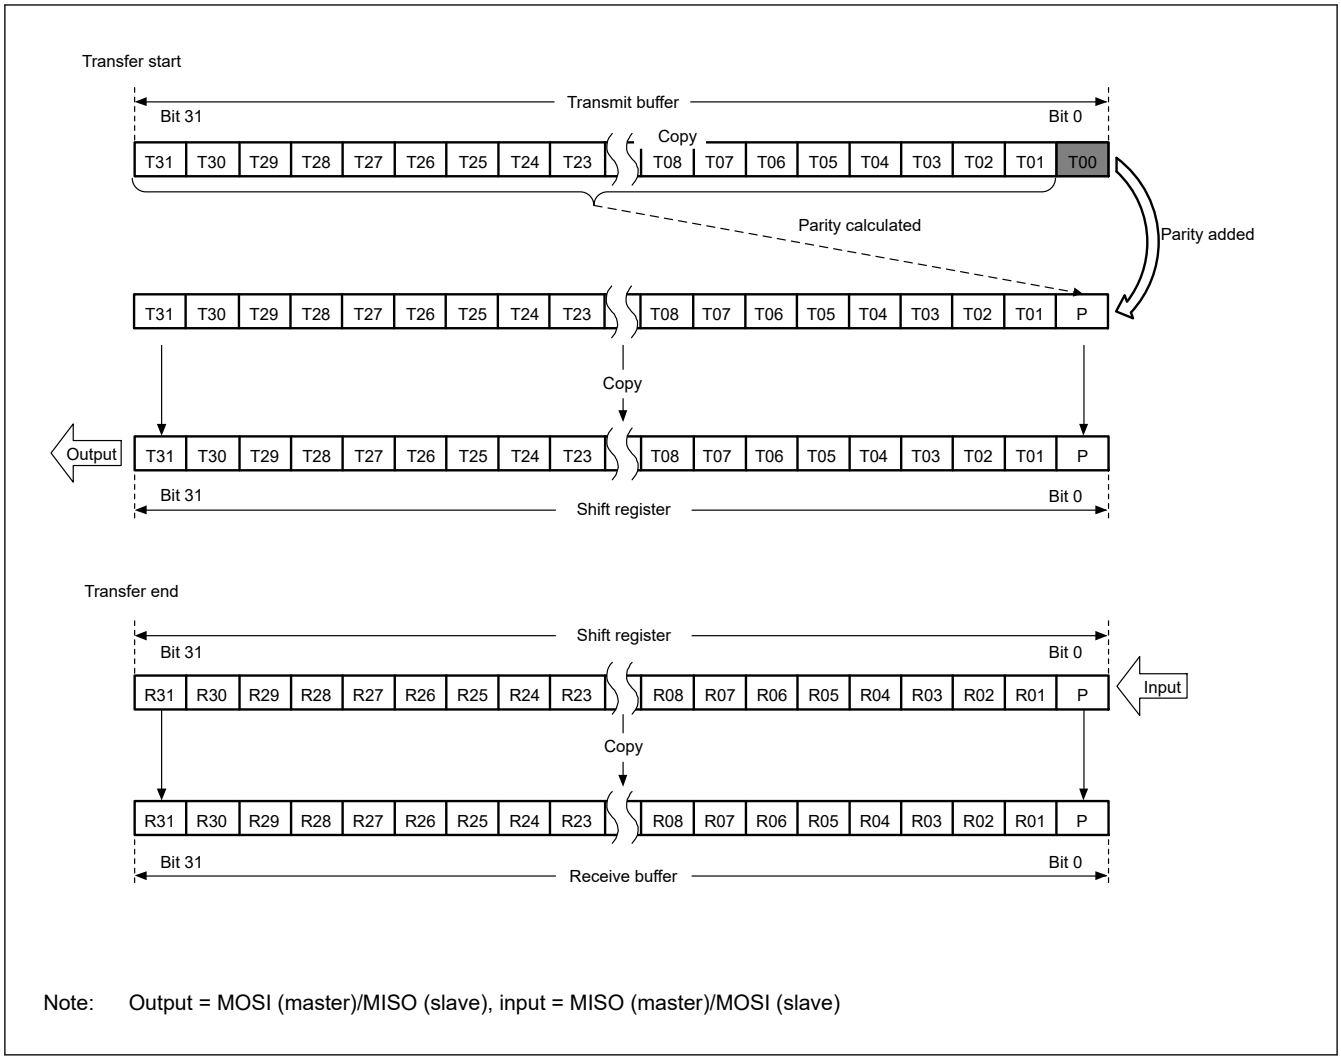

Figure 36.21 MSB first transfer (32-bit data, parity enabled)

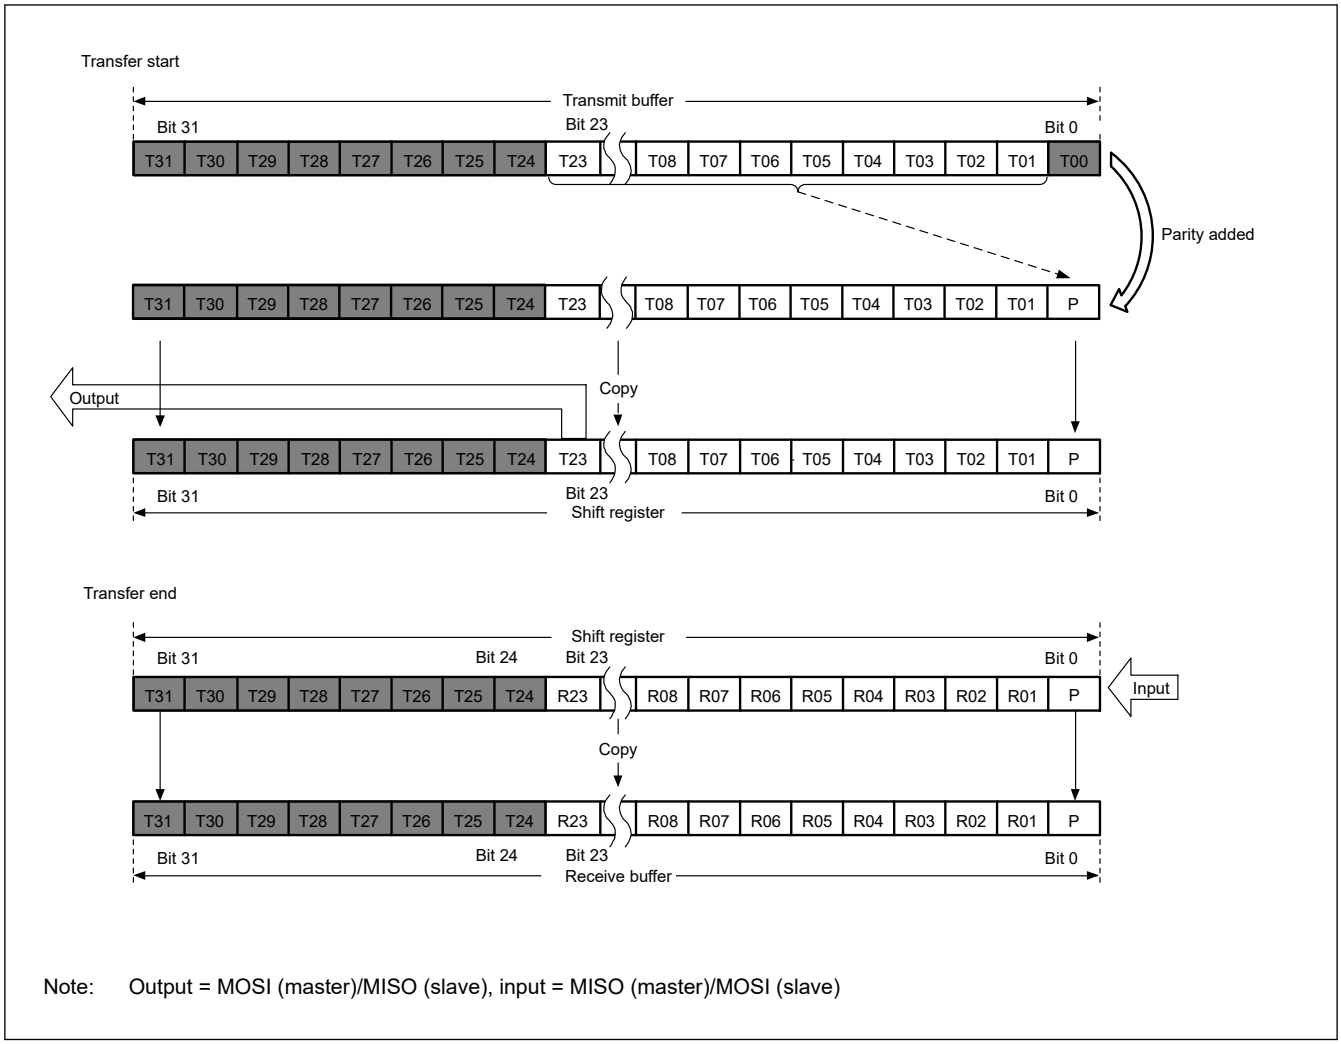
(2) MSB First Transfer (24-Bit Data)

As an example of MSB-first transfer of data other than 32 bits with the parity function enabled, Figure 36.22 shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, the parity bit (P) value is calculated first from the data value T23 to T01, then the final bit T00 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T23 → T22 → … → T01 → P.

In reception, received data is stored in bit 0 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R23 to P, the shift register value is copied to the receive buffer, and at the same time, R23 to P data is checked to determine whether a parity error is present.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

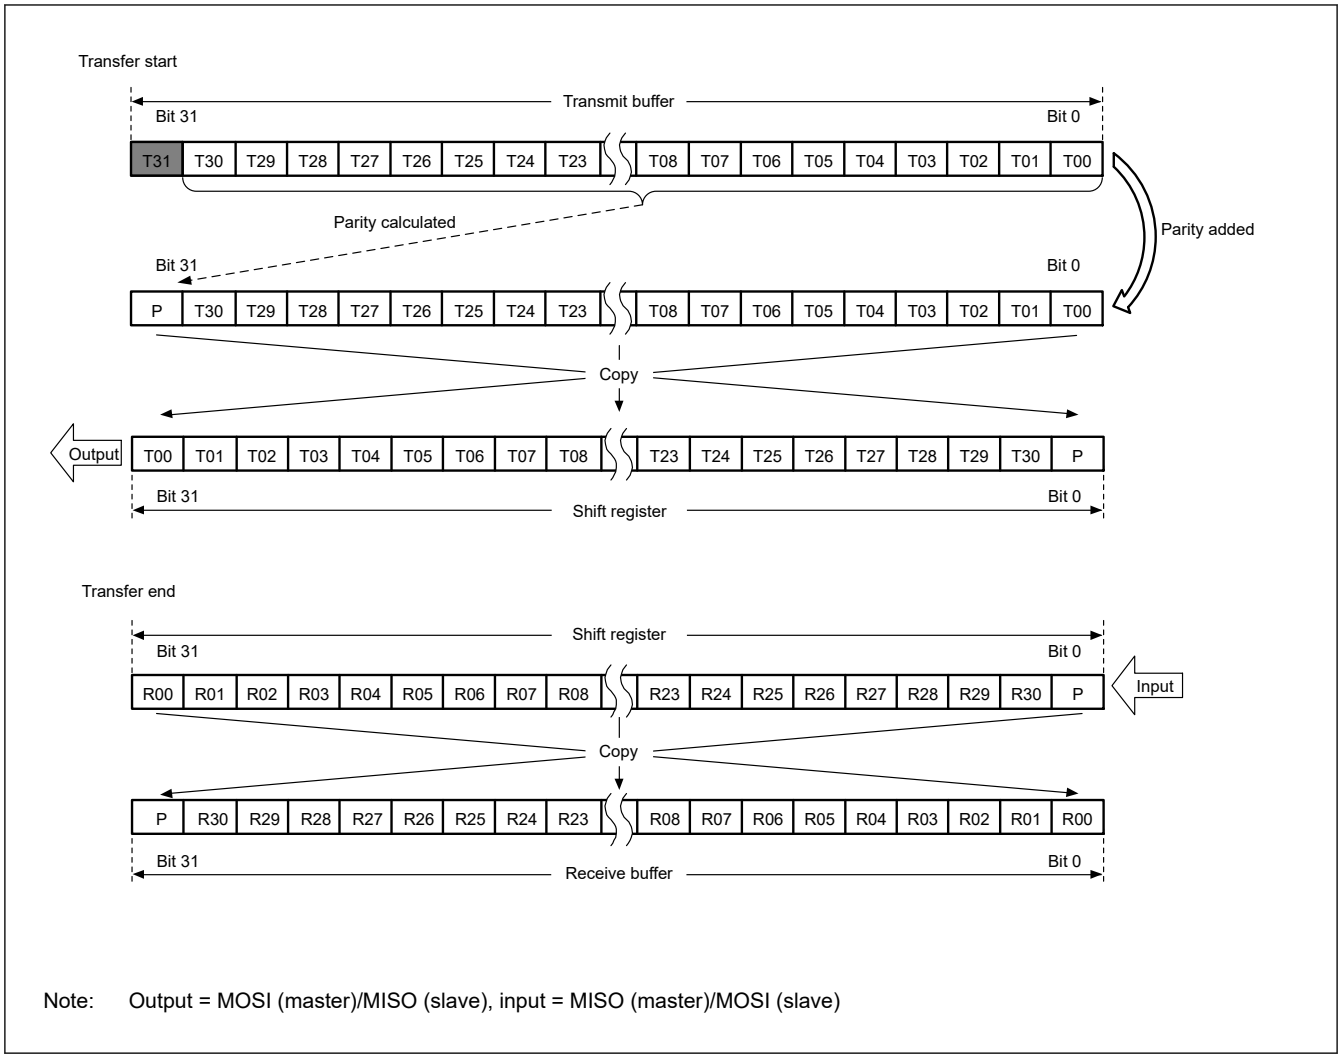
Figure 36.22 MSB first transfer (24-bit data, parity enabled)

(3) LSB First Transfer (32-Bit Data)

Figure 36.23 shows operations of the SPDR register and the shift register when the SPI performs 32-bit LSB-first transfer with the parity function enabled.

In transmission, the parity bit (P) value is calculated first from the data value T30 to T00, then the final bit T31 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T00 → T01 → … → T30 → P.

In reception, received data is stored in bit 0 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R00 to P, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of P to R00, and at the same time, R00 to P data is checked to determine whether a parity error is present.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

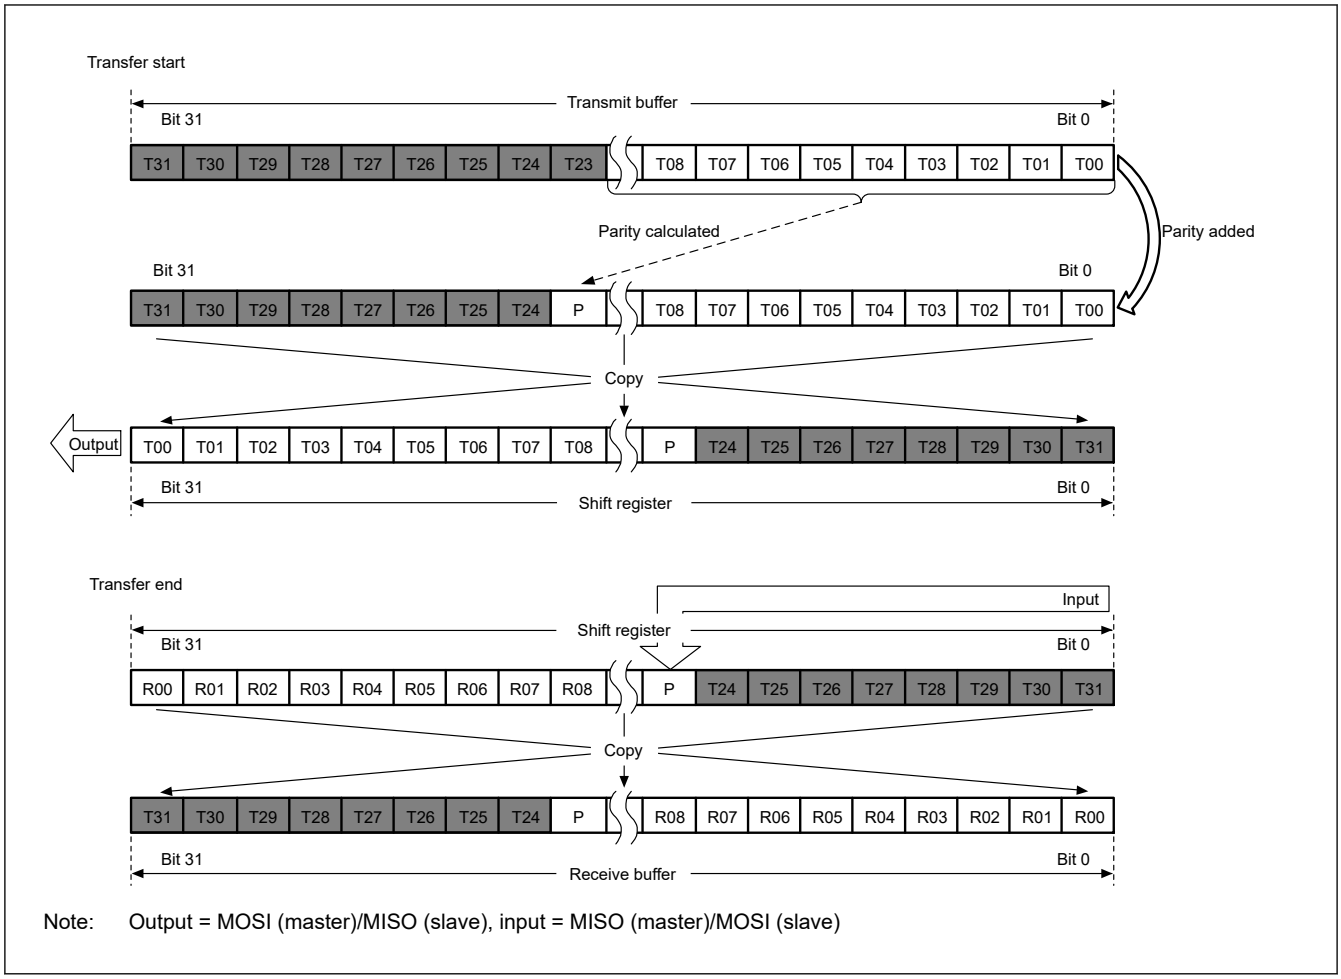
Figure 36.23 LSB first transfer (32-bit data, parity enabled)

(4) LSB First Transfer (24-Bit Data)

As an example of LSB-first transfer of data other than 32 bits with the parity function enabled, Figure 36.24 shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, the parity bit (P) value is calculated first from the data value T22 to T00, then the final bit T23 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T00→ T01 → … → T22 → P.

In reception, received data is stored in bit 8 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R00 to P, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of P (bit 23) to R00 (bit 0), and at the same time, R00 to P data is checked to determine whether a parity error is present.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 36.24 LSB first transfer (24-bit data, parity enabled)

36.4.4.4 Byte swap transmission

When byte swapping is enabled, the data in the transmission buffer, swapped in 8-bit units, is copied to the shift register.

(1) 32-bit data length

Figure 36.25 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 32-bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. **MSB First Transfer (When the byte swap is disabled.)**
   Data (Byte3 [T31 to T24] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register.
   Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → … → T00 as transmit data.
2. **MSB First Transfer (When the byte swap is enabled.)**
   Byte values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte3 [T07 to T00] to Byte0 [T31 to T24].
   Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … → T00 → T15 → T14→ … → T08 → T23 → T22 → … → T16 → T31 → T30 → … → T24 as transmit data.
3. **LSB-first transfer (When the byte swap is disabled.)**
   Bit values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T00 to T07] to Byte3 [T24 to T31].
   Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T31 as transmit data.
4. **LSB-first transfer (When the byte swap is enabled.)**
   Bit values of each byte of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte3 [T24 to T31] to Byte0 [T00 to T07].
   Bit values in the shift register are shifted and transmitted in the order of T24 → T25 → … → T31 → T16 → T17 → … → T23 → T08 → T09 → … → T15 → T00 → T01 → … → T07 as transmit data.

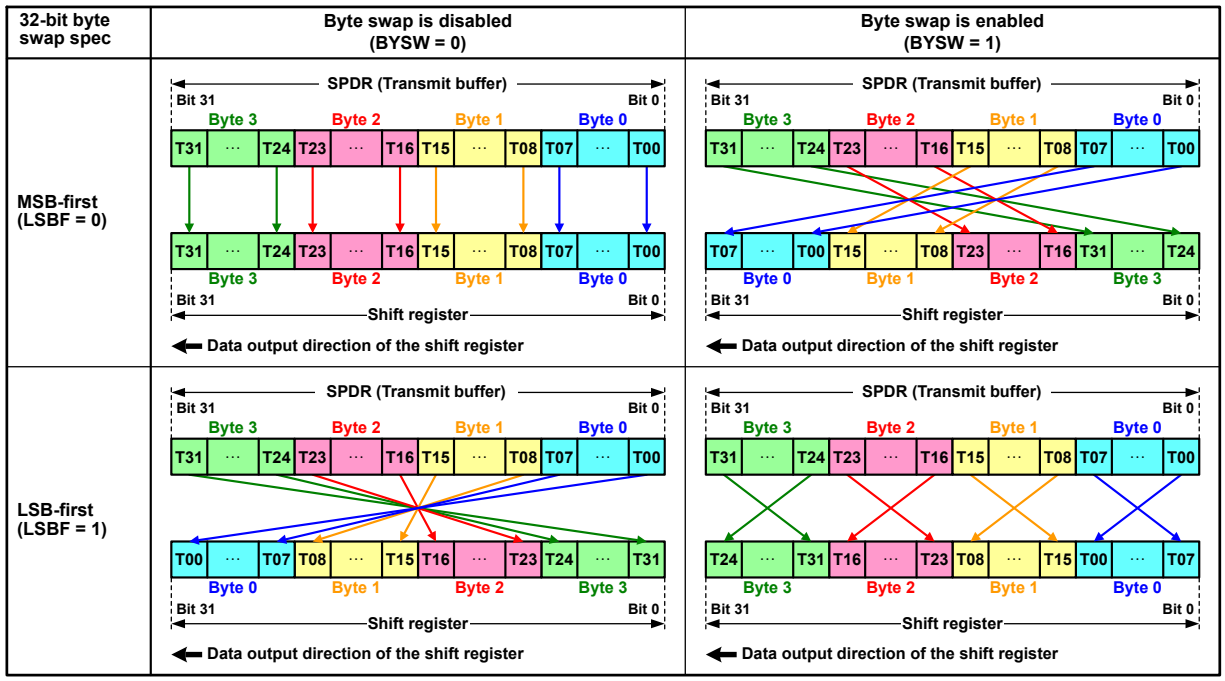


Figure 36.25 Byte swap with MSB/LSB transfer (32 bit)

(2) 16-bit data length

Figure 36.26 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 16-bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. **MSB First Transfer (When the byte swap is disabled.)**
   Data (Byte1 [T15 to T08] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register.
   Bit values in the shift register are shifted and transmitted in the order of T15 → T14 → … → T00 as transmit data.
2. **MSB First Transfer (When the byte swap is enabled.)**
   Byte values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte1 [T07 to T00] to Byte0 [T15 to T08].
   Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … → T00 → T15 → T14→ … → T08 as transmit data.
3. **LSB-first transfer (When the byte swap is disabled.)**
   Bit values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T00 to T07] to Byte1 [T08 to T15].
   Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T15 as transmit data.
4. **LSB-first transfer (When the byte swap is enabled.)**
   Bit values of each byte of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte1 [T08 to T15] to Byte0 [T00 to T07].
   Bit values in the shift register are shifted and transmitted in the order of T08 → T09 → … → T15 → T00 → T01 → … → T07 as transmit data.

Figure 36.26 Byte swap with MSB/LSB transfer (16 bit)

Note: When using the byte swap, set 16 bits or 32 bits to the data length (SPCMD.SPB[4:0] setting).
If setting the other length, the behavior is not guaranteed.

Note: When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0) .
If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.

Note: Set SPDCR.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

36.4.4.5 Byte swap reception

When byte swap is enabled, the data in the shift register, swapped in 8-bit units, is copied to the receive buffer.

(1) 32-bit data length

Figure 36.27 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 32-bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. **MSB First Transfer (When the byte swap is disabled.)**
   The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31 → R30 → … → R00.
   When necessary RSPCK cycles are input and data is stored from Byte3 [R31 to R24] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.
2. **MSB First Transfer (When the byte swap is enabled.)**
   The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08 → R23 → R22 → … → R16 → R31 → R30 → … → R24.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte3 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].
3. **LSB-first transfer (When the byte swap is disabled.)**
   The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00 → R01 → … → R31.

When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte3 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

4. **LSB-first transfer (When the byte swap is enabled.)**
   The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24 → R25 → … → R31 → R16 → R17 → … → R23 → R08 → R09 → … → R15 → R00 → R01 → … → R07.
   When necessary RSPCK cycles are input and data is stored from Byte3 [R24 to R31] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

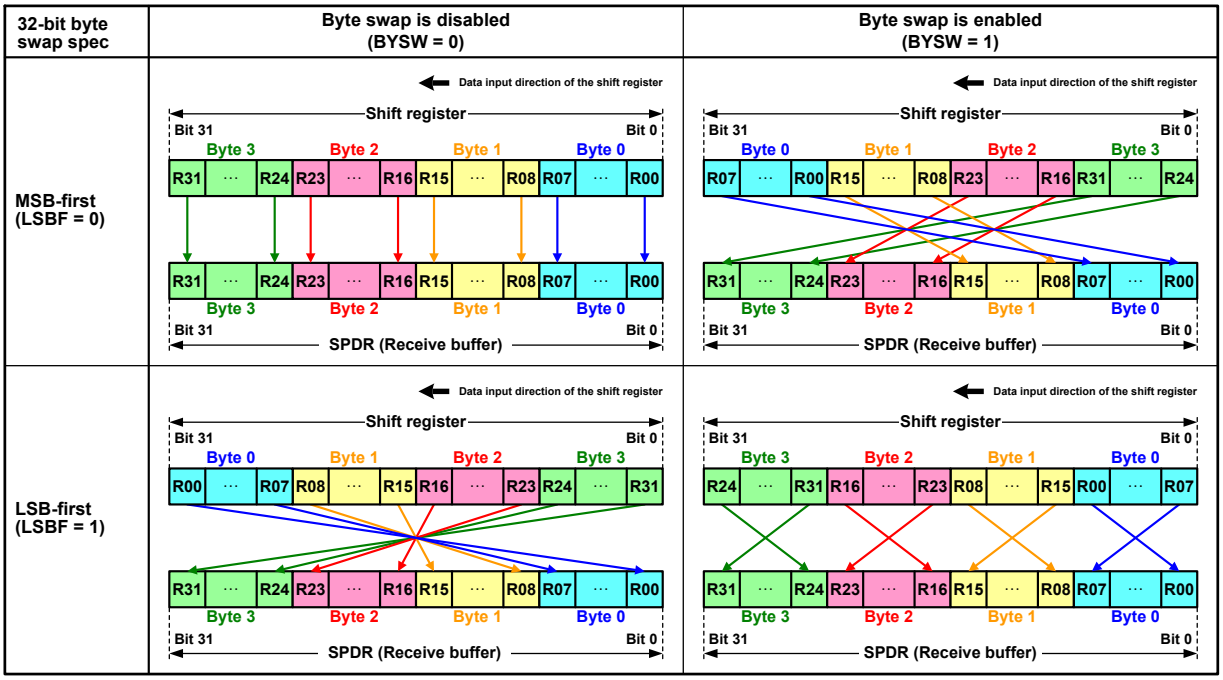

Figure 36.27 Byte swap with MSB/LSB reception (32 bit)

(2) 16-bit data length

Figure 36.28 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 16-bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. **MSB First Transfer (When the byte swap is disabled.)**
   The first received data (R15) is stored in bit 0 of the shift register, and received data is shifted in the order of R15 → R14 → … → R00.
   When necessary RSPCK cycles are input and data is stored from Byte1 [R15 to R08] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.

2. **MSB First Transfer (When the byte swap is enabled.)**
   The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte1 [R15 to R08], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte1 [R15 to R08] to Byte0 [R07 to R00].

3. **LSB-first transfer (When the byte swap is disabled.)**
   The first received data (R00) is stored in bit 15 of the shift register, and received data is shifted in the order of R00 → R01 → … → R15.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte1 [R08 to R15], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte1 [R15 to R08] to Byte0 [R07 to R00].

4. **LSB-first transfer (When the byte swap is enabled.)**
   The first received data (R08) is stored in bit 0 of the shift register, and received data is shifted in the order of R08 → R09 → … → R15 → R00 → R01 → … → R07.
   When necessary RSPCK cycles are input and data is stored from Byte1 [R08 to R15] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte1 [R15 to R08] to Byte0 [R07 to R00].

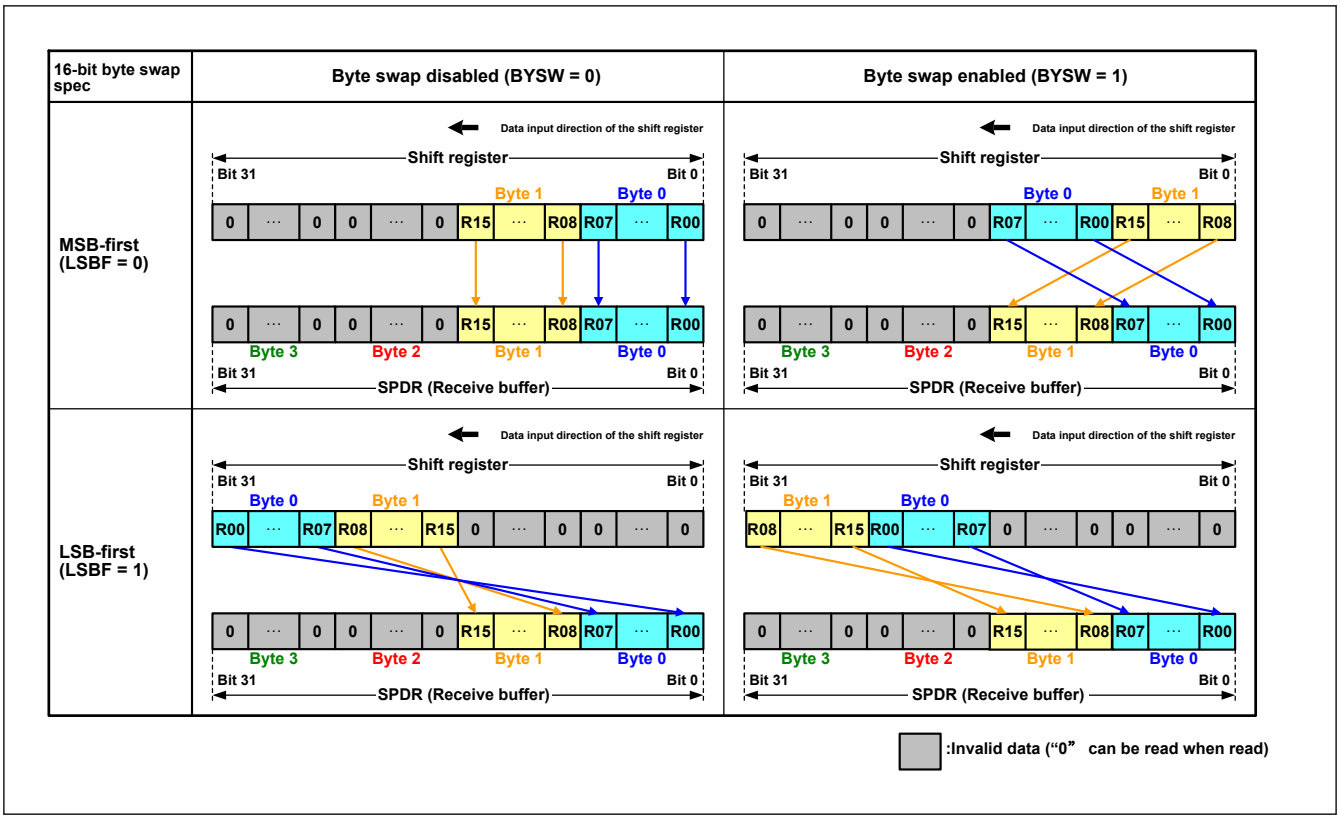

Figure 36.28 Byte swap with MSB/LSB reception (16 bit)

Note: When using the byte swap, set 16 bits or 32 bits to the data length (SPCMD.SPB[4:0] setting) .
If setting the other length, the behavior is not guaranteed.

Note: When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0).
If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.

Note: Set SPDCR2.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

36.4.5 Transfer Format (Frame Format)

36.4.5.1 CPHA = 0

Figure 36.29 shows an example of transfer format of 8-bit data serial transfer when SPCMD.CPHA = 0. However, when the SPI is in slave mode (SPCR.MSTR = 0) with the CPHA bit set to 0, clock synchronous operation (SPCR.SPMS = 1) is not guaranteed. In Figure 36.29, RSPCK (CPOL = 0) is the RSPCK signal waveform when SPCMD.CPOL = 0, and RSPCK (SPCMD.CPOL = 1) is the RSPCK signal waveform when SPCMD.CPOL = 1. The sampling timing shows the time when the SPI latches serial transfer data in the shift register. Input and output directions of each signal depend on SPI settings. (See section 36.4.2. SPI Pin Control.)

When SPCMD.CPHA = 0, output of valid data to the MOSI signal and valid data drive to the MISO signal start at the SSL signal assertion timing. The first RSPCK signal change timing after the SSL signal is asserted is the first transfer data latch timing. After this timing, data is sampled in each RSPCK cycle. The MOSI signal and the MISO signal change always after the half RSPCK cycles of the transfer data latch timing. The set CPOL bit value does not affect the RSPCK signal operation timing but affects only the signal polarity.

Period t1 is the period (RSPCK delay) from SSL signal assertion to RSPCK oscillation. Period t2 is the period (SSL negation delay) from RSPCK oscillation stop to SSL signal negation. Period t3 is the period (next-access delay) to inhibit SSL signal assertion for the next transfer after serial transfer is completed. Periods t1, t2, and t3 are controlled by the master device in the SPI system. For t1, t2, and t3 when this LSI (SPI) is in master mode, see section 36.4.13.1. Master Mode Operation.

[In the Motorola-SPI case]

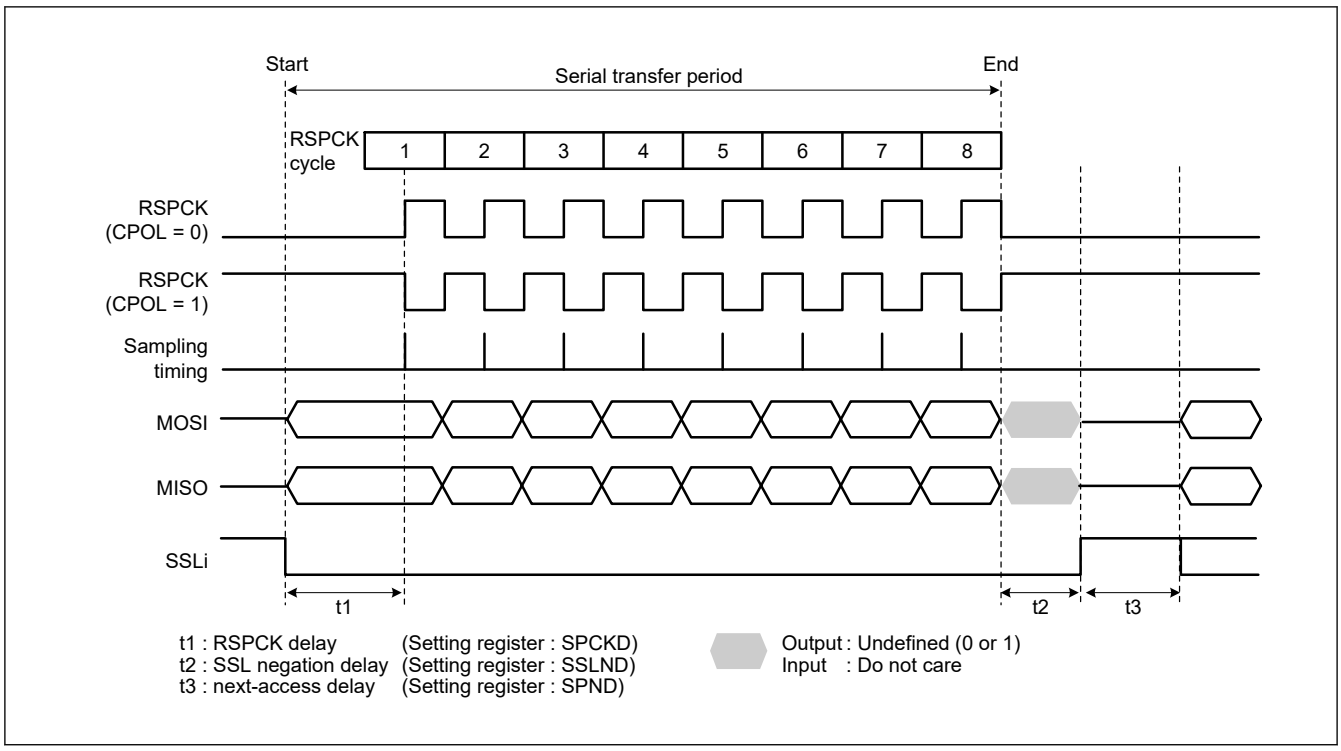

Figure 36.29 SPI transfer format (CPHA = 0, SPFRF = 0)

36.4.5.2 CPHA = 1

Figure 36.30 shows an example of transfer format of 8-bit data serial transfer when SPCMD.CPHA = 1. However, when SPCR.SPMS = 1, communication is performed by using only RSPCK, MOSI, and MISO signals without using the SSL signal. In Figure 36.30, RSPCK (CPOL = 0) is the RSPCK signal waveform when SPCMD.CPOL = 0, and RSPCK (SPCMD.CPOL = 0) is the RSPCK signal waveform when SPCMD.CPOL = 0. The sampling timing shows the time when the SPI latches serial transfer data in the shift register. Input and output directions of each signal depend on SPI mode (master or slave mode). (See section 36.4.2. SPI Pin Control.)

When SPCMD.CPHA = 1, invalid data drive to the MISO signal starts at the SSL signal assertion timing. Output of valid data to the MOSI and MISO signals starts at the first RSPCK signal change timing after the SSL signal is asserted.

After this timing, data is updated in each RSPCK cycle. Transfer data is always latched after 1/2 RSPCK cycle of this timing. The set CPOL bit value does not affect the RSPCK signal operation timing but affects only the signal polarity.

Periods t1, t2, and t3 are the same as when CPHA = 0. For t1, t2, and t3 when this LSI (SPI) is in master mode, see section 36.4.13.1. Master Mode Operation.

[In the Motorola-SPI case]

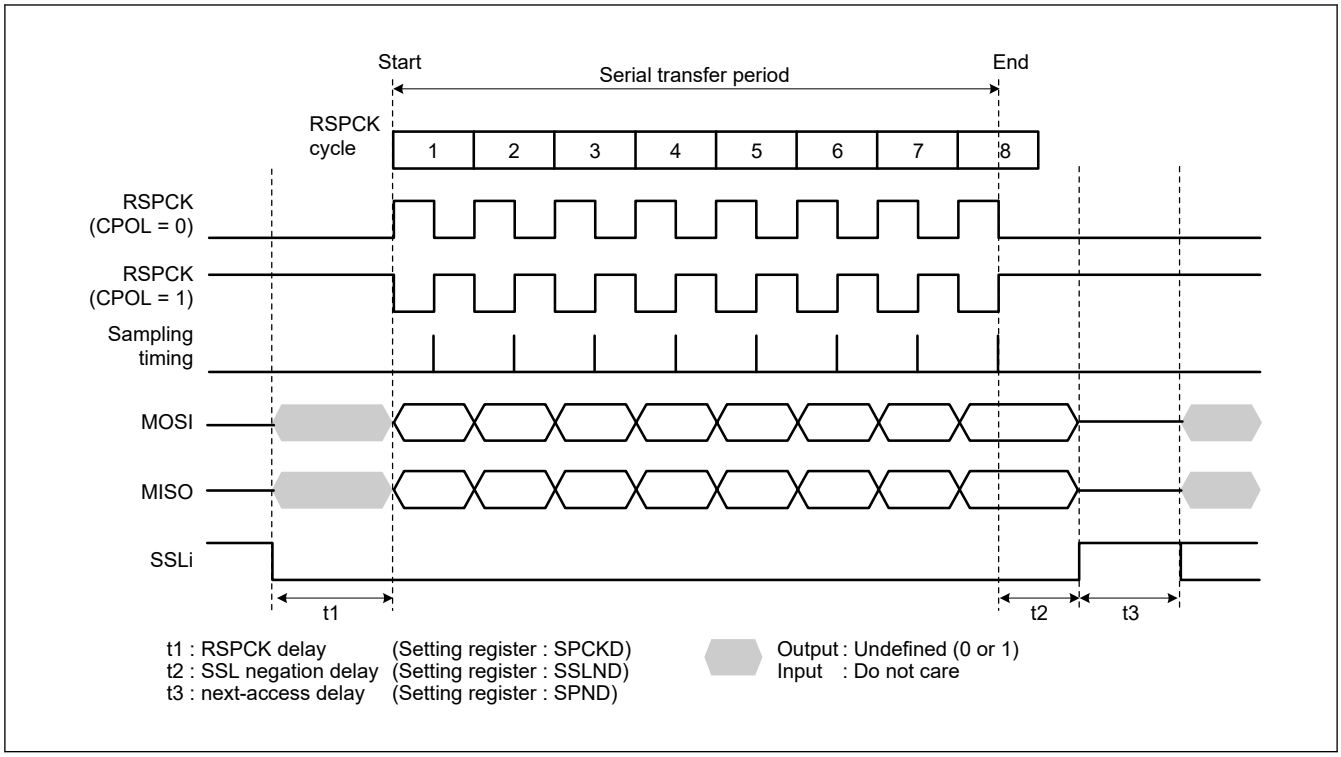

Figure 36.30 SPI transfer format (CPHA = 1, SPFRF = 0)

36.4.6 Communications Operating Mode

Transmit-Receive serial communication, transmit-only operation, and Receive-only operation are selected by setting the Communication Mode Select bits (TXMD[1:0]) of the SPCR register.

SPDR access described in Figure 36.31, Figure 36.32, and Figure 36.33 shows an access to the SPDR register. W shows a write cycle.

36.4.6.1 Transmit-Receive Serial Communication (TXMD[1:0] = 00b)

Figure 36.31 shows an example of operation when the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 00b. In the example in Figure 36.31, the SPI performs 8-bit data serial transfer with the settings of RTRG = FIFO stage - 1, SPDCR2.TTRG = 0, SPCMD.CPHA = 1, and SPCMD.CPOL = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

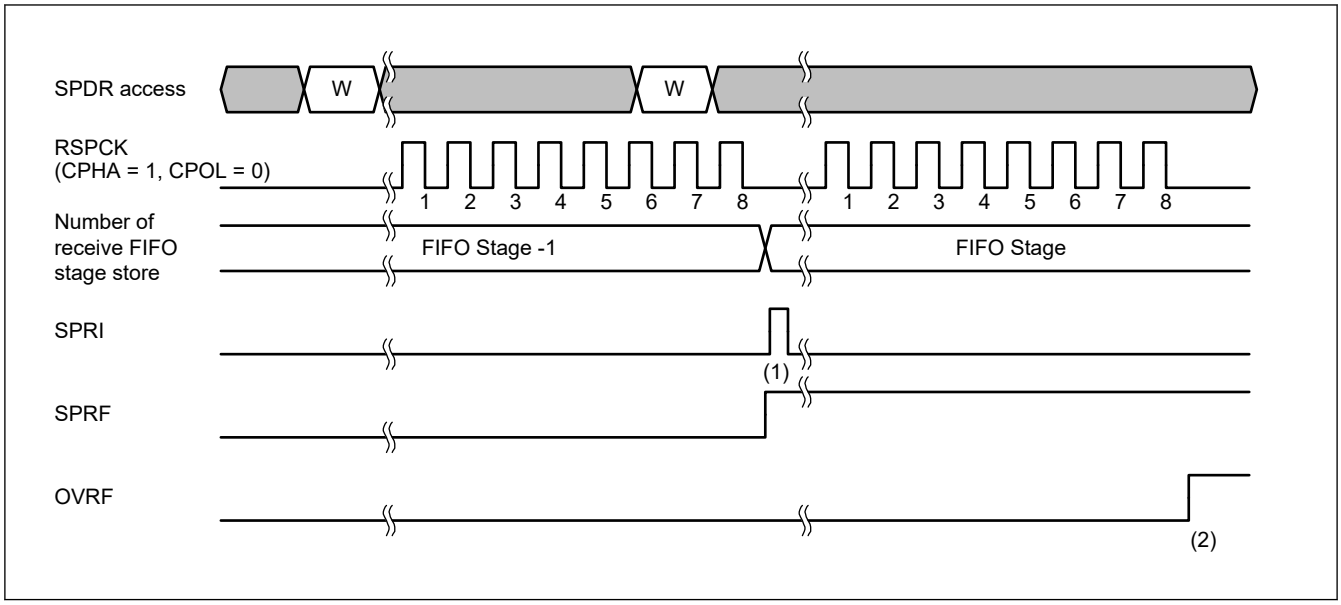

Figure 36.31 Operation example of TXMD[1:0] = 00b

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the OVRF flag in the SPSR register to 1 and discards the received data in the shift register.

In Transmit-Receive serial communication (TXMD[1:0] = 00b), transmit data is transmitted and receive data is received. Therefore, the SPRF flag and the OVRF flag are set to 1 at timings (1) and (2) respectively.

36.4.6.2 Transmit-Only Serial Communication (TXMD[1:0] = 01b)

Figure 36.32 shows an example of operation when the communication mode select bits (TXMD[1:0]) in the SPCR register are set to 01b. In the example in Figure 36.32, the SPI performs 8-bit data serial transfer with the settings of SPDCR2.TTRG[1:0] = 00b, SPDCR2.RTRG[1:0] = 00b, SPCMD.CPHA = 1, and SPCMD.CPOL = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

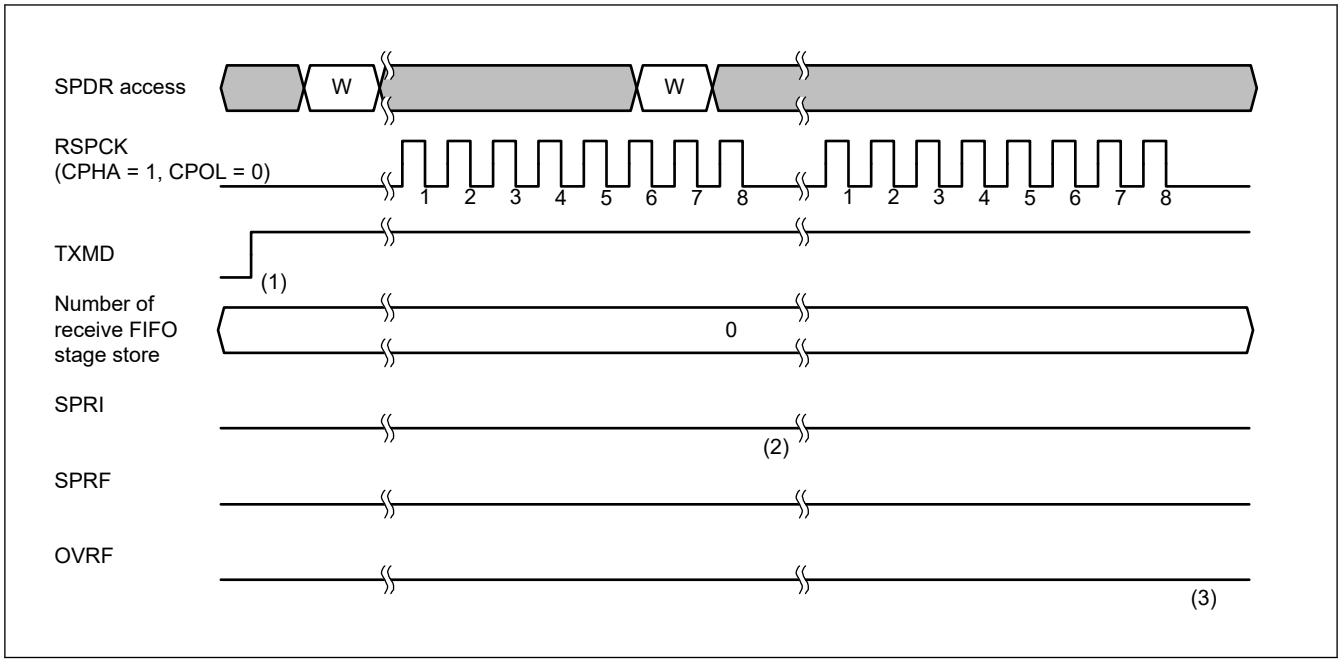

Figure 36.32 Operation example of TXMD[1:0] = 01b

The following describes operation of flags at timings (1) to (3) in the figure above.

(1) Before setting TXMD[1:0] to 01b (transmit-only serial communication), confirm that the receive buffer is empty and that the SPRF and OVRF flags in the SPSR register are 0.

(2) In transmit-only serial communication (TXMD[1:0] = 01b), when serial transfer ends without receiving data in the receiving FIFO of SPDR, the SPRF flag remains 0 and the shift register data is not copied to the receive buffer.

(3) The OVRF flag remains 0 even after serial transfer ends because previously received data is not remaining in the SPDR's receive buffer, and the shift register data is not copied to the receive buffer.

In transmit-only serial communication (TXMD[1:0] = 01b), transmit data is transmitted but receive data is not received.

Therefore, the SPRF flag and the OVRF flag remain 0 at each timing of (1) to (3).

36.4.6.3 Receive-Only Serial Communication (TXMD[1:0] = 10b)

Figure 36.33 shows an example of operation when the communication mode select bit (TXMD[1]) in the SPI control register (SPCR) is set to 1. In the example in Figure 36.33, the SPI performs 8-bit data serial transfer with the settings of SPDCR2.TTRG[1:0] = 0, SPDCR2.RTRG[1:0] = FIFO stage - 1, SPCMD.CPHA = 1, and CPOL in SPCMD = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

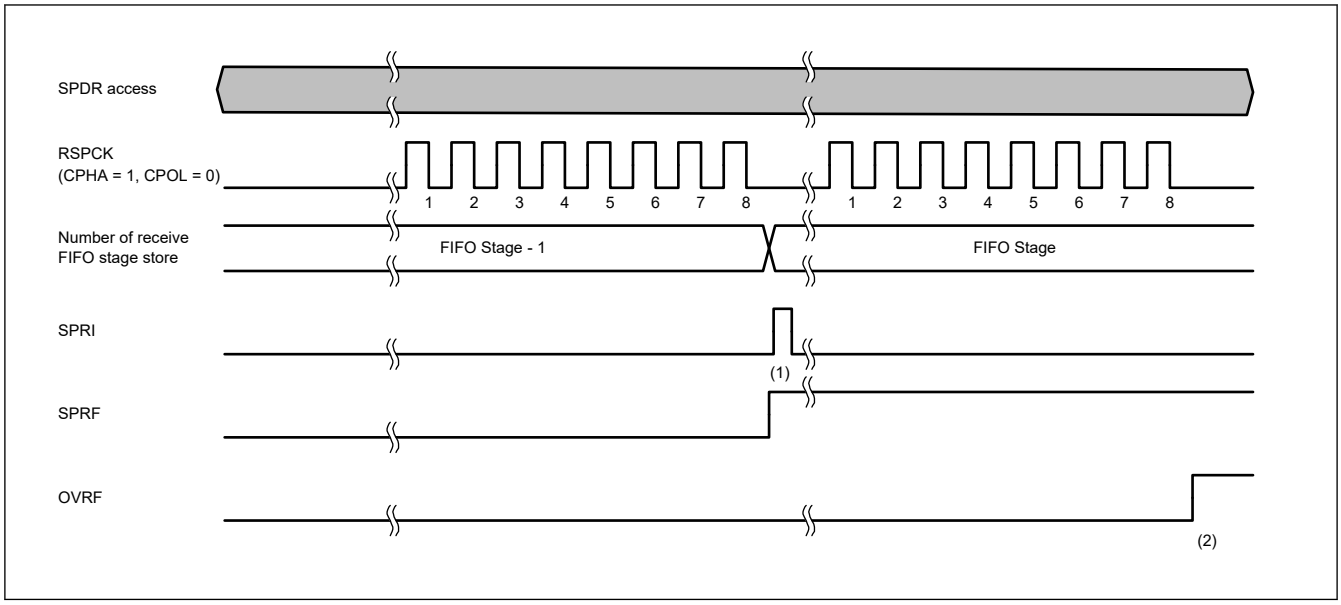

Figure 36.33 Operation example of TXMD[1:0] = 10b

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the OVRF flag in the SPSR.SPI register to 1 and discards the received data in the shift register.

36.4.7 Transmission Buffer Empty/Receive Buffer Full Interrupt

Figure 36.34 show an example of operation of SPI transmit buffer empty interrupt (SPTI) and SPI receive buffer full interrupt (SPRI) respectively. "SPDR access" described in Figure 36.34 and shows an access to the SPDR register. W shows a write cycle and R shows a read cycle. In each example of operation, the SPI performs 8-bit data serial transfer with the settings of SPCR.TXMD[1:0] = 00b, SPDCR2.TTRG = 0, SPDCR2.RTRG = 0, SPCMD.CPHA = 0 (Figure 36.34), and SPCMD.CPOL = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

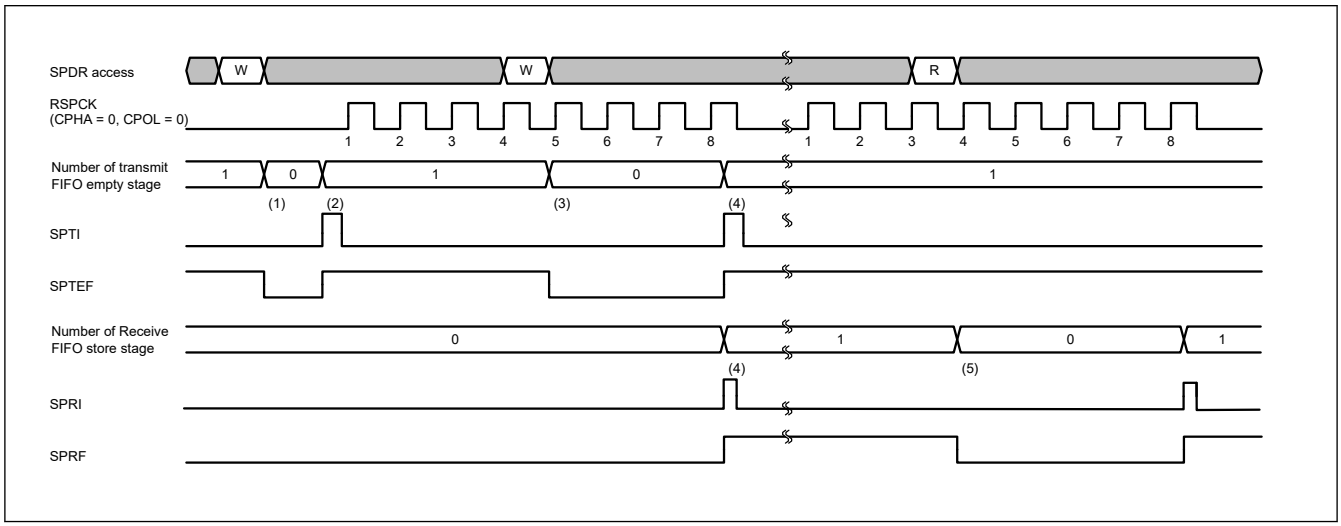

Figure 36.34 Example of SPTI interrupt and SPRI interrupt operations

The following describes operation at timings (1) to (5) in the figure above.

(1) When transmit data is written to SPDR before the data for the next transfer is not set to the FIFO of the SPDR, the SPI writes data to the transmission buffer. When transmit data is written to SPDR in one processing routine using DMAC, the SPSR.SPTEF flag is cleared to 0 at the last access.

(2) When the shift register is empty, the SPI copies transmit buffer data to the shift register. At this time, if transmit FIFO empty stage number > TTRG value, then the SPI generates a transmit buffer empty interrupt request (SPTI) and sets the SPTEF flag to 1. How to start serial transfer depends on SPI mode. (See section 36.4.13. SPI Operation and section 36.4.14. Clock Synchronous Operation.)

(3) When transmit data is written to SPDR upon a transmit buffer empty interrupt request (SPTI) or in the transmit buffer empty determination processing due to the SPTEF flag, the SPI writes data to the transmit buffer. When the transmit data is written to SPDR in one processing routine using DMAC, the SPTEF flag is cleared to 0 at the last access. The SPI does not copy transmit buffer data to the shift register because the shift register contains serial transfer data.

(4) When serial transfer ends (data sampling clock edge in the final bit is detected) while the receive buffer of SPDR > FIFO stage number, the SPI copies the received data in the shift register to the receive buffer. At this time, a receive buffer full interrupt request is generated and the SPRF flag is set to 1. When serial transfer ends, the shift register becomes empty. If the next transfer data is set in the transmit FIFO before serial transfer ends, the SPI set the SPTEF flag to 1 and copies transmit buffer data to the shift register. Even if received data is not copied from the shift register to the receive buffer while an overrun error is present, the SPI determines that the shift register is empty at the end of serial transfer, enabling data transfer from the transmit buffer to the shift register.

(5) When SPDR is read upon a receive buffer full interrupt request (SPRI) or in the receive buffer full determination processing due to the SPRF flag, received data can be read. If the received data is read from SPDR in one processing routine using DMAC, the SPRF flag is cleared to 0 at the last access.

When transmit data is written to the SPDR register while no empty stages in the transmit FIFO, the SPI does not update transmit buffer data. Write transmit data to the SPDR register upon a transmit buffer empty interrupt request or check the empty or not the transmission buffer by the SPTEF flag.

While SPCR.SPTIE = 1, when the SPI is disabled (SPCR.SPE = 0), an SPI transmit buffer empty interrupt is generated. However, SPI transmit buffer empty interrupt is inhibited by disabling SPI transmit buffer empty interrupt (SPCR.SPTIE = 0) at the same time as SPE bit setting.

When serial transfer ends while data is stored in the receive FIFO for the number of FIFO stages, the SPI detects an overrun error without copying data from the shift register to the receive buffer (as described in section 36.4.10. Error Detection). To prevent overrun of received data, read received data before the next serial transfer ends.

Transmit buffer state and receive buffer state can be monitored by an SPI transmit buffer empty interrupt and an SPI receive buffer full interrupt or a corresponding interrupt flag or by the SPTEF and SPRF flags.

36.4.8 Idle Interrupt

The idle interrupt during master mode operation is when the SPCP[2:0] of the SPSSR register becomes 000b (start of sequence control), the IDLNF flag in the SPSR register is set to 1 and an idle interrupt request is made during master mode operation. An interrupt request is also made by clearing the SPCR.SPE bit to 0.

(1) In the Motorola-SPI case

Figure 36.35 shows an example of idle interrupt operation during normal operation.

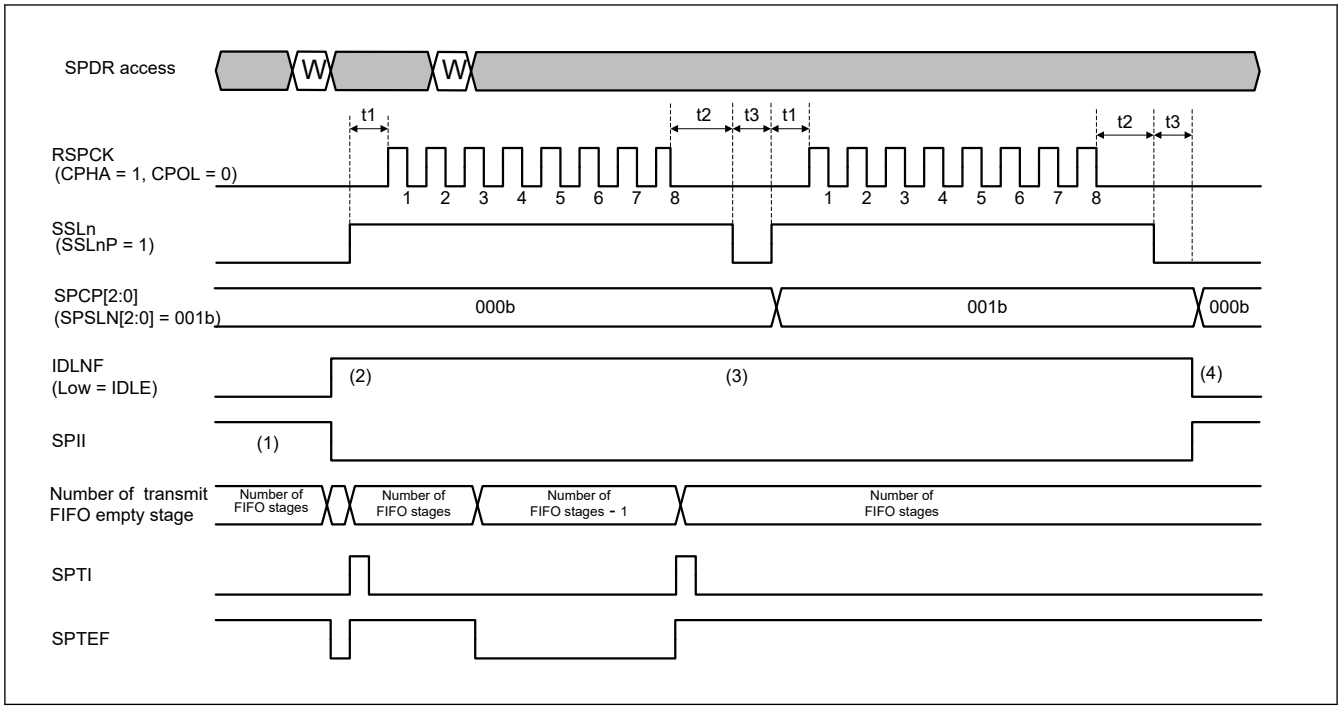

Figure 36.35 Example of idle interrupt operation (master mode / Motorola-SPI)

(1) At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data makes sets the IDLNF flag to 1 (BUSY). When the SPIIE bit in the SPI control register (SPCR) is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0 before starting transmission.

(2) After transmission has started, the IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.

(3) The SPCP[2:0] bits change the command to the next command the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The IDLNF flag is cleared to 0 (IDLE) the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPIIE bit is 1 currently, an SPII interrupt is output.

(2) In the TI-SSP case

Figure 36.36 shows an example of idle interrupt operation during normal operation.

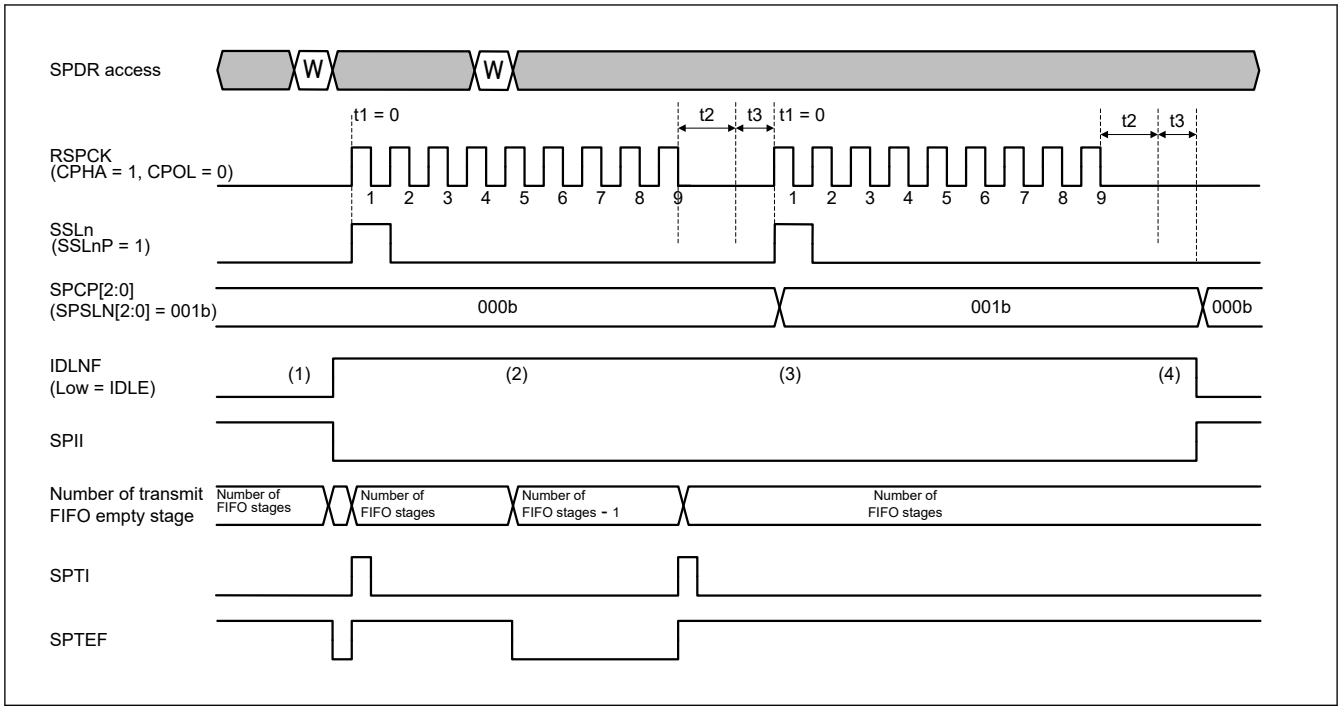

Figure 36.36 Example of idle interrupt operation (master mode / TI-SSP)

(1) At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data makes sets the IDLNF flag to 1 (BUSY). When the SPCR.SPIIE bit is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0 before starting transmission.

(2) After transmission has started, the IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.

(3) The SPCP[2:0] bits change the command to the next command the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The IDLNF flag is cleared to 0 (IDLE) the end of t3 cycle because the next command is 000b and the next transmit data is not present. When SPCR.SPIIE = 1 currently, an SPII interrupt is output.

36.4.9 Communication End Interrupt

36.4.9.1 Transmit-Receive/Transmit-only in Master Mode

Refer to the description of the CENDF bit in section 36.3.19. SPTFSR : SPI Transfer FIFO Status Register and section 36.3.18. SPSR : SPI Status Register for the setting/clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Master Mode.

(1) In the Motorola-SPI case

Figure 36.37 shows an example of communication end interrupt operation during transmit-receive/transmit master mode.

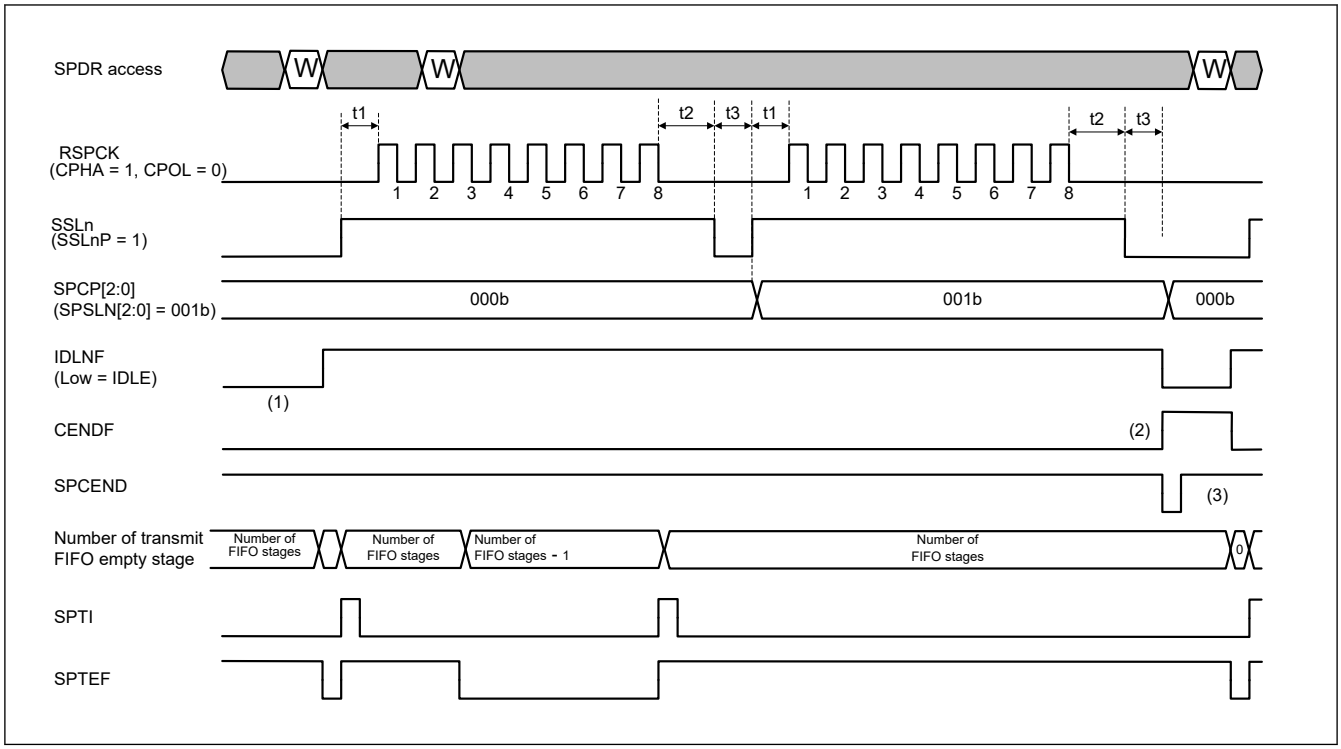

Figure 36.37 Example of communication end interrupt operation (transmit-receive/transmit-only master mode / Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. The SPCEND interrupt is then output with 1 PCLKM cycle width if the CENDIE bit is 1.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

(2) In the TI-SSP case

Figure 36.38 shows an example of communication end interrupt operation during transmit-receive/transmit-only master mode.

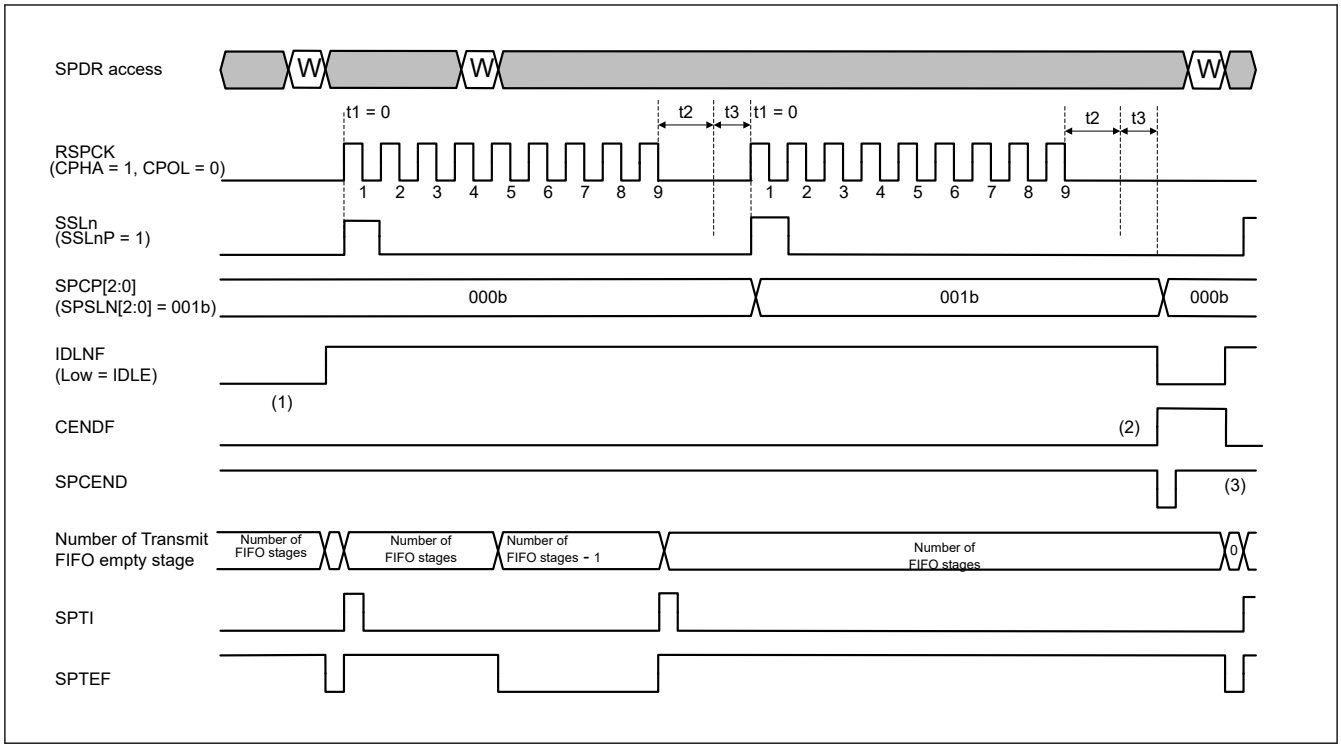

Figure 36.38 Example of communication end interrupt operation (transmit-receive/transmit-only master mode / TI-SSP)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. The SPCEND interrupt is then output with 1 PCLKM cycle width if the CENDIE bit is 1.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

36.4.9.2 Receive-only in Master Mode

Refer to the description of the CENDF bit in section 36.3.18. SPSR : SPI Status Register for the setting/clearing conditions of the communication completion flag during Receive-only in Master Mode.

Figure 36.39 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] = 0x00.

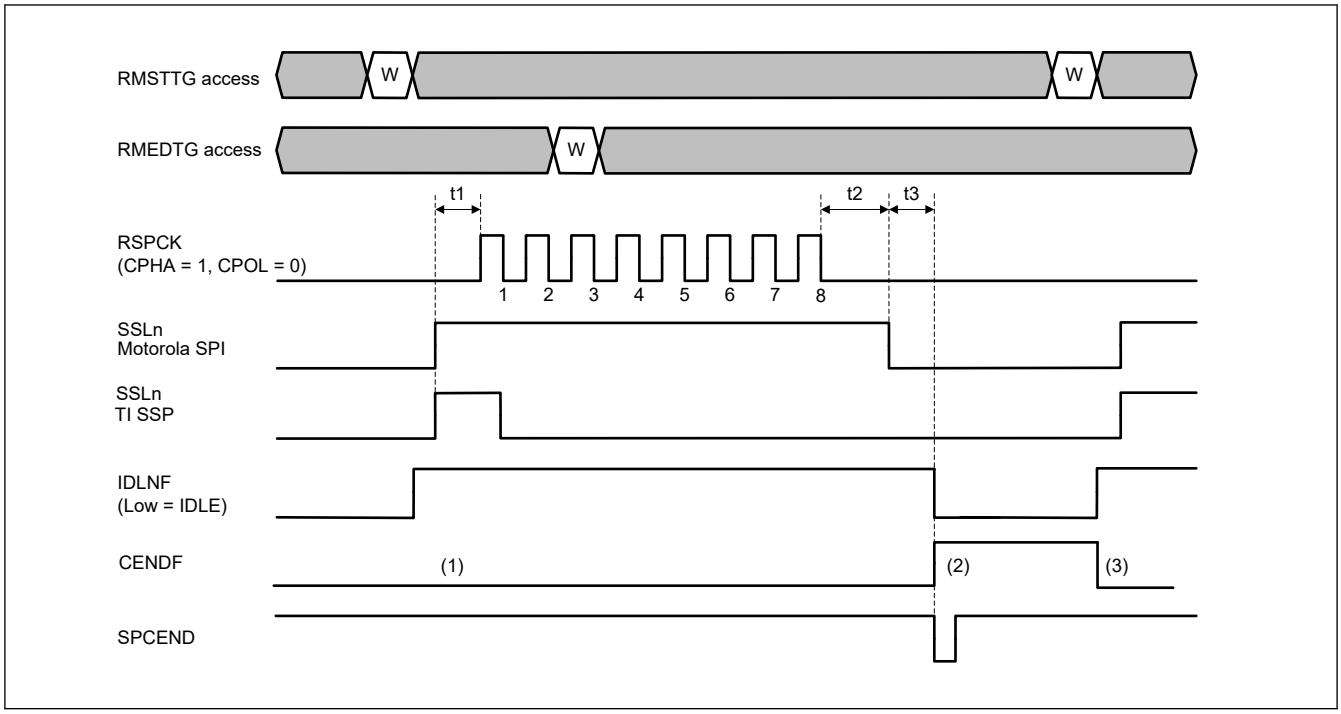

Figure 36.39 Example of communication end interrupt operation (receive-only master mode / Motorola-SPI) at RMFM[4:0] = 0x00

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, by writing 1 to RMEDTG during the communication frame. The SPCEND interrupt is then output with 1 PCLKM cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared when writing 1 to RMSTTG, or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

Figure 36.40 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] ≠ 0x00.

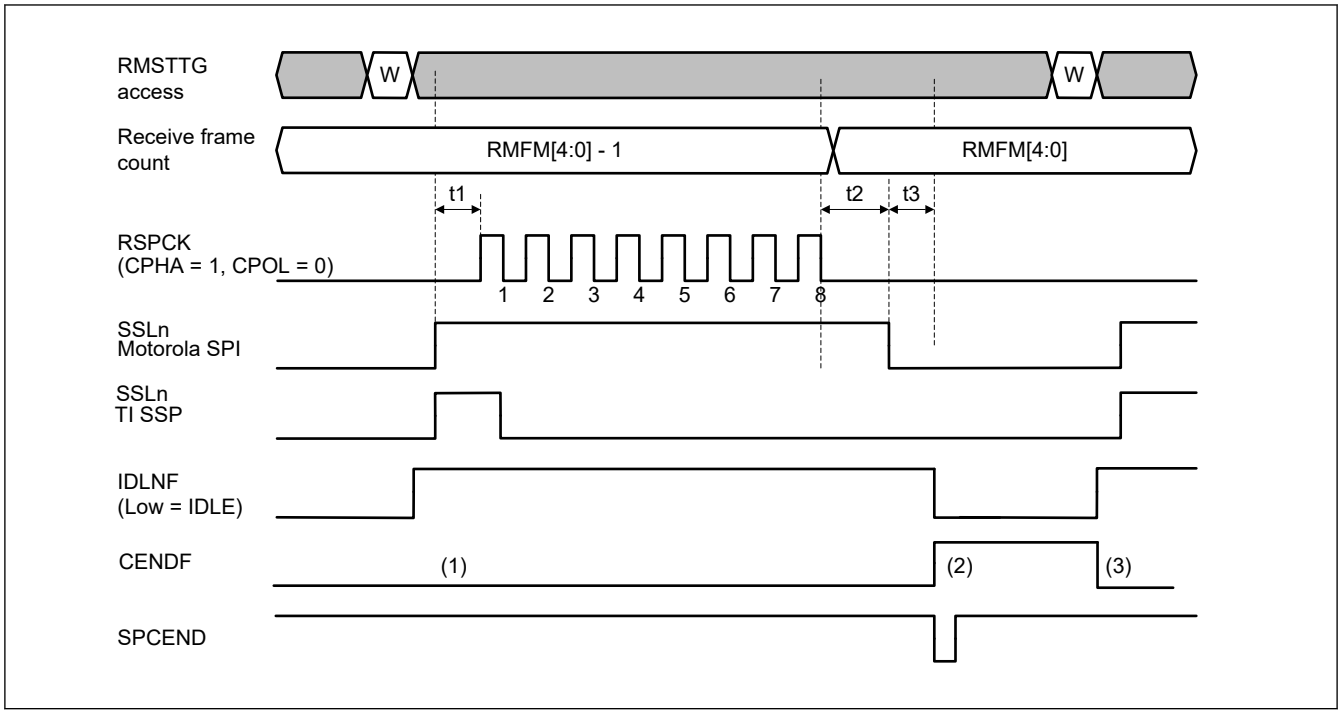

Figure 36.40 Example of communication end interrupt operation (receive-only master mode / Motorola-SPI) at RMFM[4:0] ≠ 0x00

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, after receiving the number of frames set by RMFM[4:0]. The SPCEND interrupt is then output with 1 PCLKM cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared when writing 1 to RMSTTG, or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

In slave mode operation, the output timing of the communication end interrupt is dependent on the value of the SPCR.SPMS bit (SPI mode select bit). The clear timing of the communication end interrupt is dependent on the communication mode (transmit-receive or transmit-only or receive-only).

36.4.9.3 Transmit-Receive/Transmit-only in Slave Mode on SPI Operation (4-wire)

See the description for the CENDF bit in section 36.3.18. SPSR : SPI Status Register for the setting/clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Slave Mode (4-wire).

(1) In the Motorola-SPI case

Figure 36.41 shows an example of communication end interrupt operation during transmit-receive/transmit-only slave mode on SPI operation.

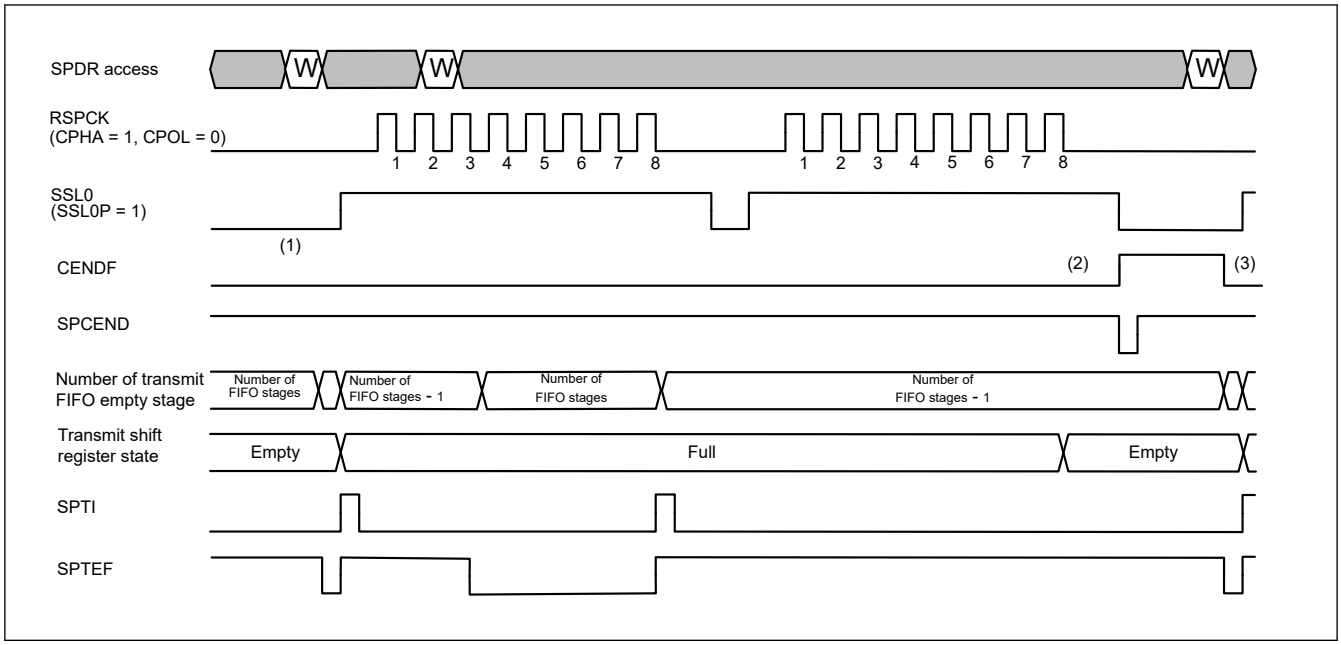

Figure 36.41 Example of communication end interrupt operation (transmit-receive/transmit-only slave mode on SPI operation / Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the timing of SSL0 negate, when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. The SPCEND interrupt is then output with 1 PCLKM cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared when the next transmition data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

(2) In the TI-SSP case

Figure 36.42 shows an example of communication end interrupt operation during transmit-receive/transmit-only slave mode on SPI operation.

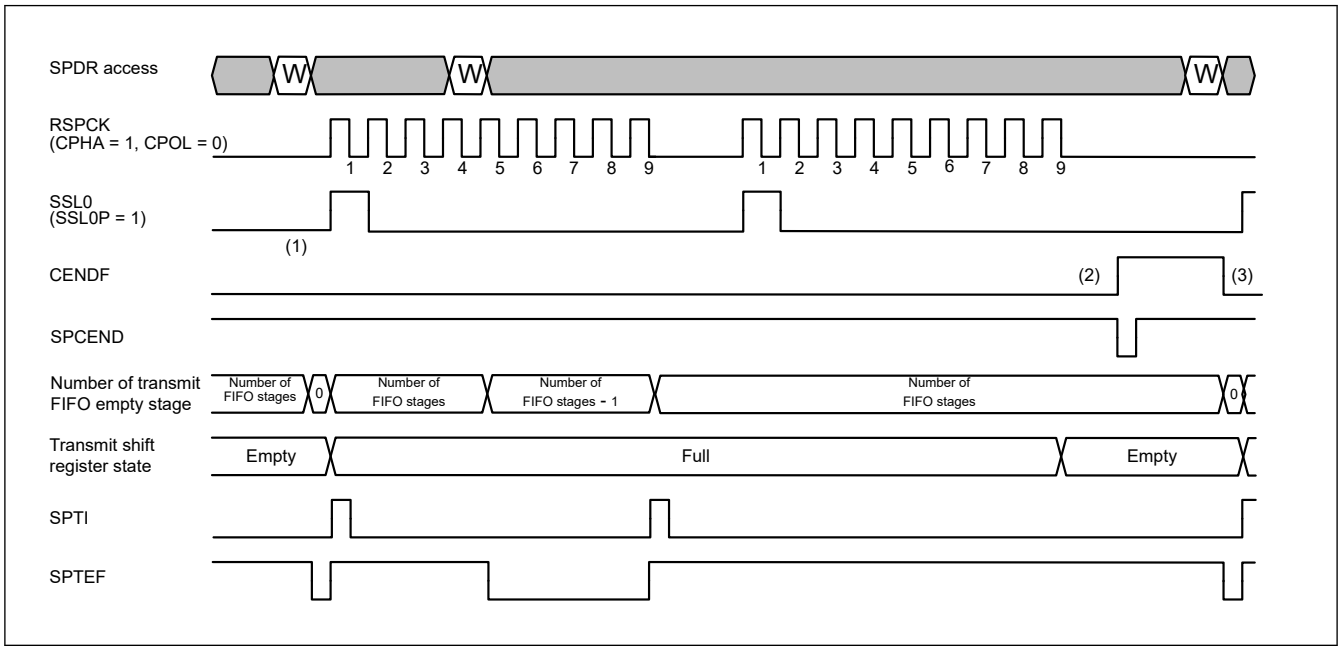

Figure 36.42 Example of communication end interrupt operation (transmit-receive/transmit-only slave mode on SPI operation / TI-SSP)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) The CENDF flag is 1 (communication end) at the RSPCK last data bit sampling, when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if the CENDIE bit is 1.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

36.4.9.4 Receive Only in Slave Mode on SPI Operation (4-wire)

Refer to the description of the CENDF bit in section 36.3.18. SPSR : SPI Status Register for the setting/clearing conditions of the communication completion flag during Receive-only in Slave Mode (4-wire).

(1) In the Motorola-SPI case

Figure 36.43 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

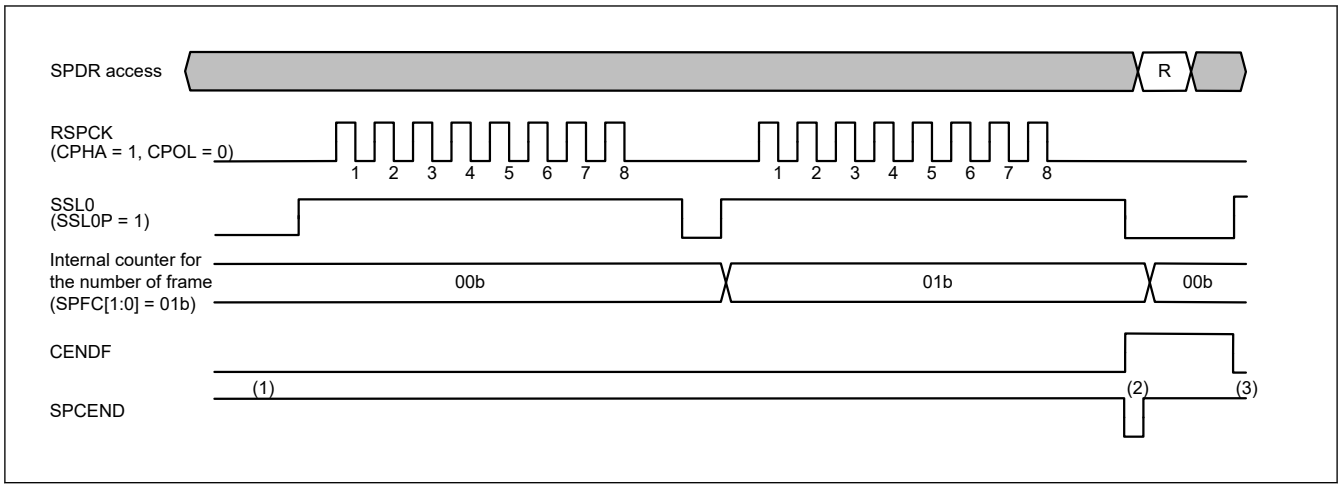

Figure 36.43 Example of communication end interrupt operation (receive-only slave mode on SPI operation / Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) After store the frames for the SPDCR.SPFC register set value in the receive buffer, the CENDF flag becomes 1 (communication completed) at the timing of SSL0 negation. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared at the SSL0 assert when the next transmission start, or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

(2) In the TI-SSP case

Figure 36.44 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

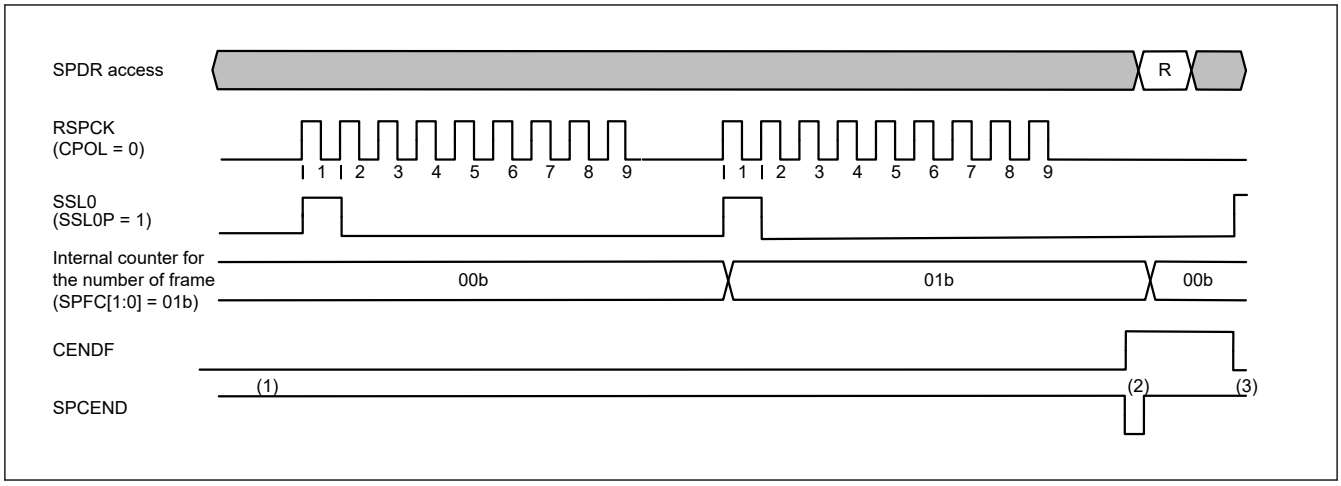

Figure 36.44 Example of communication end interrupt operation (receive-only slave mode on SPI operation / TI-SSP)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) The CENDF flag is 1 (communication end) at the RSPCK last data bit sampling, when the last frame transmission ends. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared at the SSL0 assert when the next transmission start, or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

36.4.9.5 Transmit-Receive/Transmit-only in Slave Mode on Clock Synchronous Operation (3-wire)

Refer to the description of the CENDF bit in section 36.3.18. SPSR : SPI Status Register for the setting/clearing conditions of the communication completion flag during Receive-only in Slave Mode (4-wire).

Figure 36.45 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on clock synchronous operation (3-wire).

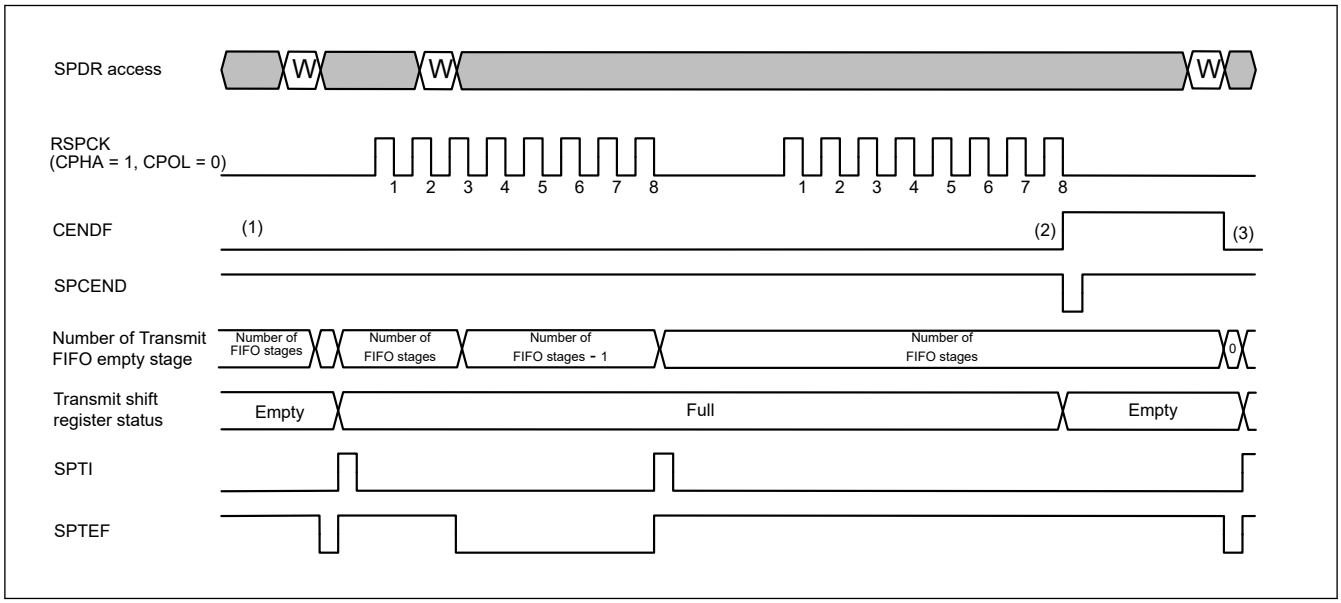

Figure 36.45 Example of communication end interrupt operation (receive-only slave mode on SPI operation / Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) When the next transfer data is not set in the transmit FIFO and the transmit shift register is empty, the SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

36.4.9.6 Receive only in Slave Mode on Clock Synchronous Operation (3-wire)

Refer to the description of the CENDF bit in section 36.3.19. SPTFSR : SPI Transfer FIFO Status Register and section 36.3.18. SPSR : SPI Status Register for the setting/clearing conditions of the communication completion flag during Receive -only in Slave Mode on Clock Synchronous (3-wire).

Figure 36.46 shows an example of communication end interrupt operation during receive only slave mode on clock synchronous operation.

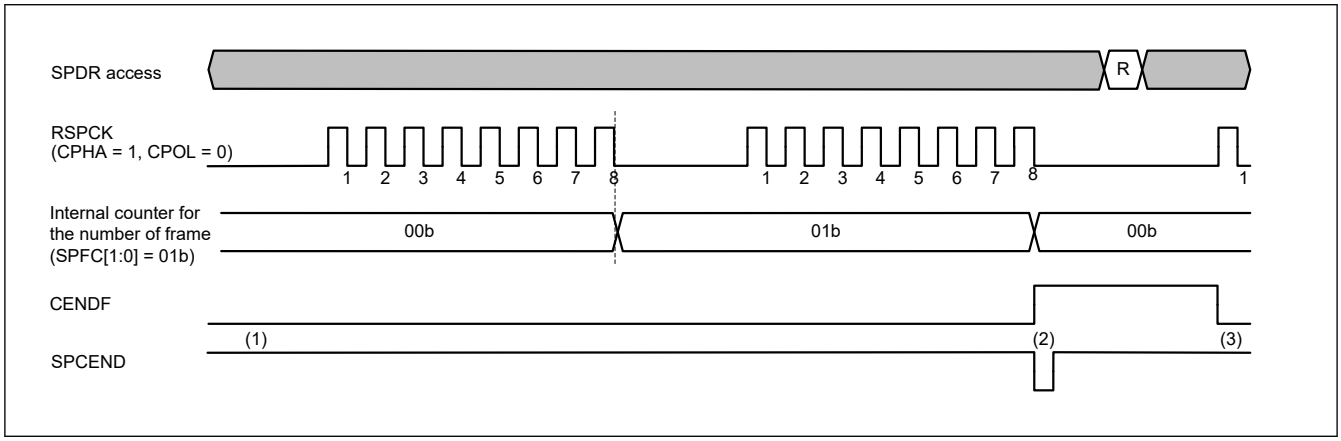

Figure 36.46 Example of communication end interrupt operation (receive-only slave mode on clock synchronous operation)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) The CENDF flag is set to 1 (communication completed) at the timing of the last data bit sampling of RSPCK in the last frame communication when the last frame of the SPDCR.SPFC bit set value is received. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared at the first edge of RSPCK for the next transmission, or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

36.4.9.7 Common Operation

In this Section, the operation common to each mode communication in section 36.4.9.1. Transmit-Receive/Transmit-only in Master Mode to section 36.4.9.6. Receive only in Slave Mode on Clock Synchronous Operation (3-wire) is explained. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, a flag of communication end (CENDF) is set, but no interrupt is output. However, if the enable of communication end interrupt (CENDIE) is set to 1 before clearing the flag of communication end (CENDF) while the enable of SPI function (SPE) is 1, the communication end interrupt is output.

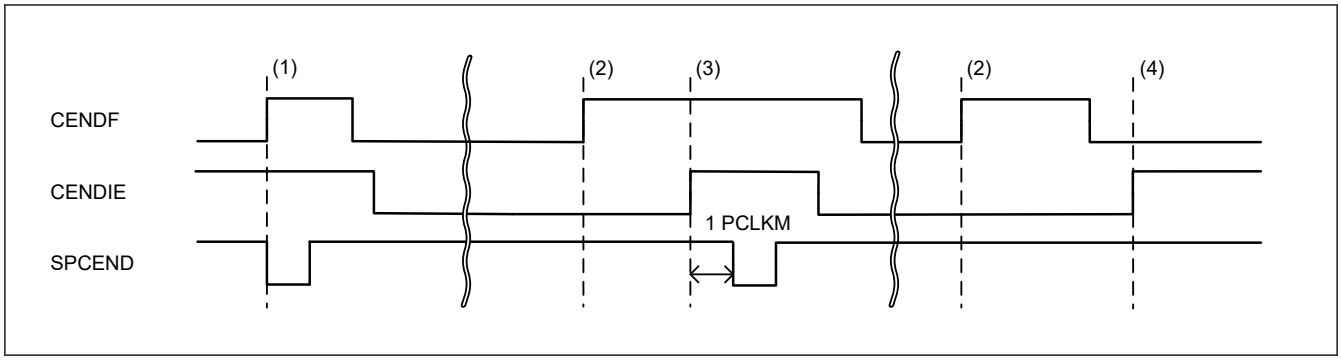

Figure 36.47 Example of communication end interrupt operation (enable control)

(1) When the enable of SPI communication end interrupt (CENDIE) is 1, at the time of communication completion, the following two are the same timing

a flag of communication end (CENDF)

the communication end interrupt

(2) When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, the following occurs, but no interrupt.

a flag of communication end (CENDF)

(3) After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt is output after 1 PCLKM.

(4) After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt is not output.

36.4.10 Error Detection

In normal serial transfer of SPI, data written to the transmit buffer in the SPDR register is transmitted in serial and received serial data can be read from the SPDR's receive buffer. Depending on the transmit buffer or receive buffer status when SPDR is accessed and the SPI status at the start or end of serial transfer, abnormal transfer is performed.

When some abnormal transfer operation takes place, the SPI detects it as an underrun error, overrun error, parity error, or mode fault error. Table 36.12 shows the relationship between abnormal transfer operation and the SPI's error detection function.

Table 36.12 Abnormal transfer occurrence conditions and error detection function of SPI (1 of 2)

	Transfer occurrence condition	SPI operation	Error detection
1	SPDR is written when while no empty stages in the transmit FIFO.	• Transmit buffer data is retained. • No write data is present.	None
2	SPDR is read while no data stored in receive FIFO.	Received data and previously received serial data are read.	None
3	Serial transfer starts in transmit slave mode or transmit-only slave mode, before transmit data output is ready.	• Serial transfer is suspended. • No transmit data or receive data is present. • Driving of the MISO output signal is stopped. • SPI function is disabled.	Underrun error
4	Serial transfer ends when data is stored in the receive FIFO for the number of FIFO stages.	• Receive FIFO data is retained. • No serial receive data is present.	Overrun error
5	Incorrect parity bit has been received with the parity function enabled in following mode. • Transmit / receive-only master mode • Transmit / receive slave mode • Receive-only slave mode	The parity error flag is asserted.	Parity error
6	The SSL0 input signal is asserted when the serial transfer is idle state in multi-master mode.	• Driving of the RSPCK, MOSI, SSL1 to SSL3 output signals is stopped. • SPI function is disabled.	Mode fault error

Table 36.12 Abnormal transfer occurrence conditions and error detection function of SPI (2 of 2)

	Transfer occurrence condition	SPI operation	Error detection
7	The SSL0 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the RSPCK, MOSI, SSL1 to SSL3 output signals is stopped. • SPI function is disabled.	Mode fault error
8	[In the Motorola-SPI case] The SSL0 input signal is negated during serial transfer in slave mode.	• Serial transfer is suspended. • No transmit data or receive data is present. • Driving of the MISO output signal is stopped. • SPI function is disabled.	Mode fault error
9	[In the TI-SSP case] The SSL0 input signal is asserted during serial transfer in slave mode.	• Serial transfer is suspended. • No transmit data or receive data is present. • Driving of the MISO output signal is stopped. • SPI function is disabled.	Mode fault error

The SPI does not detect any error for the operation shown in No.1 in Table 36.12. To prevent missing of data during SPDR writing, write data to SPDR upon a transmit buffer empty interrupt request or while the SPSR.SPTEF flag is 1.

The SPI does not detect any error also for the operation shown in No.2 in Table 36.12. To prevent reading of unnecessary data, read data from SPDR upon a receive buffer full interrupt request or while the SPSR.SPRF flag is 1.

The underrun error shown in No.3 in Table 36.12 is described in section 36.4.10.4. Underrun Error.

The overrun error shown in No.4 in Table 36.12 is described in section 36.4.10.1. Overrun Error.

The parity error shown in No.5 in Table 36.12 is described in section 36.4.10.2. Parity Error.

The mode fault error shown in No.6 to No.9 in Table 36.12 is described in section 36.4.10.3. Mode Fault Error.

For transmission and reception interrupts, see section 36.4.7. Transmission Buffer Empty/Receive Buffer Full Interrupt.

36.4.10.1 Overrun Error

When serial transfer ends while the receive buffer in the SPDR register is full, the SPI detects an overrun error and sets the OVRF flag in SPSR to 1. While the OVRF flag is 1, the SPI does not copy shift register data to the receive buffer. Therefore, data before an error occurs is retained in the receive buffer. To clear the OVRF flag in SPSR to 0, issue a system reset or 1 is written to the SPSRC.OVRFC bit.

Figure 36.48 shows operation of the SPRF flag and the OVRF flag in SPSR. "SPSR access" and "SPDR access" described in Figure 36.48 show an access to SPSR and SPDR respectively. "W" shows a write cycle and "R" shows a read cycle. In the example in Figure 36.48, the SPI performs 8-bit data serial transfer with the settings of SPCMD.CPHA = 1 and SPCMD.CPOL = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

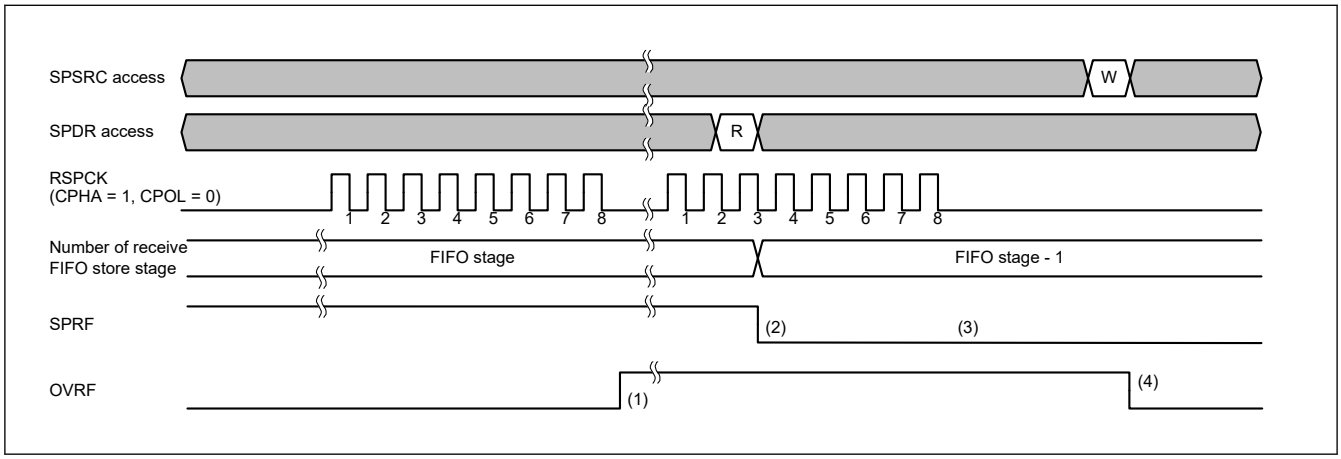

Figure 36.48 Example of operation of SPRF and OVRF flags

The following describes operation of flags at timings (1) to (4) in the figure above.

(1) When serial transfer ends while data is stored for the number of FIFO stages, the SPI detects an overrun error and sets the OVRF flag to 1. The SPI does not copy shift register data to the receive buffer. The SPI does not detect a

parity error even when SPPE = 1. In master mode, the SPI copies the value of pointer to the SPCMD register to the SPSSR.SPECM[2:0] bits.

(2) The SPI can read receive buffer data by reading SPDR. At this time, the SPRF flag is cleared to 0 at the last access when the received data is read from SPDR in one processing routine using DMAC.

(3) When serial transfer ends while the OVRF flag is 1 (overrun error), the SPI does not copy shift register data to the receive buffer (SPRF flag remains 0) and no SPI receive buffer full interrupt is generated. The SPI does not detect a parity error even when SPPE = 1. In master mode, the SPI does not update the SPSSR.SPECM[2:0] bits. When the SPI does not copy received data from the shift register to receive buffer while an overrun error is present, the SPI also determines that the shift register is empty at the end of serial transfer, enabling data transfer from the transmit buffer to the shift register.

(4) When 1 is written to the SPSRC.OVRFC bit.

Whether an overrun error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To perform serial transfer without using an SPI error interrupt, read SPDR and then immediately read SPSR to quickly detect an overrun error. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPSSR.SPECM bits. When an overrun error occurs and the OVRF flag is set to 1, successful reception is disabled until the OVRF flag is cleared to 0.

When the RSPCK auto-stop function is enabled in master mode, an overrun error does not occur. Figure 36.49 and Figure 36.50 show the clock stop waveform when a serial transfer continues while the reception buffer is full in master mode.

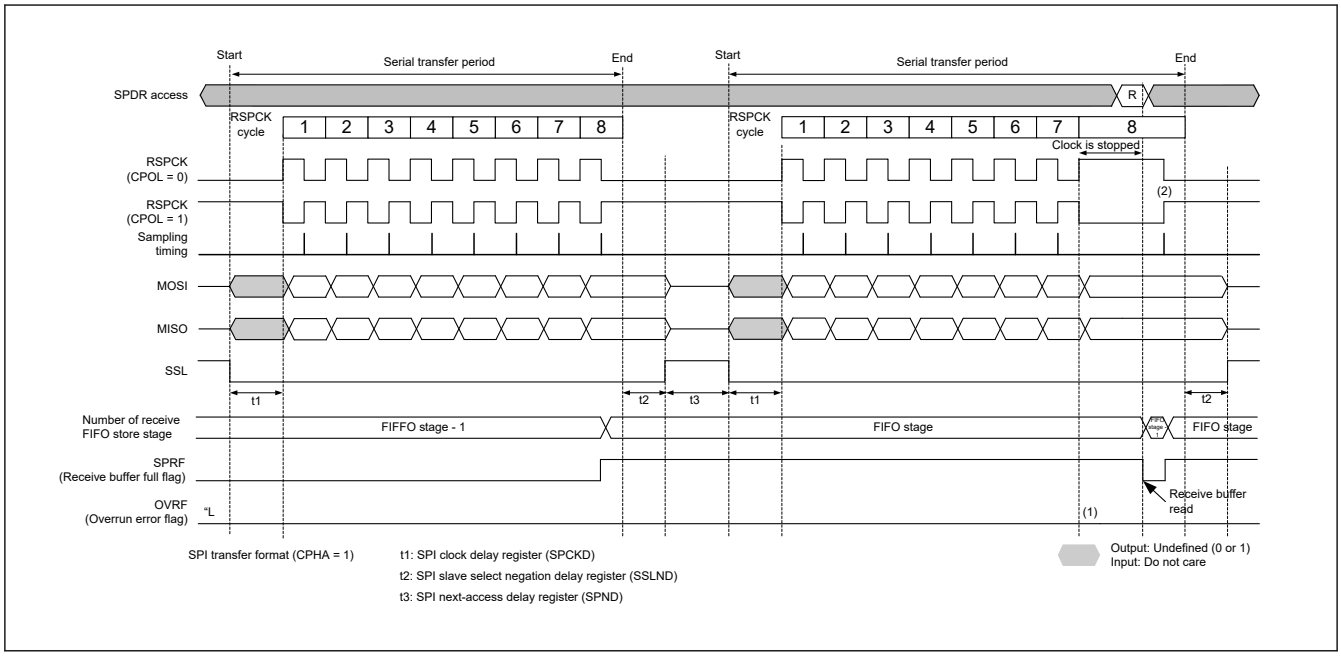

Figure 36.49 Clock stop waveform when serial transfer continues with data is stored for the number of FIFO stages in master mode (CPHA = 1)

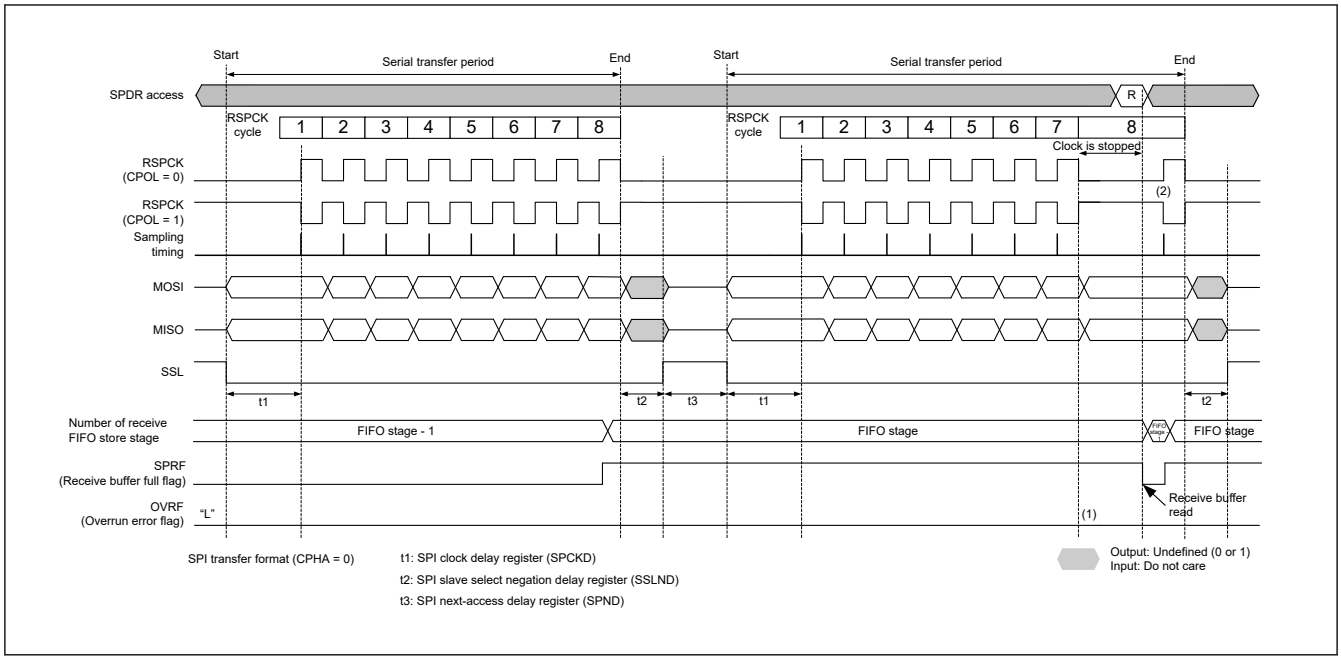

Figure 36.50 Clock stop waveform when serial transfer continues with data is stored for the number of FIFO stages in master mode (CPHA = 0)

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) While data is stored in the receive FIFO for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.

(2) Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read, the RSPCK clock restarts.

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. The Figure 36.51 and the Figure 36.52 show the clock stop waveform, when there is no delay between frames at burst transfer and the serial transfer continues in the data is stored in the receive FIFO for the number of FIFO stages.

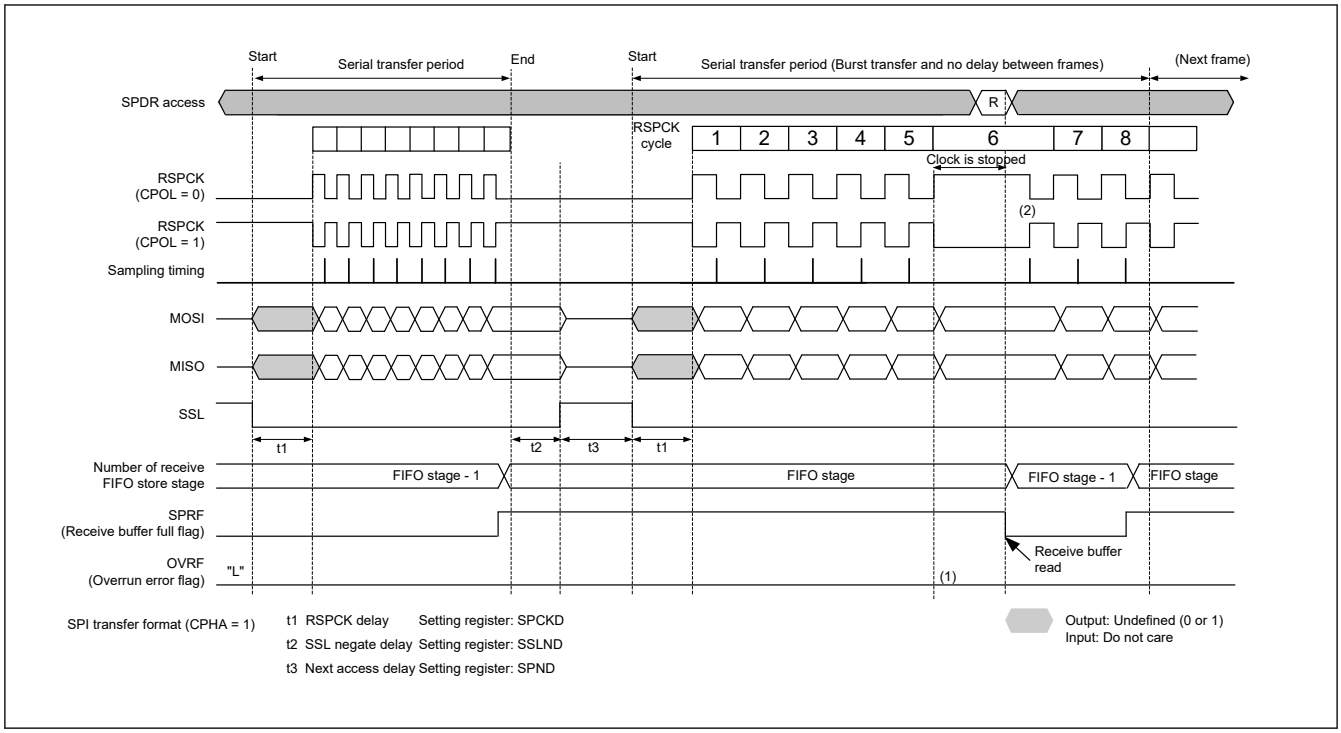

Figure 36.51 Clock stop waveform when serial transfer continues in the receive buffer full with data is stored for the number of FIFO stages in master mode (at burst transfer and no delay between frames CPHA = 1)

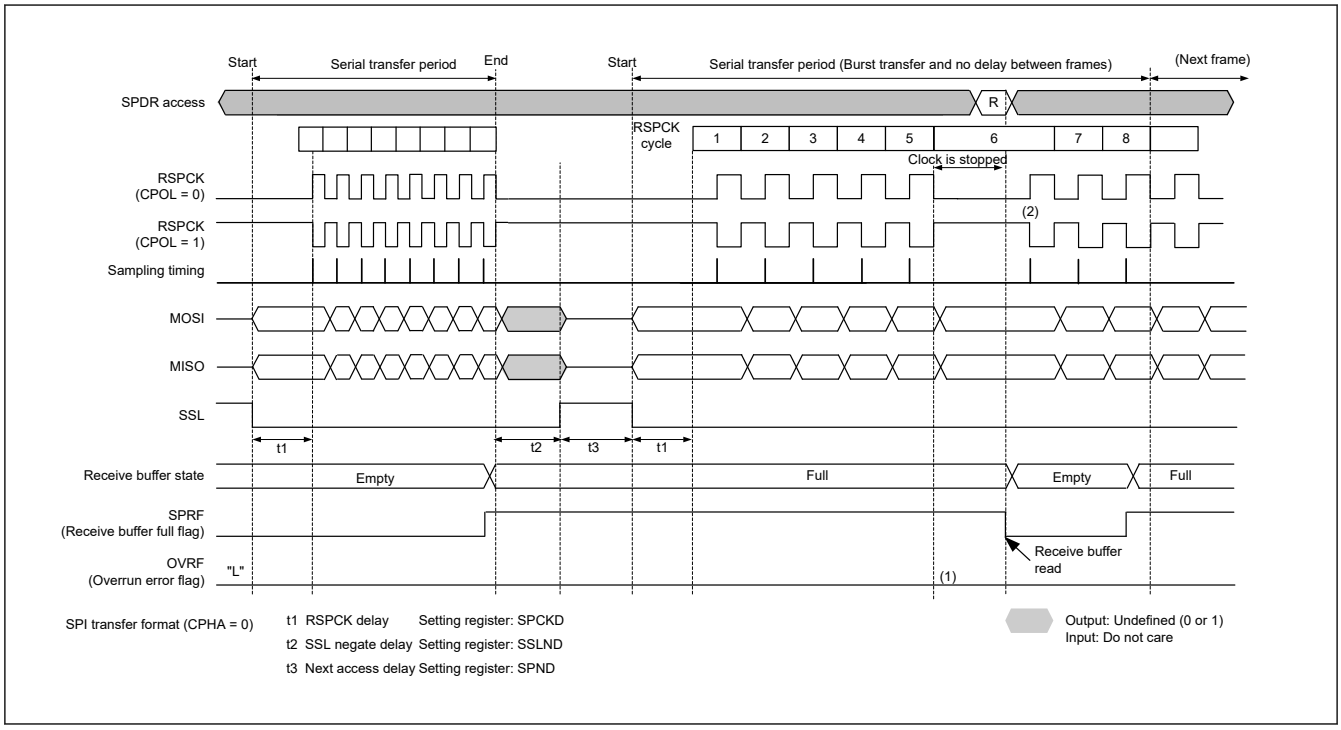

Figure 36.52 Clock stop waveform when serial transfer continues i with data is stored for the number of FIFO stages in master mode (at burst transfer and no delay between frames CPHA = 0)

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) While the data is stored for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.

(2) Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read, the RSPCK clock restarts.

36.4.10.2 Parity Error

After transfer in transmit-receive or receive-only master mode, transmit-receive slave mode or receive only slave mode while the SPCR.SPPE = 1, the SPI checks occurrence of a parity error. When the SPI detects a parity error in received data, the PERF flag in the SPSR register is set to 1. While the OVRF flag is 1, the SPI does not copy shift register data to the receive buffer. Therefore, parity error in received data is not detected. To clear the PERF flag in SPSR to 0, issue a system reset or write 1 to the SPSRC.PERFC bit.

Figure 36.53 shows operation of the OVRF and PERF flags in SPSR. "SPSR access" described in Figure 36.53 shows an access to SPSR. "W" shows a write cycle and "R" shows a read cycle. In the example in Figure 36.53, the SPI performs transmit-receive serial communication while SPCR.SPPE = 1. The SPI performs 8-bit data serial transfer with the settings of SPCMD.CPHA = 1 and SPCMD.CPOL = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

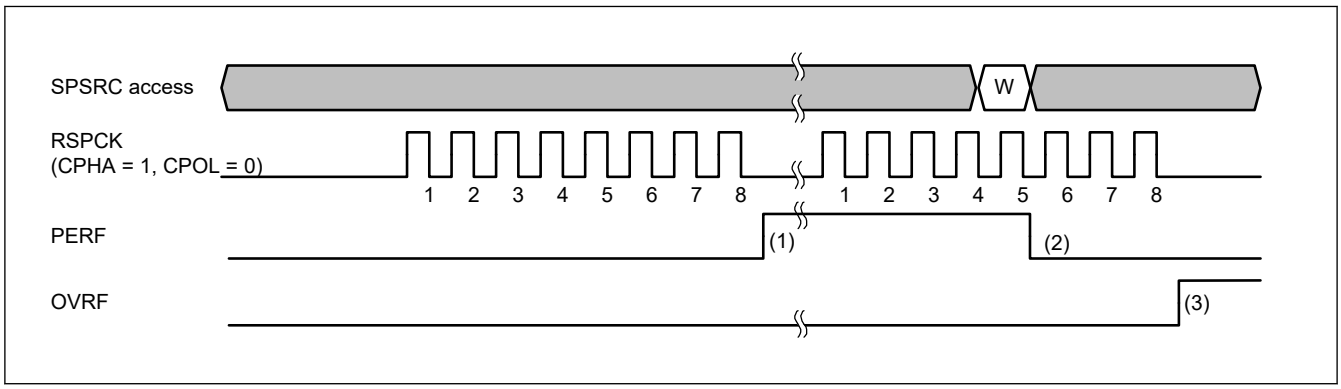

Figure 36.53 Example of operation of OVRF and PERF flags

The following describes operation of flags at timings (1) to (3) in the figure above.

(1) When the SPI does not detect an overrun error and terminates the serial transfer, the SPI copies shift register data to the receive buffer. When the SPI checks the received data and detects a parity error at this time, the PERF flag is set to 1. In master mode, the SPI copies the value of pointer to the SPCMD register to the SPSSR.SPCM [2:0] bits.

(2) When 1 is written to the SPSRC.PERFC bit.

(3) When the SPI detects an overrun error and terminates the serial transfer, the SPI does not copy shift register data to the receive buffer and does not detect a parity error.

Whether a parity error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To use an SPI error interrupt, set the SPCR.SPEIE bit to 1. To perform serial transfer without using an SPI error interrupt, read SPDR to quickly detect a parity error. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPSSR.SPECM[2:0] bits.

36.4.10.3 Mode Fault Error

When the SPCR.MSTR = 1, SPCR.SPMS = 0, and SPCR.MODFEN = 1, the SPI operates in multi-master mode. When an active level is input to the SSL0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of serial transfer status and sets the MODF flag in the SPSR register to 1. When a mode fault error is detected, the SPI copies the value of pointer to the SPCMD register to the SPSSR.SPECM[2:0] bits. The SSL0 signal active level depends on the SSL0P bit in the SSLP register.

While SPCR.MSTR = 0, the SPI operates in slave mode. When SPCR.SPMS = 0 and SPCR.MODFEN = 1 in slave mode, if the SSL0 input signal is negated during the serial transfer period (from valid data drive start to final valid data latch), the SPI detects a mode fault error while any of the following 2 conditions is met.

(1) In the Motorola-SPI case

When the SSL0 input signal is negated while serial data transfer.

(2) In the TI-SSP case

When the SSL0 input signal is asserted while serial data transfer. However, during burst transfer, no error is detected even if the SSL0 input signal is asserted during the last bit of frame.

When the SPI detects a mode fault error, it stops driving output signals and clears the SPCR.SPE bit.

When the SPE bit is cleared, the SPI function is disabled (as described in section 36.4.12. SPI Initialization). In a multi-master configuration, the mastership can be released by stopping driving output signals and disabling the SPI function by using a mode fault error.

Whether a mode fault error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To detect a mode fault error without using an SPI error interrupt, poll SPSR. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPSSR.SPECM[2:0] bits.

While the MODF flag = 1, the SPI ignores writing 1 to the SPE bit. To enable the SPI function after a mode fault error is detected, clear the MODF flag to 0 without fail.

36.4.10.4 Underrun Error

While the SPI is operating in slave mode (SPCR.MSTR = 0) and the communication mode select SPCR.TXMD[1:0] bits are set to 00b or 01b, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1 (SPI function enabled), the SPI detects an underrun error and sets the MODF and UDRF flags in the SPSR register to 1.

When the SPI detects an underrun error, it stops driving output signals and clears the SPE bit to 0. When the SPE bit is cleared, the SPI function is disabled (as described in section 36.4.12. SPI Initialization)

Whether an underrun error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR.

To detect an underrun error without using an SPI error interrupt, poll SPSR.

While the MODF flag = 1, the SPI ignores writing 1 to the SPE bit. To enable the SPI function after an underrun error is detected, clear the MODF flag to 0 without fail.

36.4.11 Received Data Ready Detection

When SPCR.TXMD[1:0] = 00b, 01b, or 11b, and SPDRCR.SPDRC[7:0] ≠ 0x00, after receiving data in the receive FIFO during communication (SPE = 1), SPDR.SPDRF flag is set to 1 when the received data is not stored even after the number of received FIFOs ≤ the threshold value and the value set in SPDRCR.SPDRC[7:0] has elapsed.

When the receive data ready is detected, the interrupt can be selected as SPRI or SPEI with the SPCR.SPDRES bit.

Figure 36.54 shows an example of reception data ready detection operation.

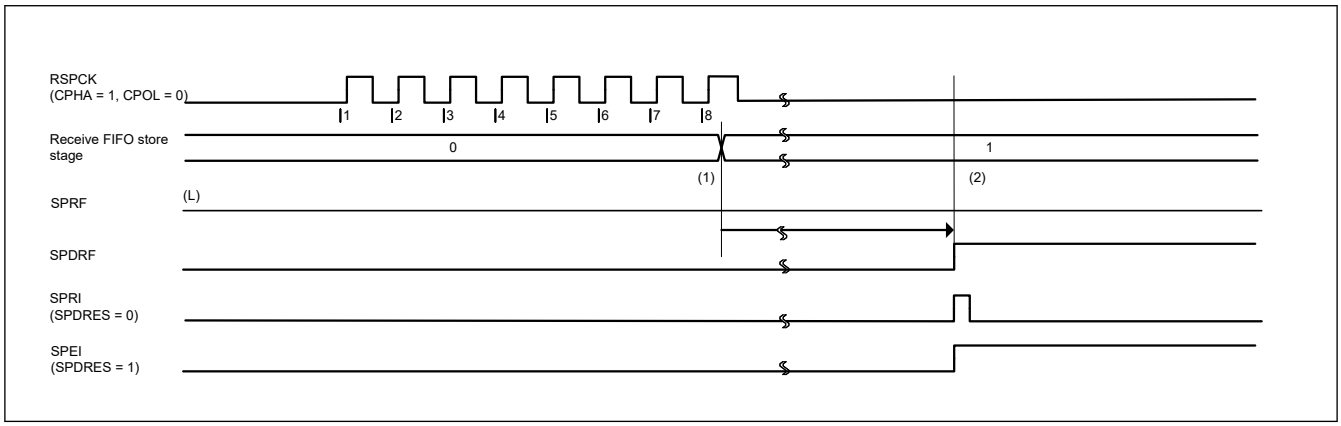

Figure 36.54 Received data ready

The following describes operation at the timings indicated by (1) and (2) in the figure.

(1) Store the received data in the receive FIFO. SPRF is 0, because receive FIFO store stage ≤ RTRG.

(2) Set SPDRF and assert SPRI or SPEI because there is no writing to the receive FIFO for the amount of SPDRC[7:0] set from (1).

36.4.12 SPI Initialization

When 0 is written to the SPCR.SPE bit or when the SPI clears the SPE bit to 0 after it detects a mode fault error or an underrun error, the SPI disables the SPI function and initializes a part of module functions. Furthermore, the SPI initializes

all module functions when a system reset occurs. The following describes initialization by clearing the SPCR.SPE bit and by using a system reset.

36.4.12.1 Initialization by Clearing the SPE Bit

When the SPCR.SPE bit is cleared to 0, the SPI performs the following initialization:

- Suspends the ongoing serial transfer.
- Stops driving output signals (Hi-Z) in slave mode.
- Resets the internal SPI state.
- SPSR.SPTEF flag = 1.

In initialization by clearing the SPE bit, control bits in SPI are not initialized. For this reason, re-setting the SPE bit to 1 activates the SPI with the pre-initialization transfer mode.

Values of the CENDF flag, the SPRF flag, OVRF flag, MODF flag, PERF flag, and UDRF flag in SPSR are not initialized. The SPSSR register value is not initialized either. For this reason, it is possible to read receive buffer data and check the communication completion status and the error status during SPI transfer also after the SPI is initialized.

SPSR.SPTEF flag is initialized to 1. Therefore, if the SPCR.SPTIE bit is set to 1 after the SPI is initialized, an SPI transmit buffer empty interrupt is generated. When the CPU initializes the SPI, write 0 to the SPE bit and the SPTIE bit to disable an SPI transmit buffer empty interrupt.

36.4.12.2 System Reset

In initialization by using a system reset, all SPI control bits, status bits, and data register are initialized in addition to the initialization described in section 36.4.12.1. Initialization by Clearing the SPE Bit to completely initialize the SPI.

36.4.13 SPI Operation

36.4.13.1 Master Mode Operation

Single master mode operation and multi-master mode operation are different from each other only in mode fault error detection (see section 36.4.10. Error Detection). The SPI in single master mode (SPI) detects no mode fault error.

The SPI in multi-master mode detects a mode fault error. The following describes operations common to single master mode and multi-master mode.

(1) Starting a Serial Transfer

When data is written to the SPDR register while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTXn, n = 0 to 3) data in SPDR.

While the shift register is empty, the SPI copies transmit buffer data to the shift register to start serial transfer. After the SPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the SPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the SPI transfer format, see section 36.4.5. Transfer Format (Frame Format). The SSL output signal polarity depends on the set SSLP register value.

(2) Terminating a Serial Transfer

[Except Receive-only in Master Mode]

After the SPI detects the RSPCK edge corresponding to the final sampling timing regardless of the SPCMD.CPHA bit value, the SPI terminates serial transfer. When the number of data stored in the receive FIFO < the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPDR register after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPCMD.SPB[4:0] bits. The SSL output signal polarity depends on the set SSLP register value. For details about the SPI transfer format, see section 36.4.5. Transfer Format (Frame Format).

[Receive-only in Master Mode]

When any of the following 2 conditions is met, then SPI terminating the serial transfer.

- After the SPI detects the RSPCK edge corresponding to the final sampling timing regardless of the SPCMD.CPHA bit value, the SPI terminates serial transfer.
- When writing SPCRRM.RMEDTG = 1 during the serial transfer period, the SPI terminates the serial transfer.

When the number of data stored in the receive FIFO < the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPDR register after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPCMD.SPB[4:0] bits. The SSL output signal polarity depends on the set SSLP register value. For details about the SPI transfer format, see section 36.4.5. Transfer Format (Frame Format).

(3) Sequence Control

The transfer format in master mode is determined as follows.

The transfer format in master mode is determined by the SPSCR register, SPCMDm (m = 0 to 7) register, SPBR register, SPCKD register, SSLND register, and SPND register.

The SPSCR register is used to determine the sequence configuration for serial transfer to be performed by the SPI in master mode. The SSL output signal value, MSB first/LSB first, data length, a part of bit rate settings, RSPCK polarity and phase, SPCKD enable/disable, SSLND enable/disable, and SPND enable/disable are set in SPCMD0 to SPCMD7.

A part of bit rate settings is set in SPBR, the SPI clock delay value is set in SPCKD, the SSL negation delay value is set in SSLND, and the access delay value is set in SPND.

The SPI configures the sequence that structures a part of or whole of SPCMD0 to SPCMD7 according to the sequence length specified in SPSCR. The SPI has a pointer to SPCMD that configures the sequence. This pointer value can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPE bit in the SPCR register is set to 1 to enable the SPI function, the SPI sets the pointer to commands in SPCMD0 and applies the SPCMD0 setting to the transfer format at the start of serial transfer. The SPI increments the pointer the next-access delay period ends in each data transfer. When the serial transfer corresponding to the final command that configures the sequence is completed, the SPI sets the pointer in SPCMD0. Thus sequence is repeatedly executed.

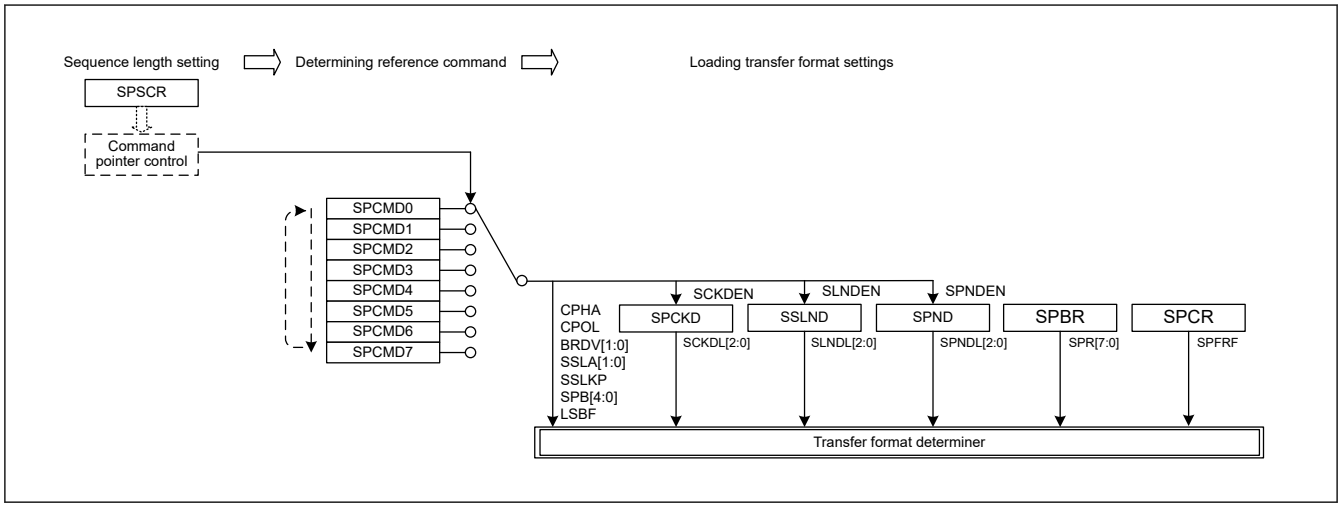

Figure 36.55 Determining serial transfer method in master mode

In this section, a frame consists of data (SPDR) and configuration (SPCMDm).

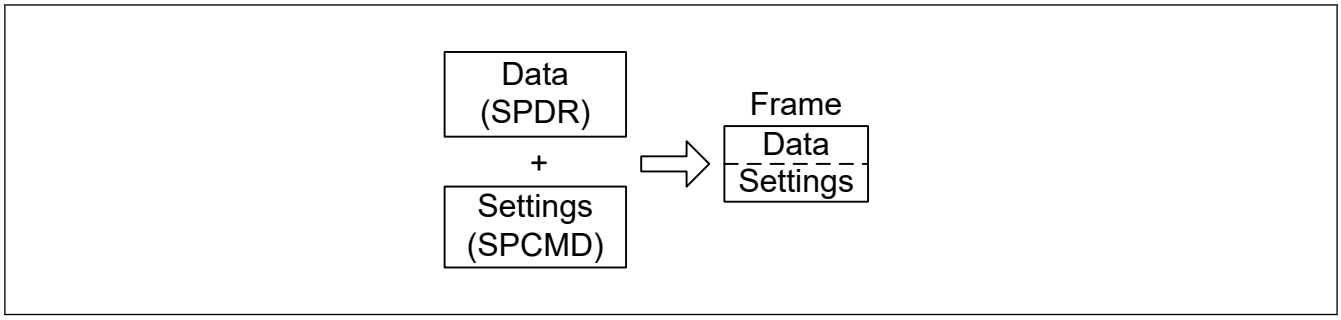

Figure 36.56 Conceptual diagram of frame

Figure 36.57 shows the correspondence between the SPI command register and transmit buffer (SPTXn, n = 0 to 3)/receive buffer (SPRXn, n = 0 to 3) in the sequence operation.

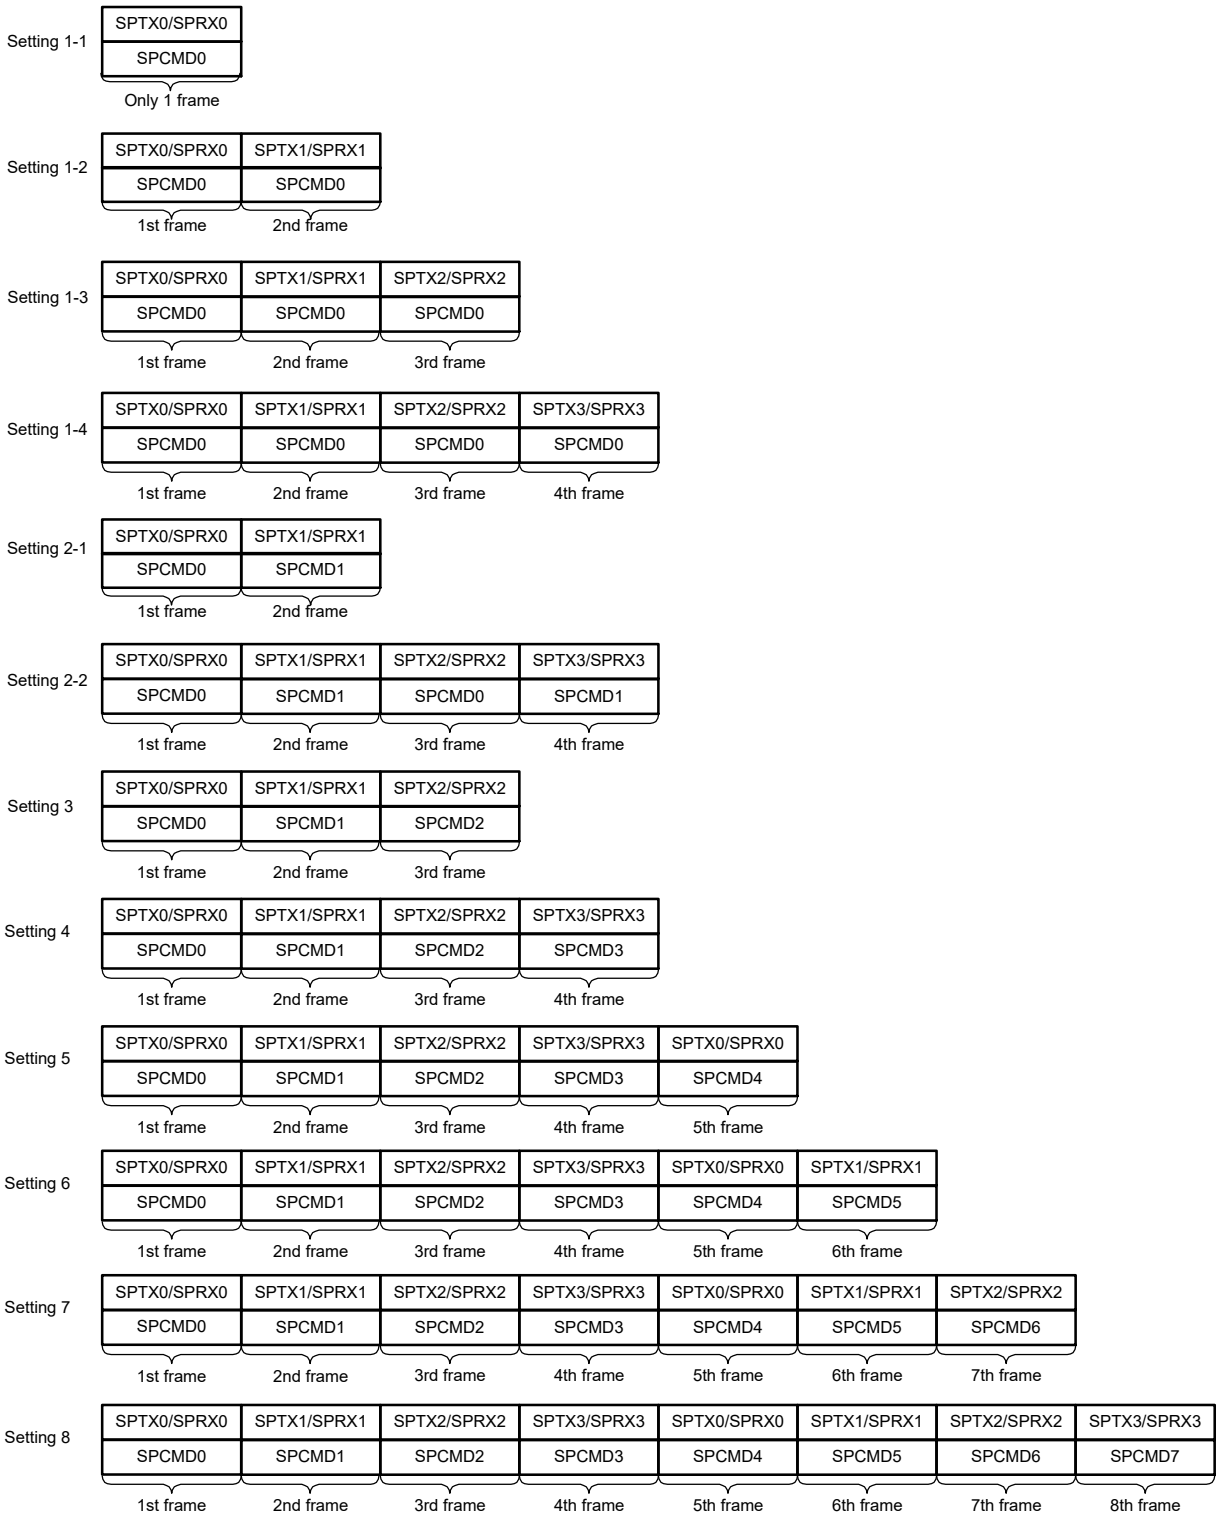

Figure 36.57 Correspondence between SPI command register and transmit/receive buffers in sequence operation

(4) Burst Transfer

This section describes burst transfer during transmit-receive / transmit-only operation.

[In the Motorola-SPI case]

When the SPCMD.SSLKP bit, which the SPI references in the current serial transfer, is 1, the SPI retains the SSL signal level during serial transfer until the SSL signal assertion of the next serial transfer starts. When the SSL signal level in the next serial transfer is the same as the SSL signal level in the current serial transfer, the SPI can continuously perform serial transfer while holding the SSL signal assertion status (burst transfer).

(a) SPCR.BFDS = 0

Figure 36.58 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (8) shown in Figure 36.58. The SSL output signal polarity depends on the set the SSLP register.

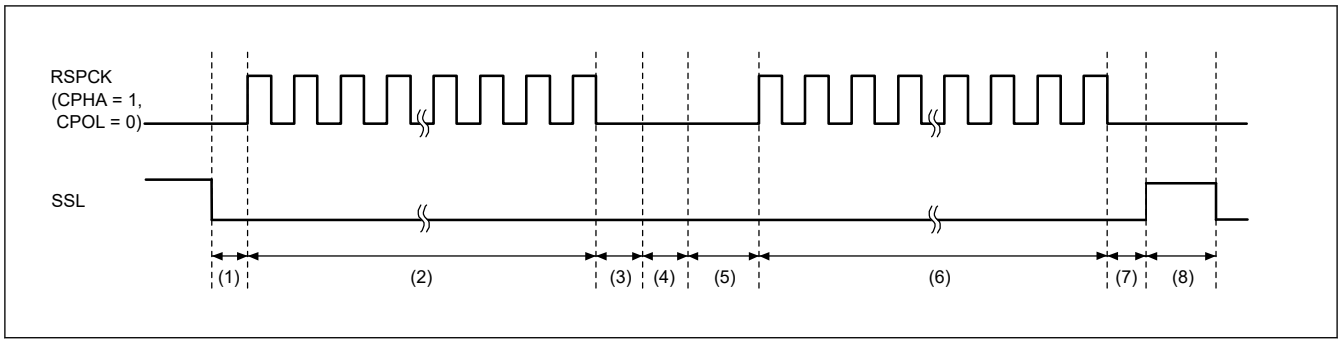

Figure 36.58 Example of burst transfer operation using SSLKP bit (BFDS = 0, SPFRF = 0)

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0.

(2) Perform serial transfer according to SPCMD0.

(3) Insert an SSL negation delay.

(4) The SSL signal value in SPCMD0 is retained because SPCMD0.SSLKP = 1. This period additionally continues for 5 PCLKSPIn cycles (at minimum) that is the same as the next-access delay time of SPCMD0. When the shift register is empty after the minimum period has passed, this period continues until transmit data for the next transfer is stored in the shift register.

(5) Assert the SSL signal and insert an RSPCK delay according to SPCMD1.

(6) Perform serial transfer according to SPCMD1.

(7) Insert SSL negate delay.

(8) The SSL signal is negated because SPCMD1.SSLKP = 0. Furthermore, the next-access delay is inserted according to SPCMD1.

If the SSL signal output setting in SPCMD with the SSLKP bit set to 1 differs from the SSL signal output setting in SPCMD to be used for the next transfer, the SPI changes the SSL signal state when the SSL signal corresponding to the next-transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

The SPI in master mode references the SSL signal operation in the module when SSLKP is not used. Even when SPCMD.CPHA = 0, the SPI can accurately start serial transfer by using the next-transfer SSL signal assertion detected internally. For this reason, burst transfer in master mode is enabled regardless of the set CPHA bit value. (See section 36.4.13. SPI Operation.)

(b) SPCR.BFDS = 1

Figure 36.59 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 36.59. The SSL output signal polarity depends on the set SSSLP register value.

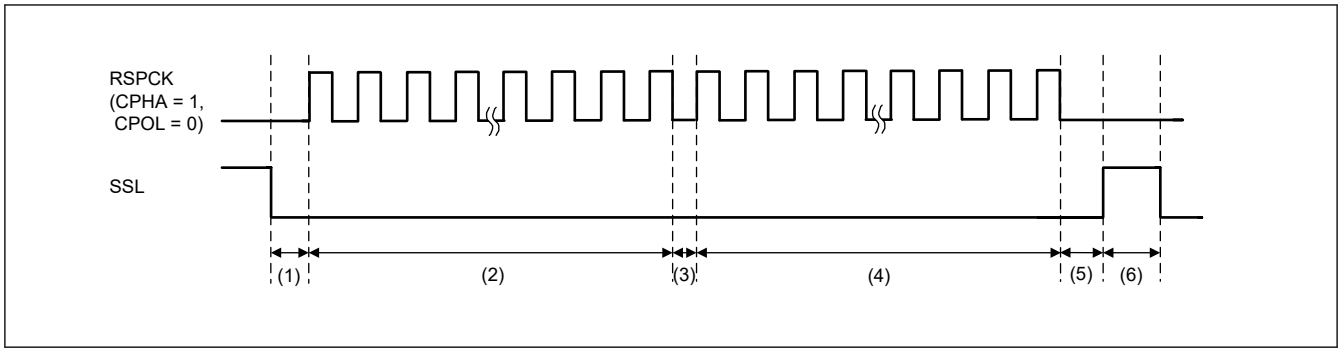

Figure 36.59 Example of burst transfer operation using SSLKP bit (BFDS = 1, SPFRF = 0)

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmisshon.

(2) Perform serial transfer according to SPCMD0. Wait last clock until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.

(3) The value of SSL signal according to SPCMD0 was hold, because SPCMD0.SSLKP = 1. RSPCK negate period between frames is 0.5RSPCK, if the shift register is not empty.

(4) Perform serial transfer according to SPCMD1.

(5) Insert SSL negate delay for the last frame.

(6) The SSL signal is negated because SPCMD1.SSLKP = 0. Furthermore, the next-access delay is inserted according to SPCMD1.

[In the TI-SSP case]

SPI asserts the SSL signal for one cycle at the start of serial transfer.

Serial transfer can be executed continuously by asserting the SSL signal for one cycle at the start of the next serial transfer (burst transfer).

(a) SPCMD.SSLKP = 1 and SPCR.BFDS = 1

SPCMD0 to SPCMD1 are shown in Figure 36.60. The following shows an example of SSL signal operation and serial data MISO/MOSI when burst transfer is realized using the settings. The SSL output signal polarity depends on the set SPI slave select polarity register (SSLP) value.

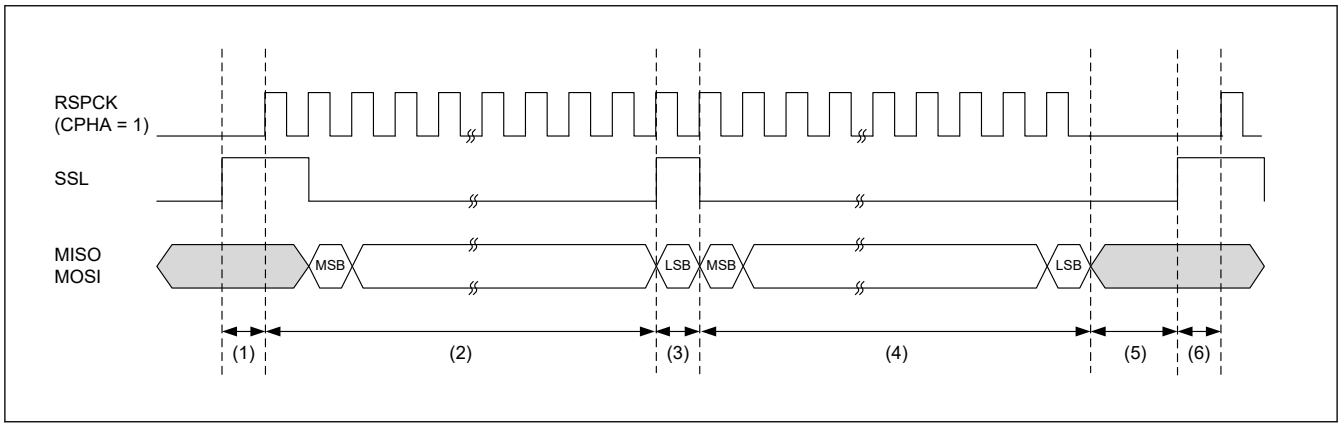

Figure 36.60 Example of burst transfer operation (SPFRF = 1)

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.

(2) Perform serial transfer according to SPCMD0.

(3) Final data transfer and SSL assertion are performed simultaneously. If the shift register is empty during the RSPCK negation period between frames, wait for the output of the last clock until the transmission data for the next transfer is stored in the shift register.

(4) Perform serial transfer according to SPCMD1.

(5) Insert SSL negate delay for the last frame.

(6) The SSL signal is negated because the SPCMD1.SSLKP = 0.

If the SSL signal output setting in SPCMD with the SSLKP bit set to 1 differs from the SSL signal output setting in SPCMD to be used for the next transfer, the SPI changes the SSL signal state when the SSL signal corresponding to the next-transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

This section describes burst transfer during receive-only operation.

[In the Motorola-SPI case]

When the SPCMD.SSLKP bit, which the SPI references in the current serial transfer, is 1, the SPI retains the SSL signal level during serial transfer until the SSL signal assertion of the next serial transfer starts. When the SSL signal level in the next serial transfer is the same as the SSL signal level in the current serial transfer, the SPI can continuously perform serial transfer while holding the SSL signal assertion status (burst transfer).

(a) SPCR.BFDS = 0

Figure 36.61 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (8) shown in Figure 36.61. The SSL output signal polarity depends on the set SSLP register value.

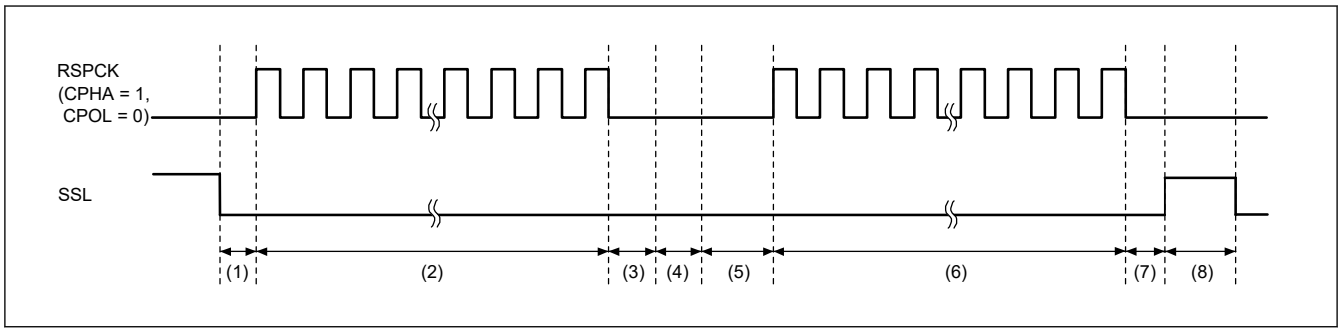

Figure 36.61 Example of burst transfer operation using SSLKP bit (BFDS = 0, SPFRF = 0)

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0.

(2) Perform serial transfer according to SPCMD0.

(3) Insert an SSL negation delay.

(4) The SSL signal value in SPCMD0 is retained because SPCMD0.SSLKP = 1. This period additionally continues for 5 PCLKSPIn cycles (at minimum) that is the same as the next-access delay time of SPCMD0.

(5) Assert the SSL signal and insert an RSPCK delay according to SPCMD1.

(6) Perform serial transfer according to SPCMD1.

(7) Insert SSL negate delay.

(8) The SSL signal is negated because SPCMD1.SSLKP = 0. Furthermore, the next-access delay is inserted according to SPCMD1

If the SSL signal output setting and the SSL signal output setting between SPCMDs used for burst transfer are different, SPI switches the SSL signal state when the SSL signal corresponding to the next transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

The SPI in master mode references the SSL signal operation in the module when SSLKP is not used. Even when SPCMD.CPHA = 0, the SPI can accurately start serial transfer by using the next-transfer SSL signal assertion detected internally. For this reason, burst transfer in master mode is enabled regardless of the set CPHA bit value. (See section 36.4.13. SPI Operation.)

(b) SPCR.BFDS = 1

Figure 36.62 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 36.62. The SSL output signal polarity depends on the set SSLP register value.

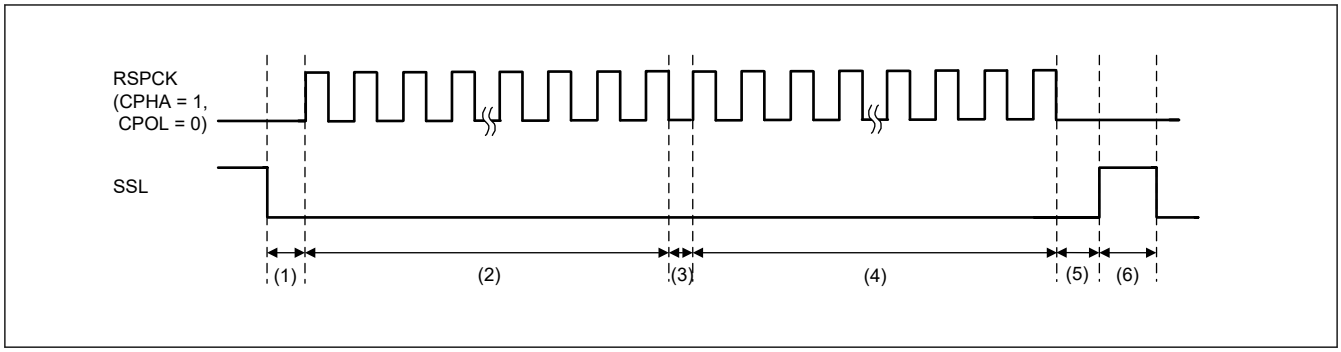

Figure 36.62 Example of burst transfer operation using SSLKP bit (BFDS = 1, SPFRF = 0)

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst.

(2) Perform serial transfer according to SPCMD0.

(3) Since it is not the last frame, the SSL signal value at SPCMD0 is retained. RSPCK negation between frames is 0.5 RSPCK for the next frame.

(4) Perform serial transfer according to SPCMD1.

(5) Insert SSL negate delay for the last time.

(6) The SSL signal is negated because SPCMD1.SSLKP = 0. Furthermore, the next-access delay is inserted according to SPCMD1.

Note: "Last frame": Frame set by RMFM[4:0] bits when SPCRRM.RMFM[4:0] ≠ 0x00
Or, a frame in which SPCRRM.RMEDTG = 1 has been accepted.

[In the TI-SSP case]

SPI asserts the SSL signal for one cycle at the start of serial transfer.

Serial transfer can be executed continuously by asserting the SSL signal for one cycle at the start of the next serial transfer (burst transfer).

(a) SPCMD.SSLKP = 1 and SPCR.BFDS = 1

SPCMD0 to SPCMD1 are shown in Figure 36.63. The following shows an example of SSL signal operation and serial data MISO/MOSI when burst transfer is realized using the settings. The SSL output signal polarity depends on the set SSLP register value.

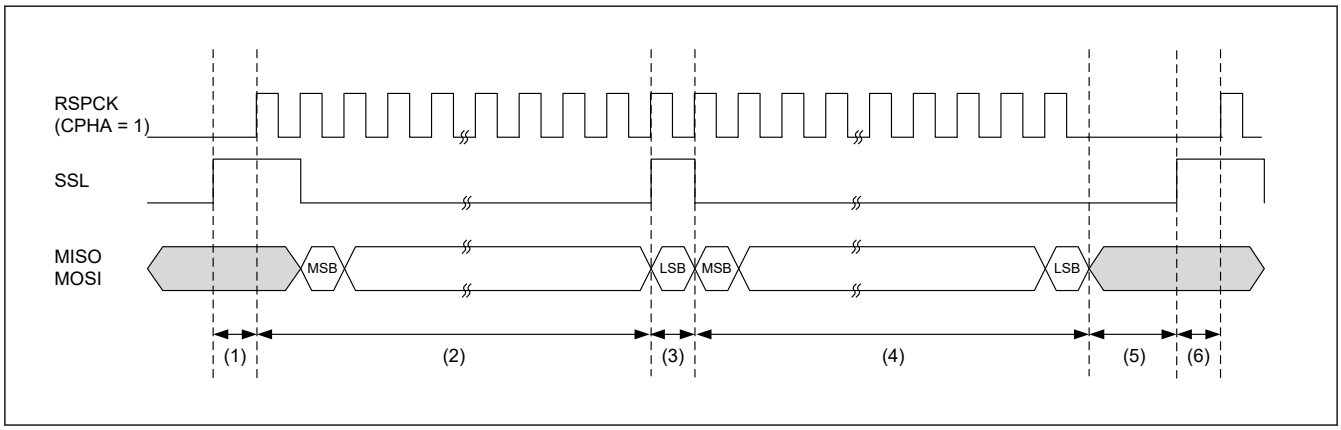

Figure 36.63 Example of burst transfer operation (SPFRF = 0)

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst.

(2) Perform serial transfer according to SPCMD0.

(3) Final data transfer and SSL assertion are performed simultaneously.

(4) Perform serial transfer according to SPCMD1.

(5) Insert Output disable delay for the last frame.

(6) The SSL signal is negated because SPCMD1.SSLKP = 0.

Note: "Last frame": Frame set by RMFM[4:0] bits when SPCRRM.RMFM[4:0] ≠ 0x00
Or, a frame in which SPCRRM.RMEDTG = 1 has been accepted.

If the SSL signal output setting between the SPCMDs used for burst transfer differs from the SSL signal output setting, SPI switches the SSL signal state when the SSL signal corresponding to the next transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

(5) RSPCK Delay (t1)

The RSPCK delay value of the SPI in master mode depends on the settings of the SPCMD.SCKDEN and SPCKD.SCKDL[2:0] bits. The SPI determines SPCMD to be referenced in serial transfer by the pointer control, and then determines the RSPCK delay value for serial transfer by using the selected SPCMD.SCKDEN bit and SPCKD.SCKDL[2:0] bits as shown in Table 36.13. For the definition of RSPCK delay, see section 36.4.5. Transfer Format (Frame Format).

RSPCK delay insert to only the first frame of burst transmission, when transmit without "Between Burst Transfer Frames Delay" (SPCMD.SSLKP = 1, SPCR.BFDS = 1).

Table 36.13 Relationship between SCKDEN/SPCKD and RSPCK delay value

SPCMDm.SCKDEN bit	SPCKD.SCKDL[2:0] bits	RSPCK delay value	
		Motorola-SPI	TI-SSP
0	000b to 111b	1 RSPCK	0 RSPCK
1	000b	1 RSPCK	1 RSPCK
	001b	2 RSPCK	2 RSPCK
	010b	3 RSPCK	3 RSPCK
	011b	4 RSPCK	4 RSPCK
	100b	5 RSPCK	5 RSPCK
	101b	6 RSPCK	6 RSPCK
	110b	7 RSPCK	7 RSPCK
	111b	8 RSPCK	8 RSPCK

(6) SSL Negation Delay (t2)

The SSL negation delay value of the SPI in master mode depends on the settings of the SPCMD.SLNDEN bit and SSLND.SLNDL[2:0]. The SPI determines SPCMD to be referenced in serial transfer by the pointer control, and then determines the SSL negation delay value for serial transfer by using the selected SPCMD.SLNDEN and SSLND.SLNDL[2:0] as shown in Table 36.14. For the definition of SSL negation delay, see section 36.4.5. Transfer Format (Frame Format).

SSL negate delay insert to only the last frame of burst transmission, when transmit without "Between Burst Transfer Frames Delay" (SPCMD.SSLKP = 1, SPCR.BFDS = 1).

Table 36.14 Relationship between SSLND and SSL negation delay value (1 of 2)

SLNDEN	SSLND.SLNDL[2:0] bits	SSL negation delay value
0	000b to 111b	1 RSPCK cycle

Table 36.14 Relationship between SSLND and SSL negation delay value (2 of 2)

SLNDEN	SSLND.SLNDL[2:0] bits	SSL negation delay value
1	000b	1 RSPCK cycle
	001b	2 RSPCK cycle
	010b	3 RSPCK cycle
	011b	4 RSPCK cycle
	100b	5 RSPCK cycle
	101b	6 RSPCK cycle
	110b	7 RSPCK cycle
	111b	8 RSPCK cycle

(7) Next-Access Delay (t3)

The next-access delay value of the SPI in master mode depends on the settings of the SPCMD.SPNDEN bit and SPND.SPNDL[2:0] bits. The SPI determines SPCMD to be referenced in serial transfer by the pointer control, and then determines the RSPCK delay value for serial transfer by using the selected SPCMD.SPNDEN bit and SPND.SPNDL[2:0] bits as shown in Table 36.15. For the definition of next-access delay, see section 36.4.5. Transfer Format (Frame Format).

Next-Access delay insert to only the last frame of burst transmission, when transmit without "Between Burst Transfer Frames Delay" (SPCMD.SSLKP = 1, SPCR.BFDS = 1).

Table 36.15 Relationship between SPNDEN bit, SPND bits, and next-access delay value

SPNDEN bit	SPND.SPNDL[2:0] bits	Next-access delay value
0	000b to 111b	1 RSPCK + 5 PCLKSPIn cycle
1	000b	1 RSPCK + 5 PCLKSPIn cycle
	001b	2 RSPCK + 5 PCLKSPIn cycle
	010b	3 RSPCK + 5 PCLKSPIn cycle
	011b	4 RSPCK + 5 PCLKSPIn cycle
	100b	5 RSPCK + 5 PCLKSPIn cycle
	101b	6 RSPCK + 5 PCLKSPIn cycle
	110b	7 RSPCK + 5 PCLKSPIn cycle
	111b	8 RSPCK + 5 PCLKSPIn cycle

(8) Initialization Flowchart

Figure 36.64 shows an example of initialization flow when using the SPI in master-mode SPI operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

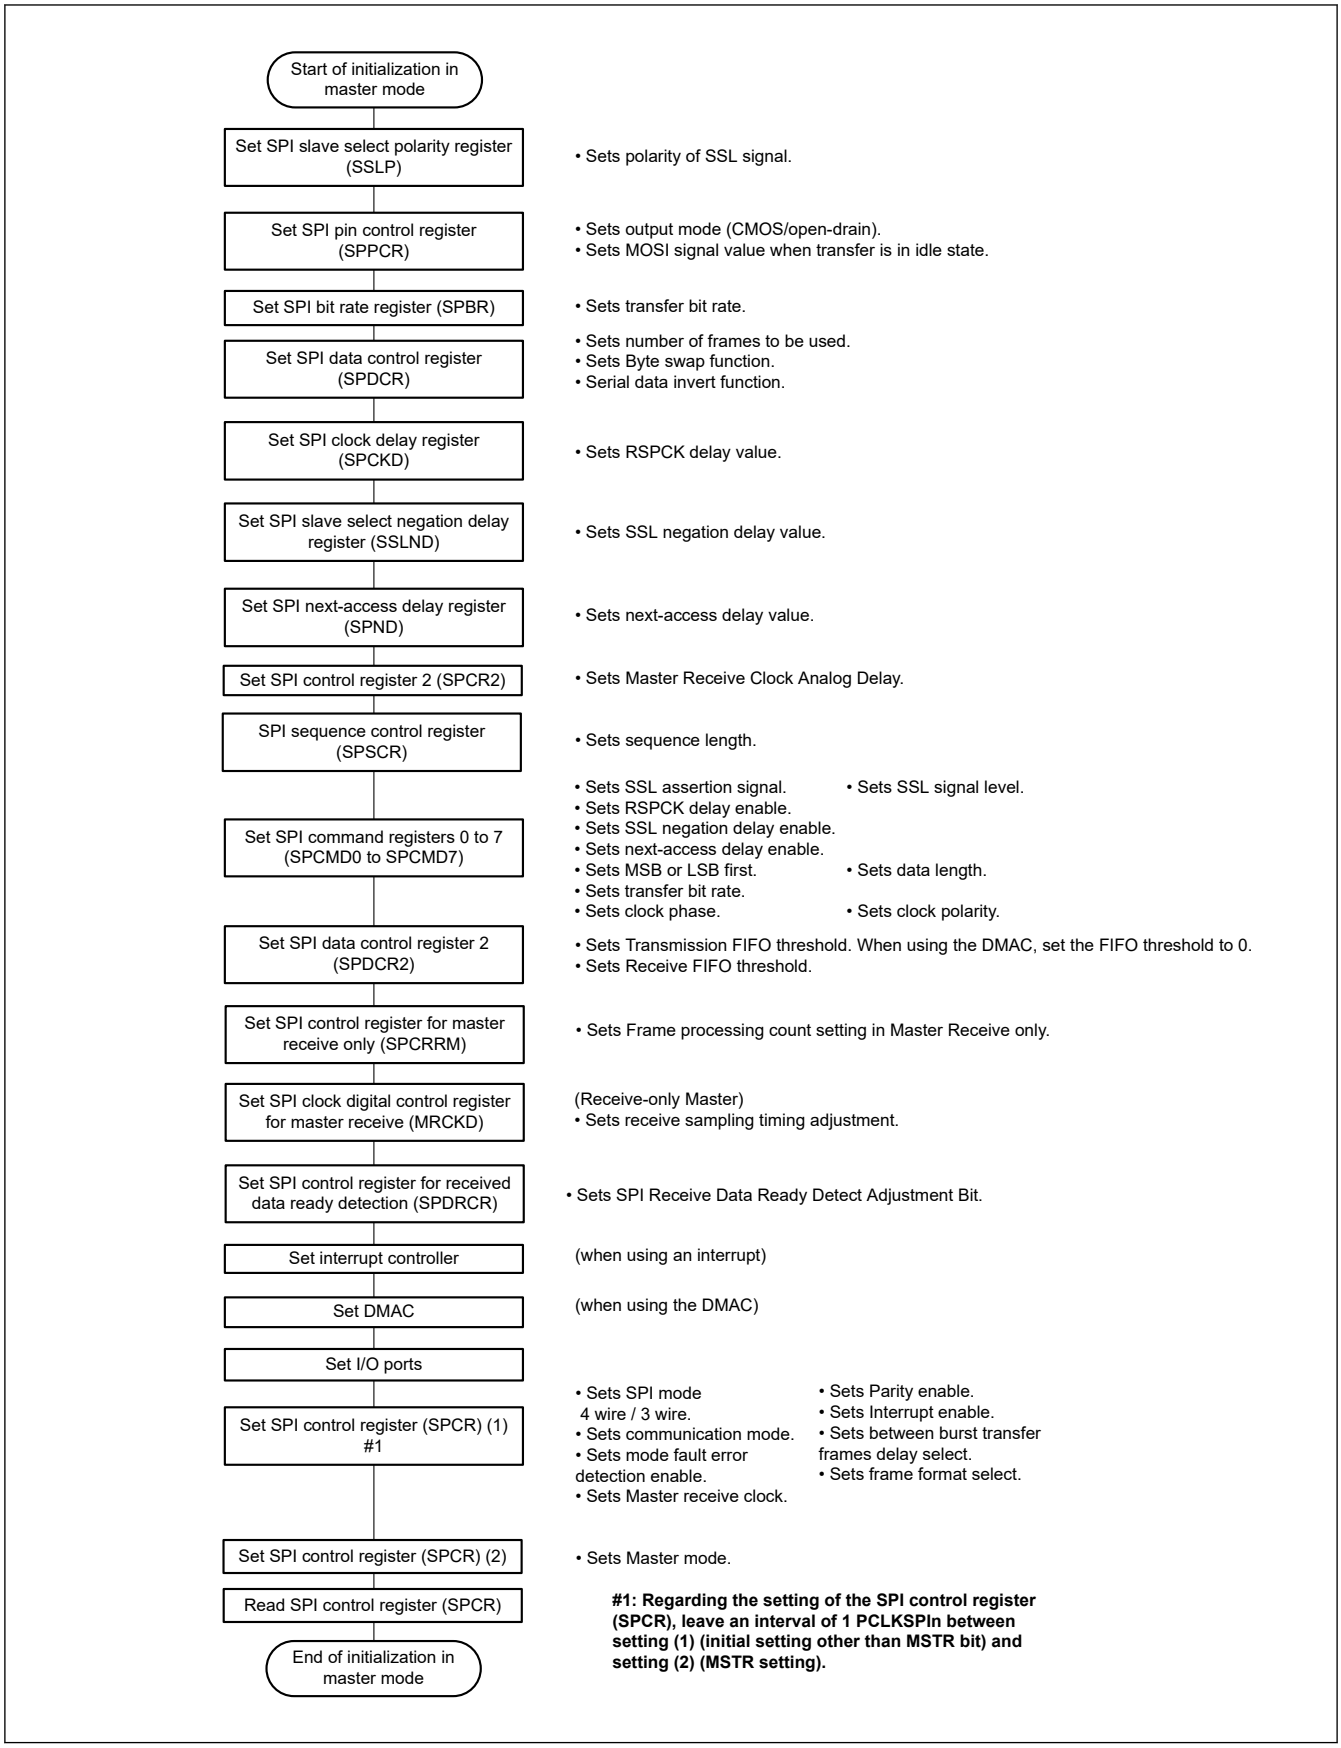

Figure 36.64 Example of initialization flowchart in master mode (SPI operation)

(9) Software Processing Flow

Figure 36.65 to Figure 36.68 show examples of the flow of software processing.

(a) Transmit Processing Flow

Enabling an SPII or SPCEND interrupt after final transmit data is written makes it possible to notify the CPU that transmission of all data has been completed.

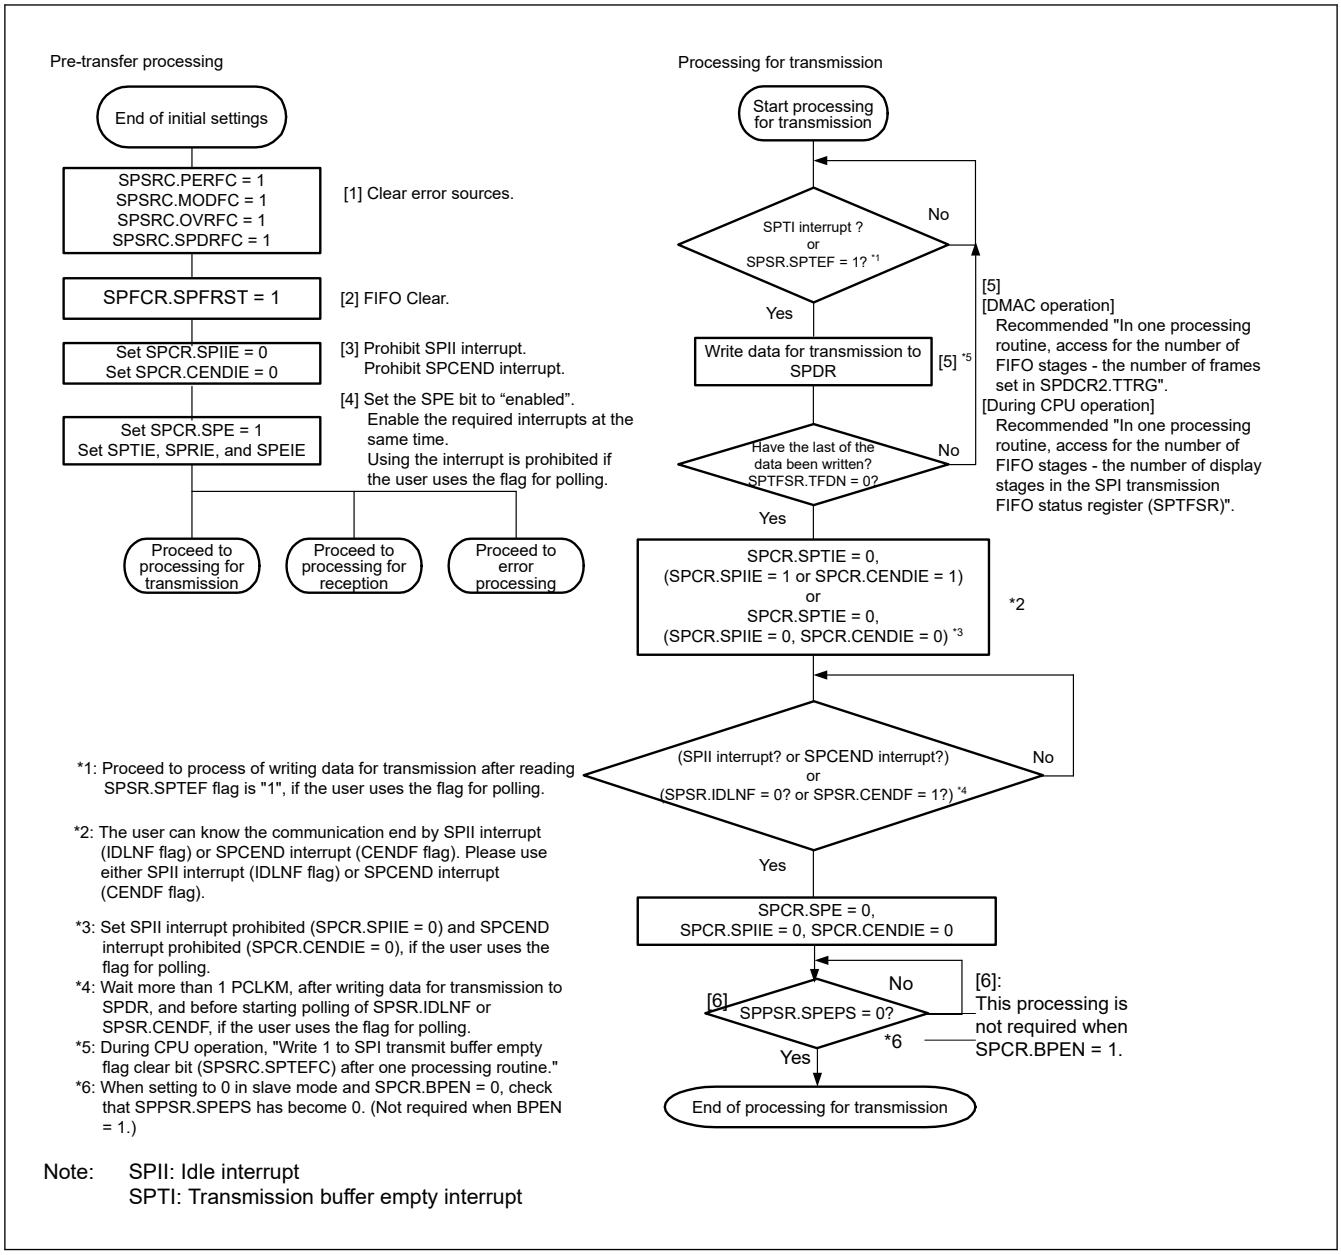

Figure 36.65 Software processing flowchart in master mode (transmission)

(b) Reception Processing Flow

The SPI always requires transmission because it does not have reception-only operation.

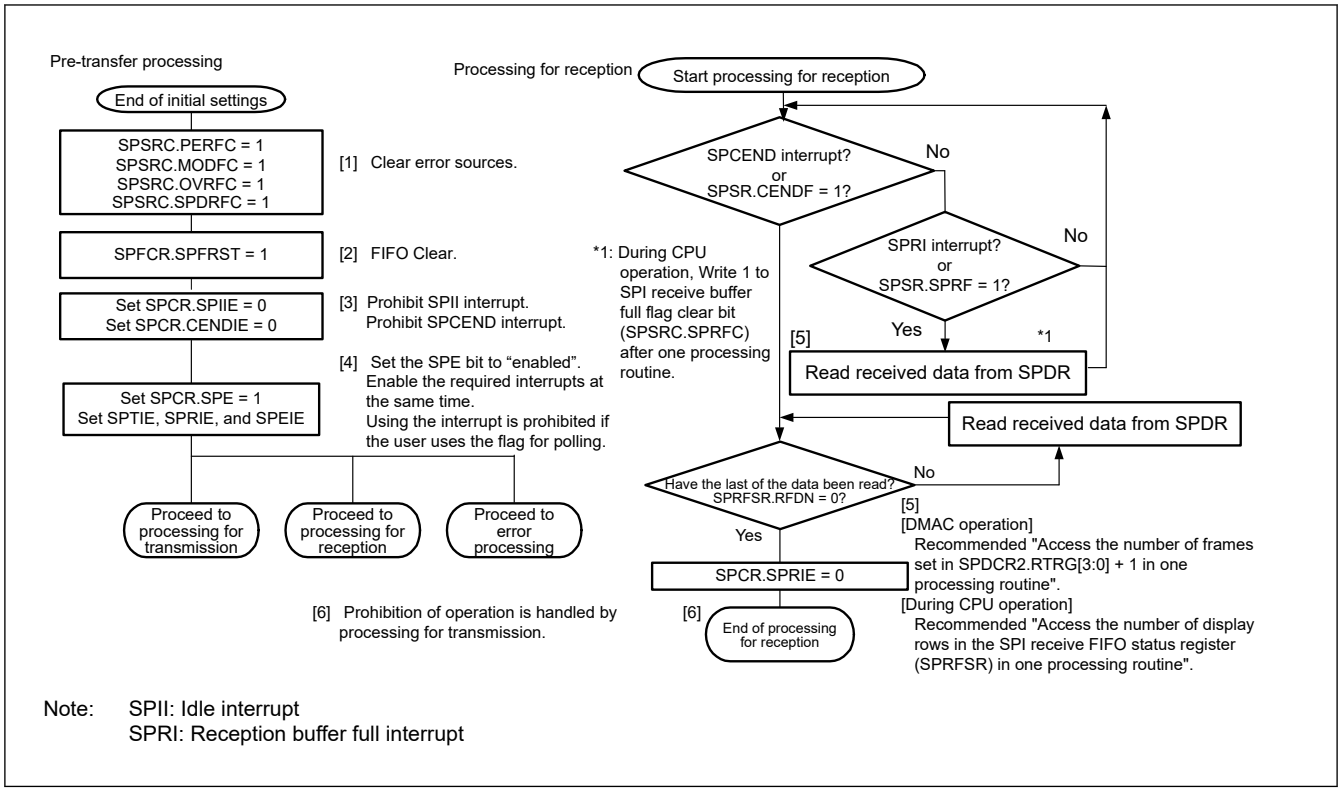

Figure 36.66 Software processing flowchart in master mode (reception)

(c) Master Reception-only processing flow

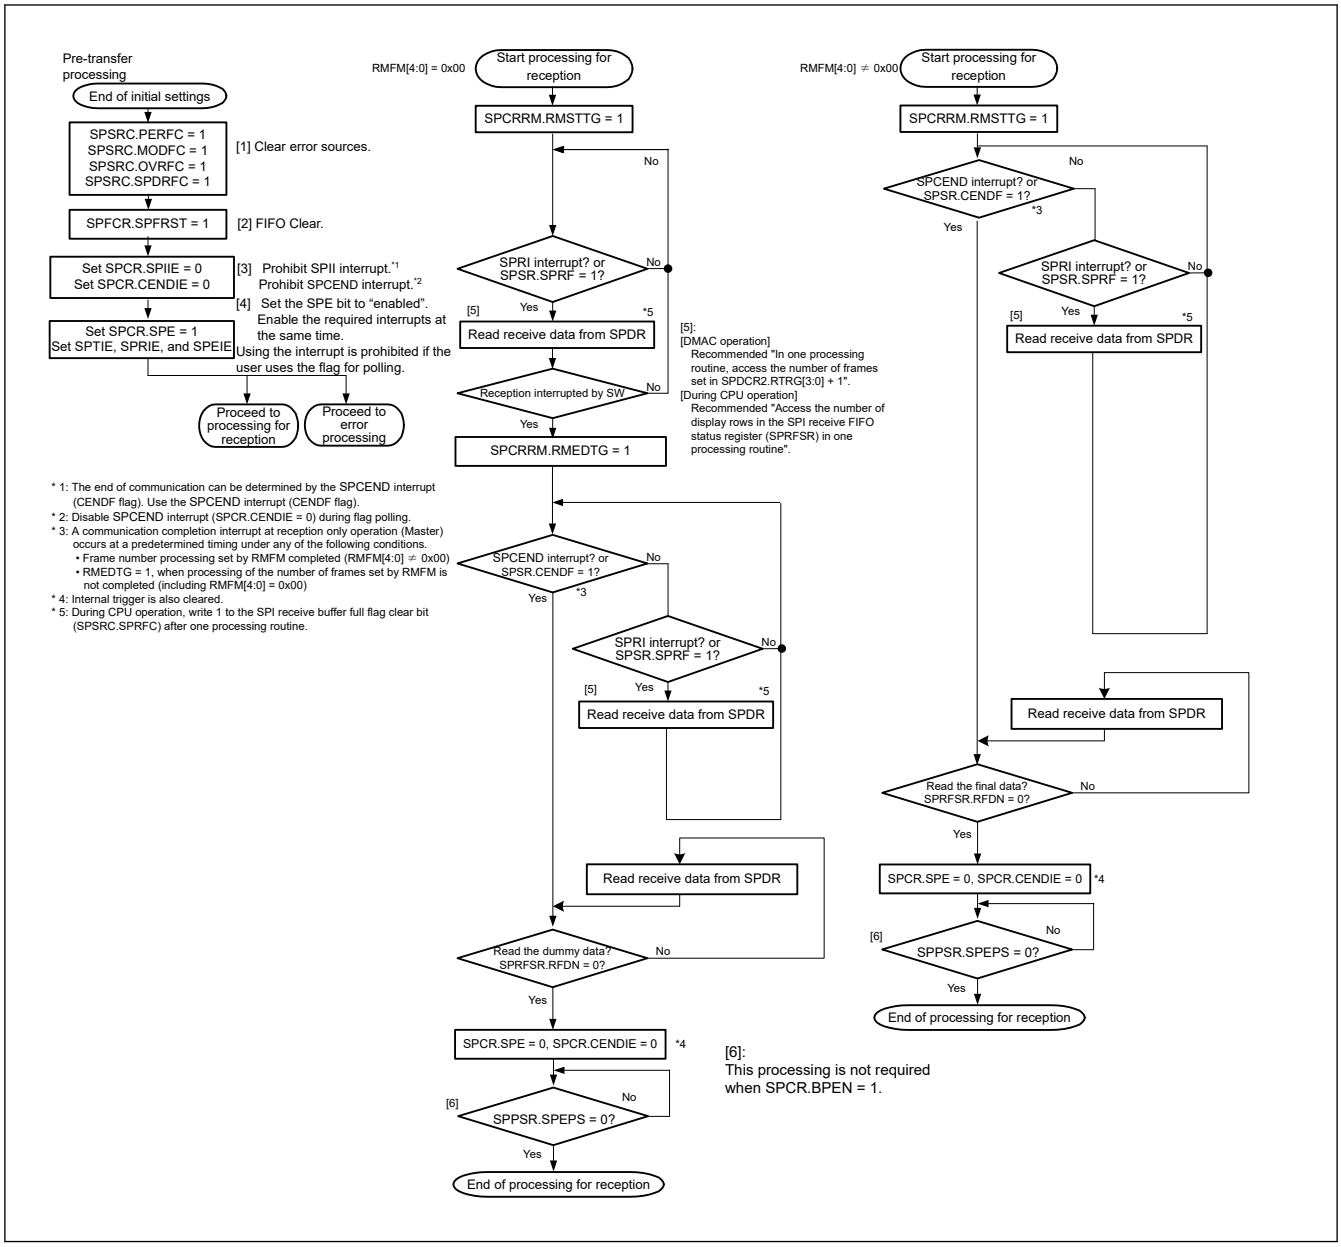

Figure 36.67 Software processing flowchart in master mode (reception-only)

(d) Error processing flow

When a mode fault error occurs, the SPE bit is automatically cleared to stop transmission and reception operations.

However, other error sources do not clear the SPE bit or stop transmission and reception operations. For this reason, if an error occurs due to another source different from the source of the error occurred first, the SPECM[2:0] value is updated. Therefore, we recommend that you clear the SPE bit to stop the ongoing operation.

When interrupts are used and an error has occurred, clear an Interrupt flag in the error processing because an SPTI interrupt request or an SPRI interrupt request may be remaining in an Interrupt flag. Furthermore, when an SPRI interrupt request is remaining, read the receive buffer to initialize the SPI's internal sequencer.

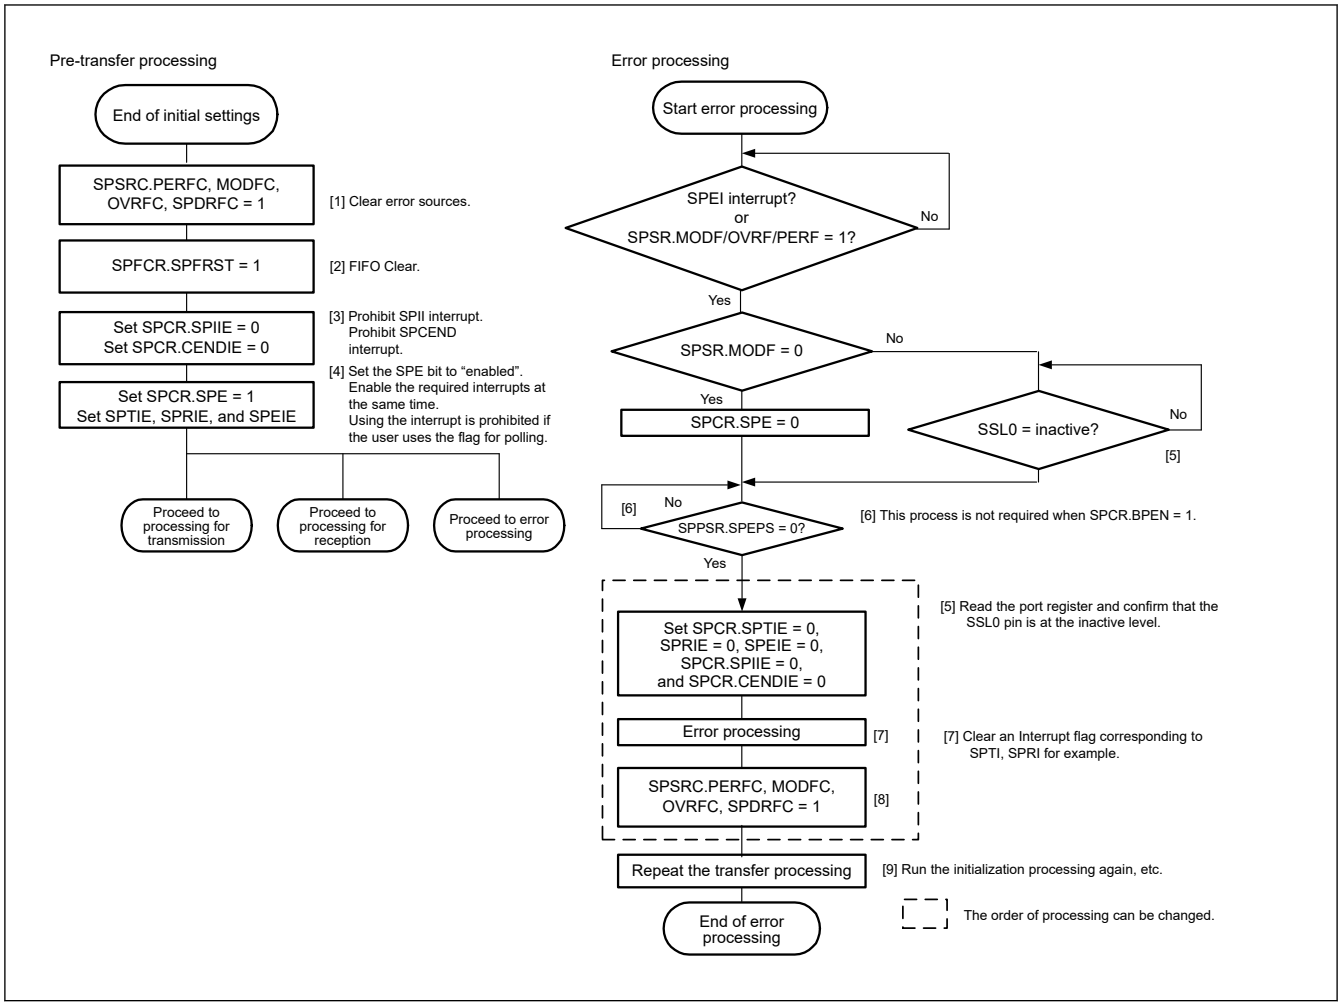

Figure 36.68 Flowchart for master mode (error processing)

36.4.13.2 Slave Mode Operation

(1) Starting a Serial Transfer

When the SPI detects SSL0 input signal assertion while SPCMD0.CPHA = 0, valid data drive to the MISO output signal must be started. For this reason, the SSL0 input signal assertion becomes a trigger to start serial transfer.

While SPCMD0.CPHA = 1, when the SPI detects the first RSPCK edge with the SSL0 input signal asserted, valid data drive to the MISO output signal must be started. For this reason, the first RSPCK edge in the SSL0 signal assertion state becomes a trigger to start serial transfer when SPCMD0.CPHA = 1.

The SPI starts driving the MISO output signal at the SSL0 signal assertion timing independently of the CPHA bit setting. Data that the SPI outputs is enabled or disabled depending on the set CPHA bit value.

For details about the SPI transfer format, see section 36.4.5. Transfer Format (Frame Format). The SSL0 input signal polarity depends on the set SSL0P bit value in the SSLP register.

(2) Terminating a Serial Transfer

Upon detecting the RSPCK edge corresponding to the final sampling timing regardless of the value of SPCMD0.CPHA bit, the SPI terminates serial transfer. When the number of data stored in the receive FIFO is smaller than the number of FIFO stages, the SPI copies received data from the shift register to the receive buffer in the SPDR register after serial transfer. The SPI also changes the shift register status to empty after serial transfer regardless of the receive buffer status. When the SPI detects SSL0 input signal negation during a period from serial transfer start to the end of serial transfer, a mode fault error occurs. (See section 36.4.10. Error Detection.)

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in slave mode depends on the set value of the SPCMD0.SPB[4:0] bits. The SSL0 input signal polarity depends on the set value of SSLP.SSL0P bit. For details about the SPI transfer format, see section 36.4.5. Transfer Format (Frame Format).

(3) Notes on Single-Slave Operations

[In the Motorola-SPI case]

Upon detecting the SSL0 input signal assertion edge while SPCMD0.CPHA = 0, the SPI starts serial transfer. When using the SPI in single slave mode in a configuration as shown in the example in Figure 36.9, the SPI cannot start serial transfer correctly while CPHA is set to 0 because the SSL0 input signal is always active. To correctly perform transmission and reception of the SPI in slave mode in a configuration where the SSL0 input signal is fixed to active state, set the CPHA bit to 1. If the CPHA bit needs to be set to 0, do not fix the SSL0 input signal.

[In the TI-SSP case]

When TI SSP is set, when SPI is used as a single slave in the configuration shown in the example of Figure 36.9, the SSL0 input signal is always fixed to the inactive state, SPI cannot start serial transfer correctly.

When using a single slave, use the configuration shown in the example in Figure 36.8.

(4) Burst Transfer

[In the Motorola-SPI case]

When SPCMD0.CPHA = 1, continuous serial transfer (burst transfer) is possible while maintaining the SSL0 input signal assertion state. When SPCMD0.CPHA = 1, the period (from the first RSPCK edge in the SSL0 input signal active state until the sampling timing for receiving the final bit) corresponds to the serial transfer period. Even if the SSL0 input signal is always at the active level, start of an access can be detected, which allows burst transfer.

When SPCMD0.CPHA = 0, the second and subsequent serial burst transfers cannot be performed correctly for the same reason as (3).

[In the TI-SSP case]

In serial transfer, data transfer starts after the SSL input signal is asserted for RSPCK 1 cycle. Since frame transfer starts from the SSL input signal, SSL must be asserted between frames.

(5) Initialization Flowchart

Figure 36.69 shows an example of initialization flow when using the SPI in slave-mode SPI operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

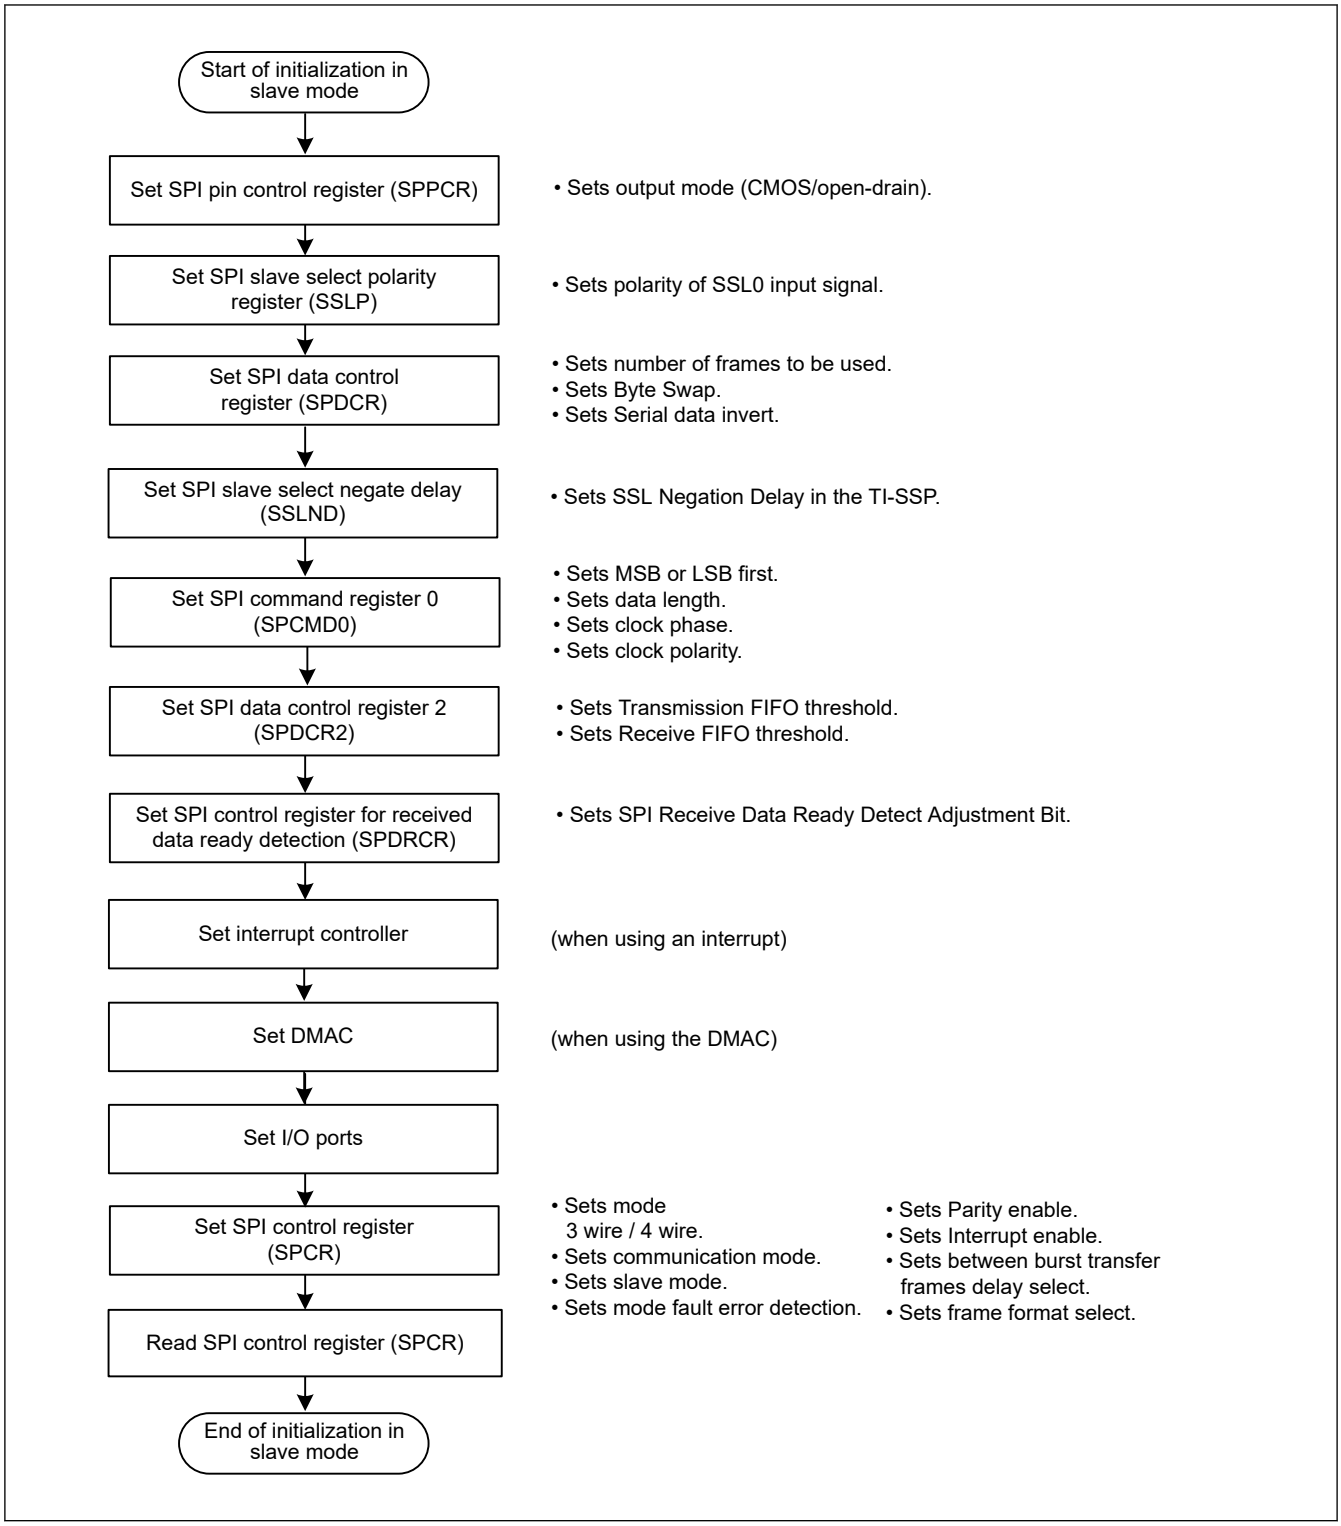

Figure 36.69 Example of initialization flow in slave mode

(6) Software Processing Flow

Figure 36.70 to Figure 36.73 show examples of the flow of software processing.

(a) Transmit Processing Flow

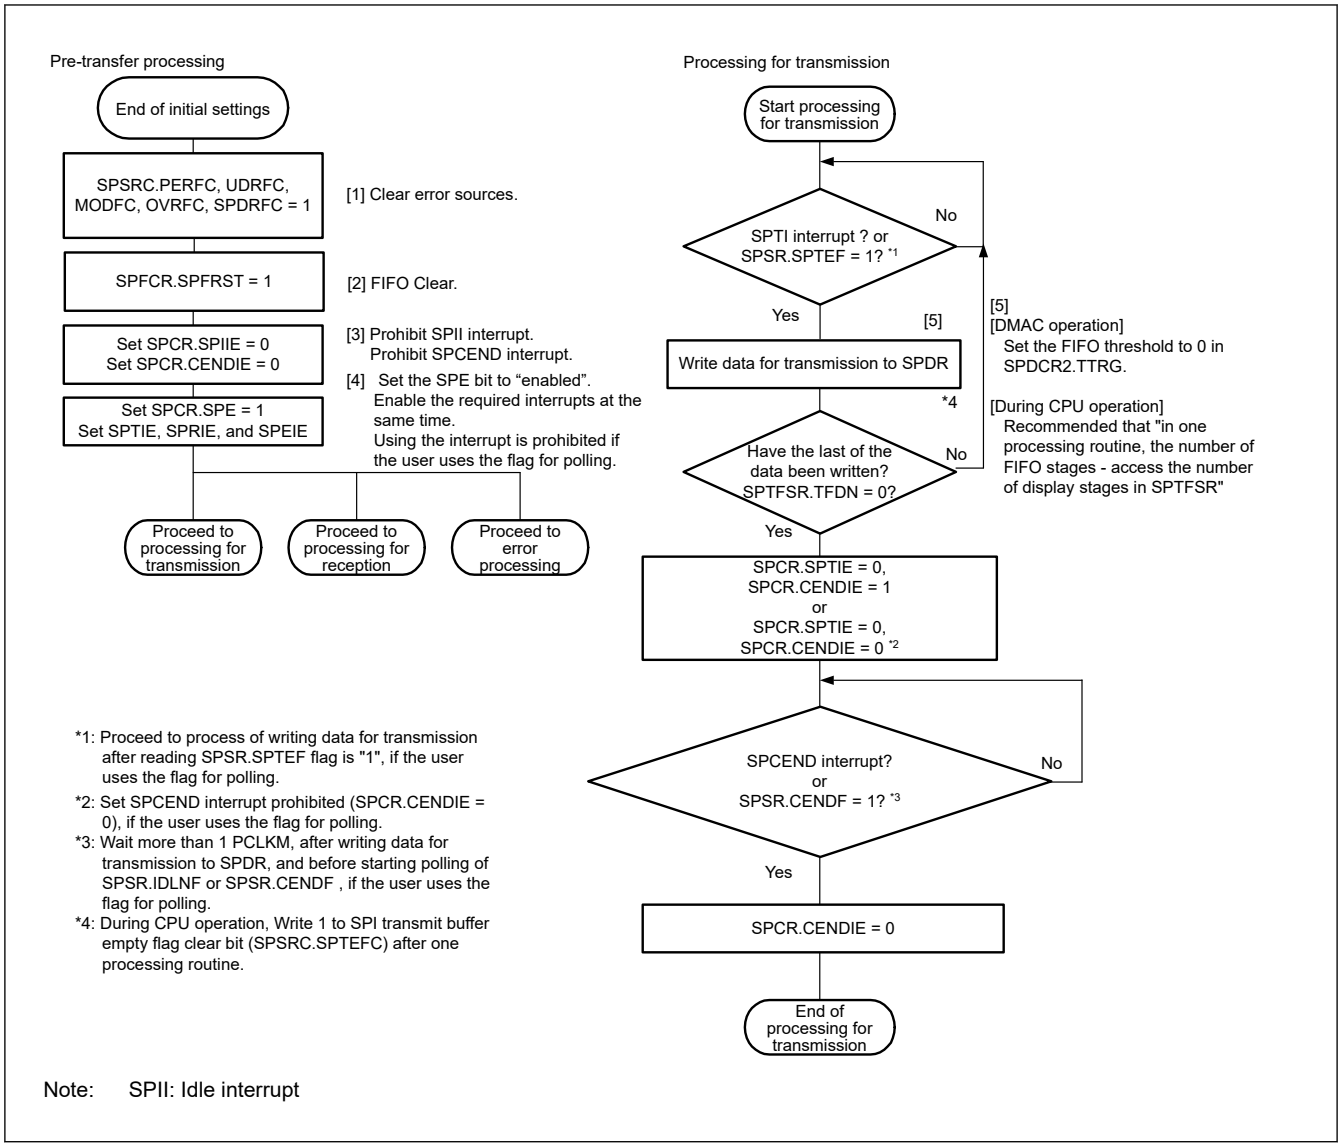

Figure 36.70 Software processing flowchart in slave mode (transmission)

(b) Reception Processing Flow

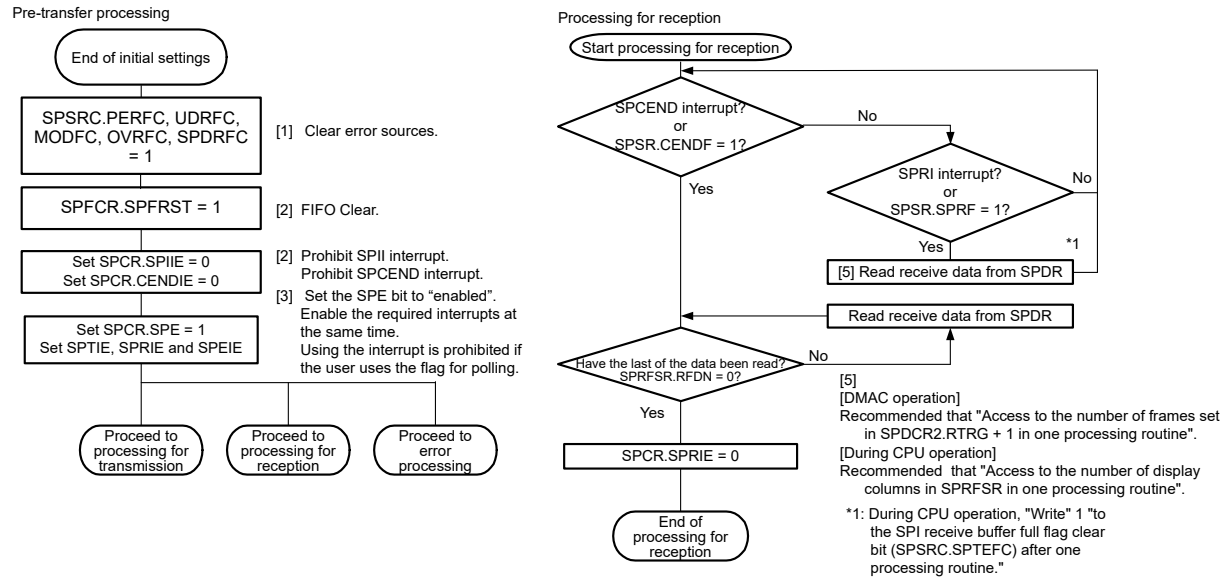

Figure 36.71 Flowchart in slave mode (reception)

(c) Master Reception-only processing Flow

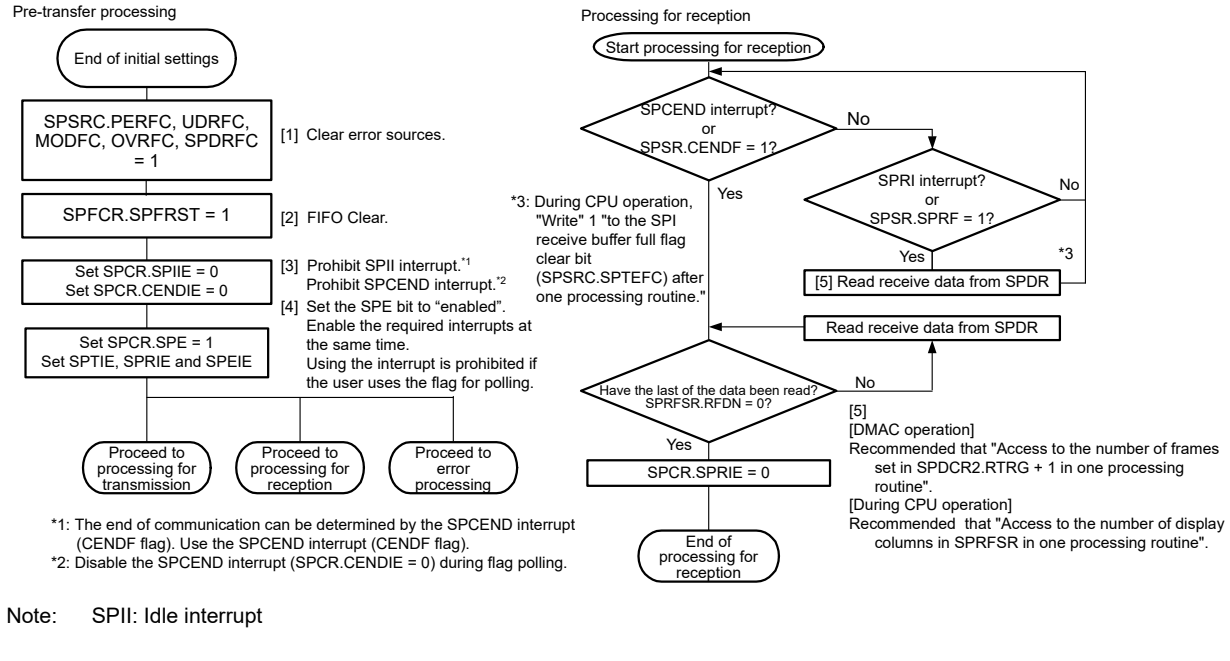

Figure 36.72 Software processing flowchart in slave mode (reception-only)

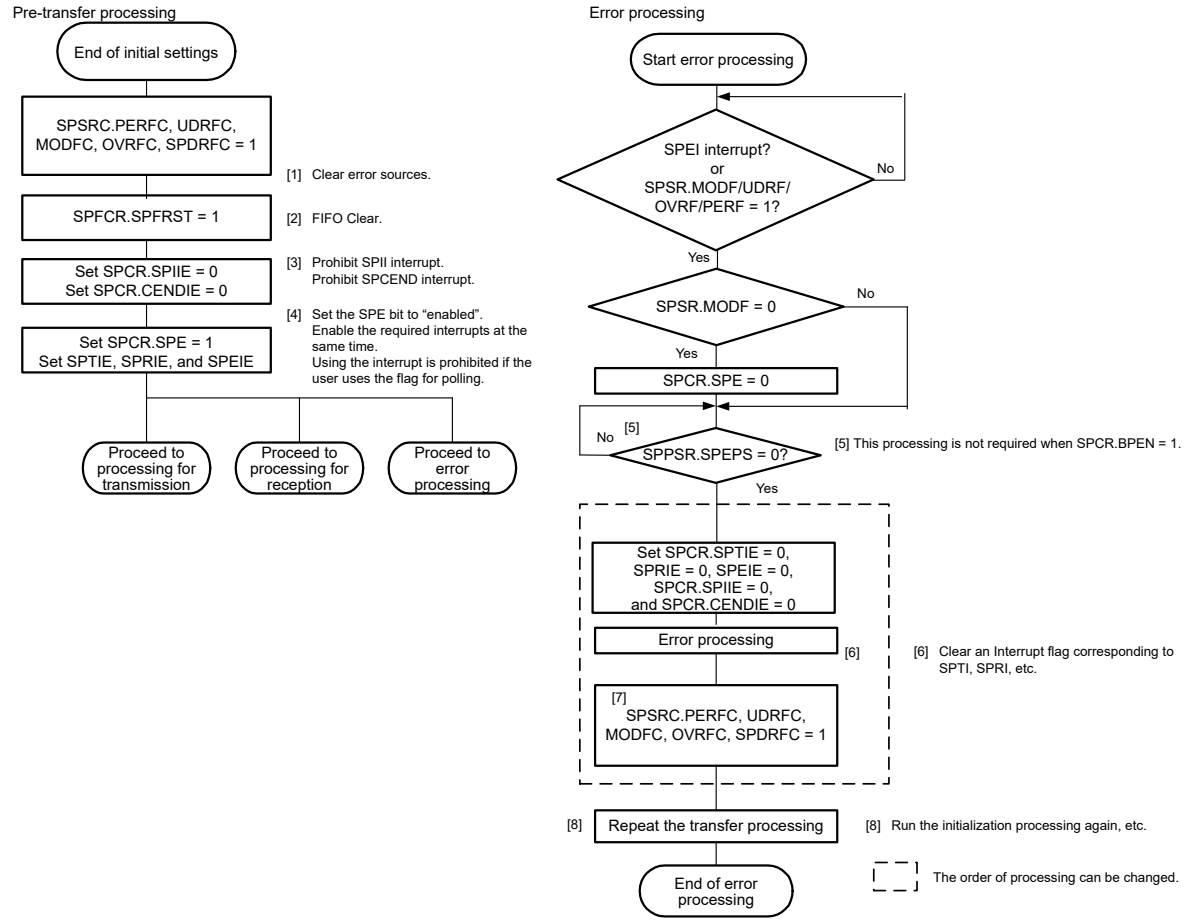
(d) Error processing flow

In slave mode operation, the MODF flag can be cleared regardless of the SSL0 pin status even when a mode fault error is present.

When interrupts are used and an error has occurred, clear an Interrupt flag in the error processing because an SPTI interrupt request or an SPRI interrupt request may be remaining in an Interrupt flag. Furthermore, when an SPRI interrupt request is remaining, read the receive buffer to initialize the SPI's internal sequencer.



Note: SPEI: SPI error interrupt
SPII: Idle interrupt
SPRI: Reception buffer full interrupt
SPTI: Transmission buffer empty interrupt

Figure 36.73 Software processing flowchart in slave mode (error processing)

36.4.14 Clock Synchronous Operation

When SPCR.SPMS bit = 1, the SPI operates in synchronization with clock. Clock synchronous operation enables communication by using three pins RSPCK, MOSI, and MISO without using SSL pins. SSL pins can be used as I/O ports.

Clock synchronous operation does not use SSL pins for communication, but the module operates internally in the similar manner to SPI operation. In master mode operation and slave mode operation, communication is possible according to the flow similar to SPI operation, but no mode fault error is detected because SSL pins are not used.

In clock synchronous operation, if the SPCMD.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0), subsequent operation is not guaranteed.

36.4.14.1 Master Mode Operation

(1) Starting a Serial Transfer

When data is written to the SPDR register while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTXn, n = 0 to 3) data in SPDR. While the shift register is empty, the SPI copies transmit buffer data to the shift register to start serial transfer. After the SPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the SPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the SPI transfer format, see section 36.4.5. Transfer Format (Frame Format). In clock synchronous operation, however, the SSL0 output signal is not used for communication.

(2) Terminating a Serial Transfer

Upon detecting the RSPCK edge corresponding to the final sampling timing, the SPI terminates serial transfer. When the number of data stored in the receive FIFO < the number of FIFO stages, the SPI copies received data from the shift register to the receive buffer in the SPDR register after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPCMD.SPB[4:0] bits. For details about the SPI transfer format, see section 36.4.5. Transfer Format (Frame Format). In clock synchronous operation, however, the SSL0 output signal is not used for communication.

(3) Sequence Control

The transfer format in master mode is determined by the SPSCR, SPCMDm (m = 0 to 7), SPBR, SPCKD, SSLND, and SPND registers. These settings are valid though SSL signals are not output in clock synchronous operation.

The SPSCR register is used to determine the sequence configuration for serial transfer to be performed by the SPI in master mode. MSB first/LSB first, data length, a part of bit rate settings, RSPCK polarity and phase, SPCKD enable/disable, SSLND enable/disable, and SPND enable/disable are set in SPCMD0 to SPCMD7. A part of bit rate settings is set in SPBR, the SPI clock delay value is set in SPCKD, the SSL negation delay value is set in SSLND, and the access delay value is set in SPND.

The SPI configures the sequence that structures a part of or whole of SPCMD0 to SPCMD7 according to the sequence length specified in SPSCR. The SPI has a pointer to SPCMD that configures the sequence. This pointer value can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 to enable the SPI function, the SPI sets the pointer to commands in SPCMD0 and applies the SPCMD0 setting to the transfer format at the start of serial transfer. The SPI increments the pointer when the next-access delay period ends in each data transfer. When the serial transfer corresponding to the final command that configures the sequence is completed, the SPI sets the pointer in SPCMD0. Thus sequence is repeatedly executed.

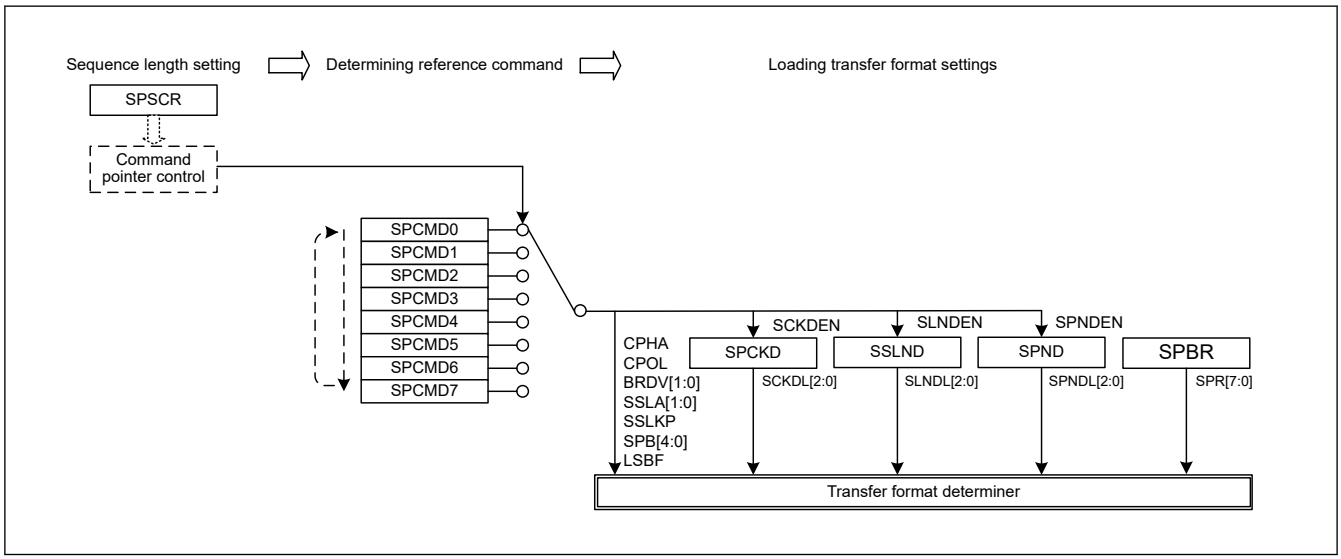


Figure 36.74 Determining serial transfer method in master mode

In this section, a frame consists of data (SPDR) and configuration (SPCMDm (m = 0 to 7)).

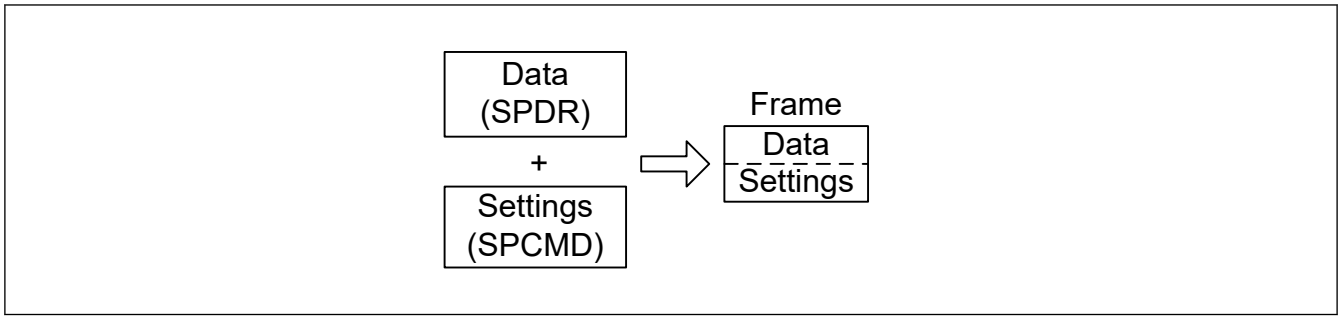

Figure 36.75 Conceptual diagram of frame

Figure 36.76 shows the correspondence between the command in the sequence operation performed and the transmit buffer/ receive buffer.

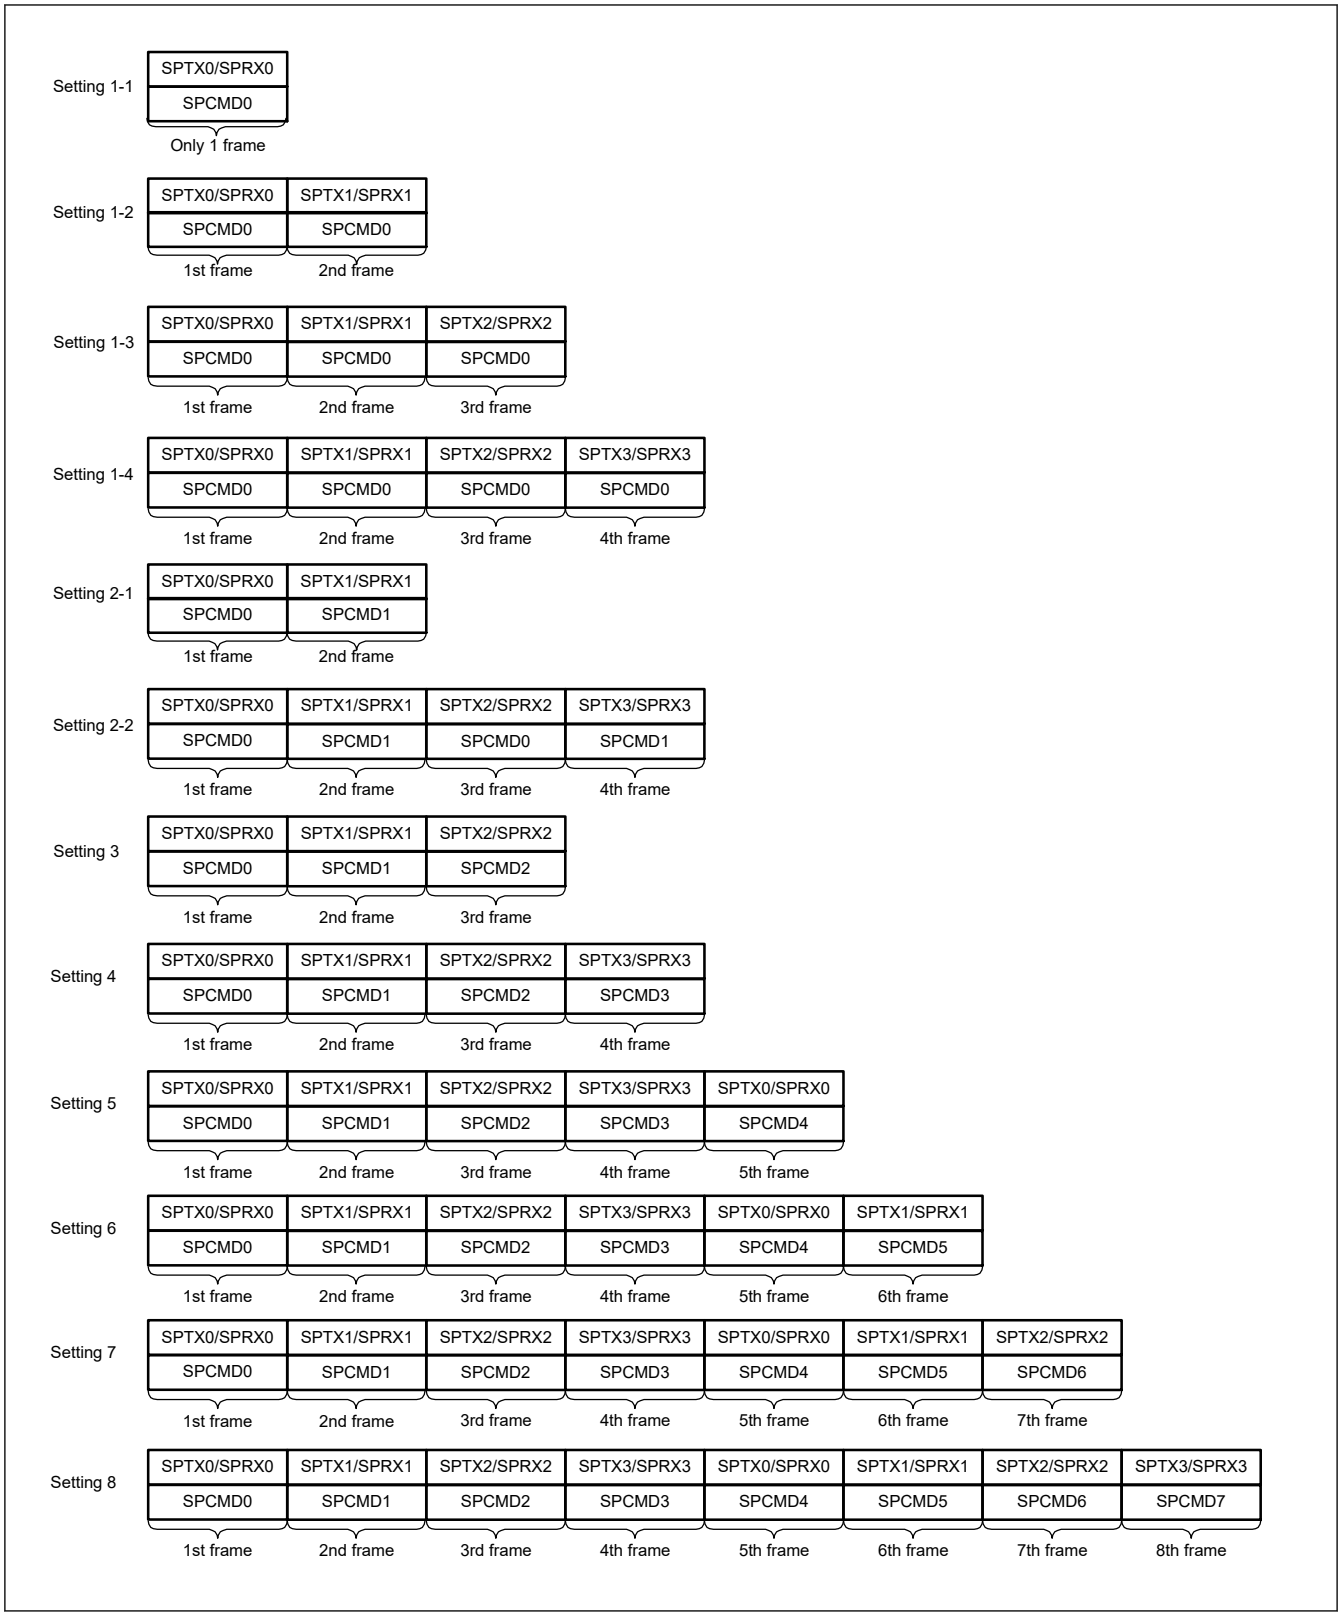

Figure 36.76 Correspondence between SPI command register and transmit/receive buffers in sequence operation

(4) Initialization Flow

Figure 36.77 shows an example of initialization flow when using the SPI in master-mode clock synchronous operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

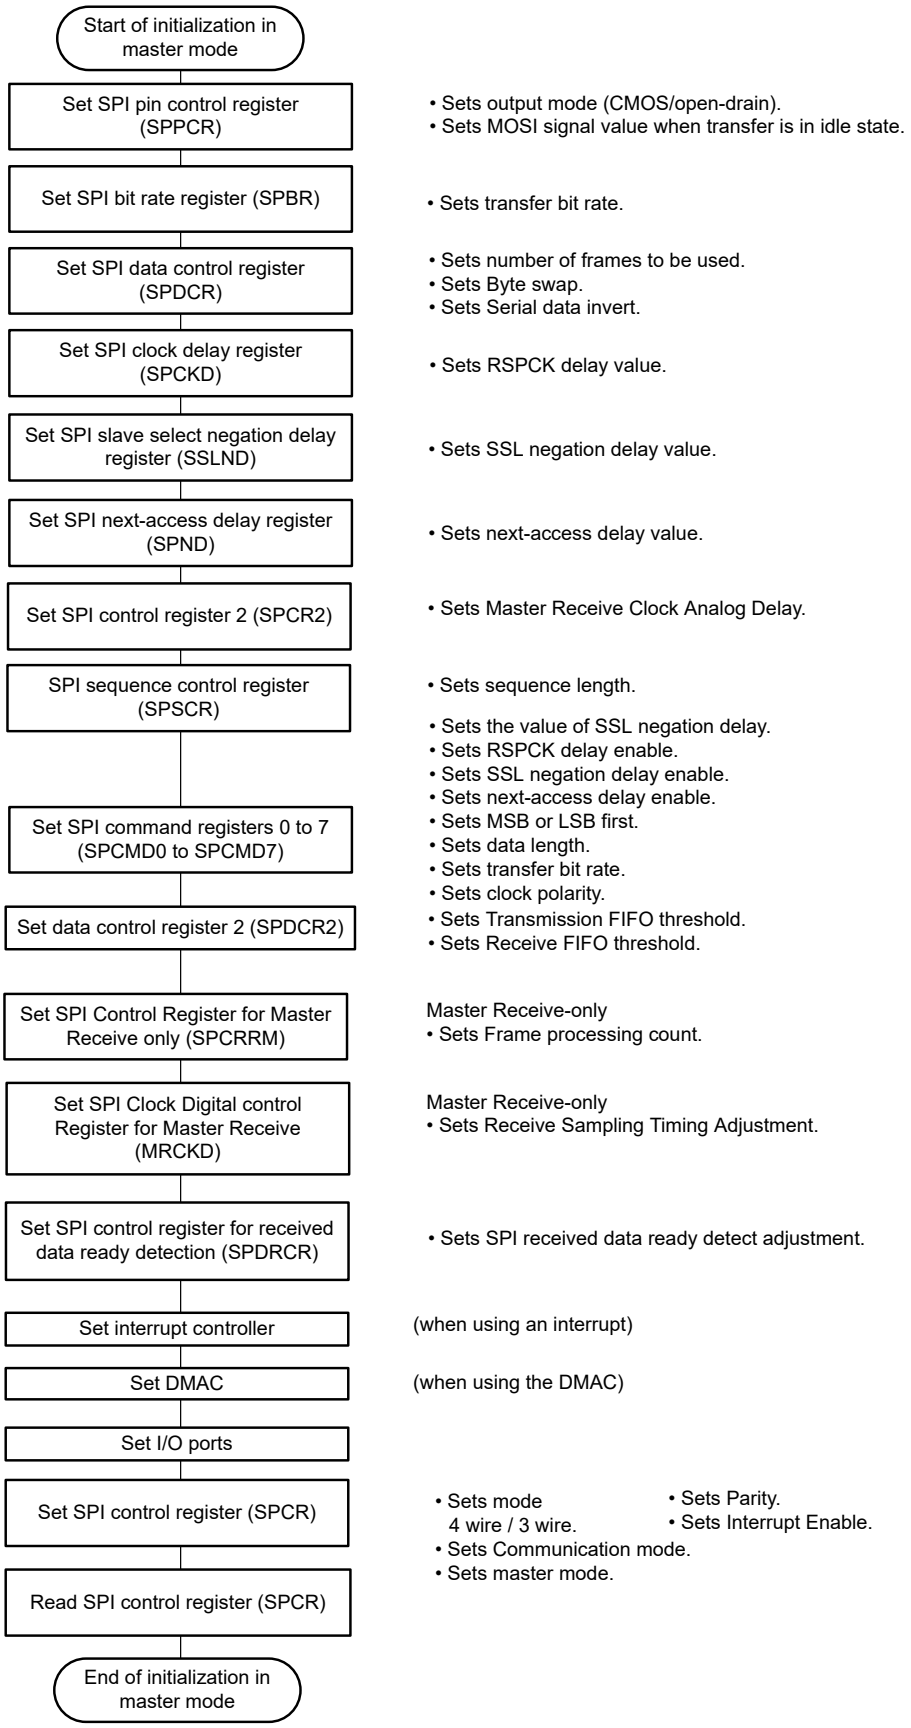

Figure 36.77 Example of initialization flowchart in master mode (clock synchronous operation)

(5) Flow of Software Processing

The software processing flow is omitted here because it is similar to the flow for SPI operation. However, no mode fault error occurs.

36.4.14.2 Slave Mode Operation

(1) Starting a Serial Transfer

When SPCR.SPMS = 1, the first RSPCK edge becomes a trigger to start serial transfer of the SPI.

While SPCR.SPMS = 1, the SPI always drives the MISO output signal.

For details about the SPI transfer format, see section 36.4.5. Transfer Format (Frame Format). In clock synchronous operation, however, the SSL0 input signal is not used.

(2) Terminating a Serial Transfer

Upon detecting the RSPCK edge corresponding to the final sampling timing, the SPI terminates serial transfer. When the number of data stored in the receive FIFO < the number of FIFO stages, the SPI copies received data from the shift register to the receive buffer in the SPDR register after serial transfer. The SPI also changes the shift register status to empty after serial transfer regardless of the receive buffer status. The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in slave mode depends on the set value of the SPCMD0.SPB[4:0] bits. For details about the SPI transfer format, see section 36.4.5. Transfer Format (Frame Format).

(3) Initialization Flowchart

Figure 36.78 shows an example of initialization flow when using the SPI in slave-mode clock synchronous operation.

For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

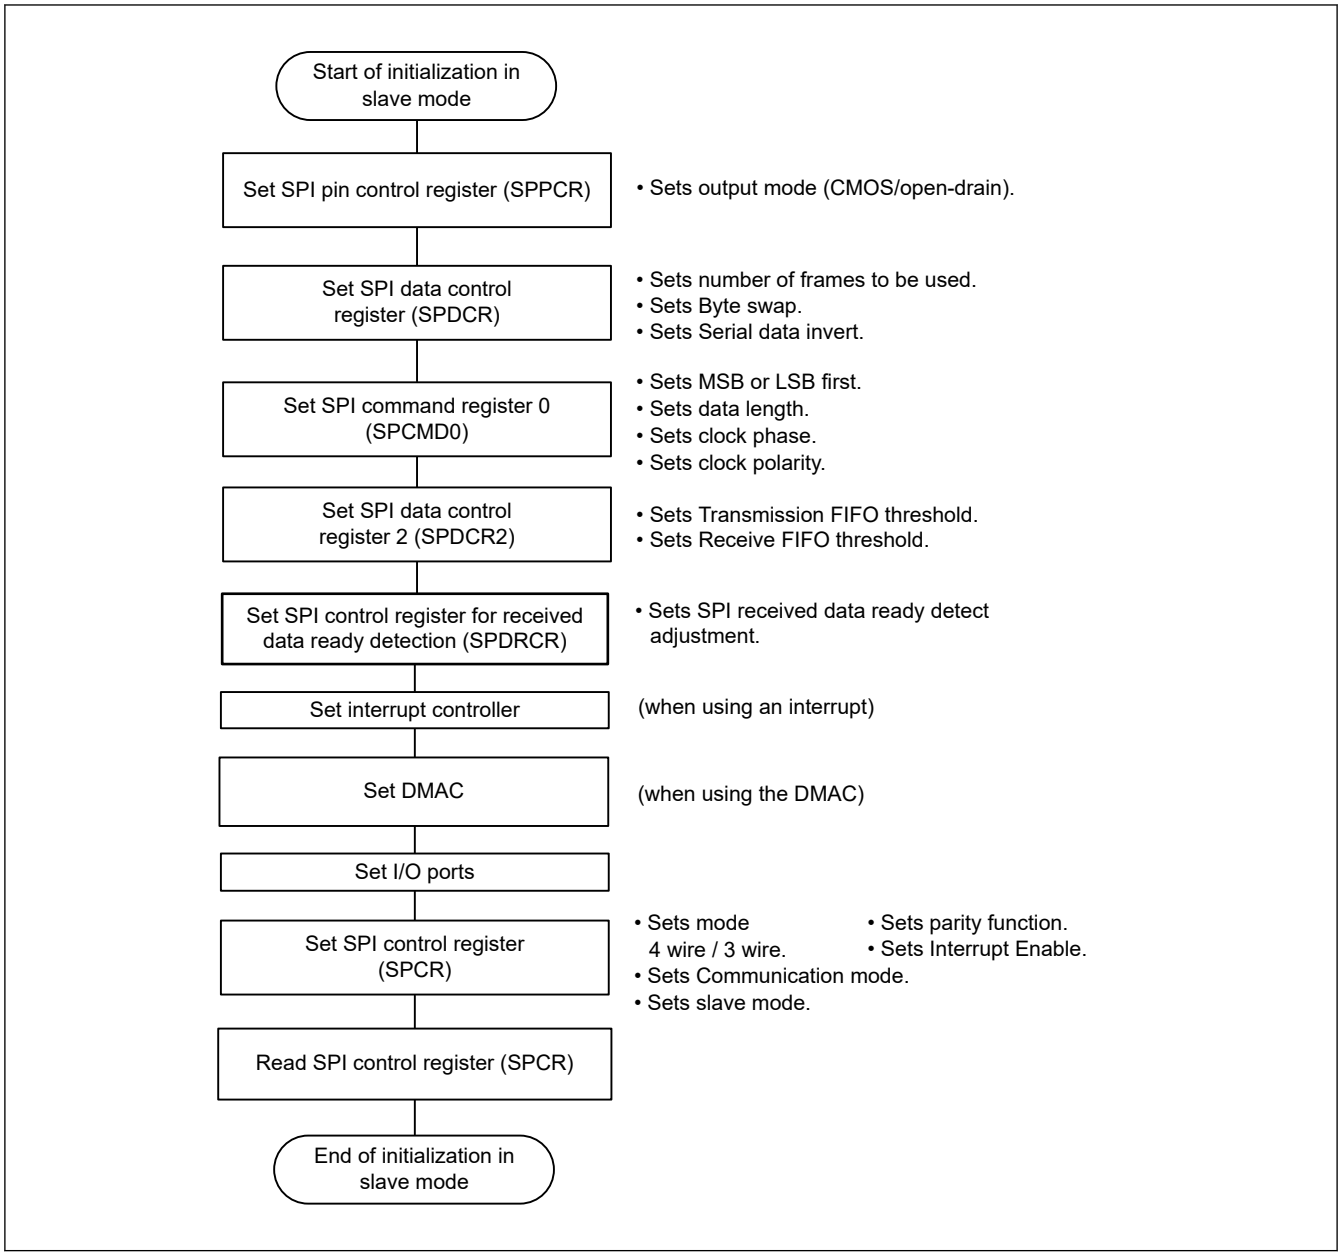

Figure 36.78 Example of initialization flow in slave mode

(4) Flow of Software Processing

The software processing flow is omitted here because it is similar to the flow for SPI operation. However, no mode fault error occurs.

36.4.15 Loopback Mode

When 1 is written to the SPPCR.SPLP bit or SPPCR.SPLP2 bit, the SPI disconnects the path between MISO pin and shift register (when SPCR.MSTR = 1) or between MOSI pin and shift register (when SPCR.MSTR = 0), and then connects the shift register input path to the output path. When SPCR.MSTR = 1, the SPI does not disconnect the path between MOSI pin and shift register. When SPCR.MSTR = 0, the SPI does not disconnect the path between MISO pin and shift register.

When serial transfer is performed in loopback mode, transmit data or inverted transmit data of the SPI becomes received data of the SPI.

Figure 36.79 shows the relationship between settings of the SPLP2 and SPLP bits and received data.

Table 36.16 SPLP2 and SPLP bit settings and received data

SPPCR.SPLP2 bit	SPPCR.SPLP bit	Received data
0	0	Input data from the MOSI pin or MISO pin
0	1	Inversed transmit data
1	0	Transmit data
1	1	Transmit data

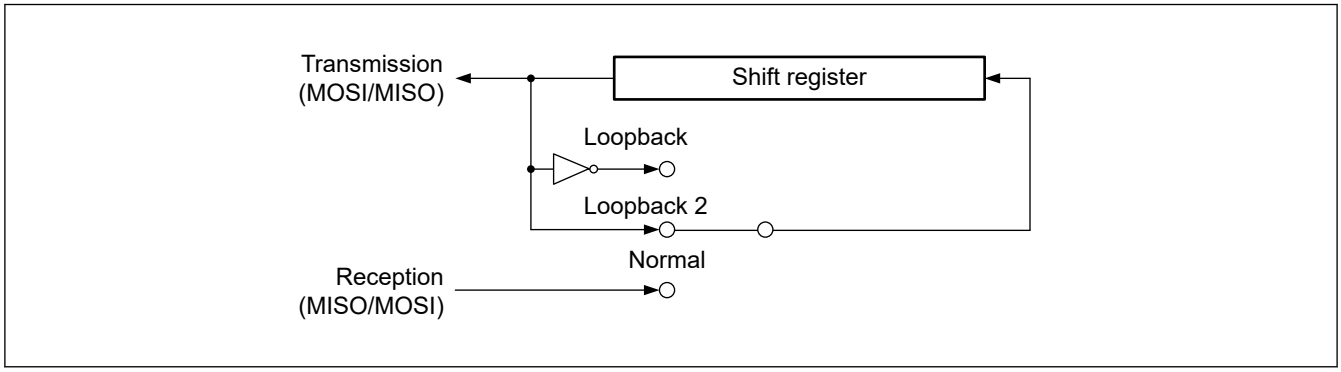

Figure 36.79 Configuration of shift register I/O paths in loopback mode

36.4.16 Self-Diagnosis of Parity Function

The parity circuit consists of a section to add a parity bit to transmit data and a section to detect an error in receive data.

To detect a failure of these sections of the parity circuit, self-diagnosis of the parity circuit is performed according to the flow in Figure 36.80.

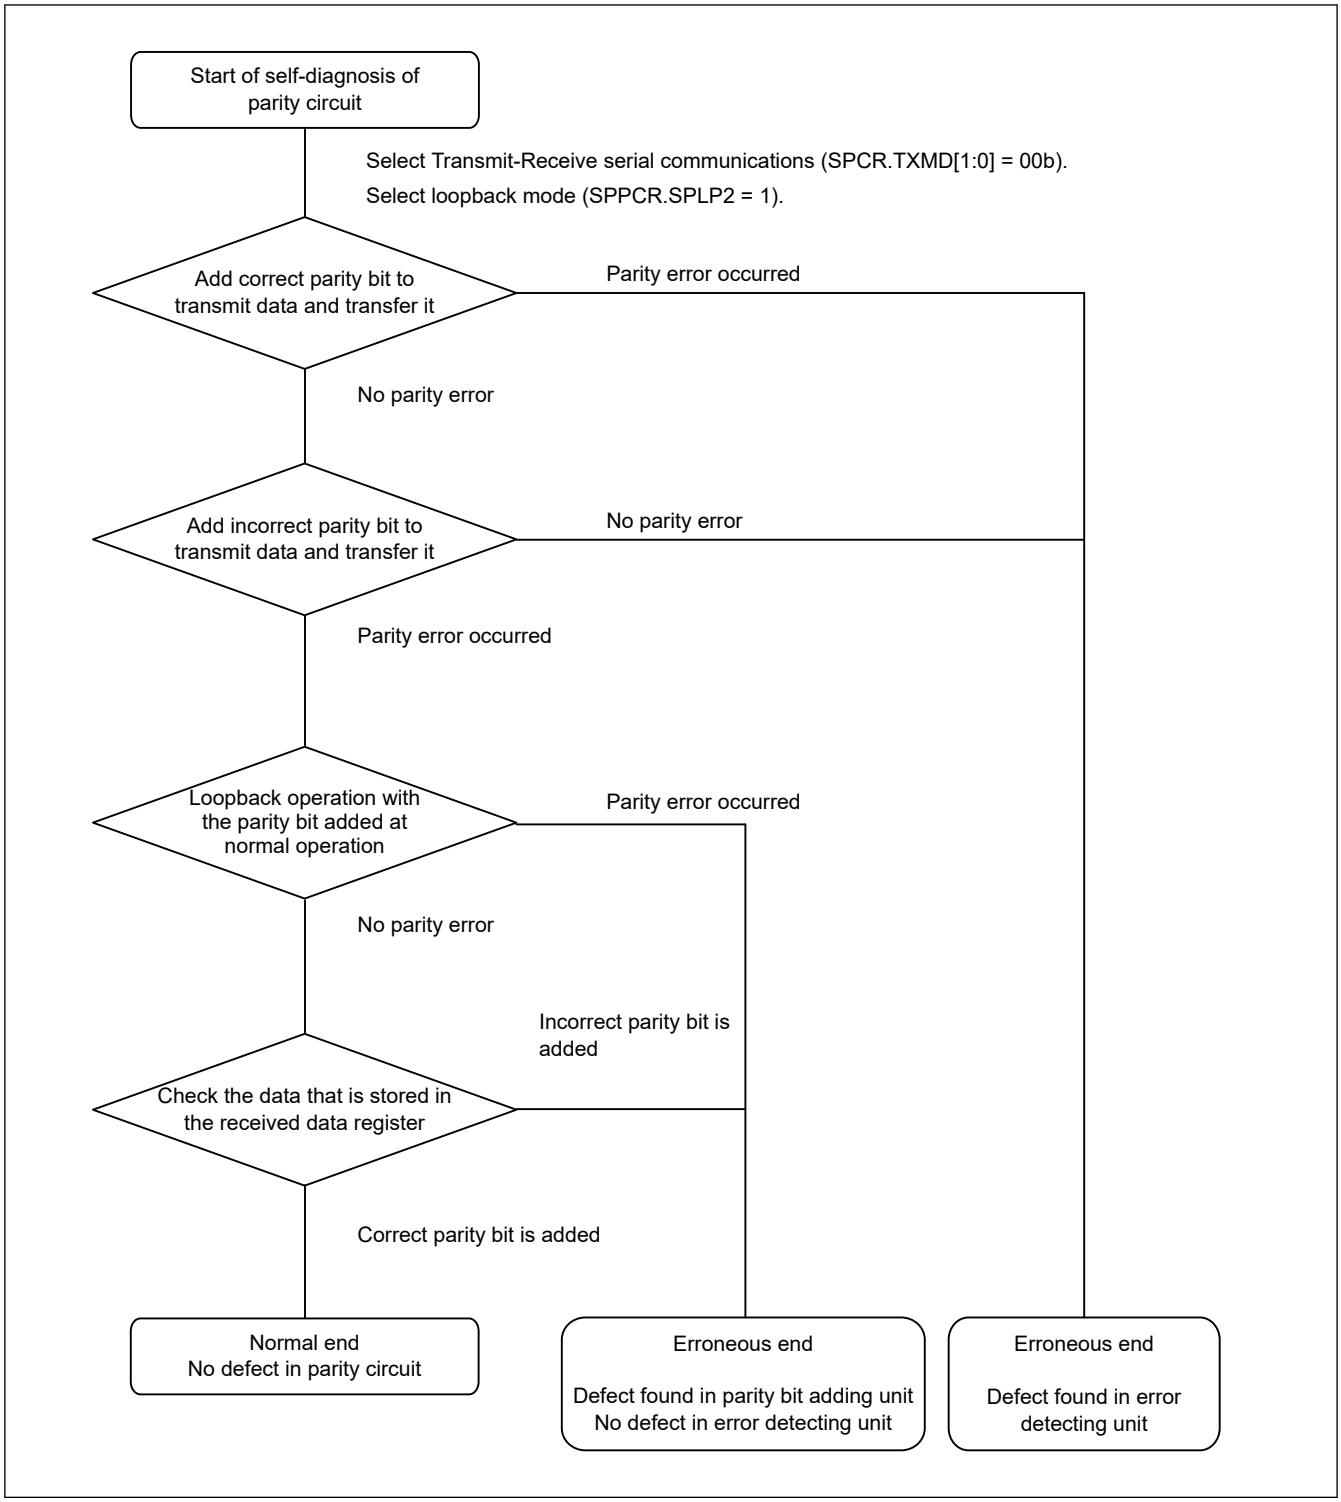

Figure 36.80 Parity circuit self-diagnosis flow

36.4.17 Interrupt Requests

The SPI has the following interrupt sources: receive buffer full, transmit buffer empty, mode fault, underrun, overrun, parity error, SPI idle, communication end, and received data ready. Furthermore, the DMAC can be activated by a receive buffer full interrupt request and a transmit buffer empty interrupt request to start data transfer.

Mode fault, underrun, overrun, parity error, and received data ready (SPCR.SPDRES = 1) interrupt requests are allocated to vector addresses in SPEI. Therefore, identify these interrupt sources by reading respective flags. Table 36.17 lists SPI's interrupt sources. When each interrupt condition in Table 36.17 is met, an interrupt is generated. Clear the receive buffer full and transmit buffer empty interrupt sources by performing data transfer.

When starting transmission or reception by using the DMAC, configure the DMAC to enable it, and then configure the SPI.

Even when the transmit buffer empty interrupt or receive buffer full interrupt condition is met while an Interrupt flag is 1, an interrupt request is not output to ICU but is internally retained. (Only one request per source can be internally retained.) When an Interrupt flag is cleared to 0, the retained interrupt request is output to ICU and then automatically cleared. An internally retained interrupt request can also be cleared by setting the corresponding interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.

Table 36.17 Interrupt sources of SPI

Interrupt source	Symbol	Interrupt condition	DMAC activation
Reception buffer full	SPRI	SPRIE = 1 and (receive buffer full (SPRF = 1) | (SPDRES = 0 and Receive data ready (SPDRF = 1)))	Activated
Transmission buffer empty	SPTI	SPTIE = 1 and transmit buffer empty (SPTEF = 1)	Activated
SPI errors (mode fault, underrun, overrun, and parity error, received data ready)	SPEI	SPEIE = 1 and (MODF = 1 | UDRF = 1 | OVRF = 1 | PERF = 1 | (SPDRES = 1 and SPDRF = 1))	—
SPI idle	SPII	SPIIE = 1 and IDLNF = 0	—
Communication end*1	SPCEND	CENDIE = 1 and CENDF = 1	—

Note 1. See section 36.4.9.7. Common Operation for details on the communication completion interrupt output conditions.

36.5 Usage Notes

36.5.1 Notes on Communication Start

When an Interrupt flag is 1 at the beginning of communication, perform the following procedure to clear an interrupt request before enabling operation (setting the SPCR.SPE bit to 1).

1. Confirm that communication is not going (SPCR.SPE = 0).
2. Set the corresponding interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.
3. Read the corresponding interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that it is 0.
4. Set the Interrupt flag to 0.

36.5.2 Notes on the Module-Stop Function

To stop this module using the power consumption reducing function, be sure to set the SPE bit in SPCR to 0 to terminate communication and then use the power consumption reducing function.

36.5.3 Notes on SPRF and SPTEF Flags

When using the SPRF and SPTEF flags in SPSR by polling them, set the SPRIE and SPTIE bits in SPCR to 0.

36.5.4 Notes on Receive Sampling Function

When using the receive sampling function (sampling receive data with MRIOCLK or MRCLK), set the SSLND register considering the delay of the receive data sampling clock (MRIOCLK or MRCLK) from RSPCK. Please see section 36.3.3. SSLND : SPI Slave Select Negation Delay Register.

36.5.5 Notes on Burst Transfer in Master Mode

During burst transfer, changing the following settings between SPCMD with the SSLKP bit set to 1 and SPCMD used in the next transfer is prohibited.

1. SSL Signal Assertion setting (SSLA[1:0] bits)
2. RSPCK output setting (CPHA, CPOL, BRDV[1:0] bits)

36.5.6 Notes on TI-SSP in Slave Mode

In the slave TI SSP mode, the delay between frames must observe the following intervals.

Secure the following intervals on the master side.

[Master side: interval from RSPCK edge of last bit to RSPCK edge of next SSL] > [Slave side: Output enable delay time = PCLKSPIn × (1 to 2) + SLNDL[2:0] setting value]

36.5.7 Notes at SPE = 1

(1) When SPCR.SPE = 1, if the following register bits are rewritten, subsequent operations are not guaranteed.

Table 36.18 Communication end event generating conditions (receive only slave mode) (1 of 2)

Register name	Bit name
SPCKD	SCKDL[2:0]
SSLND	SLNDL[2:0]

Note 1. Rewriting prohibited in slave mode. In master mode, this is possible only when there is no next transfer data in the transmit FIFO.

(2) After rewriting from SPE = 1 to 0 when SPCR.BPEN = 0, or when SPSR.MODF is set to 1, check that the SPPSR.SPEPS bit is set to 0, then do the next operation.

37. Expanded Serial Peripheral Interface (xSPI)

37.1 Overview

This LSI has two units of Expanded Serial Peripheral Interface (xSPI). The xSPI protocol specifies the interface for Memory Devices, which provides high data throughput, low signal count, and limited backward compatibility with legacy SPI devices. The electrical interface can deliver up to 266 MB per second raw data throughput.

Table 37.1 lists the xSPI specifications, Figure 37.1 shows a block diagram, and Table 37.2 lists the I/O pins.

Table 37.1 xSPI Specifications

Item	Description
Number of channels	2 units
Protocol	Compliant for the xSPI protocol
Data transmission and reception	Issue the transaction for up to 2 Slave as Master
Transfer speed	Support the transfer at xSPI266
Mode	• Support Protocol modes below – 1/4/8pin with SDR/DDR (1S-1S-1S, 4S-4D-4D, 8D-8D-8D) – 2/4pin with SDR (1S-2S-2S, 2S-2S-2S, 1S-4S-4S, 4S-4S-4S) • Configurable address length • Configurable initial access latency cycle • Support XiP mode
xSPI function	• Support Write Data Mask • Support In-band Reset • Memory-mapping – Support up to 256 MB address space (Sum of CS0 and CS1 is up to 256 MB.) – Prefetch function for burst-read with low latency – Outstanding buffer for burst-write with high throughput • Manual command – Configurable up to 4 commands – Status Register Polling function • Input Strobe port timing shift
Interrupt source	2 interrupts
Module-stop function	Module-stop state can be set to reduce power consumption

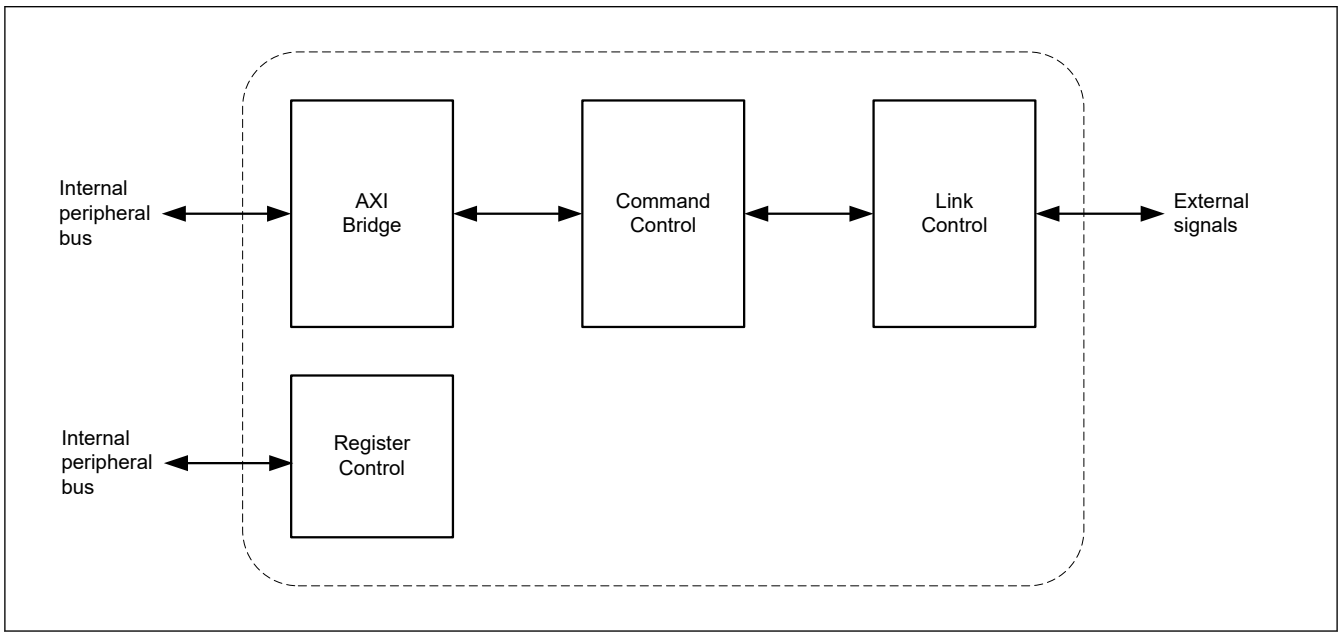

Figure 37.1 Block diagram

Table 37.5 xSPI related system control register

Unit	Module Reset Control Register	Module Stop Control Register	Slave Access Control Register
0	MRCTLA.MRCTLA04	MSTPCRA.MSTPCRA04	SLVACCCTL8.xSPI0_SL
1	MRCTLA.MRCTLA05	MSTPCRA.MSTPCRA05	SLVACCCTL8.xSPI1_SL

Note: Access to memory area is protected by TZC-400. Its slave access control register is SLVACCCTL8.TZCXSPI_SL.

37.3 Register Descriptions

37.3.1 xSPI Configuration Registers

These registers configure xSPI Master function. These registers should be configured in the initialization phase before issuing xSPI transaction.

37.3.1.1 WRAPCFG : xSPI Wrapper Configuration Register

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	DSSFTCS1[4:0]					—	—	—	—	—	—	—	—	—	—	—	DSSFTCS0[4:0]					—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
12:8	DSSFTCS0[4:0]	DS shift for slave0 These bits configure the number of delay cell for XSPIm_DS pin. It is used to adjust the DS sampling timing. 1 cell delay is around 125 ps. When enabled automatic calibration, it can be updated automatically. 0x00: No shift 0x01: Add a delay of 1 cell ⋮ 0x1E: Add a delay of 30 cells 0x1F: Add a delay of 31 cells	R/W
23:13	—	These bits are read as 0. The write value should be 0.	R/W
28:24	DSSFTCS1[4:0]	DS shift for slave1 The function is same as one of slave0.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to configure xSPI Master function.

37.3.1.2 COMCFG : xSPI Common Configuration Register

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OENEGEX	OEASTEX
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
16	OEASTEX	Output Enable Asserting extension This bit extends 1 cycle output enable of Data and DS during output enable asserting. When set to 1, CS asserting should be extended (LIOCFGCSn.CSASTEX = 1 (n = 0, 1)). This bit shall not be used in case of no latency cycle. Because xSPI output data could be conflicted with xSPI input data. 0: No extend 1 cycle Output enable 1: Extend 1 cycle Output enable	R/W
17	OENEGEX	Output Enable Negating extension This bit extends 1 cycle output enable of Data and DS during output enable negating. This bit should not be used in case of no latency cycle. Because SPI output data could be conflicted with SPI input data. 0: No extend 1 cycle Output enable 1: Extend 1 cycle Output enable	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to configure xSPI Master function.

37.3.1.3 BMCFG : xSPI Bridge Map Configuration Register

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CMBTIM[7:0]								—	—	—	—	—	—	—	PREEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MWRSIZE[7:0]								MWRCOMB	—	—	—	—	—	—	WRMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	WRMD	AXI Write Response mode This bit selects the timing of system bus write response in memory-mapping mode. When set to 1, it returns the response after transmitting a frame on xSPI bus. When enabled this mode, Memory Write Combination mode must be disabled. 0: Return response after storing to Internal Write Buffer 1: Return response after issuing write transaction to xSPI bus	R/W
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	MWRCOMB	Memory Write Combination mode This bit selects to combine the xSPI data in write access of memory-mapping mode. When set to 0, xSPI data size depends on AXI Burst type. When set to 1, it depends on Memory Write Size bit. When set to 1, any write transaction could be held in this xSPI master temporarily. 0: Disable combination mode 1: Enable combination mode	R/W
15:8	MWRSIZE[7:0]	Memory Write Size These bits select the size to combine incremental address in memory-mapping mode. It transmits an xSPI frame with the data combined up to the configured size while the address is incremental. When detected non-incremental address or a read transaction before reaching to the target size, it transmits the pending data into xSPI bus. 0x00: Combine incremental address up to 4 bytes 0x01: Combine incremental address up to 8 bytes ⋮ 0x0E: Combine incremental address up to 60 bytes 0x0F: Combine incremental address up to 64 bytes Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
16	PREEN	Prefetch enable This bit enables prefetch function for read transaction in memory-mapping mode. It could reduce the latency for read transaction with incremental address. 0: Disable prefetch function 1: Enable prefetch function	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
31:24	CMBTIM[7:0]	Combination timer This field specifies expiration period of combination timer. 0x00 means disabling the combination timer. When the timer is expired, the data in the combination buffer is pushed to memory device.	R/W

This register has functions to configure xSPI Master function.

37.3.1.4 CMCFG0CSn : xSPI Command Map Configuration Register 0 CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x010 + 0x010 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ADDRPCD[7:0]								ADDRPEN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	ARYAMD	WPBSTMD	ADDSIZE[1:0]		FFMT[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	FFMT[1:0]	Frame format These bits configure xSPI frame format in memory-mapping mode. Please see Table 37.11 for detail. 0 0: Normal format: Command 1 byte, Address ADDSIZE, Data to AXI bus transaction. 0 1: 8D-8D-8D profile 1.0 format: Command 2 bytes, Address ADDSIZE, Data to AXI bus transaction 1 0: 8D-8D-8D profile 2.0 Command Modifier format: Command & Modifier 6 bytes, Data to AXI bus transaction 1 1: 8D-8D-8D profile 2.0 Commands with Extended Command Modifier format: Command & Modifier 6 bytes, Data to AXI bus transaction	R/W
3:2	ADDSIZE[1:0]	Address size These bits configure the number of address byte in memory-mapping mode. In case of 8D-8D-8D profile 2.0, it should be configured to 4 bytes. 0 0: 1 byte (256-byte address space) 0 1: 2 bytes (64 KB address space) 1 0: 3 bytes (16 MB address space) 1 1: 4 bytes (4 GB address space)	R/W
4	WPBSTMD	Wrapping burst mode When this field is set to 1, the wrapping boundary between system bus access and xSPI memory shall be matched. 0: Separate xSPI transfer at the wrapping address boundary 1: Not separate xSPI transfer at the wrapping address boundary	R/W
5	ARYAMD	Array address mode When this field is set to 1, address for memory is mapped as {A[25:10], A[9:4], 6{RSV}, A[3:0]} where A[25:0] is normal address, and RSV is reserved value (0b). This field is effective only when FFMT = 1xb. 0: Normal address mode 1: Array address mode	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
23:16	ADDRPEN[7:0]	Address Replace Enable These bits select the bits to replace for MSByte of AXI bus address in memory-mapping mode. 0: No replacement (xSPI frame address field is same as AXI bus address) 1: Replacement	R/W
31:24	ADDRPCD[7:0]	Address Replace Code These bits configure the code to replace the MSByte of AXI bus address in memory-mapping mode. It replaces the corresponding bits when Address Replace Enable bit is set to 1.	R/W

This register has functions to configure xSPI Master function.

37.3.1.5 CMCFG1CSn : xSPI Command Map Configuration Register 1 CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x014 + 0x010 × n

Bit position:	31											20			16	15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	RDLATE[4:0]				RDCMD[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RDCMD[15:0]	Read command These bits configure the command field of read transaction in memory-mapping mode. Normal format and 8D-8D-8D profile 2.0 format use only upper 1 byte. 8D-8D-8D profile 1.0 format uses 2 bytes.	R/W
20:16	RDLATE[4:0]	Read latency cycle These bits configure the latency cycle of read transaction in memory-mapping mode. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to configure xSPI Master function.

37.3.1.6 CMCFG2CSn : xSPI Command Map Configuration Register 2 CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x018 + 0x010 × n

Bit position:	31											20			16	15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	WRLATE[4:0]				WRCMD[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WRCMD[15:0]	Write command These bits configure the command field of write transaction in memory-mapping mode. Normal format and 8D-8D-8D profile 2.0 format use only upper 1 byte. 8D-8D-8D profile 1.0 format uses 2 bytes.	R/W

Bit	Symbol	Function	R/W
20:16	WRLATE[4:0]	Write latency cycle These bits configure the latency cycle of write transaction in memory-mapping mode. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to configure xSPI Master function.

37.3.1.7 LIOCFGCSn : xSPI Link I/O Configuration Register CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x050 + 0x004 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DDRSMPEX[3:0]				SDRSMPSFT[3:0]				SDRSMPMD	SDRDRV	CSNEGEX	CSASTEX	CSMIN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	WRMSKMD	LATEMD	PRTMD[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PRTMD[9:0]	Protocol mode These bits configure the protocol mode and the pin to sample data inputs. In case of using not SPI clock but Data strobe for sampling in SDR mode, it is required to set PRTMD[9] to 1. 0x000: 1S-1S-1S 0x3B2: 4S-4D-4D 0x3FF: 8D-8D-8D 0x048: 1S-2S-2S 0x049: 2S-2S-2S 0x090: 1S-4S-4S 0x092: 4S-4S-4S Others: Setting prohibited	R/W
10	LATEMD	Latency mode This bit selects the behavior of initial access latency phase for both direct-manual mode and memory-mapping mode. When set to 0, the latency cycle is equal to each configured cycle from transmitting address field. When set to 1, the latency cycle is incremented from the last byte-pair of Address field and is extended 2 times of each configured cycle depending on data strobe port. It is used only for profile 2.0 frame format of 8D-8D-8D protocol mode with 6 bytes command/address field. Please refer to xSPI protocol for detail.	R/W

Value: Function	Frame format	Usage
0: Configurable latency	profile 2.0	The configurable latency cycle should be set as minus 1.
	Others	Latency cycle increments after address field.
1: Variable latency	profile 2.0	Latency cycle increments from address [23:16]. And it should not be set to 1.
	Others	Not support

Bit	Symbol	Function	R/W
11	WRMSKMD	Write mask mode This bit selects to use Data strobe port as write data mask. It could be useful for write access of odd byte. It is used only for 8D-8D-8D protocol mode. 0: Write mask disable 1: Write mask enable	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
19:16	CSMIN[3:0]	CS minimum idle term This bit configures the minimum cycle between xSPI frames. 0x0: 1 cycle 0x1: 2 cycles ⋮ 0xE: 15 cycles 0xF: 16 cycles	R/W
20	CSASTEX	CS asserting extension This bit extends 1 cycle chip select pins when asserting. 0: No extension 1: Extend 1 cycle	R/W
21	CSNEGEX	CS negating extension This bit extends 1 cycle chip select pins when negating. 0: No extension 1: Extend 1 cycle	R/W
22	SDRDRV	SDR driving timing This bit configures the timing of data output in SDR. This bit should not be used in case of no latency cycle. Because SPI output data could be conflicted with SPI input data. 0: Drive at 1/2 cycle before CK rising-edge 1: Drive at CK rising-edge	R/W
23	SDRSMPMD	SDR Sampling mode This bit selects the edge of sampling in SDR. In DDR, regardless of this setting, it samples data input ports with both edges of DS. When set to 1, it samples at rising-edge before falling-edge. 0: Samples data input at falling-edge 1: Samples data input at rising-edge	R/W
27:24	SDRSMPSFT[3:0]	SDR Sampling window shift These bits shift the timing of CK sampling in SDR. In case of using DS in SDR, there is no influence on the behavior. In case of DDR or using DS in SDR, it should be set to 0. 0x0: Sample without delay 0x1: Sample at 1 cycle delay ⋮ 0x6: Sample at 6 cycle delay 0x7: Sample at 7 cycle delay Others: Setting prohibited	R/W
31:28	DDRSMPEX[3:0]	DDR sampling window extend These bits configure the cycle of extending the sampling window in DDR. In DDR, the input data is sampled during the expected cycle soon after latency cycle. The input data out of range is ignored. It can be configured depending on DS propagation delay. 0x0: Expand no cycle 0x1: Expand 1 cycle ⋮ 0x6: Expand 6 cycles 0x7: Expand 7 cycles Others: Setting prohibited	R/W

This register has functions to configure xSPI Master function.

37.3.2 xSPI Control Registers

These registers control xSPI Master function.

37.3.2.1 BMCTL0 : xSPI Bridge Map Control Register 0

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x060

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CS1ACC[1:0]		CS0ACC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
1:0	CS0ACC[1:0]	AXI bus channel to slave0 memory area access enable These bits enable the access from AXI bus channel to CS0 memory. 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W
3:2	CS1ACC[1:0]	AXI bus channel to slave1 memory area access enable These bits enable the access from AXI bus channel to CS1 memory. 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W
7:4	—	These bits are read as 1. The write value should be 1.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function.

37.3.2.2 BMCTL1 : xSPI Bridge Map Control Register 1

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x064

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	PBUF CLR	—	MWRP USH	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	The write value should be 0.	W
8	MWRPUSH	Memory Write Data Push This bit requests to push the pending data in combination mode. 0: No command 1: Push request	W
9	—	The write value should be 0.	W

Bit	Symbol	Function	R/W
10	PBUFCLR	Prefetch Buffer clear This bit requests to clear the prefetch buffer when enabled the prefetch function. It should not be set during memory access (COMSTT.MEMACC = 1). 0: No command 1: Clear request	W
31:11	—	The write value should be 0.	W

This register has functions to control xSPI Master function.

37.3.2.3 CMCTL : xSPI Command Map Control Register

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x068

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	XIPEN	XIPEXCODE[7:0]								XIPENCODE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	XIPENCODE[7:0]	XiP mode enter code These bits configure the code to enter XiP mode in memory-mapping mode.	R/W
15:8	XIPEXCODE[7:0]	XiP mode exit code These bits configure the code to exit XiP mode in memory-mapping mode.	R/W
16	XIPEN	XiP mode enable This bit enables XiP mode in memory-mapping mode. When set to 1, XiP enter code is inserted in the latency field, and the command field in next transaction is omitted. When set to 0, XiP exit code is inserted in the latency field. And it is set to 0 automatically when transmitting XiP disable pattern. It should not be used for 8D-8D-8D protocol mode profile 2.0 frame format. 0: Disable XiP mode 1: Enable XiP mode	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function.

37.3.2.4 CDCTL0 : xSPI Command Manual Control Register 0

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	PERREP[3:0]				—	—	—	PERITV[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TRNUM[1:0]		CSSEL	—	PERMD	TRREQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TRREQ	Transaction request This bit requests to issue the transaction of manual-command. When set to 1, it starts the transaction. It is cleared to 0 when the transaction completed. The transaction is canceled by clearing to 0 while the transaction is ongoing. 0: No transaction 1: Request transaction	R/W
1	PERMD	Periodic mode This bit enables the periodic transaction mode. When set to 1, it repeats a transaction periodically and compares the read value with the expected value. It alternates the status polling operation for external memory. 0: Direct manual-command mode 1: Periodic manual-command mode	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue manual-command. 0: CS0 1: CS1	R/W
5:4	TRNUM[1:0]	Transaction number These bits configure the number of transactions in normal manual-command mode. In periodic manual-command, regardless of this setting, it issues the transaction using only command buffer 0. 0 0: Issue 1 command (using command buffer 0) 0 1: Issue 2 commands (using command buffer 0-1) 1 0: Issue 3 commands (using command buffer 0-2) 1 1: Issue 4 commands (using command buffer 0-3)	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W
20:16	PERITV[4:0]	Periodic transaction interval These bits configure the interval of transaction in periodic manual-command mode. Too short interval compared with CPU bus cycle could result in no store into command buffer0. The interval should be longer than 4 times of CPU bus cycle. 0x00: 2 (= 2^1) cycles 0x01: 4 (= 2^2) cycles ⋮ 0x1E: 2,147,483,648 (= 2^{31}) cycles 0x1F: 4,294,967,296 (= 2^{32}) cycles	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
27:24	PERREP[3:0]	Periodic transaction repeat These bits configure the number of transaction repetitions in periodic manual-command mode. 0x0: 1 (= 2^0) time 0x1: 2 (= 2^1) times ⋮ 0xE: 16384 (= 2^{14}) times 0xF: 32768 (= 2^{15}) times	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function.

37.3.2.5 CDCTL1 : xSPI Command Manual Control Register 1

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x074

Bit position:	31																												0
Bit field:	PEREXP[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

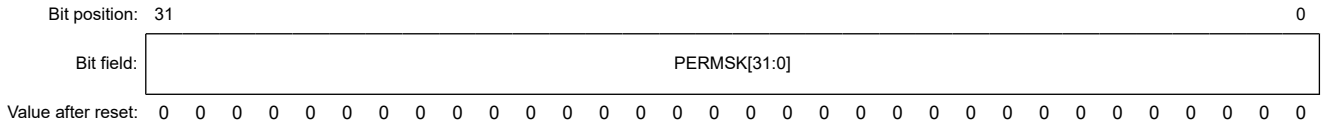
Bit	Symbol	Function	R/W
31:0	PEREXP[31:0]	Periodic transaction expected value These bits configure the expected value to compare with the read value in periodic manual-command mode. For example, in case of comparing 1 byte, the lower byte should be configured.	R/W

This register has functions to control xSPI Master function.

37.3.2.6 CDCTL2 : xSPI Command Manual Control Register 2

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x078



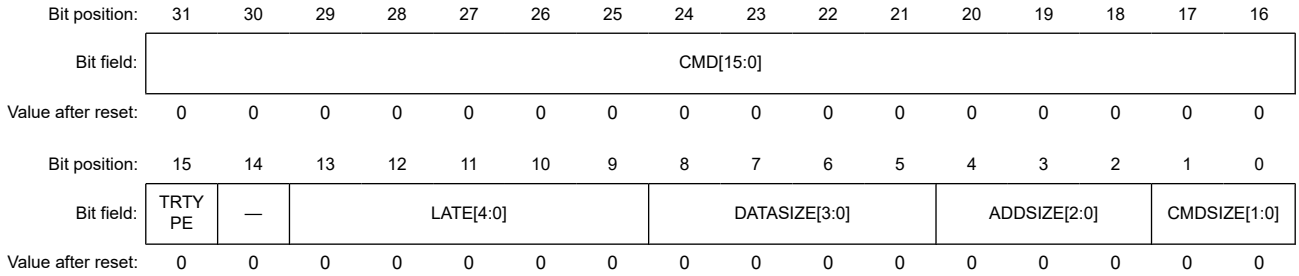
Bit	Symbol	Function	R/W
31:0	PERMSK[31:0]	Periodic transaction masked value These bits configure the masked value for the expected value in periodic manual-command mode. When set 1 to any bit, the corresponding bit configured as expected value (CDCTL1.PEREXP[31:0]) is ignored. In 8D-8D-8D, the data bytes are transferred only in byte pairs on SPI bus. It means the dummy read data could be stored. It should be masked for unused bits. For example, in case of read lower 1 byte, it should be configured to 0xFFFFFF00.	R/W

This register has functions to control xSPI Master function.

37.3.2.7 CDTBUFn : xSPI Command Manual Type Buf n (n = 0 to 3)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x080 + 0x010 × n



Bit	Symbol	Function	R/W
1:0	CMDSIZE[1:0]	Command Size These bits configure the size of command field. In case of 8D-8D-8D, it should be fixed to 10b. It should not be configured both command size and address size to zero. 0 0: 0 bytes (No command phase) 0 1: 1 byte 1 0: 2 bytes Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
4:2	ADDSIZE[2:0]	Address size These bits configure the size of address field. 0 0 0: 0 bytes (No address phase) 0 0 1: 1 byte 0 1 0: 2 bytes 0 1 1: 3 bytes 1 0 0: 4 bytes Others: Setting prohibited	R/W
8:5	DATASIZE[3:0]	Write/Read Data Size These bits configure the size of data field. In 8D-8D-8D, the data bytes are transferred only in byte pairs on SPI bus. For example, even if configuring 1 byte for read, 2 bytes data is received. The last byte should be ignored. The 0 bytes must not configured for read transaction. 0x0: 0 bytes (No data phase) 0x1: 1 byte ⋮ 0x7: 7 bytes 0x8: 8 bytes Others: Setting prohibited	R/W
13:9	LATE[4:0]	Latency cycle These bits configure the latency cycle in manual-command mode. 0x0: No latency 0x1: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
14	—	This bit is read as 0. The write value should be 0.	R/W
15	TRTYPE	Transaction Type This bit selects the type of transaction. 0: Read transaction (Readout data from slave device) 1: Not read transaction	R/W
31:16	CMD[15:0]	Command (1-2 bytes) These bits configure the command field in manual-command mode. The number of bytes configured in Command Size bit is transferred. 1S-1S-1S, 4S-4D-4D: CMD[15:8] is command field, CMD[7:0] is not used. 8D-8D-8D profile 1.0: CMD[15:8] is command field, CMD[7:0] is extension field. 8D-8D-8D profile 2.0: CMD[15:0] is upper 2 bytes of command & modifier field. (bit 47-32 in xSPI protocol)	R/W

This register has functions to control xSPI Master function.

37.3.2.8 CDABUFn : xSPI Command Manual Address Buf n (n = 0 to 3)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x084 + 0x10 × n

Bit position:	31																												0
Bit field:	ADD[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ADD[31:0]	Address These bits configure the address field in manual-command mode. 1S-1S-1S, 4S-4D-4D, 8D-8D-8D profile 1.0: It is address field. 8D-8D-8D profile 2.0: It is lower 4 bytes of command & modifier field. (bit 31-0 in xSPI protocol)	R/W

This register has functions to control xSPI Master function.

37.3.2.9 CDD0BUFn : xSPI Command Manual Data 0 Buf n (n = 0 to 3)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x088 + 0x10 × n

Bit position:	31																												0
Bit field:	DATA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DATA[31:0]	Write/Read Data These bits configure the data field in manual-command mode. In case of write transaction, the write data should be configured. In case of read transaction, the read data is stored.	R/W

This register has functions to control xSPI Master function.

37.3.2.10 CDD1BUFn : xSPI Command Manual Data 1 Buf n (n = 0 to 3)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x08C + 0x10 × n

Bit position:	31																												0
Bit field:	DATA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DATA[31:0]	Write/Read Data These bits configure the data field in manual-command mode. In case of write transaction, the write data should be configured. In case of read transaction, the read data is stored.	R/W

This register has functions to control xSPI Master function.

37.3.2.11 LPCTL0 : xSPI Link Pattern Control Register 0

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x100

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	XD2VAL	—	—	XD2LEN[4:0]					XD1VAL	—	—	XD1LEN[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	XDPIN[1:0]		CSSEL	—	—	PATREQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PATREQ	Pattern request This bit requests to issue the pattern. When set to 1, it starts the pattern. It is cleared to 0 when the pattern completed. 0: No request XiP Disable pattern 1: Request XiP Disable pattern	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue a pattern. 0: slave0 (CS0) 1: slave1 (CS1)	R/W
5:4	XDPIN[1:0]	XiP Disable pattern pin These bits select the data output pins to transmit XiP Disable pattern. 0 0: 1 pin 0 1: 2 pins 1 0: 4 pins 1 1: 8 pins	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W
20:16	XD1LEN[4:0]	XiP Disable pattern 1st phase length These bits select the length of 1st phase in XiP disable pattern. The pattern with zero-length both 1st phase and 2nd phase should not be configured. 0x0: 0 cycles 0x1: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
22:21	—	These bits are read as 0. The write value should be 0.	R/W
23	XD1VAL	XiP Disable pattern 1st phase value This bit selects the value of 1st phase in XiP disable pattern. 0: Low drive 1: High drive	R/W
28:24	XD2LEN[4:0]	XiP Disable pattern 2nd phase length These bits select the length of 2nd phase in XiP disable pattern. 0x00: 0 cycles 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
30:29	—	These bits are read as 0. The write value should be 0.	R/W
31	XD2VAL	XiP Disable pattern 2nd phase value This bit selects the value of 2nd phase in XiP disable pattern. 0: Low drive 1: High drive	R/W

This register has functions to control xSPI Master function.

37.3.2.12 LPCTL1 : xSPI Link Pattern Control Register 1

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x104

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	RSTSU[2:0]			—	RSTWID[2:0]			—	—	RSTREP[1:0]		CSSEL	—	PATREQ[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PATREQ[1:0]	Pattern request These bits request to issue the pattern. When set to 01b or 10b, it starts the pattern. It is cleared to 00b when the pattern completed. 0 0: No request 0 1: Request Reset pattern 1 0: Request CS only pattern 1 1: Setting prohibited	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue a pattern. 0: slave0 (CS0) 1: slave1 (CS1)	R/W
5:4	RSTREP[1:0]	Reset pattern repeat These bits select the repeating time to toggle CS from LOW to HIGH. 0 0: 4 times (Specified on Reset Signaling Protocol) 0 1: 5 times 1 0: 6 times 1 1: 7 times	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
10:8	RSTWID[2:0]	Reset pattern width These bits configure the width of cycle in reset pattern and CS only pattern. It toggles CS with the configured cycle. 0 0 0: 2 (= 2^1) cycles 0 0 1: 4 (= 2^2) cycles ⋮ 1 1 0: 128 (= 2^7) cycles 1 1 1: 256 (= 2^8) cycles	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
14:12	RSTSU[2:0]	Reset pattern data output setup time These bits configure the number of setup cycle for data output based on the edge of CS in reset pattern. It needs enough setup time because xSPI slave samples any data at the rising edge of CS. This cycle of setup time should be less than the cycle of reset pattern width (RSTWID[2:0]). 0 0 0: 1 cycle 0 0 1: 2 cycles ⋮ 1 1 0: 7 cycles 1 1 1: 8 cycles	R/W
31:15	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function.

37.3.2.13 LIOCTL : xSPI Link I/O Control Register

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x108

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RSTCS1	RSTCS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WPCS1	WPCS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
0	WPCS0*1	WP drive for slave0 This bit controls the value of Write Protect (WP0#) port. It can be useful only for xSPI slave with write protect port. 0: Drive Low level 1: Drive High level	R/W
1	WPCS1*1	WP drive for slave1 This function is same as WPCS0. 0: Drive Low level 1: Drive High level	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W
16	RSTCS0*1	Reset drive for slave0 This bit controls the value of xSPI reset (RESET0#) port. It can be useful only for xSPI slave with reset port. 0: Drive Low level 1: Drive High level	R/W
17	RSTCS1*1	Reset drive for slave1 This function is same as RSTCS0. 0: Drive Low level 1: Drive High level	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. For unit 1, these bits are reserved. The write value should be 0.

This register has functions to control xSPI Master function.

37.3.2.14 CCCTL0CSn : xSPI Command Calibration Control Register 0 CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x130 + 0x020 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	CASFTEND[4:0]					—	—	—	CASFTSTA[4:0]				
Value after reset:	0	0	0	1	1	1	1	1	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CAITV[4:0]					—	—	—	—	—	—	CANOWR	CAEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CAEN	Automatic Calibration Enable This bit enables the automatic calibration. When set to 1, it transmits the calibration sequence periodically and adjusts the value of phase shift. When set to 0 during the calibration sequence, it stops after completed ongoing calibration sequence, and then this bit is cleared. 0: Disable automatic calibration 1: Enable automatic calibration	R/W
1	CANOWR	Calibration no write mode This bit selects to omit write command in calibration sequence. It can be used for any slave device with fixed calibration pattern data. 0: Calibration sequence with write command 1: Calibration sequence without write command	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
12:8	CAITV[4:0]	Calibration interval These bits configure the interval between calibration patterns. 0x00: 2 (= 2^1) cycle wait 0x01: 4 (= 2^2) cycle wait ⋮ 0x1E: 2,147,483,648 (= 2^{31}) cycle wait 0x1F: 4,294,967,296 (= 2^{32}) cycle wait	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
20:16	CASFTSTA[4:0]	Calibration DS shift start value These bits configure the start value of DS shift.	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
28:24	CASFTEND[4:0]	Calibration DS shift end value These bits configure the end value of DS shift. It should be equal or more than the start value (CASFTSTA).	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function.

37.3.2.15 CCCTL1CSn : xSPI Command Calibration Control Register 1 CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x134 + 0x020 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	CARDLATE[4:0]					—	—	—	CAWRLATE[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CADATASIZE[3:0]				CAADDSIZE[2:0]			CACMDSIZE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CACMDSIZE[1:0]	Command Size These bits configure the size of command field. In case of 8D-8D-8D, it should be fixed to 10b. It should not be configured both command size and address size to zero. 0 0: 0 bytes (No command phase) 0 1: 1 byte 1 0: 2 bytes 1 1: Setting prohibited	R/W

Bit	Symbol	Function	R/W
4:2	CAADDSIZE[2:0]	Address size These bits configure the size of address field. 0 0 0: 0 bytes (No address phase) 0 0 1: 1 byte 0 1 0: 2 bytes 0 1 1: 3 bytes 1 0 0: 4 bytes Others: Setting prohibited	R/W
8:5	CADATASIZE[3:0]	Write/Read Data Size These bits configure the size of data field. In 8D-8D-8D, it should be configured with even byte. 0x0: 1 byte 0x1: 2 bytes ⋮ 0xE: 15 bytes 0xF: 16 bytes	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
20:16	CAWRLATE[4:0]	Write Latency cycle These bits configure the latency cycle in calibration frame. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
28:24	CARDLATE[4:0]	Read Latency cycle These bits configure the latency cycle in calibration frame. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.3.2.16 CCCTL2CSn : xSPI Command Calibration Control Register 2 CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x138 + 0x020 × n

Bit position:	31															16	15														0
Bit field:	CARDCMD[15:0]																CAWRCMD[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CAWRCMD[15:0]	Calibration pattern write command These bits configure the calibration pattern write command.	R/W
31:16	CARDCMD[15:0]	Calibration pattern read command These bits configure the calibration pattern read command.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.3.2.17 CCCTL3CSn : xSPI Command Calibration Control Register 3 CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x13C + 0x020 × n

Bit position:	31																												0
Bit field:	CAADD[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CAADD[31:0]	Calibration pattern address These bits configure the calibration pattern address.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.3.2.18 CCCTL4CSn : xSPI Command Calibration Control Register 4 CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x140 + 0x020 × n

Bit position:	31																												0
Bit field:	CADATA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.3.2.19 CCCTL5CSn : xSPI Command Calibration Control Register 5 CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x144 + 0x020 × n

Bit position:	31																												0
Bit field:	CADATA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

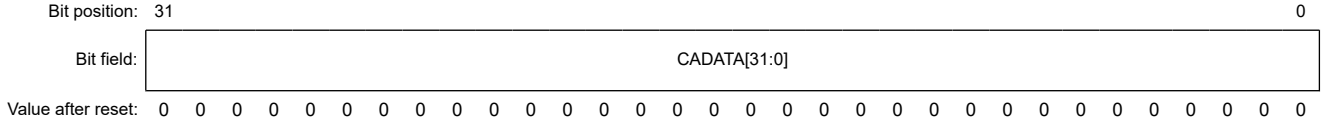
Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.3.2.20 CCCTL6CSn : xSPI Command Calibration Control Register 6 CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x148 + 0x020 × n



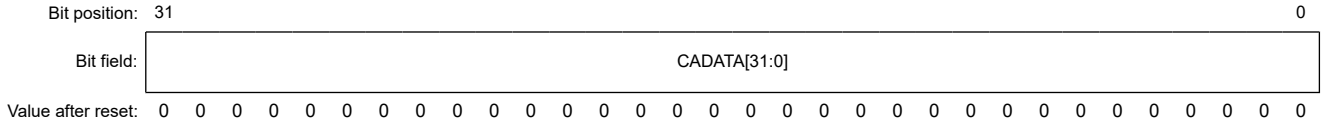
Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.3.2.21 CCCTL7CSn : xSPI Command Calibration Control Register 7 CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x14C + 0x020 × n



Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

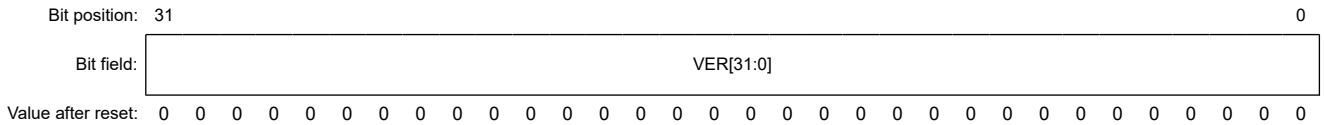
37.3.3 xSPI Status Registers

These registers monitor the status of xSPI Master.

37.3.3.1 VERSTT : xSPI Version Register

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x180



Bit	Symbol	Function	R/W
31:0	VER[31:0]	Version These bits indicate this IP version.	R

This register indicates the status of xSPI Master.

37.3.3.2 COMSTT : xSPI Common Status Register

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x184

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	RSTOCS1	INTCS1	ECSCS1	—	RSTOCS0	INTCS0	ECSCS0
Value after reset:	0	0	0	0	0	0	0	0	0	*1	*1	*1	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	WRBUFNE	—	PBUFNE	—	—	—	MEMACC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MEMACC	Memory access ongoing 0: AXI bus is not accessing to memory. 1: AXI bus is accessing to memory.	R
3:1	—	These bits are read as 0.	R
4	PBUFNE	Prefetch Buffer Not Empty 0: Empty 1: Not empty	R
5	—	This bit is read as 0.	R
6	WRBUFNE	Write Buffer Not Empty 0: Empty 1: Not empty	R
15:7	—	These bits are read as 0.	R
16	ECSCS0*2	ECS monitor for slave0 This bit indicates the value of ECS port. 0: Low level 1: High level	R
17	INTCS0*2	INT monitor for slave0 This bit indicates the value of INT port. 0: Low level 1: High level	R
18	RSTOCS0*2	RSTO monitor for slave0 This bit indicates the value of RSTO port. 0: Low level 1: High level	R
19	—	This bit is read as 0.	R
20	ECSCS1*2	ECS monitor for slave1 This function is same as ECSCS0. 0: Low level 1: High level	R
21	INTCS1*2	INT monitor for slave1 This function is same as INTCS0. 0: Low level 1: High level	R
22	RSTOCS1*2	RSTO monitor for slave1 This function is same as RSTOCS0. 0: Low level 1: High level	R
31:23	—	These bits are read as 0.	R

Note 1. Value after reset is 1 for unit 0 and 0 for unit 1.
Note 2. These bits are reserved for unit 1.

This register indicates the status of xSPI Master.

37.3.3.3 CASTTCSn : xSPI Calibration Status Register CSn (n = 0, 1)

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x188 + 0x004 × n

Bit position:	31																												0
Bit field:	CASUC[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CASUC[31:0]	Calibration Success These bits indicate the calibration success for each DS shift value. It is updated when completed each calibration sequence. CASUC[x] indicates calibration success in DS shift value = x.	R

This register indicates the status of xSPI Master.

37.3.4 xSPI Interrupt Registers

These registers control the interrupt function of xSPI Master.

37.3.4.1 INTS : xSPI Interrupt Status Register

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x190

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CASUCCS1	CASUCCS0	CAFAILCS1	CAFAILCS0	—	—	—	—	—	—	—	BUSERR	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	INTCS1	INTCS0	—	—	ECSCS1	ECSCS0	—	—	DSTOCS1	DSTOCS0	PERTO	INICMP	PATCMP	CMDCMP
Value after reset:	0	0	*1	*1	0	0	*1	*1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMDCMP	Command Completed This bit is set to 1 when completed the requested manual-command. In direct manual-command, it means all transactions completed. In periodic manual-command, it means the read data matches with the expected data. 0: No detection 1: Detection	R
1	PATCMP	Pattern Completed This bit is set to 1 when completed the requested pattern. 0: No detection 1: Detection	R
2	INICMP	Initial Sequence Completed This bit is set to 1 when completed the initial sequence. 0: No detection 1: Detection	R
3	PERTO	Periodic transaction timeout This bit is set to 1 when the read value does not match with the expected value in periodic manual-command mode. 0: No detection 1: Detection	R

Bit	Symbol	Function	R/W
4	DSTOCS0	DS timeout for slave0 This bit is set to 1 when lost DS in read transaction with using DS. It means not receiving the data during expected read phase. In this case, xSPI master stops the read transaction and the following transaction. 0: No detection 1: Detection	R
5	DSTOCS1	DS timeout for slave1 This function is same as DSTOCS0. 0: No detection 1: Detection	R
7:6	—	These bits are read as 0.	R
8	ECSCS0*2	ECC error detection for slave0 This bit is set to 1 when detected the falling edge on ECS0# port. It can be useful only for xSPI slave with ECC detection function. 0: No detection 1: Detection	R
9	ECSCS1*2	ECC error detection for slave1 This function is same as ECSCS0. 0: No detection 1: Detection	R
11:10	—	These bits are read as 0.	R
12	INTCS0*2	Interrupt detection for slave0 This bit is set to 1 when detected the falling edge on INT0# port. It can be useful only for xSPI slave with interrupt function. 0: No detection 1: Detection	R
13	INTCS1*2	Interrupt detection for slave1 This function is same as INTCS0. 0: No detection 1: Detection	R
19:14	—	These bits are read as 0.	R
20	BUSERR	AXI bus error This bit is set to 1 when an error response occurs on AXI bus.	R
27:21	—	These bits are read as 0.	R
28	CAFAILCS0	Calibration failed for slave0 This bit is set to 1 when failed calibration. 0: No detection 1: Detection	R
29	CAFAILCS1	Calibration failed for slave1 This function is same as CAFAILCS0. 0: No detection 1: Detection	R
30	CASUCCS0	Calibration success for slave0 This bit is set to 1 when success calibration. 0: No detection 1: Detection	R
31	CASUCCS1	Calibration success for slave1 This function is same as CASUCCS0. 0: No detection 1: Detection	R

Note 1. Value after reset is 0 for unit 0 and 1 for unit 1.
Note 2. These bits are reserved for unit 1.

This register indicates the status of interrupt. The bits in this register are cleared to 0 when writing 1 on the corresponding bit of INTC register.

37.3.4.2 INTC : xSPI Interrupt Clear Register

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x194

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CASUCCS1C	CASUCCS0C	CAFAILCS1C	CAFAILCS0C	—	—	—	—	—	—	—	BUSERRC	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	INTCS1C	INTCS0C	—	—	ECSCS1C	ECSCS0C	—	—	DSTOCS1C	DSTOCS0C	PERTOC	INICMPC	PATCMPC	CMDCMPC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMDCMPC	Command Completed interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
1	PATCMPC	Pattern Completed interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
2	INICMPC	Initial Sequence Completed interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
3	PERTOC	Periodic transaction timeout interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
4	DSTOCS0C	DS timeout for slave0 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
5	DSTOCS1C	DS timeout for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
7:6	—	The write value should be 0.	W
8	ECSCS0C*1	ECC error detection for slave0 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
9	ECSCS1C*1	ECC error detection for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
11:10	—	The write value should be 0.	W
12	INTCS0C*1	Interrupt detection for slave0 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
13	INTCS1C*1	Interrupt detection for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
19:14	—	The write value should be 0.	W
20	BUSERRC	AXI bus error interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
27:21	—	The write value should be 0.	W

Bit	Symbol	Function	R/W
28	CAFAILCS0C	Calibration failed for slave0 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
29	CAFAILCS1C	Calibration failed for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
30	CASUCCS0C	Calibration success for slave0 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
31	CASUCCS1C	Calibration success for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W

Note 1. For unit 1, these bits are reserved. The write value should be 1.

This register clears the status of interrupt.

37.3.4.3 INTE : xSPI Interrupt Enable Register

Base address: XSPIm = 0x801C_0000 + 0x1000 × m (m = 0, 1)

Offset address: 0x198

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CASUCCS1E	CASUCCS0E	CAFAILCS1E	CAFAILCS0E	—	—	—	—	—	—	—	BUSERRE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	INTCS1E	INTCS0E	—	—	ECSCS1E	ECSCS0E	—	—	DSTOCS1E	DSTOCS0E	PERTOE	INICMPE	PATCMPE	CMDCMPE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMDCMPE	Command Completed interrupt enable 0: Disabled 1: Enabled	R/W
1	PATCMPE	Pattern Completed interrupt enable 0: Disabled 1: Enabled	R/W
2	INICMPE	Initial Sequence Completed interrupt enable 0: Disabled 1: Enabled	R/W
3	PERTOE	Periodic transaction timeout interrupt enable 0: Disabled 1: Enabled	R/W
4	DSTOCS0E	DS timeout for slave0 interrupt enable 0: Disabled 1: Enabled	R/W
5	DSTOCS1E	DS timeout for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	ECSCS0E*1	ECC error detection for slave0 interrupt enable 0: Disabled 1: Enabled	R/W

Bit	Symbol	Function	R/W
9	ECSCS1E*1	ECC error detection for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
12	INTCS0E*1	Interrupt detection for slave0 interrupt enable 0: Disabled 1: Enabled	R/W
13	INTCS1E*1	Interrupt detection for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
19:14	—	These bits are read as 0. The write value should be 0.	R/W
20	BUSERRE	AXI bus error interrupt enable 0: Disabled 1: Enabled	R/W
27:21	—	These bits are read as 0. The write value should be 0.	R/W
28	CAFAILCS0E	Calibration failed for slave0 interrupt enable 0: Disabled 1: Enabled	R/W
29	CAFAILCS1E	Calibration failed for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
30	CASUCCS0E	Calibration success for slave0 interrupt enable 0: Disabled 1: Enabled	R/W
31	CASUCCS1E	Calibration success for slave1 interrupt enable 0: Disabled 1: Enabled	R/W

Note 1. For unit 1, these bits are reserved. The write value should be 0.

This register enables the interrupt.

37.3.5 xSPI Voltage and Size Registers

37.3.5.1 IOVOLCTL : xSPI IO Voltage Control Register

Base address: XSPI_MISC = 0x8029_3000 + 0x100 × m (m = 0, 1)

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	XSPI_MDV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	XSPI_MDV	Operation voltage of xSPI IO domain 0: 1.8 V 1: 3.3 V	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

This register has functions to configure xSPI Master function.

37.3.5.2 CS0ENDAD : xSPI CS0 End Address Register

Base address: XSPI_MISC = 0x8029_3000 + 0x100 × m (m = 0, 1)

Offset address: 0x004

Bit position:	31																												0
Bit field:	CS0_END_ADD[31:0]																												
Value after reset:	0	1	0	*1	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
31:0	CS0_END_ADD[31:0]	CS0 (slave 0) area end address Value after reset is different between units. xSPI unit 0: 0x400F_FFFF xSPI unit 1: 0x500F_FFFF	R/W

Note 1. 0 for unit 0 and 1 for unit 1

This register is used to specify CS0 area end address. Set the value according to size of the connected slave device.

Note that CS0 area start address is fixed to 0x4000_0000 for unit 0 and 0x5000_0000 for unit 1. They are not configurable.

37.3.5.3 CS1STRAD : xSPI CS1 Start Address Register

Base address: XSPI_MISC = 0x8029_3000 + 0x100 × m (m = 0, 1)

Offset address: 0x008

Bit position:	31																												0
Bit field:	CS1_STR_ADD[31:0]																												
Value after reset:	0	1	0	*1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CS1_STR_ADD[31:0]	CS1 (slave 1) area start address Value after reset is different between units. xSPI unit 0: 0x4800_0000 xSPI unit 1: 0x5800_0000	R/W

Note 1. 0 for unit 0 and 1 for unit 1

This register is used to specify CS1 area start address.

37.3.5.4 CS1ENDAD : xSPI CS1 End Address Register

Base address: XSPI_MISC = 0x8029_3000 + 0x100 × m (m = 0, 1)

Offset address: 0x00C

Bit position:	31																												0
Bit field:	CS1_END_ADD[31:0]																												
Value after reset:	0	1	0	*1	1	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
31:0	CS1_END_ADD[31:0]	CS1 (slave 0) area end address Value after reset is different between units. xSPI unit 0: 0x480F_FFFF xSPI unit 1: 0x580F_FFFF	R/W

Note 1. 0 for unit 0 and 1 for unit 1

This register is used to specify CS1 area end address. Set the value according to size of the connected slave device.

37.4 Operation

xSPI Master interface has the functions to issue the transaction for external memory with xSPI Slave interface. It allows to write to registers in external memory or read from it.

This xSPI Master mainly has two modes to issue the transaction. One is a manual-command mode; Software configures all fields of xSPI frame and starts the transaction by software request. The other is a memory-mapping mode; it automatically converts AXI bus access for pre-configured memory area into xSPI transaction. It enables to access from AXI bus to external memory area outside of chip via xSPI bus.

This section describes the xSPI bus operation, the direct control of xSPI frame (manual-command), the control of memory access (memory-mapping), the error operation, and the flow to operation.

37.4.1 xSPI Bus

This section describes the xSPI bus operation.

37.4.1.1 Supported Protocol Mode

This xSPI Master supports various protocol modes. It is configured by Protocol mode bits (LIOCFGCSn.PRTMD[9:0]). Table 37.6 lists the supported protocol mode.

Table 37.6 Supported protocol mode

Protocol mode	Function	PRTMD[9:0]	Note
1S-1S-1S	Command, Address, and Data fields are transferred at SDR with using 1 pin. Read data is sampled with CK.	0x000	Specified by xSPI protocol
4S-4D-4D	Command field is transferred at SDR with using 4 pins. Address and Data fields are transferred at DDR with using 4 pins. Read data is sampled with DS.	0x3B2	Specified by xSPI protocol
8D-8D-8D	Command, Address, and Data fields are transferred at DDR with using 8 pins. Read data is sampled with DS.	0x3FF	Specified by xSPI protocol
1S-2S-2S	Command field is transferred at SDR with using 1 pin. Address and Data fields are transferred at SDR with using 2 pins. Read data is sampled with CK.	0x048	—
2S-2S-2S	Command, Address, and Data fields are transferred at SDR with using 2 pins. Read data is sampled with CK.	0x049	—
1S-4S-4S	Command field is transferred at SDR with using 1 pin. Address and Data fields are transferred at SDR with using 4 pins. Read data is sampled with CK.	0x090	—
4S-4S-4S	Command, Address, and Data fields are transferred at SDR with using 4 pins. Read data is sampled with CK.	0x092	—

Note: In case of XiP mode enable, XiP code is inserted in Latency field. It is valid only for memory-mapping mode.

Table 37.7 lists a description of the main internal signals.

Table 37.7 Internal signals (1 of 2)

Signal name	I/O	Function
clk_spi	I	xSPI control clock
spi_ck	O	xSPI Clock (Same as XSPIm_CKP pin)
spi_cs0	O	xSPI Chip Select for slave0 (Same as XSPIm_CS0# pin)
spi_cs1	O	xSPI Chip Select for slave1 (Same as XSPIm_CS1# pin)
spi_doe[7:0]	O	xSPI Data Output Enable
spi_do[7:0]	O	xSPI Data Output
spi_di[7:0]	I	xSPI Data Input
spi_dsoe	O	xSPI Data Strobe Output Enable
spi_dso	O	xSPI Data Strobe Output

Table 37.7 Internal signals (2 of 2)

Signal name	I/O	Function
spi_dsi	I	xSPI Data Strobe Input

The bytes of Command and Address fields are transferred in highest order to lowest order sequence. The sequential bytes of Data field are transferred in lowest address to highest address order. In case of using multiple pins, the least significant bit of each byte is placed on spi_do/di[0] with each higher order bit on the successively higher numbered spi_do/di signals.

Figure 37.2 shows timing-chart for 1S-1S-1S protocol mode. The spi_do[0] signal is used for output data and the spi_di[1] signal is used for input data.

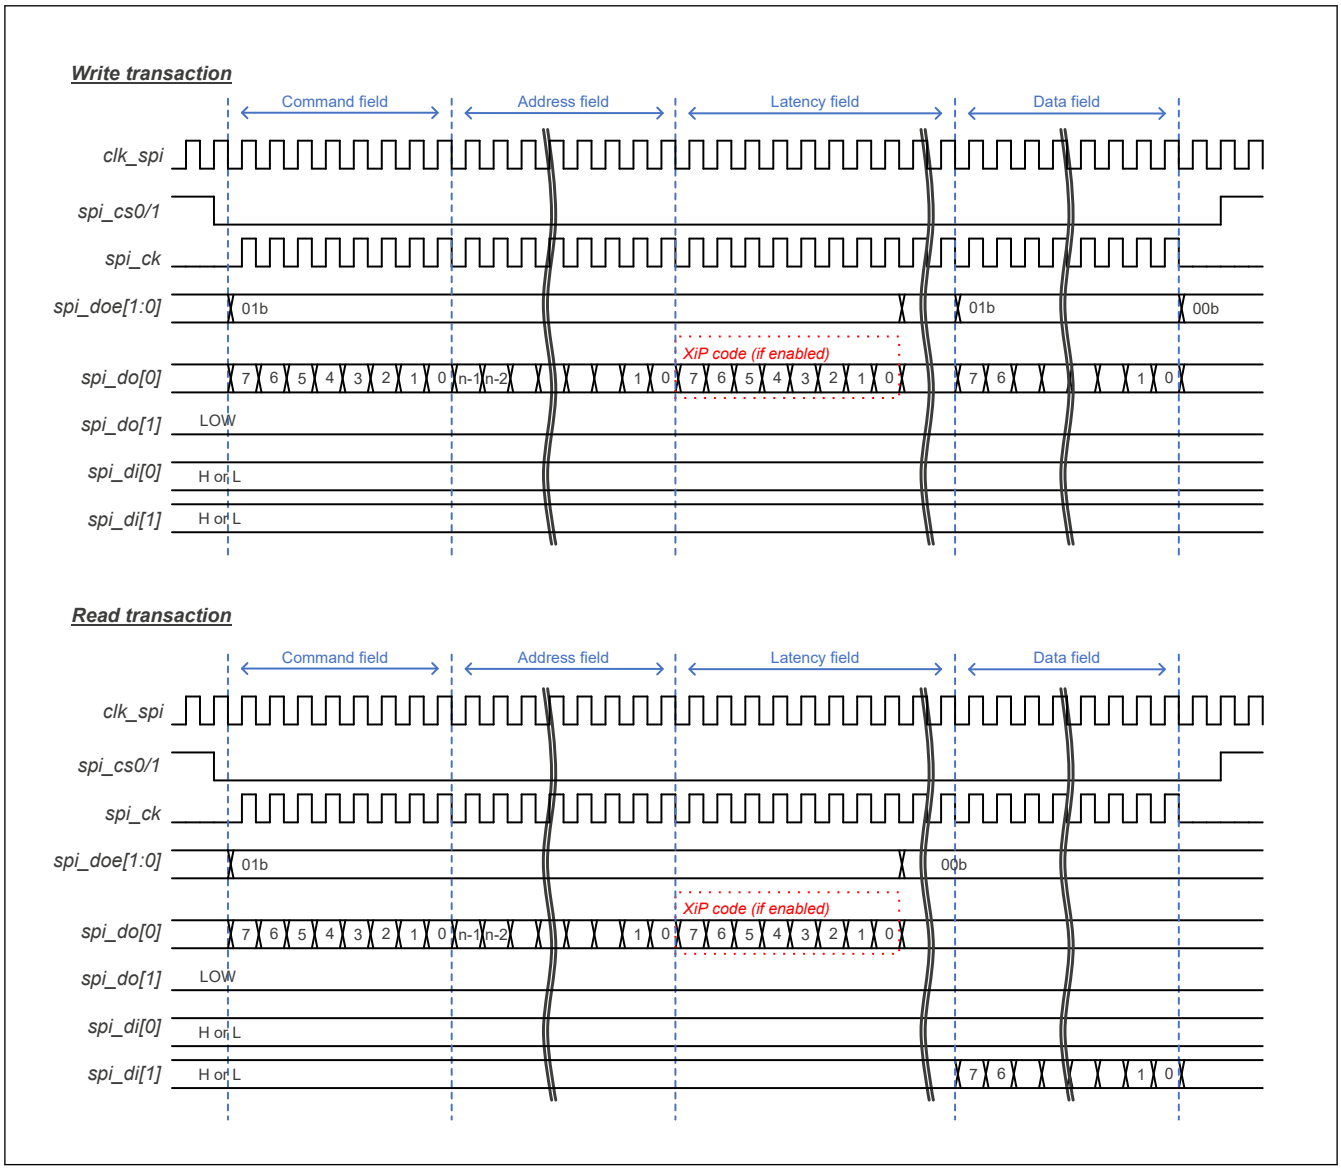


Figure 37.2 1S-1S-1S timing-chart

Figure 37.3 shows timing-chart for 1S-2S-2S protocol mode.

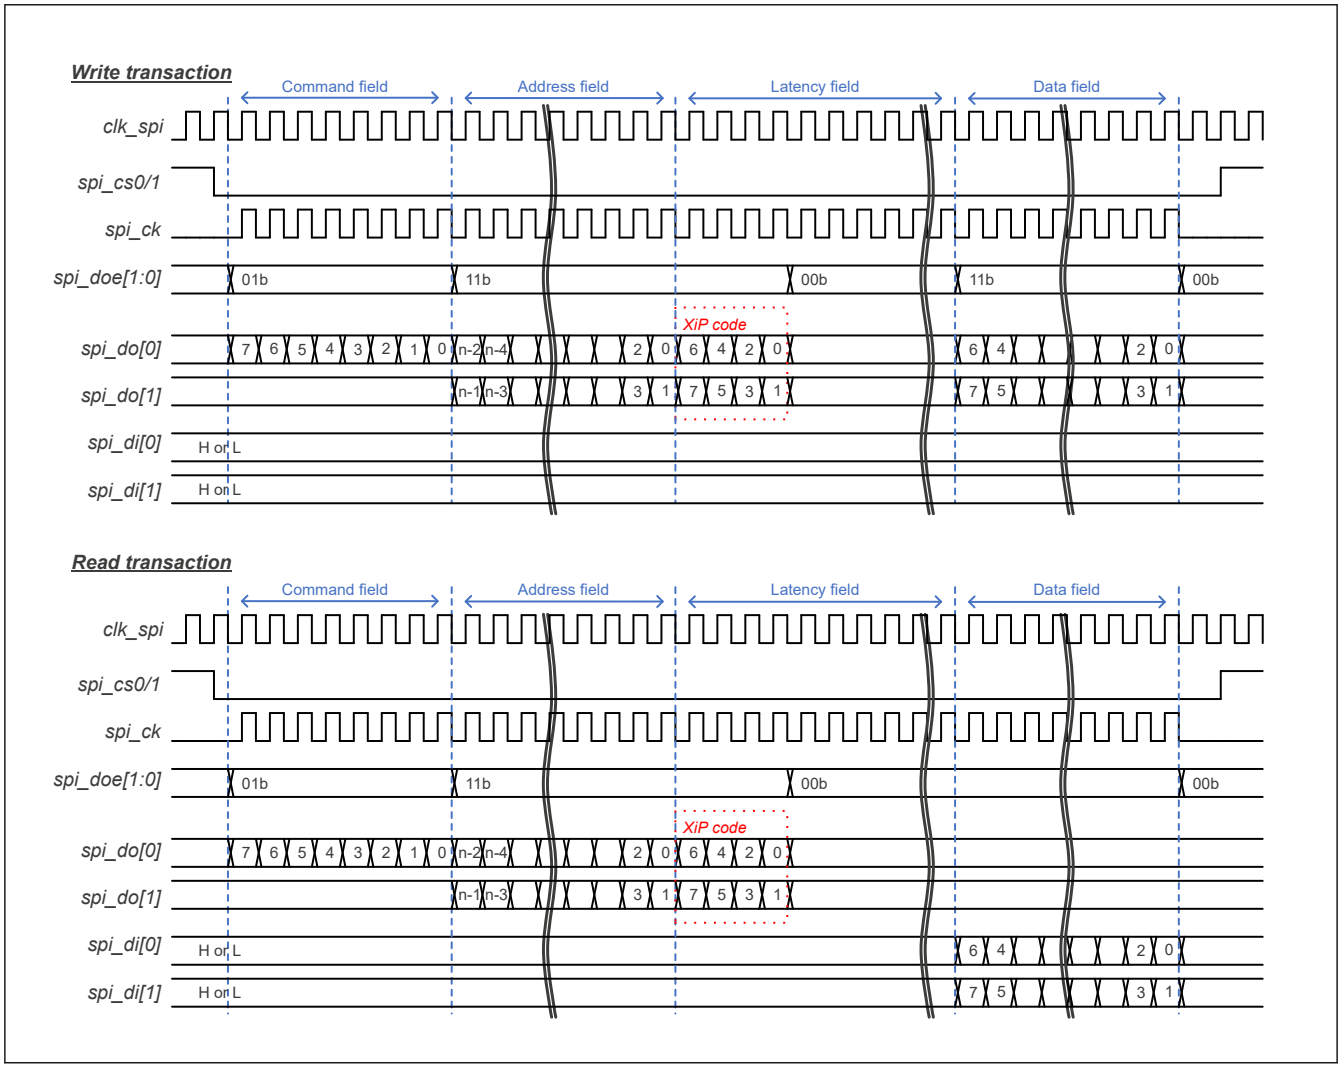

Figure 37.3 1S-2S-2S timing-chart

Figure 37.4 shows timing-chart for 4S-4D-4D protocol mode.

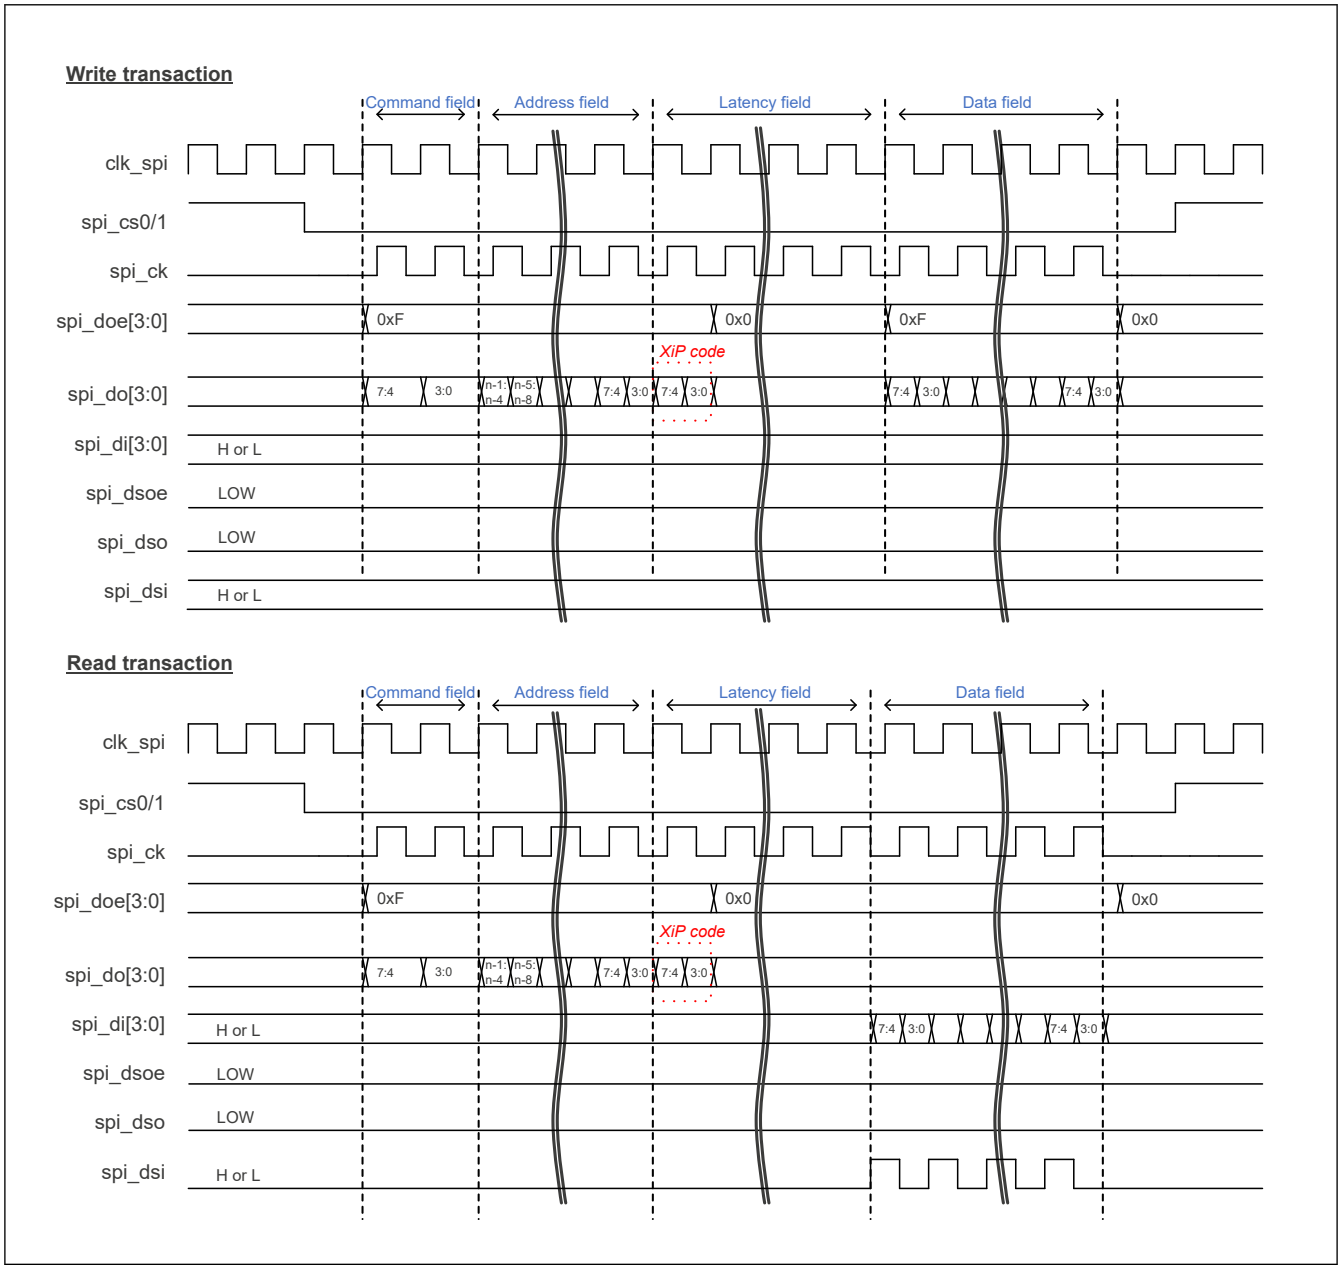

Figure 37.4 4S-4D-4D timing-chart

Figure 37.5 shows timing-chart for 8D-8D-8D profile 1.0 protocol mode. In 8D-8D-8D, the data is always transmitted with byte-pair. In case each field is odd byte, last one byte is padded with invalid data.

Figure 37.6 shows timing-chart for 8D-8D-8D profile 2.0 protocol mode. In 8D-8D-8D, the data is always transmitted with byte-pair. In case each field is odd byte, last one byte is padded with invalid data.

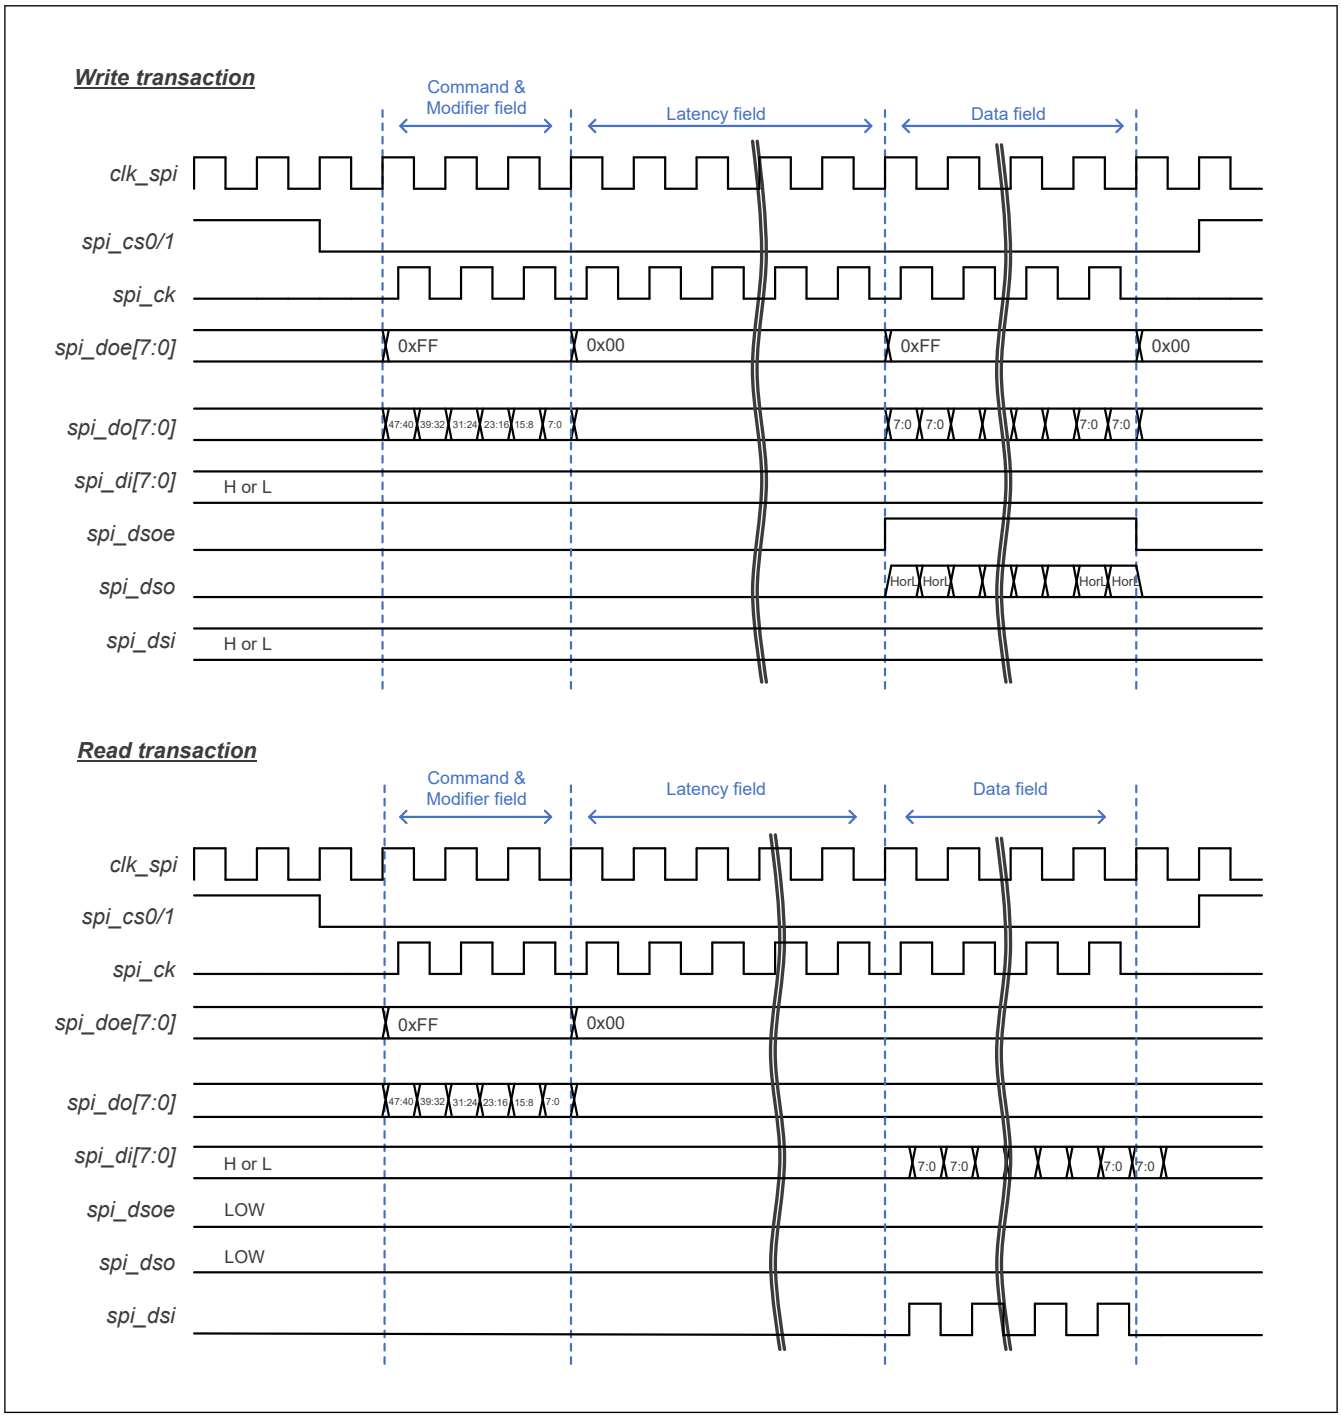

Figure 37.6 8D-8D-8D profile 2.0 timing-chart

37.4.1.2 xSPI Frame Interval

The interval between xSPI frames is configured with CS minimum idle term bits (LIOCFGCSn.CSMIN[3:0]). It depends on the specification of xSPI slave device.

37.4.1.3 xSPI Signals Timing Control

This xSPI Master supports both SDR and DDR. And it is possible to sample input data with Data-Strobe (DS) signal at SDR. For various modes and easy implementation, this xSPI Master could adjust the timing to drive/sample xSPI interface signals statically. Table 37.8 lists the summary of xSPI Interface signal timing control.

Table 37.8 Summary of xSPI signals timing control

Signal	Mode	Default operation	Timing Control (n = 0, 1)
CS (spi_cs) drive	—	Asserting 1 cycle before the rising-edge of first spi_ck	1 cycle extension for asserting with LIOCFGCSn.CSASTEX bit
		Negating 1.5 cycle after the falling-edge of last spi_ck	1 cycle extension for negating with LIOCFGCSn.CSNEGEX bit
CK (spi_ck) drive	SDR without DS SDR with DS	Reference point	—
	DDR with DS	Reference point	—
DO/DOE (spi_do/doe) drive	SDR without DS SDR with DS	Falling edge of clk_spi	0 or 0.5 cycle shift with LIOCFGCSn.SDRDRV bit
	DDR with DS	Both edges of clk_spi	—
DI (spi_di) sample	SDR without DS	Falling edge of spi_ck on expected data size	0 to 7 cycle shift (1 cycle unit) with LIOCFGCSn.SDRSMPSFT[3:0] bits 0 or 0.5 cycle shift with LIOCFGCSn.SDRSMPMD bit
	SDR with DS	Falling edge of spi_dsi signal on expected data size	Sample at rising edge with LIOCFGCSn.SDRSMPMD bit 0 to 1 cycle phase shift with WRAPCFG.DSSFTCSn[4:0] bits 0 to 7 cycle extension with LIOCFGCSn.DDRSMPEX[3:0] bits
	DDR with DS	Both edges of spi_dsi signal on expected data size	0 to 1 cycle phase shift with WRAPCFG.DSSFTCSn[4:0] bits 0 to 7 cycle extension with LIOCFGCSn.DDRSMPEX[3:0] bits

Note: In DDR on xSPI protocol, CK or DS should be aligned for center of data. It means to shift the phase by 0.25 cycle (90 degrees). This xSPI master supports to adjust this phase depending on the usage conditions.

Figure 37.7 shows the default operation and timing control for SDR without DS.

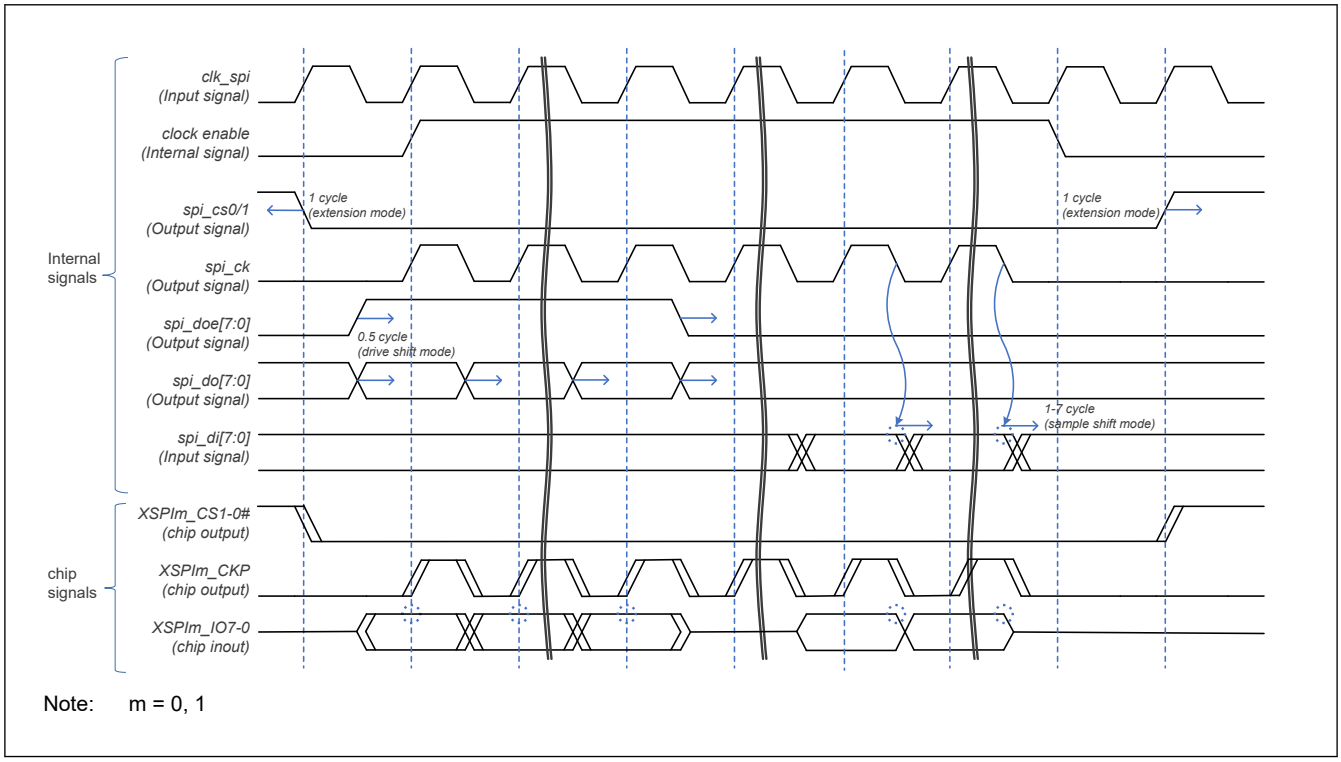

Figure 37.7 Timing control for SDR without DS

Figure 37.8 shows the default operation and timing control for SDR with DS.

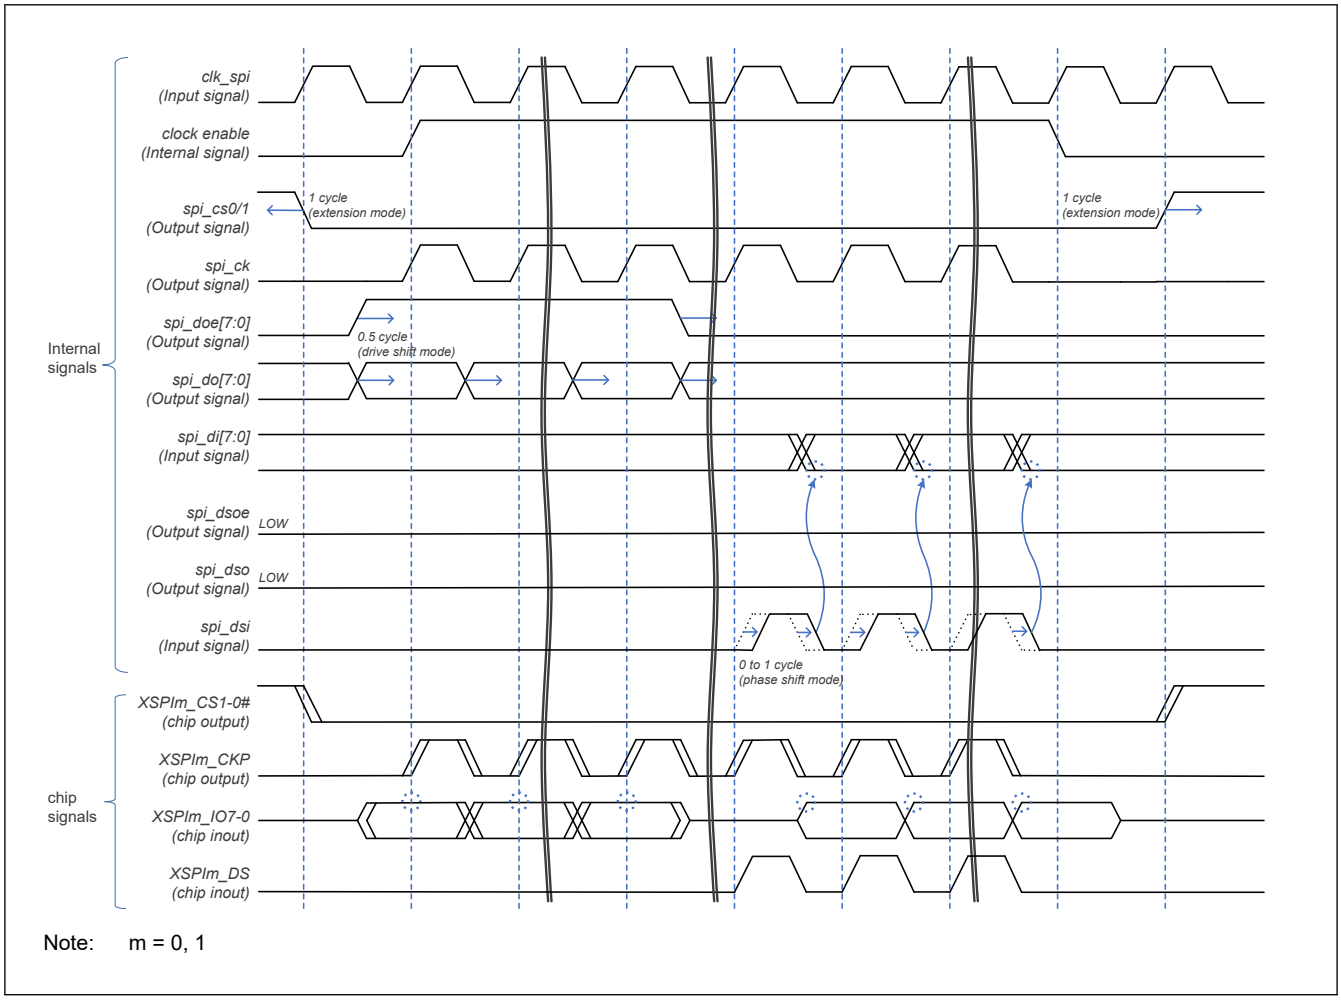

Figure 37.8 Timing control for SDR with DS

Figure 37.9 shows the default operation and timing control for DDR with DS.

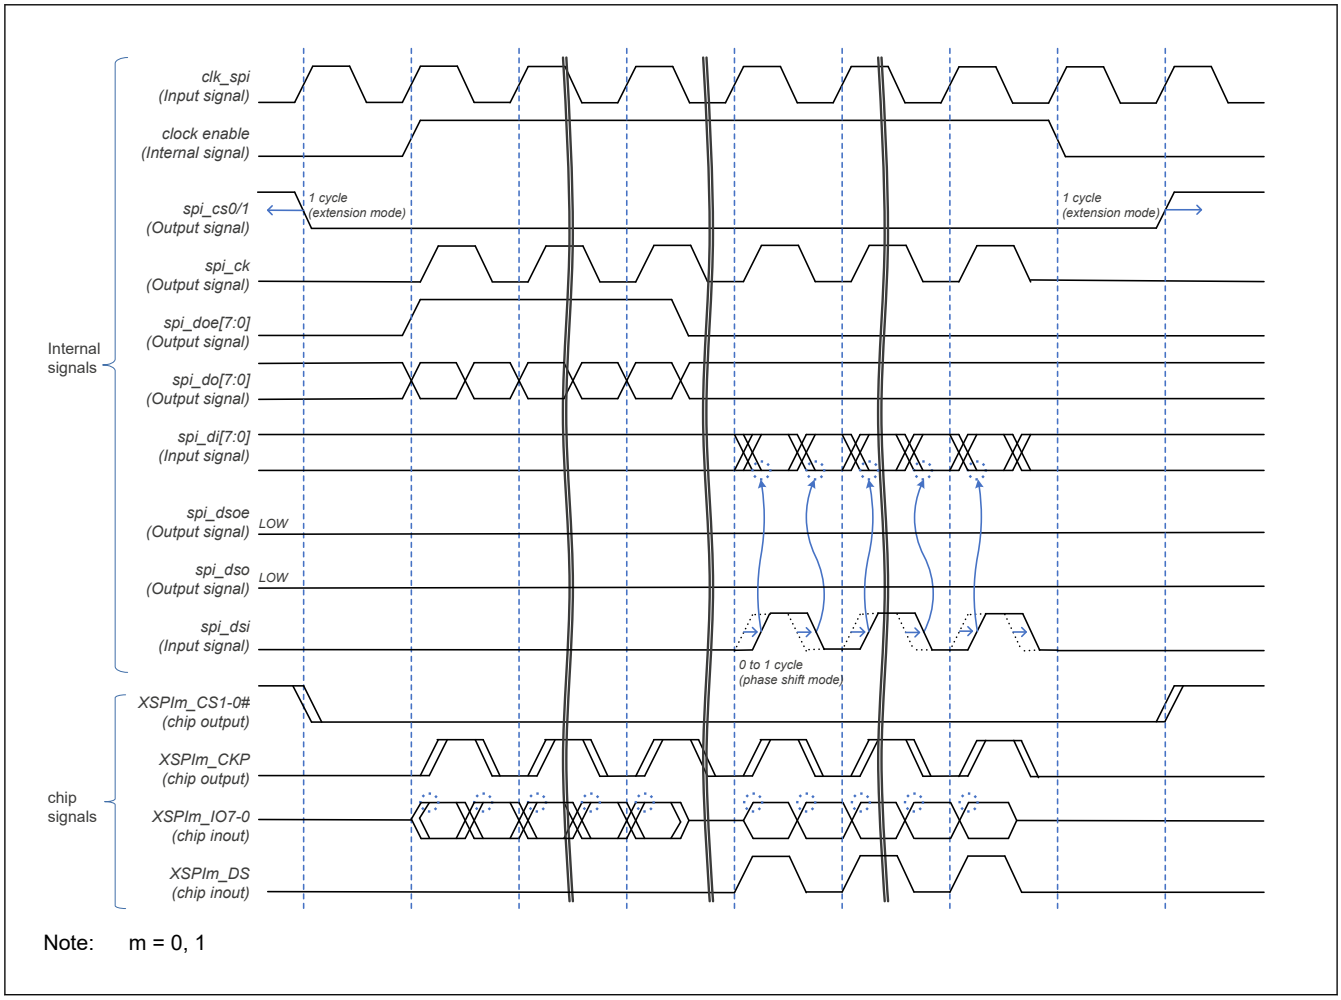

Figure 37.9 Timing control for DDR with DS

37.4.2 Manual-command

This section describes the manual-command mode. The manual-command has two functional modes: direct mode and periodic mode.

37.4.2.1 Direct Mode

This mode sequentially can issue up to four xSPI transactions configured and requested by Software. A series of transaction can be issued by a transaction request (CDCTL0.TRREQ = 1 with PERMD = 0). The number of transactions (CDCTL0.TRNUM[1:0]) can be configured up to 4. It can be used to change the mode or read the status of xSPI slave device.

Table 37.9 lists the configured register bits for direct manual-command. The operating flow is illustrated in Figure 37.23.

Table 37.9 Manual-command configuration for direct mode (1 of 2)

Transaction	Transaction type	Command	Command size	Address	Address size	Data (x = 0, 1)	Data size	Latency cycle
1st Transaction	CDTBUF0. TRTYPE	CDTBUF0. CMD[15:0]	CDTBUF0. CMDSIZE[1:0]	CDABUF0. ADD[31:0]	CDTBUF0. ADDSIZE[2:0]	CDDxBUF0. DATA[31:0]	CDTBUF0. DATASIZE[3:0]	CDTBUF0. LATE[4:0]
2nd Transaction	CDTBUF1. TRTYPE	CDTBUF1. CMD[15:0]	CDTBUF1. CMDSIZE[1:0]	CDABUF1. ADD[31:0]	CDTBUF1. ADDSIZE[2:0]	CDDxBUF1. DATA[31:0]	CDTBUF1. DATASIZE[3:0]	CDTBUF1. LATE[4:0]

Table 37.9 Manual-command configuration for direct mode (2 of 2)

Transaction	Transaction type	Command	Command size	Address	Address size	Data (x = 0, 1)	Data size	Latency cycle
3rd Transaction	CDTBUF2.TRTYPE	CDTBUF2.CMD[15:0]	CDTBUF2.CMDSIZE[1:0]	CDABUF2.ADD[31:0]	CDTBUF2.ADDSIZE[2:0]	CDDxBUF2.DATA[31:0]	CDTBUF2.DATASIZE[3:0]	CDTBUF2.LATE[4:0]
4th Transaction	CDTBUF3.TRTYPE	CDTBUF3.CMD[15:0]	CDTBUF3.CMDSIZE[1:0]	CDABUF3.ADD[31:0]	CDTBUF3.ADDSIZE[2:0]	CDDxBUF3.DATA[31:0]	CDTBUF3.DATASIZE[3:0]	CDTBUF3.LATE[4:0]

37.4.2.2 Periodic Mode

This mode periodically issues an xSPI read transaction configured and requested by Software. And it can compare the read value up to 4 bytes with expected value. The transaction is issued by a transaction request (CDCTL0.TRREQ = 1 with PERMD = 1). It can be used to alternate the status polling operation of xSPI slave device.

The periodic term is configured in Periodic transaction interval bits (CDCTL0.PERITV[4:0]). The expected value is configured in Periodic transaction expected and masked value bits (CDCTL1.PEREXP[31:0] and CDCTL2.PERMSK[31:0]). Table 37.10 lists the configured register bits for periodic manual-command. The operating flow is illustrated in Figure 37.24.

Table 37.10 Manual-command configuration for periodic mode

Transaction	Transaction type	Command	Command size	Address	Address size	Data (x = 0, 1)	Data size	Latency cycle
Read Transaction	CDTBUF0.TRTYPE	CDTBUF0.CMD[15:0]	CDTBUF0.CMDSIZE[1:0]	CDABUF0.ADD[31:0]	CDTBUF0.ADDSIZE[2:0]	CDDxBUF0.DATA[31:0]	CDTBUF0.DATASIZE[3:0]	CDTBUF0.LATE[4:0]

Note: In this mode, it is possible to repeat multiple commands by configuring multiple buffers. In the case, only the last command shall be Read transaction and the others shall be Write transaction. The read data of last command is compared with expected value.

37.4.3 Memory-mapping

This section describes the memory-mapping mode. This mode automatically converts AXI access for pre-configured memory area into xSPI transaction.

37.4.3.1 Configuration

In this operation, the payload of address and data field are delivered from AXI signals. The information of command field and size are delivered from the configured register bits. Table 37.11 lists the register bits configured for memory-mapping.

Table 37.11 Memory-mapping configuration for memory area access (n = 0, 1) (1 of 2)

AXI Transaction	Format Change mode	Command	Command size	Address size	Latency cycle
Write for slave n memory area	Normal	CMCFG2CSn.WRCMD[15:8]	1 byte	CMCFG0CSn.ADDSIZE[1:0]	CMCFG2CSn.WRLATE[4:0]
	8D-8D-8D profile 1.0	CMCFG2CSn.WRCMD[15:0]	2 bytes		
	8D-8D-8D profile 2.0 Command Modifier	CMCFG2CSn.WRCMD[15:8]	1 byte	5 bytes	
	8D-8D-8D profile 2.0 Extended Command Modifier	CMCFG2CSn.WRCMD[15:13]	3 bits	45 bits	

Table 37.11 Memory-mapping configuration for memory area access (n = 0, 1) (2 of 2)

AXI Transaction	Format Change mode	Command	Command size	Address size	Latency cycle
Read for slave n memory area	Normal	CMCFG1CSn. RDCMD[15:8]	1 byte	CMCFG0CSn. ADDSIZE[1:0]	CMCFG1CSn. RDLATE[4:0]
	8D-8D-8D profile 1.0	CMCFG1CSn. RDCMD[15:0]	2 bytes		
	8D-8D-8D profile 2.0 Command Modifier	CMCFG1CSn. RDCMD[15:8]	1 byte	5 bytes	
	8D-8D-8D profile 2.0 Extended Command Modifier	CMCFG1CSn. RDCMD[15:13]	3 bits	45 bits	

Note: The MSByte of Address can be replaced with Address Replace Enable and Code bits (CMCFG0CSn.ADDRPEN[7:0] / ADDRPCD[7:0]).

37.4.3.2 Write Access Operation

In AXI write access for memory area, this xSPI Master stores all payload data in internal bridge buffer and then issues a write transaction into xSPI slave. Figure 37.10 shows the operation summary.

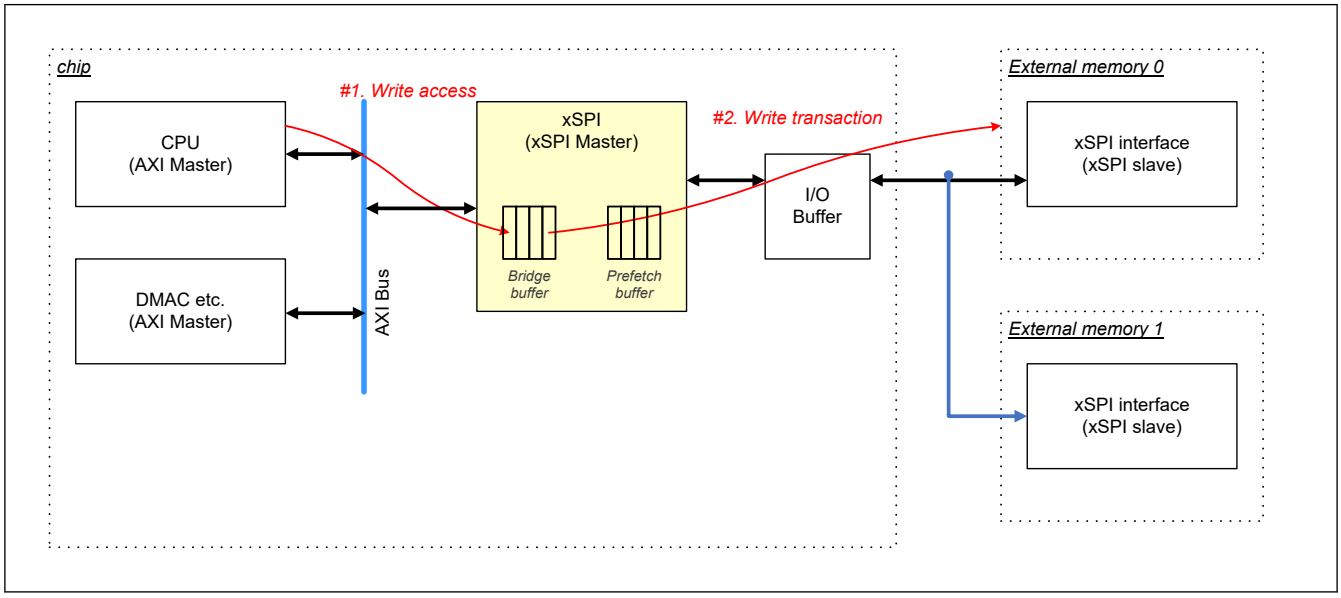

Figure 37.10 Write access for memory area

The operation of xSPI bus changes depending on AXI burst type. When the burst type is single type or incremental type, one AXI transaction triggers for one xSPI frame. When the burst type is wrap type and the CMCFG0CSx.WPBSTMD is 0, one AXI transaction triggers two xSPI frames. Figure 37.11 shows the relationship between AXI and xSPI frame.

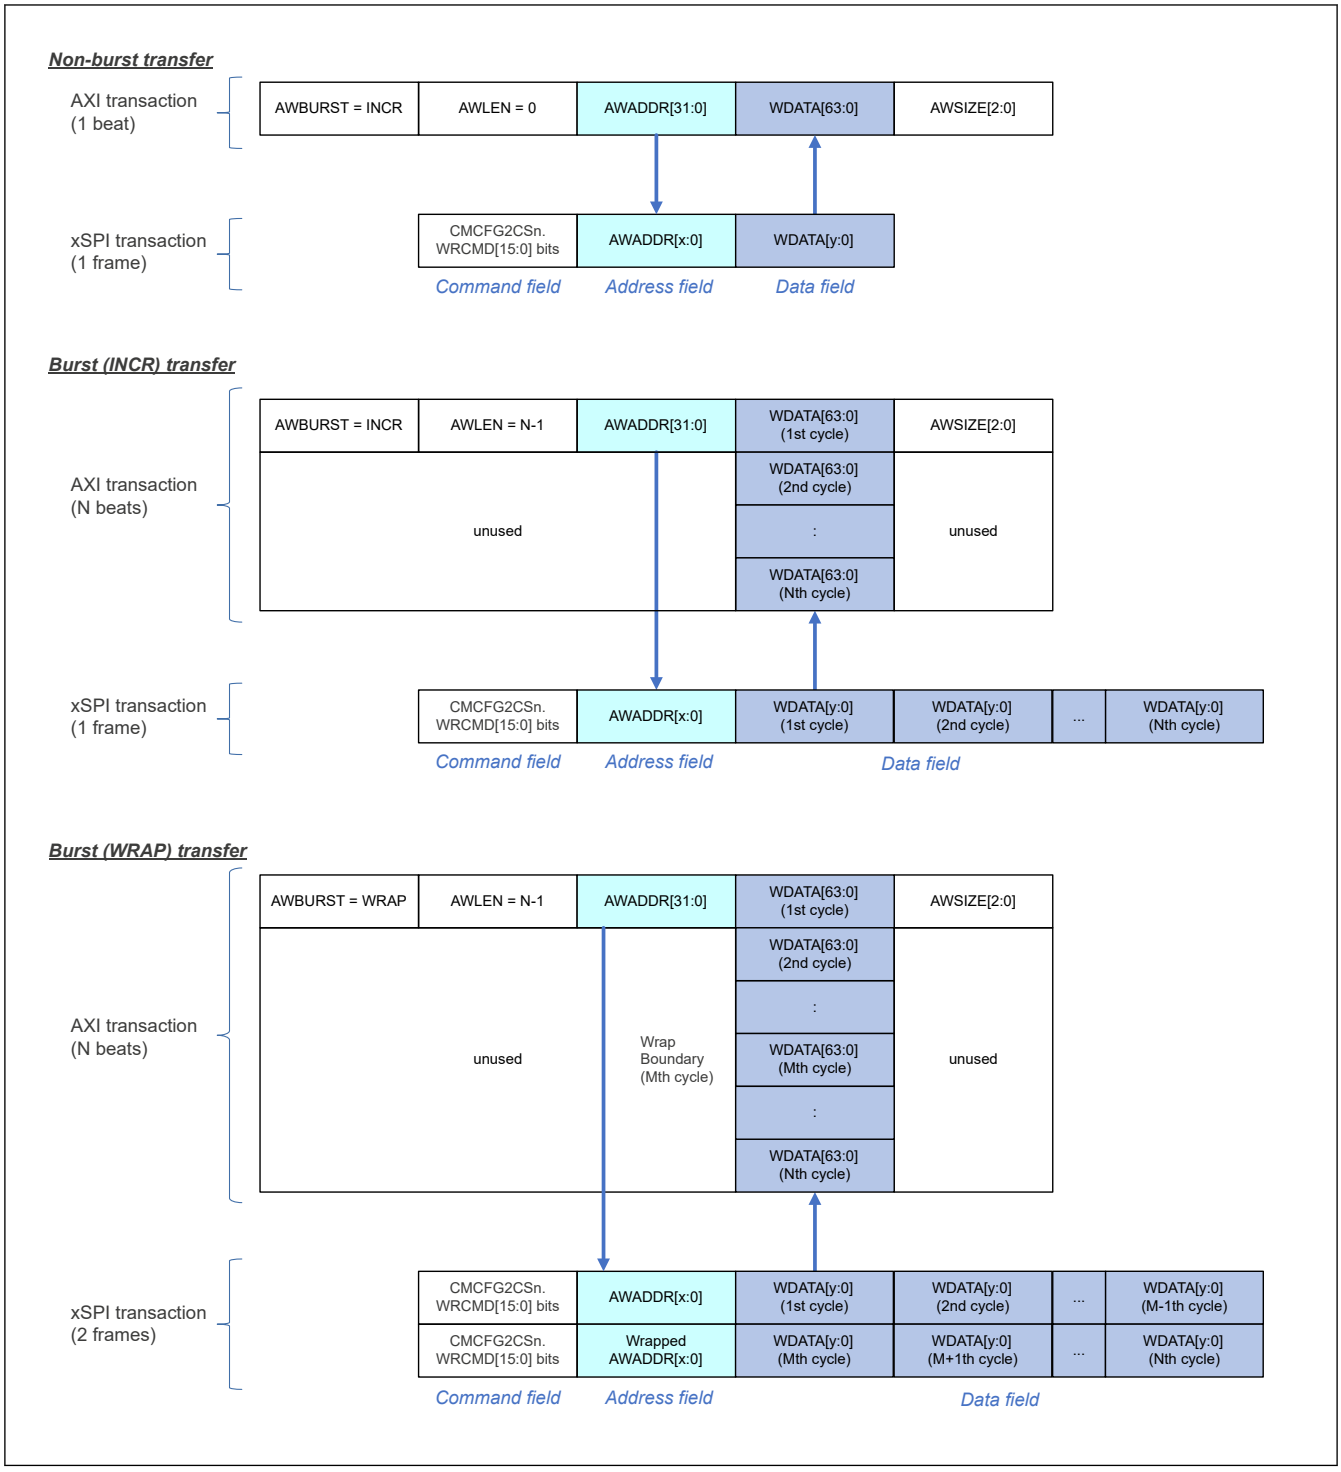

Figure 37.11 xSPI frame format in write access (Normal format)

37.4.3.3 Combination Function

In AXI write access for memory area, this xSPI master has the function to combinate the write data for high throughput on xSPI bus. When enabled this function (BMCFG.MWRCOMB = 1), this xSPI master transmits an xSPI frame with the selected size while the sequential address is incremental[*1]. When one of the below conditions is detected, even though not reaching to the target size (BMCFG.MWRSIZE), this xSPI master transmits the pending data into xSPI bus.

- Non-incremental address is detected.
- Different burst type is detected.
- Read transaction is detected.

- Access for different slave is detected.
- Memory Write Data Push bit (BMCTL1.MWRPUSHCHx) is set.

Note 1. The access which comply all below condition is considered as incremental address.
- Transaction type is INCR.
- The access's start address is continuous to the previous last write address.
  - The access's start position of WSTRB is treated as start address.
  - Previous access's last WSTRB is treated last write address.

This function could be useful for any slave device to request a chunk of data at a time. In the case, AXI Master should continue to provide the fixed data size with incremental address. Ex. there is any device to request to write in page unit.

Note that combination function should not be used in case of programming to Serial Flash since write enable command is basically need before data programming and it may cause the unexpected order of the transaction.

Figure 37.12 shows the operation when enable the combination function.

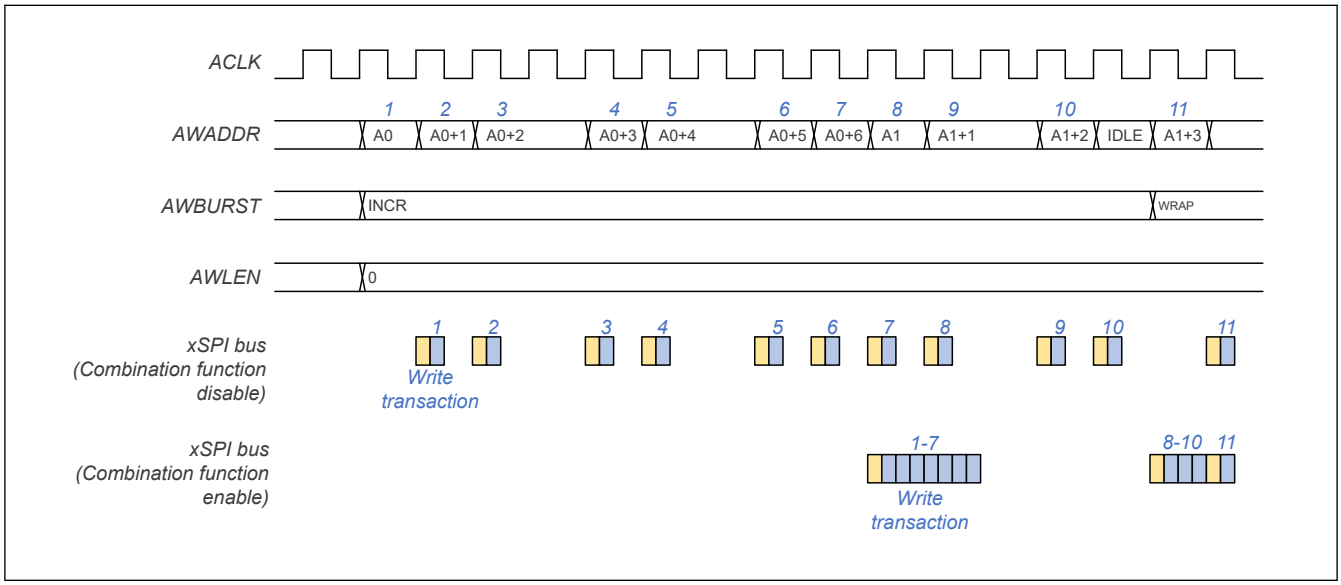

Figure 37.12 Combination function

Figure 37.13 shows data combined example with AXI access.

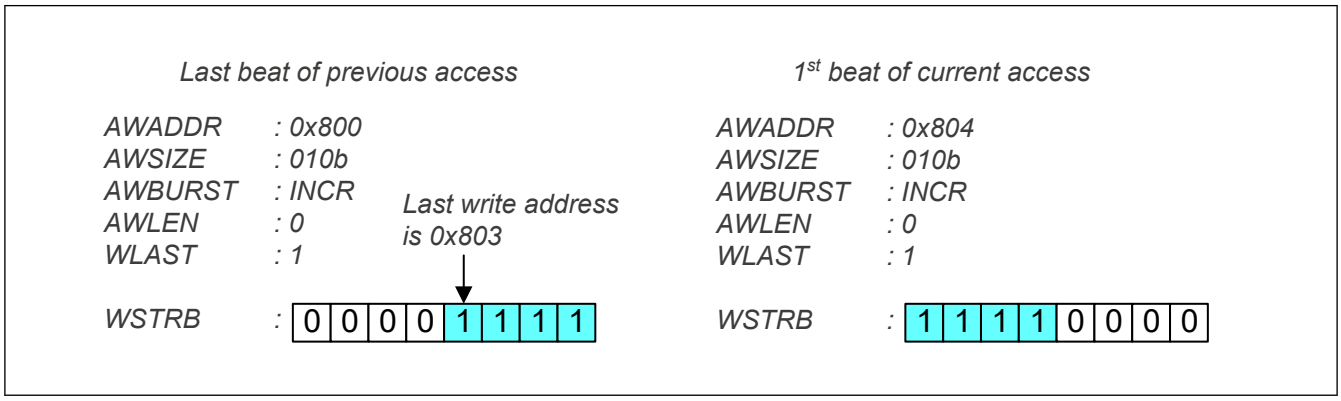

Figure 37.13 Data combined example with AXI access

37.4.3.4 Read Access Operation

In AXI read access for memory area, soon after detected the read access, this xSPI Master issues a read transaction into xSPI slave. Figure 37.14 shows the operation summary.

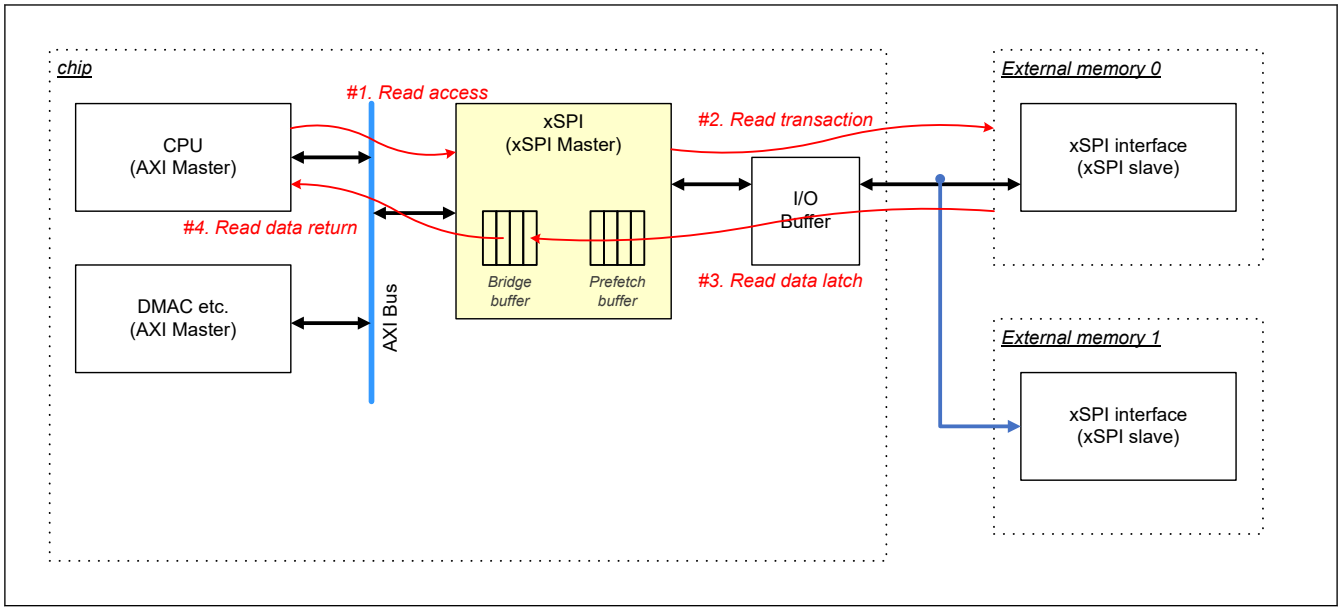

Figure 37.14 Read access for memory area

The operation of xSPI bus changes depending on burst type. When the type is single or increment type, one AXI read transaction triggers one xSPI frame. When the type is wrap type and the CMCFG0CSx.WPBSTMD is 0, one AXI read transactions triggers two xSPI frame. Figure 37.15 shows the relationship between AXI and xSPI frame.

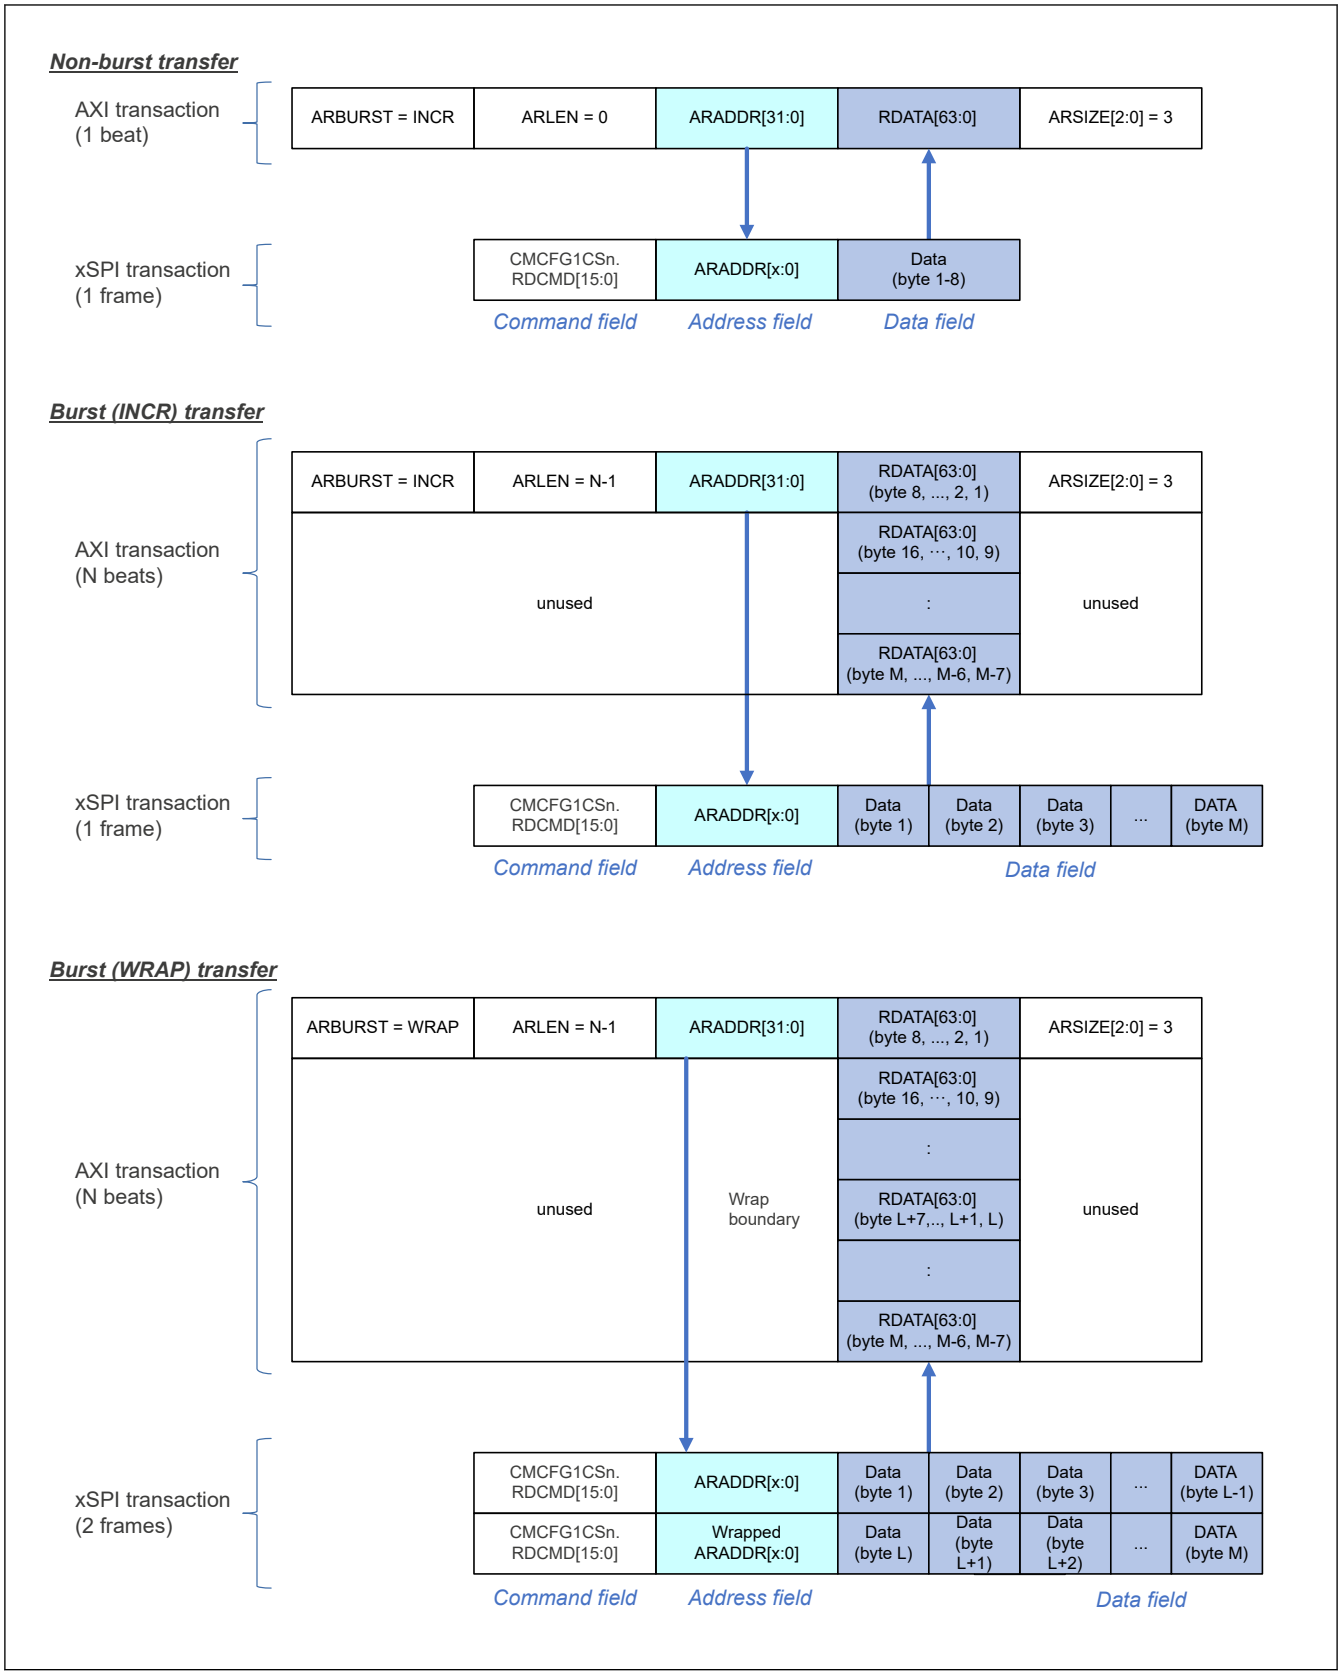

Figure 37.15 xSPI frame format in read access (Normal format)

37.4.3.5 Prefetch Function

In AXI read access for memory area, this xSPI Master has the function to prefetch the read data for lower latency. When enabled this function (BMCFG.PREEN = 1), this xSPI Master continues to read the incremental address and store the read

data from xSPI slave in internal prefetch buffer. And the following AXI read access searches for prefetch buffer. If found the target read data in prefetch buffer, this xSPI Master returns the data from prefetch buffer. If not found, this xSPI Master clears prefetch buffer and newly issues a read transaction into xSPI slave. This function is effective in application such as the consecutive read addresses are close. But it is not effective in application such as the consecutive read addresses are not incremental because xSPI read frame for prefetch uses xSPI bus. Figure 37.16 shows the operation summary.

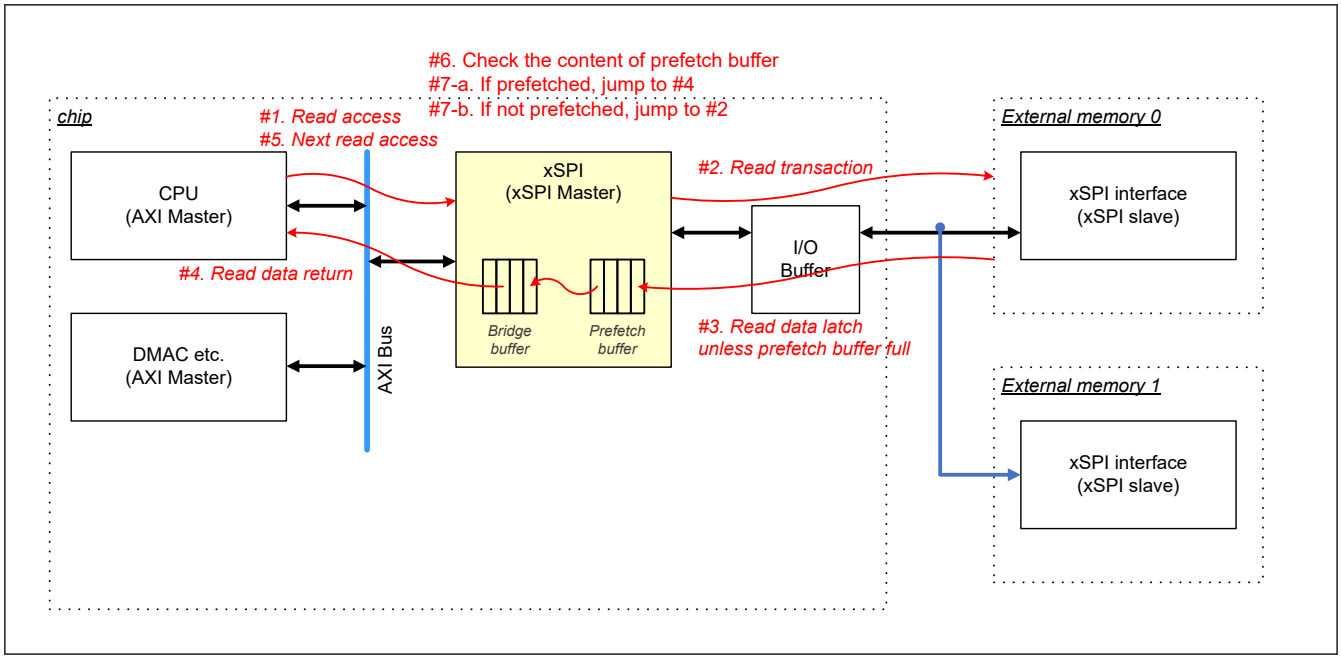

Figure 37.16 Read access for memory area with prefetch enabled

Note: When enabled this prefetch function, AXI Master could read from not a slave device but the internal prefetch buffer. When accessed to the same address from multiple AXI Masters, this xSPI Master does not guarantee to read the latest data. If AXI Master wish to read the latest data from a slave device, it should read after cleared the prefetch buffer (BMCTL1.PBUFCLR).

Note: Prefetch buffer is implemented as FIFO-based, and when read access is issued, the data before the access address is discarded from the buffer. And when next access is issued to the region which is discarded at previous access, this module issues the xSPI read access again to fill the prefetch buffer.

37.4.3.6 XiP Mode

Some slave devices have a mode (XiP mode) in which the command phase is not required for lower latency. While in this mode, the xSPI master skips sending the command and the slave device implicitly performs the command that was executed in the previous transaction. When enabled XiP mode bit (CMCTL.XIPEN = 1), this xSPI master inserts XiP enter code (CMCTL.XIPENCODE[7:0]) in latency field. When disabled XiP mode bit (CMCTL.XIPEN = 0), this xSPI master inserts XiP exit code (CMCTL.XIPEXCODE[7:0]) in latency field. This function is available only for memory-mapping mode.

And when transmitting XiP disable pattern, this xSPI master clears XiP mode bit and disables XiP mode.

Note: In case of no cycle inserting XiP code in latency field, this xSPI Master could not insert XiP code.

Note: XiP mode could be used only for unidirectional access to a slave. The write transaction and read transaction should be separated.

37.4.4 Pattern Control

This xSPI Master has the function to transmit any pattern which is not xSPI frame format. It starts to transmit by the pattern issue trigger bits (LPCTL0-1.PATREQ). It is possible to transmit 3 types of patterns.

37.4.4.1 XiP Disable Pattern

XiP Disable pattern transmits any pattern with the configured length and value (LPCTL0.XD1LEN[4:0] / XD1VAL / XD2LEN[4:0] / XD2VAL). It uses spi_ck, spi_doe/do signals. The number of output pin can be configured by XiP Disable

pattern pin bits (LPCTL0.XDPIN[1:0]). It may be used to disable XiP mode for legacy SPI. Figure 37.17 shows the timing-chart.

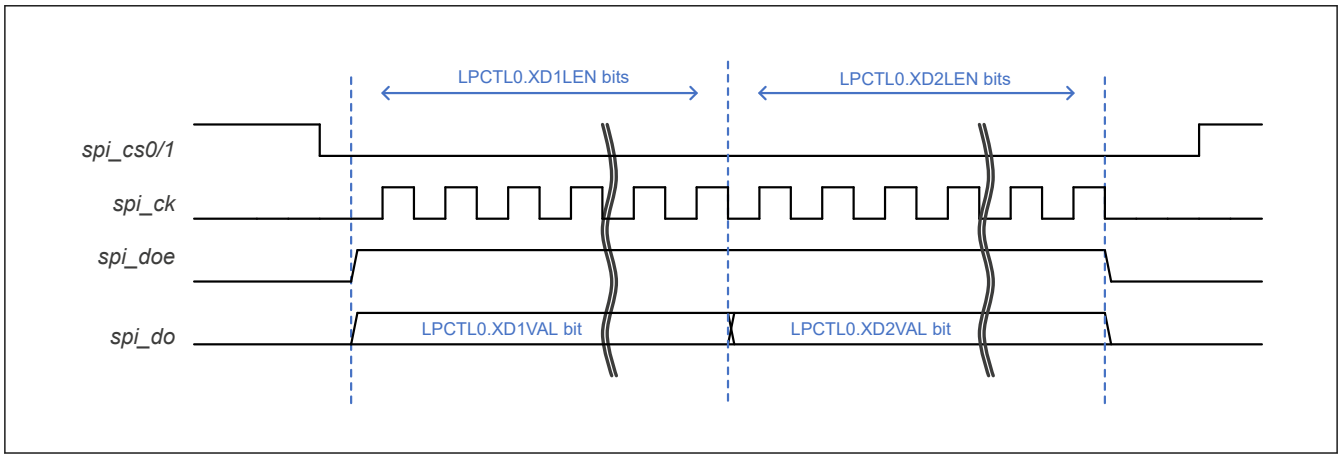

Figure 37.17 XiP Disable pattern

37.4.4.2 Reset Pattern

Reset pattern transmits the pattern specified in Serial Flash Reset Signaling Protocol. CS Low/High width is configured with Reset Pattern Length bits (LPCTL1.RSTWID[2:0]). xSPI slave will sample the data input at the rising edge of CS. Setup time for data output is configured with Reset pattern data output setup time bits (LPCTL1.RSTSU[2:0]). The setup time should be less than Reset pattern width always. Figure 37.18 shows the timing-chart.

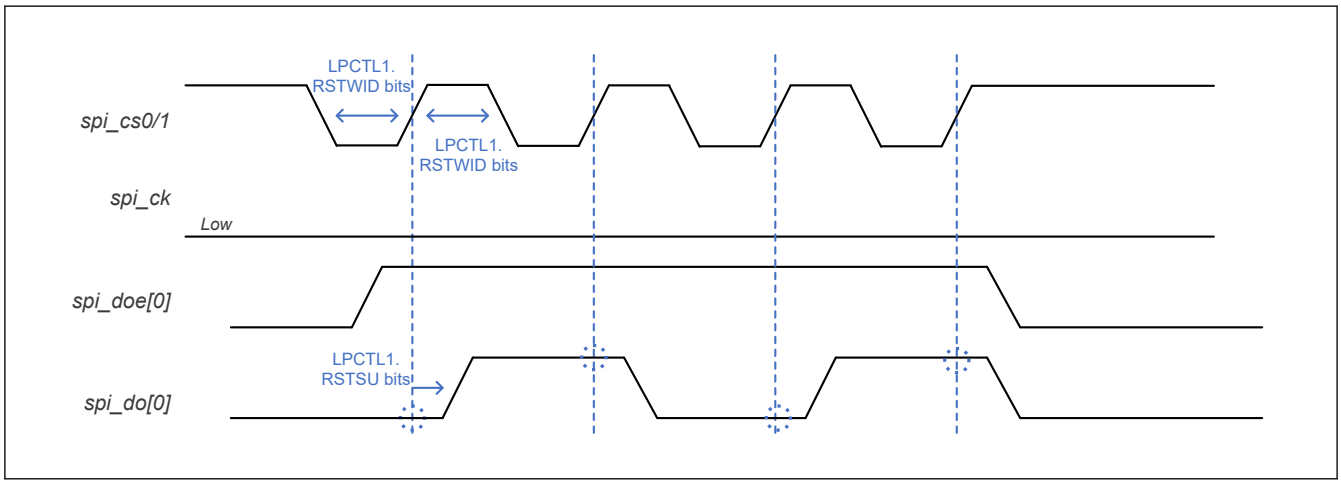

Figure 37.18 Reset pattern

Note: In the protocol, CS Low/High width is defined as minimum 500 ns and Setup time is defined as minimum 6 ns.

37.4.4.3 CS Only Pattern

CS Only pattern activates CS port with the configured length bits (LPCTL1.RSTWID[2:0]). It may be used to resume from Deep Power Down state. Figure 37.19 shows the timing-chart.

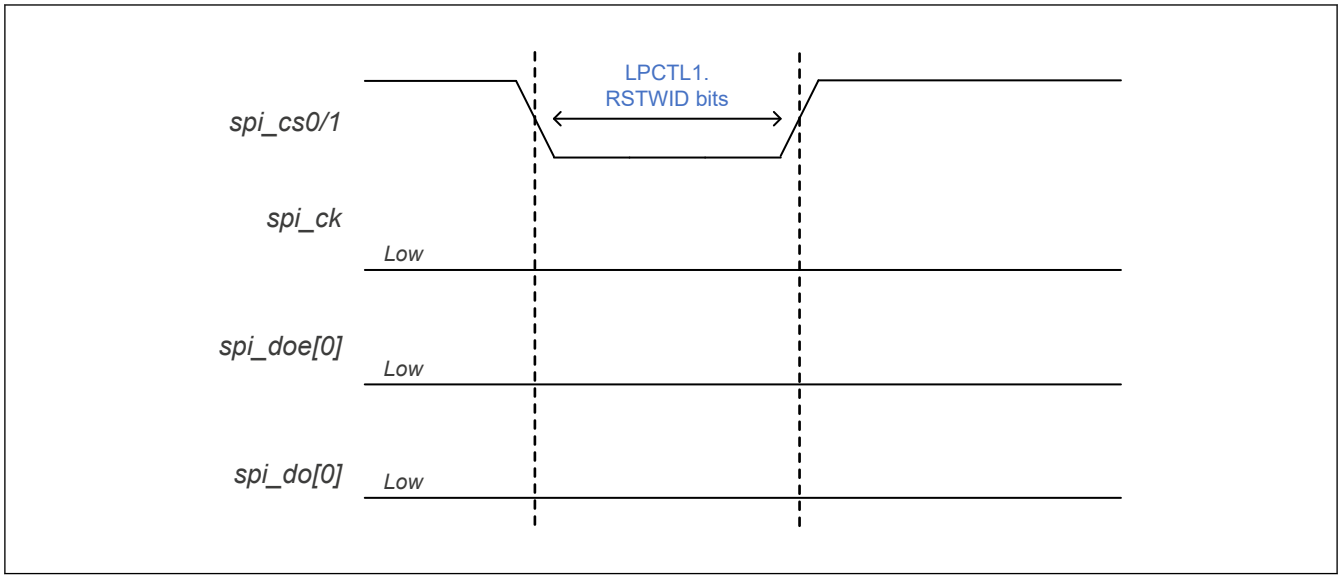

Figure 37.19 CS Only pattern

37.4.5 Integrity Checking

This xSPI Master can detect some errors. Table 37.12 lists the error list and the detail behavior.

When reset of xSPI master is needed due to fatal error, set module reset register (MRCTLA) to reset xSPI master. After confirming it is reset surely, release module reset.

Table 37.12 Error list

Error type	Event	Flag bit	Note (action)
Calibration failed	When the read data did not match the expected value during automatic calibration	INTS. CAFAILCS0-1	It results in writing unexpected data to xSPI slave.
AXI bus error	When an error response occurred on AXI slave interface for memory-mapping	INTS. BUSERR	This is a fatal error. This xSPI master shall be initialized.
ECC error detection	When detected the falling edge on ECSn# port It can be useful only for xSPI slave with ECC detection function.	INTS. ECSCS0-1	Only notify the error event of xSPI slave.
DS timeout	When DS does not toggle in read transaction with using DS	INTS. DSTOCS0-1	Both xSPI master and xSPI slave should be reset for fatal error.
Periodic transaction timeout	When the read value does not match with the expected value in periodic manual-command mode	INTS. PERTO	Depending on the status of function

37.4.6 Interrupts

This xSPI Master has an interrupt port.

It can monitor with Interrupt Status Register (INTS). In case of initialization phase, it can be programmable with Interrupt Enable register (INTE). Table 37.13 lists the related register bit.

Table 37.13 xSPI interrupt sources

Name	Interrupt Sources	CPU0 GIC Request	CPU1 GIC Request	DMAC Activation
XSPIm_INT	Interrupt	Possible	Possible	Not possible
XSPIm_INTERR	Error interrupt	Possible	Possible	Not possible

Note: m = 0, 1

Table 37.14 Interrupt register bit

Flag bit	Enable bit	Clear bit	Interrupt Sources (m = 0, 1)
CASUCCS1	CASUCCS1E	CASUCCS1C	XSPIm_INT
CASUCCS0	CASUCCS0E	CASUCCS0C	
CAFAILCS1	CAFAILCS1E	CAFAILCS1C	XSPIm_INTERR
CAFAILCS0	CAFAILCS0E	CAFAILCS0C	
BUSERR	BUSERRE	BUSERRC	XSPIm_INTERR

Figure 37.28 shows flow of XiP mode enable/disable.

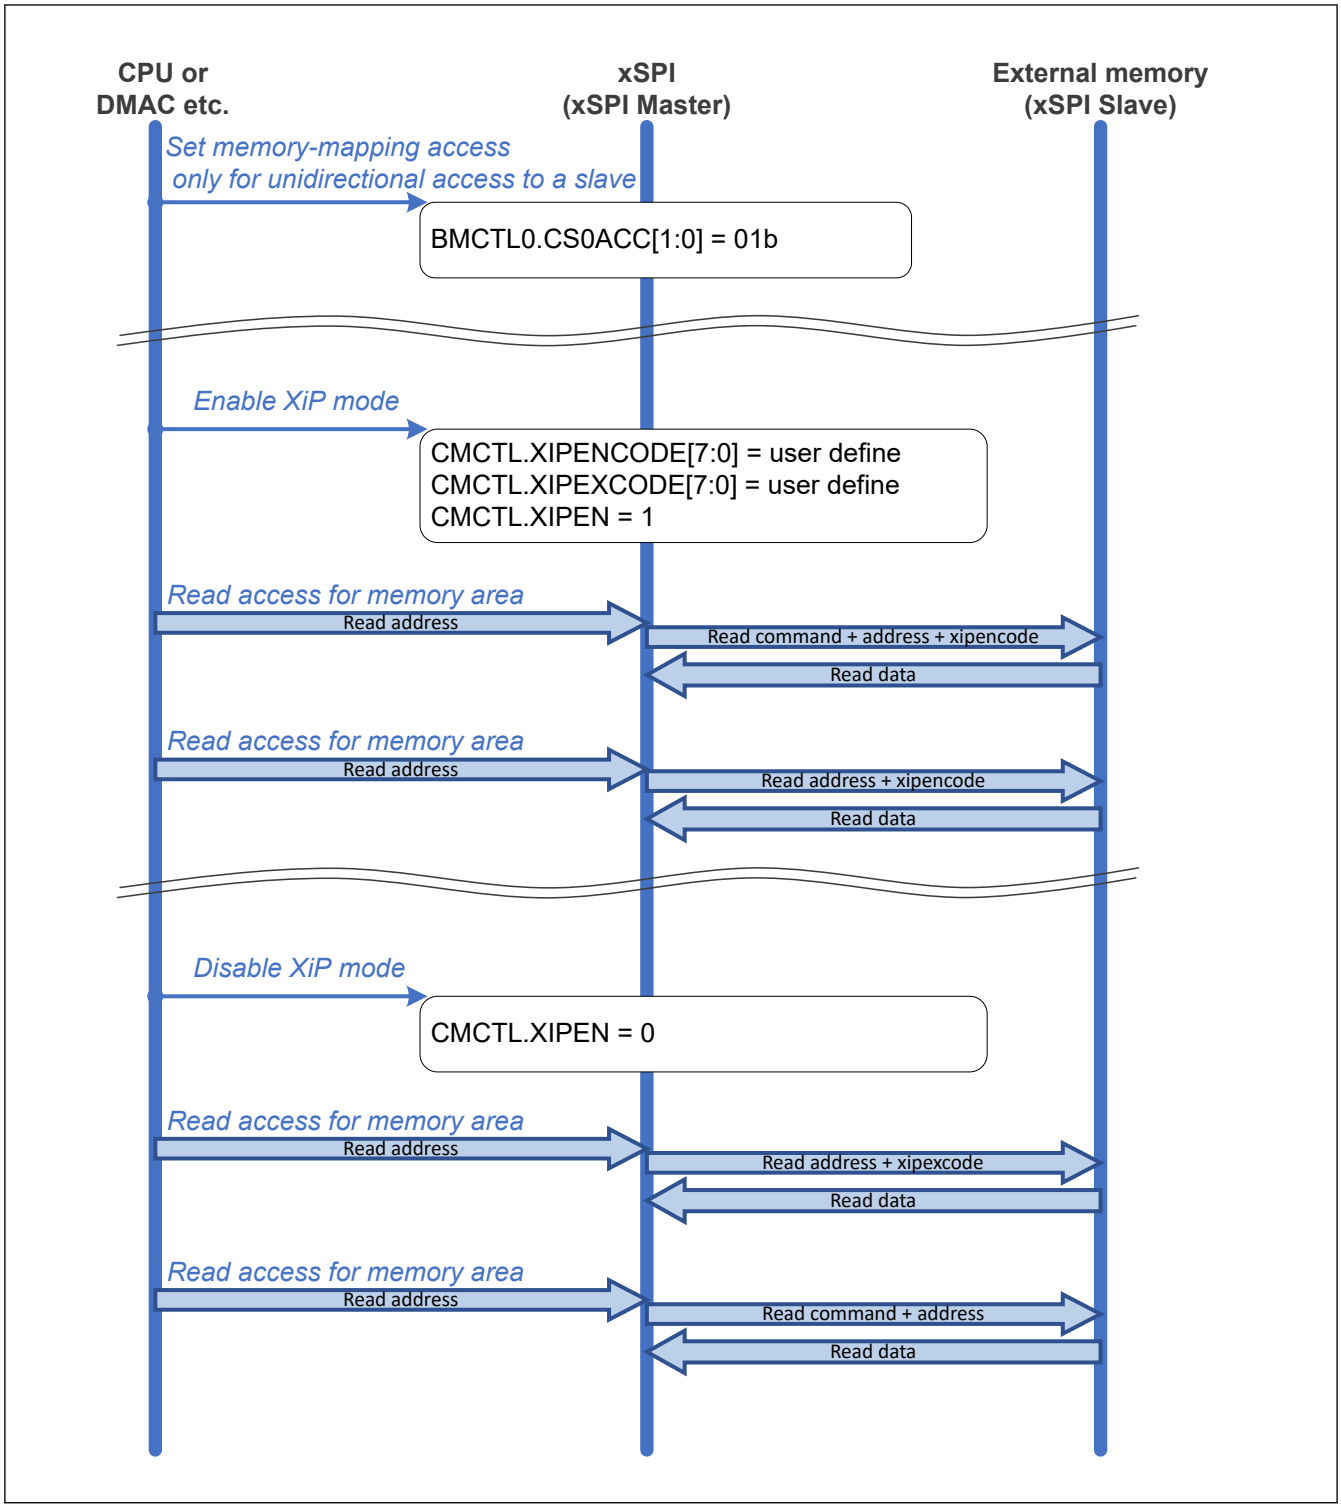

Figure 37.28 Flow of XiP mode enable/disable

37.4.8 Usage Notes

- If prefetch function is enabled and xSPI CS1 Start Address Register and CSn End Address Register (CS1STRAD and CSnENDAD) is not set correctly compared to size of connected slave device, xSPI master may access outside of the slave device address. It may cause DS timeout in case of 8D-8D-8D. Make sure to set the adequate start address and end address to CS1STRAD and CSnENDAD registers considering the size of the connected slave device.
- DDR access without DS is not supported.

38. CRC Operation Unit (CRC)

38.1 Overview

Cyclic redundancy check (CRC) operation units generate CRC codes. Table 38.1 lists the specifications of the CRC operation unit, and Figure 38.1 shows a block diagram of the CRC operation unit.

Table 38.1 CRC specifications

Parameter	Description	
Number of channels	2 channels	
Data size	8 bits	32 bits
Data for CRC calculation*1	CRC codes are generated for any desired data in 8n-bit units (where n is a natural number)	CRC codes are generated for any desired data in 32n-bit units (where n is a natural number)
CRC processor unit	8-bit parallel processing	32-bit parallel processing
CRC generating polynomial	One of three generating polynomials is selectable • 8-bit CRC $X^8 + X^2 + X + 1$ (CRC-8) • 16-bit CRC $X^{16} + X^{15} + X^2 + 1$ (CRC-16) $X^{16} + X^{12} + X^5 + 1$ (CRC-CCITT)	One of two generating polynomials is selectable • 32-bit CRC $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ (CRC-32) $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$ (CRC-32C)
CRC calculation switching	The order of the bits produced by CRC calculation can be switched for LSB first or MSB first communication	
Low power consumption	Module-stop state can be set.	

Note 1. The circuit does not have a function to divide data for calculation into CRC calculation units. Write data in 8-bit or 32-bit units.

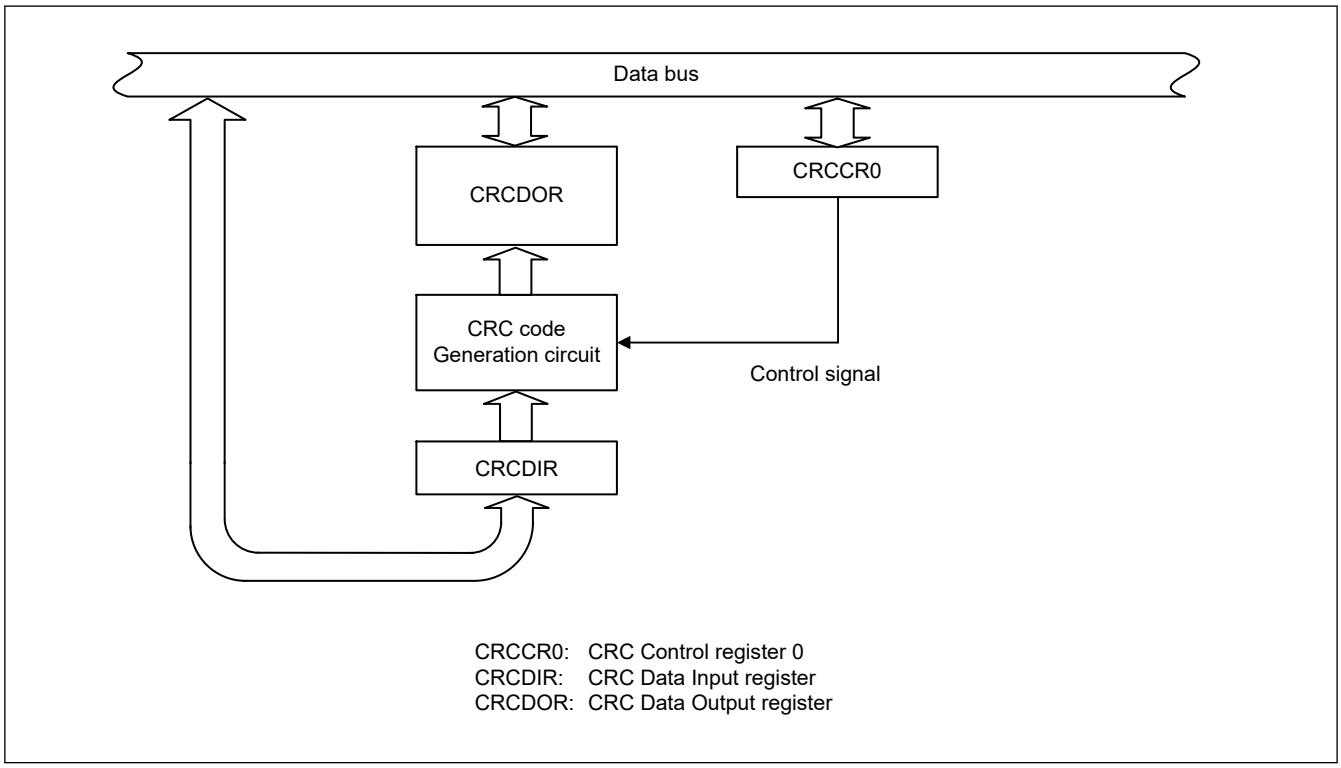

Figure 38.1 CRC block diagram

38.2 Register Map

Table 38.2 CRC register map

38.3 Register Descriptions

38.3.1 CRCCR0 : CRC Control Register 0

Base address: CRC0 = 0x8000_4000
CRC1 = 0x8100_4000

Offset address: 0x0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DORCLR	LMS	—	—	—	GPS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	GPS[2:0]	CRC Generating Polynomial Switching 0 0 0: No calculation is executed. 0 0 1: 8-bit CRC-8 ($X^8 + X^2 + X + 1$) 0 1 0: 16-bit CRC-16 ($X^{16} + X^{15} + X^2 + 1$) 0 1 1: 16-bit CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$) 1 0 0: 32-bit CRC-32 ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 1 0 1: 32-bit CRC-32C ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$) Others: No calculation is executed.	R/W
5:3	—	These bits are read as 0. The write value should be 0.	R/W
6	LMS	CRC Calculation Switching 0: Generates CRC for LSB first communication. 1: Generates CRC for MSB first communication.	R/W
7	DORCLR	CRCDOR Register Clear 0: No effect 1: Clears the CRCDOR register	W

GPS[2:0] bits (CRC Generating Polynomial Switching)

Set these bits to select the CRC Generating Polynomial.

LMS bit (CRC Calculation Switching)

The setting this bit selects the order of the bits of generated CRC codes. The bit selects transmission of the lower-order byte of the CRC code first for LSB first communication, or the higher-order byte first for MSB first communication. For details on the transmission and reception of CRC codes, see section 38.4. Operation.

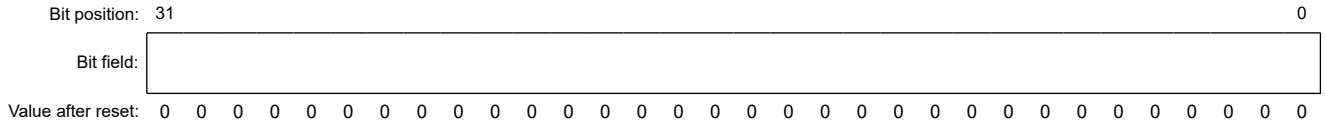
DORCLR bit (CRCDOR Register Clear)

Write 1 to this bit so that the CRCDOR register is set to 0x00000000.

38.3.2 CRCDIR/CRCDIR_BY : CRC Data Input Register

Base address: CRC0 = 0x8000_4000
CRC1 = 0x8100_4000

Offset address: 0x4



Bit	Symbol	Function	R/W
31:0	n/a	CRC Data Input	R/W

CRCDIR or CRCDIR_BY is written with data for the CRC calculation.

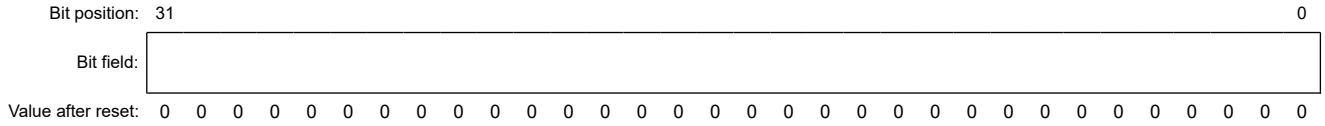
CRCDIR is the register symbol for R/W access in 32-bit units. When generating a 32-bit CRC code, the input data should be written to CRCDR.

CRCDIR_BY is the register symbol for R/W access in 8-bit units. When generating an 8- or 16-bit CRC code, the input data should be written to CRCDID_BY.

38.3.3 CRCDOR/CRCDOR_HA/CRCDOR_BY : CRC Data Output Register

Base address: CRC0 = 0x8000_4000
CRC1 = 0x8100_4000

Offset address: 0x8



Bit	Symbol	Function	R/W
31:0	n/a	CRC Data Output	R/W

When calculating with the initial value set to a value other than 0x00000000, rewrite the CRCDOR register.

The CRC code should be written to the CRCDIR register following the communication data. If the calculation result is 0x00000000, there is no error in the communication data.

If a 32-bit CRC is selected, the CRCDOR register should be accessed. If a 16-bit CRC is selected, the CRCDOR_HA register should be accessed. If an 8-bit CRC is selected, the CRCDOR_BY register should be accessed.

38.4 Operation

The CRC calculator generates CRC codes for use in LSB first or MSB first communication.

The following shows examples of generating the CRC code for input data (0xF0) using the 16-bit CRC-CCITT generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before the CRC calculation (when a 16-bit CRC is in use, bits [31:16] of CRCDOR are not updated).

When an 8-bit CRC is in use, the valid bits of the CRC code is obtained in the lower-order byte of CRCDOR. When a 32-bit CRC is in use, the valid bits of the CRC code is obtained in bits [31:0] of CRCDOR.

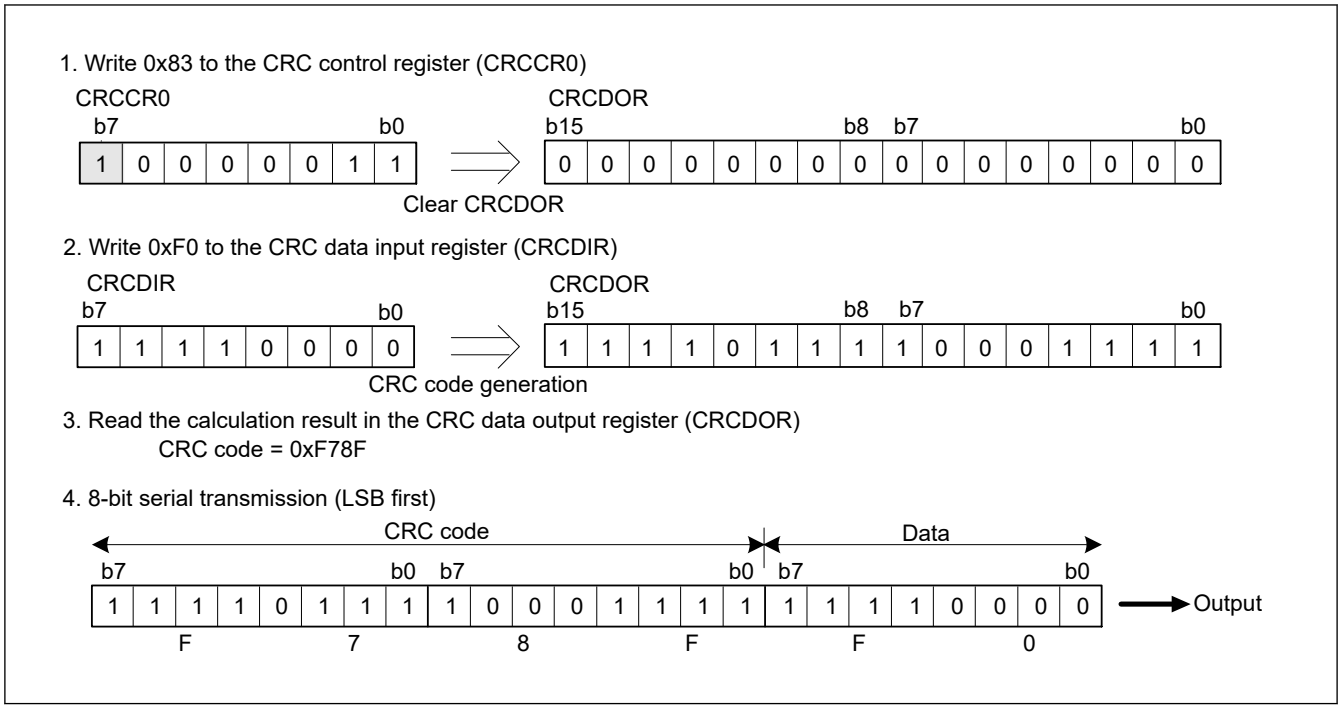


Figure 38.2 LSB first data transmission

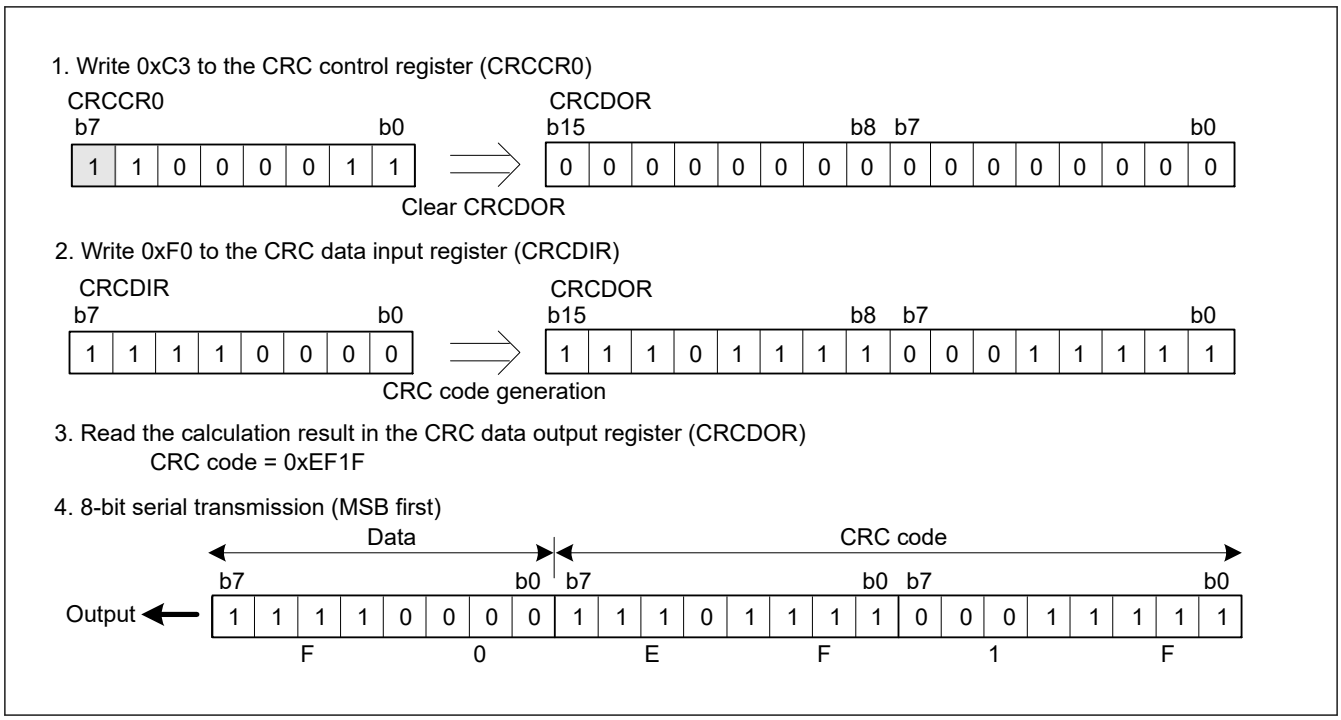

Figure 38.3 MSB first data transmission

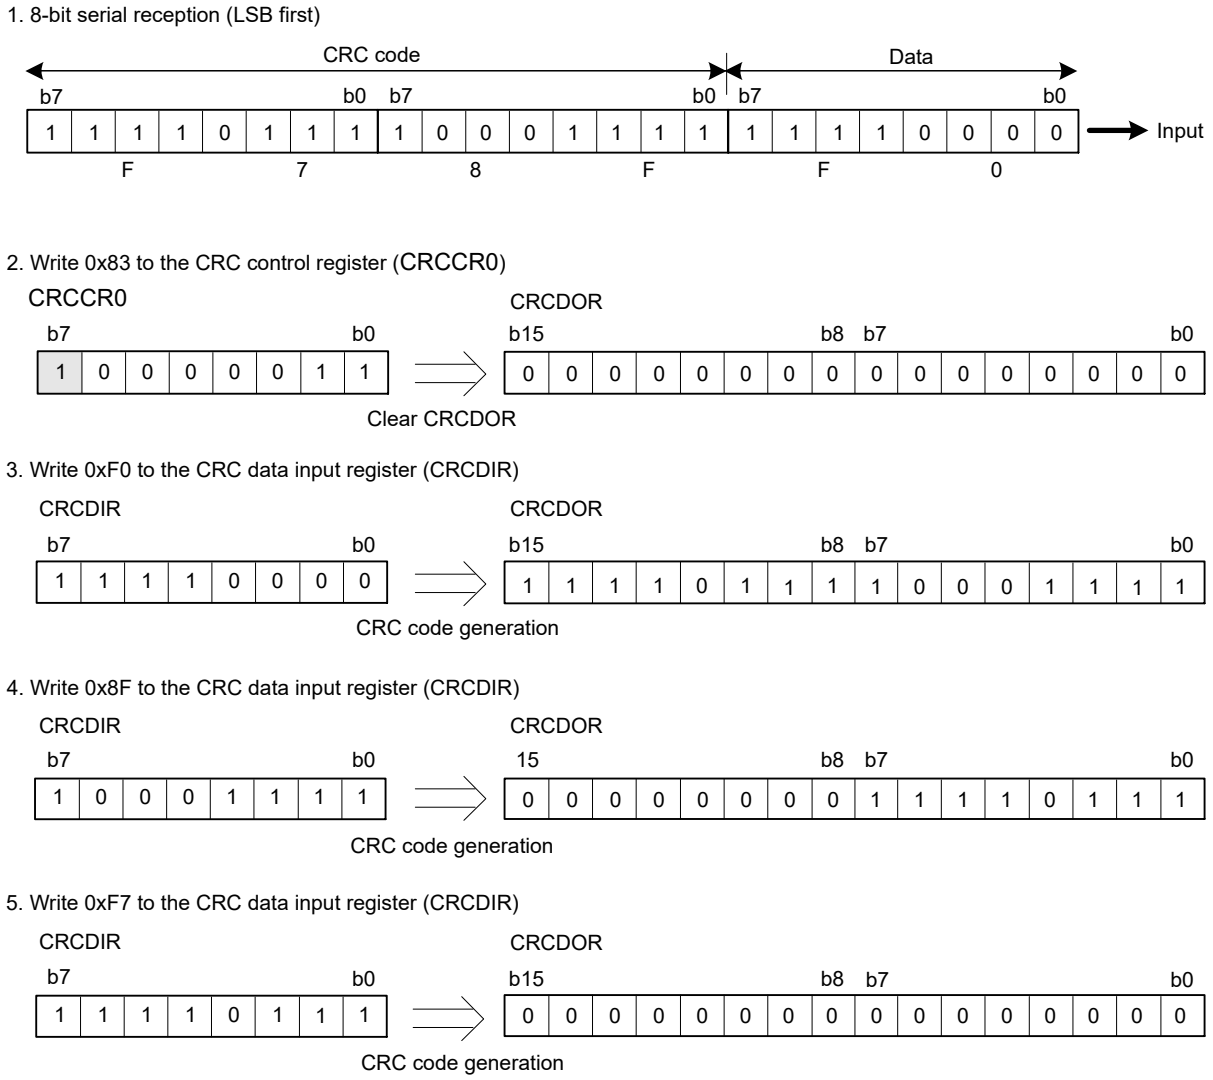

Figure 38.4 LSB first data reception

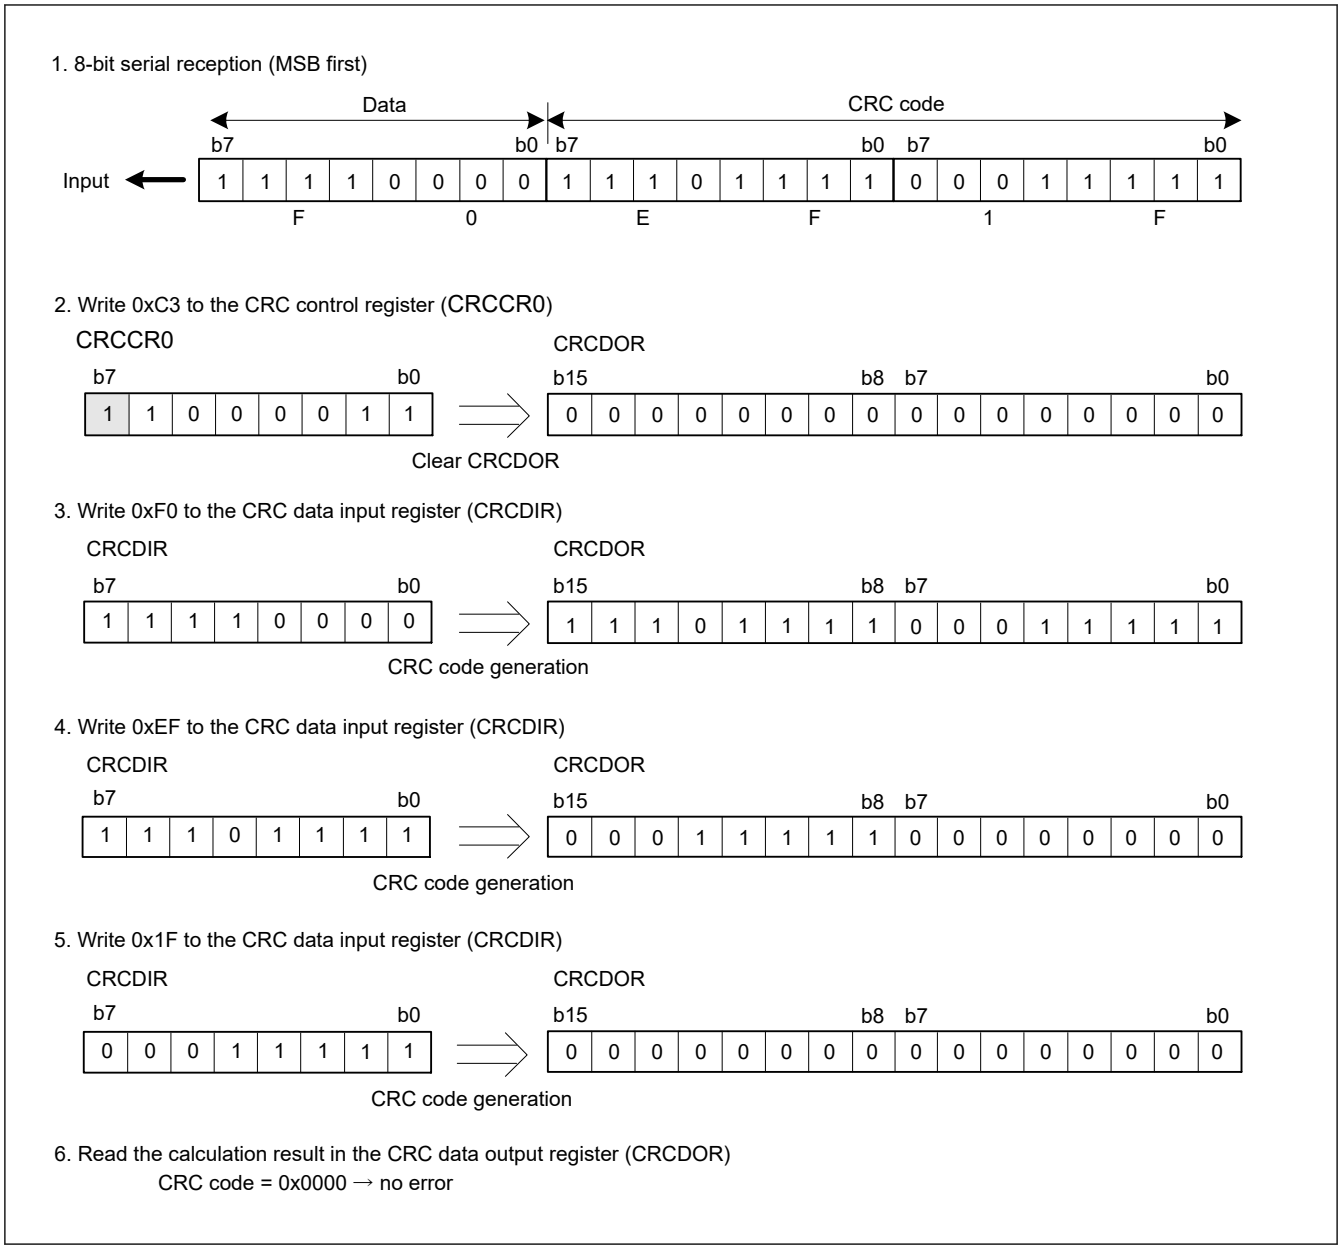

Figure 38.5 MSB first data reception

38.5 Usage Notes

38.5.1 Module-Stop Function Setting

Operation of the CRC calculator can be disabled or enabled using the Module Stop Control Register D and G (MSTPCRD and MSTPCRG). After a reset, the CRC is in the module-stop state. Register access is enabled by releasing the module-stop state.

For details, see section 9, Low-Power Consumption Function.

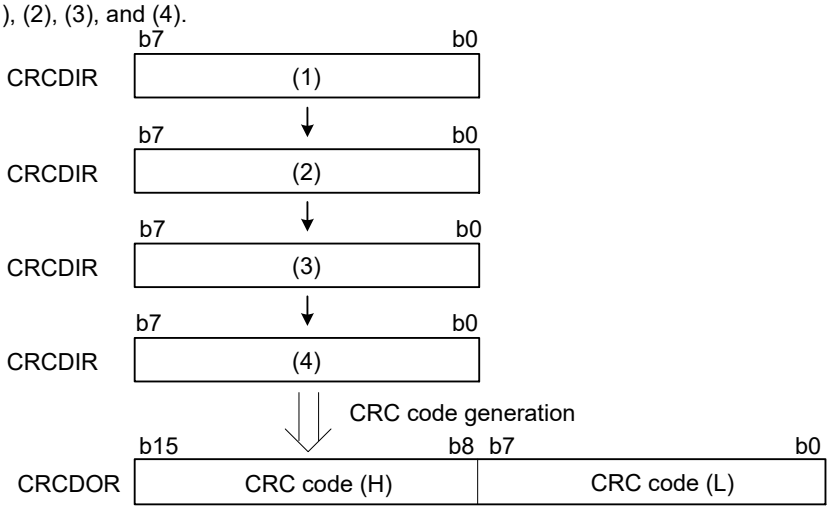
38.5.2 Note on Transmission

Note that the sequence of transmission for the CRC code differs according to whether transmission is LSB first or MSB first.

When transmitting 32-bit data (in case operation executed on 8 bits in parallel)

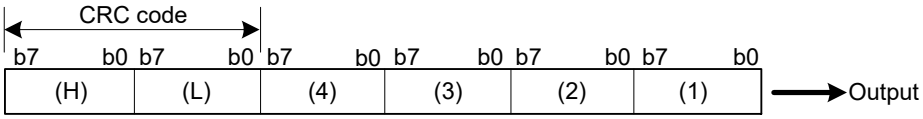
1. CRC code

After specifying the method for generation calculation, write data to the CRCDIR register in the order of (1), (2), (3), and (4).



2. Transmit data

(i) When transmission is LSB first



(ii) When transmission is MSB first

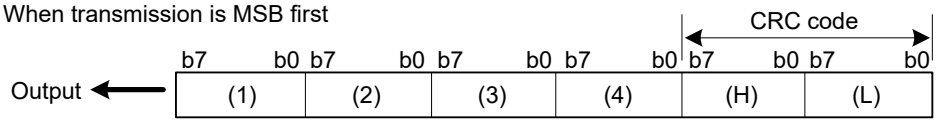


Figure 38.6 LSB first and MSB first data transmission

39. Boundary Scan

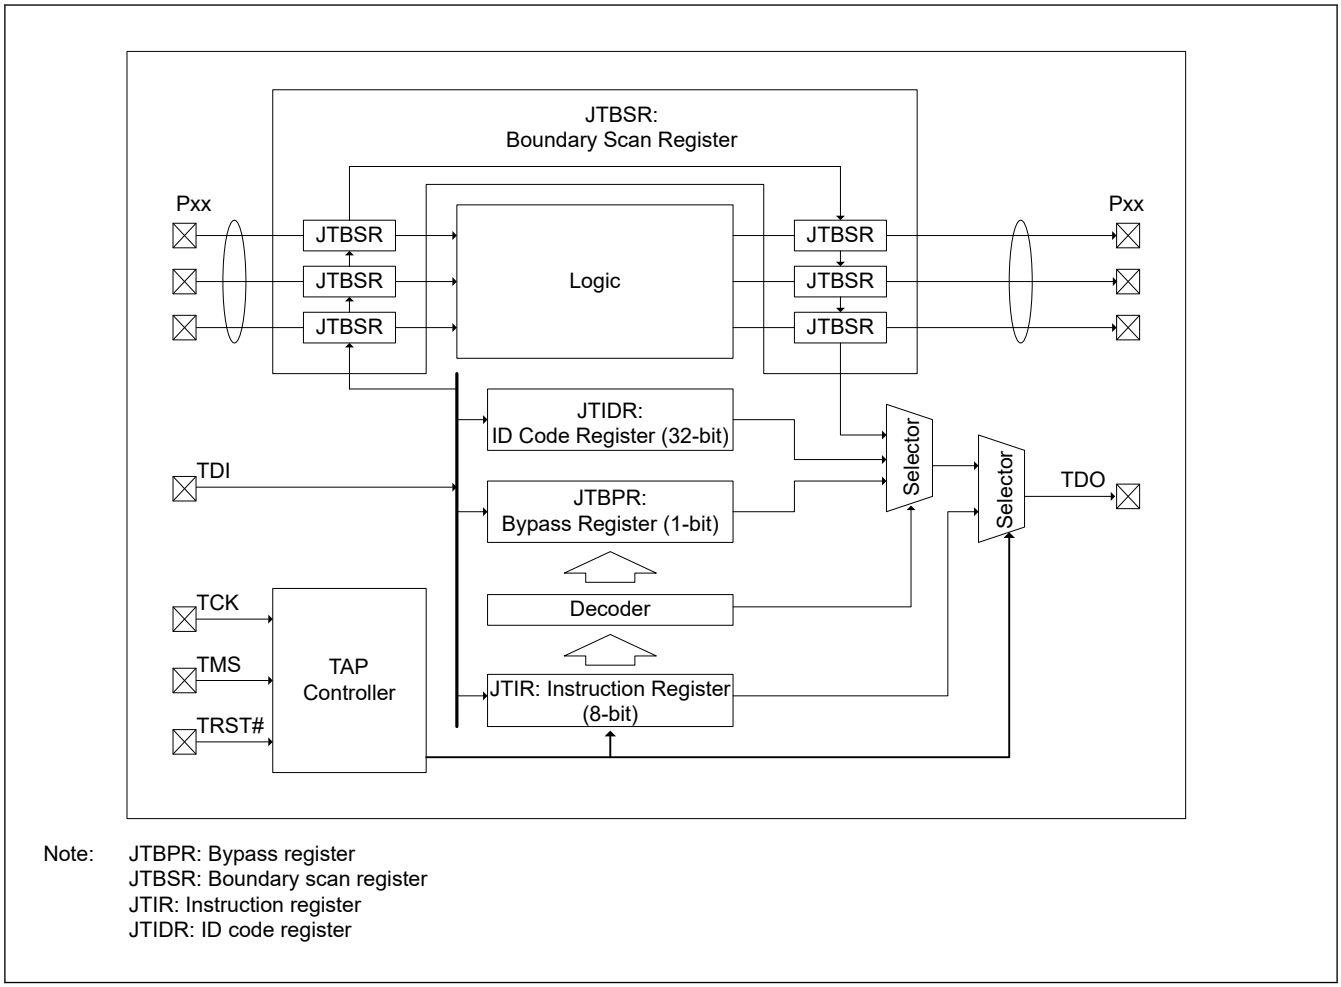
39.1 Overview

The LSI has a boundary scan function. The boundary scan is a serial I/O interface based on the JTAG (Joint Test Action Group), IEEE Std.1149.1, and IEEE Standard Test Access Port and Boundary-Scan Architecture.

Table 39.1 lists the specifications of boundary scan and Figure 39.1 shows a block diagram of the boundary scan function.

Table 39.1 Boundary scan specifications

Parameter	Specifications
Boundary scan enabled/disabled	Boundary scan function is enabled when the BSCANP pin is driven high.
Dedicated boundary scan pins	The TDO, TCK, TDI, TMS, and TRST# pins are dedicated for the JTAG when the boundary scan function is enabled.
Six test modes	• BYPASS mode • EXTEST mode • SAMPLE/PRELOAD mode • CLAMP mode • HIGHZ mode • IDCODE mode



Note: JTBPR: Bypass register
JTBSR: Boundary scan register
JTIR: Instruction register
JTIDR: ID code register

Figure 39.1 JTAG block diagram

Table 39.2 shows the I/O pins used in the boundary scan function.

Table 39.2 Pin configuration of JTAG

Pin name	I/O	Description
TCK	Input	Test clock input pin Clock signal for boundary scan. Input the clock the duty cycle of which is 50% when boundary scan function is used.
TMS	Input	Test mode select pin
TDI	Input	Test data input pin
TDO	Output	Test data output pin
TRST#	Input	Test reset input pin

39.2 Register Descriptions

Instructions can be input to the instruction register via the TDI pin by serial transfer.

The bypass register, which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.

The boundary scan register, which is configured according to the BSDL description, is connected between the TDI and TDO pins when test data are being shifted in.

None of the registers is accessible from the CPU. Table 39.3 shows the availability of serial transfer for the registers.

Table 39.3 Serial transfer for the registers

Register	Serial input	Serial output
Instruction register	Available	Available
ID code register	Available	Available
Bypass register	Available	Available
Boundary scan register	Available	Available

Note: Any serial transfer is available if standards for the boundary scan function are satisfied.

39.2.1 JTIR : Instruction Register

Base address: —

Offset address: —

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TS[7:0]							
Value after reset:	0	1	0	1	0	1	0	1

Bit	Symbol	Function	R/W
7:0	TS[7:0]	Test Bit Set The command configuration is as shown in Table 39.4.	—

The JTIR register is an 8-bit register.

Boundary scan instructions can be transferred to the instruction register by serial input from the TDI pin.

The instruction register is initialized when the TRST# pin is driven to the low level or when the TAP controller is in the Test-Logic-Reset state.

Table 39.4 Command configuration (1 of 2)

TS7	TS6	TS5	TS4	TS3	TS2	TS1	TS0	Instruction
0	0	0	0	0	0	0	0	EXTEST
0	1	0	0	0	0	0	0	SAMPLE/PRELOAD
0	1	0	1	0	1	0	1	IDCODE (value after reset)

Table 39.4 Command configuration (2 of 2)

TS7	TS6	TS5	TS4	TS3	TS2	TS1	TS0	Instruction
1	1	0	1	0	0	0	0	CLAMP
1	0	0	0	0	0	0	0	HIGHZ
1	1	1	1	1	1	1	1	BYPASS
Other than above								Reserved

39.2.2 JTIDR : ID Code Register

Base address: —

Offset address: —

Bit position:	31																												0
Bit field:	DID[31:0]																												
Value after reset:	0	0	0	0	1	0	0	0	0	1	1	0	0	1	0	1	1	1	1	0	0	1	0	0	0	1	0	0	0	1	1	1

Bit	Symbol	Function	R/W
31:0	DID[31:0]	This register has the fixed value that indicates the device IDCODE.	—

The JTIDR register is a 32-bit register.

ID code register data is output from the TDO pin when the IDCODE instruction is executed.

39.2.3 JTBPR : Bypass Register

The JTBPR register is a 1-bit register.

This register is connected between the TDI and TDO pins when BYPASS mode is set.

The JTBPR register cannot be read from or written to by the CPU.

39.2.4 JTBSR : Boundary Scan Register

The JTBSR register is a shift register to control the external input and output pins of this LSI and is distributed across the pad.

The EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ instructions are issued to apply the JTBSR register in boundary-scan testing.

Refer to the BSDL file for the correspondences between the pins of this LSI and the bits of the boundary scan register.

The value is undefined after a reset.

39.3 Operation

The boundary scan function is valid when the RES# and BSCANP pins are driven high.

39.3.1 TAP Controller

Figure 39.2 shows the state transition diagram of the TAP controller. Table 39.5 describes each state.

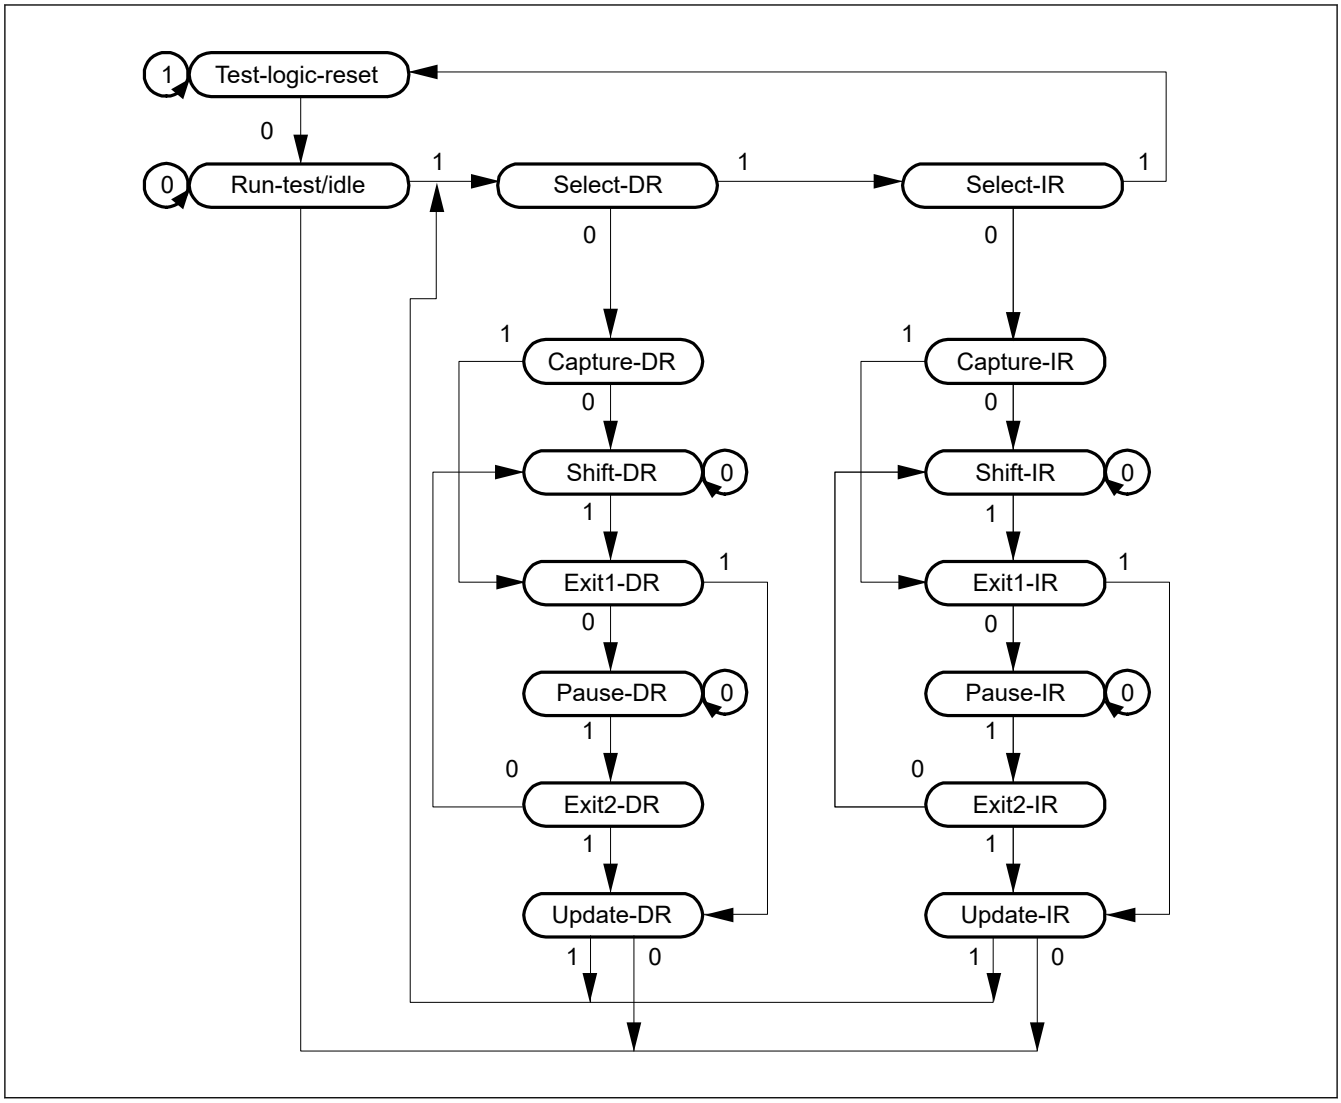


Figure 39.2 State transition diagram of TAP controller

Table 39.5 Explanation of states (1 of 2)

State	Explanation
Test Logic Reset	Reset state of the TAP controller The LSI is in this state during normal operation.
Run Test/Idle	Test execution state
Select DR Scan	Temporary state used for selecting a data register
Select IR Scan	Temporary state used for selecting an instruction register
Capture DR	Data of the test data register corresponding to the current instruction is captured in parallel.
Shift DR	The test data register corresponding to the current instruction is connected between the TDI and TDO pins, and data is transferred serially.
Exit DR	Temporary state
Pause DR	Clocks are applied while the value input in the Shift DR state is retained.
Exit2 DR	Temporary state
Update DR	Output latches of the test data register corresponding to the current instruction are updated.
Capture IR	A fixed value is input to the instruction register.
Shift IR	The instruction register is connected between the TDI and TDO pins, and data is transferred serially.
Exit IR	Temporary state

Table 39.5 Explanation of states (2 of 2)

State	Explanation
Pause IR	Clocks are applied while the value input in the Shift IR state is retained.
Exit2 IR	Temporary state
Update IR	The current instruction is updated to the instruction input in the Shift IR state.

39.3.2 List of Commands

(1) BYPASS [Instruction Code: 1111 1111b]

The BYPASS instruction drives the bypass register. This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed-circuit board at higher speeds. While this instruction is being executed, the test circuit does not affect the system circuit.

The bypass register is connected between the TDI and TDO pins. Bypass operation is initiated from shift-DR operation. The TDO is set to 0 in the first clock cycle in the Shift-DR state. In the subsequent clock cycles, the TDI signal is output on the TDO pin.

(2) EXTEST [Instruction Code: 0000 0000b]

The EXTEST instruction is used to test external circuits when this LSI is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified by the SAMPLE/PRELOAD instruction) from the boundary scan register to the print circuit board, and input pins are used to input test result to the boundary scan register from the print circuit board.

(3) SAMPLE/PRELOAD [Instruction Code: 0100 0000b]

The SAMPLE/PRELOAD instruction is used to input data from this LSI's internal circuits to the boundary scan register, output data from the scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to this LSI and output signals are also directly output to the external circuits. The system circuit of this LSI is not affected by this instruction.

In SAMPLE operation, the boundary scan register latches the snapshot of data transferred from input pins to internal circuit or data transferred from internal circuit to output pins. The latched data is read from the scan path. The scan register latches the snapshot at the rising edge of the TCK in Capture-DR state. The scan register latches snapshots without affecting the LSI normal operation.

In PRELOAD operation, the value after reset is written from the scan path to the parallel output latch of the boundary scan register prior to the EXTEST instruction execution. If the EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In the EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE [Instruction Code: 0101 0101b]

When the IDCODE instruction is selected, the ID code register value is output from the TDO in LSB-first order in Shift-DR state of the TAP controller. While this instruction is being executed, the test circuit does not affect the system circuit. The instruction register is initialized by the IDCODE instruction in Test-Logic-Reset state of the TAP controller.

(5) CLAMP [Instruction Code: 1101 0000b]

When the CLAMP instruction is selected, output pins output the boundary scan register value which was specified by the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of the boundary scan register is maintained regardless of the TAP controller state.

The bypass register is connected between the TDI and TDO pins, leading to the same operation as when BYPASS mode has been selected.

(6) HIGHZ [Instruction Code: 1000 0000b]

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the status of the boundary scan register is maintained regardless of the TAP controller state. The bypass register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction has been selected.

39.4 Usage Notes

1. For serial transfer, data are input or output in LSB-first order. See Figure 39.3.
2. Pins of the boundary scan (TDI, TMS, and TRST#) have to be pulled up by pull-up resistors.
   However, if an on-chip emulator is in use, handle the TRST# pin according to the manual for the given on-chip emulator.
3. Power supply pins (VDD33, VDD1833_0 to VDD1833_7, VDDP_18_33, VDDP_18_0 to VDDP_18_7, VDD08, VDD18_PLL0 to VDD18_PLL4, VDD08_PLL0 to VDD08_PLL4, VDD33_X, VDDP_18_X, AVDD18A_TSU, DVDD08A_TSU, OTPVDD18, OTPVDD08, VSS, VSS_PLL0 to VSS_PLL4, USB_USVDD33, USB_USVDD18, USB_USDVDD, AVDD_ADC0 to AVDD_ADC2, AVDDIO_ADC0 to AVDDIO_ADC2, AVSS_ADC0 to AVSS_ADC2, AVSSIO_ADC0 to AVSSIO_ADC2, PCIE_VDD18A_CMN, PCIE_VDD18A_L0, PCIE_VDD18A_L1, PCIE_VDD08A_L0, PCIE_VDD08A_L1 DDR_VAA, DDR_VDDQ) cannot be boundary-scanned.
4. Analog reference pins (AVDDREF_ADC0 to AVDDREF_ADC2, USB_TXRTUNE) cannot be boundary-scanned.
5. Analog input pins (AN000 to AN003, AN100 to AN103, AN200 to AN215) cannot be boundary-scanned.
6. Clock pins (EXTAL, XTAL, EXTCLKIN, and XTALSEL) cannot be boundary-scanned.
7. The reset pin (RES#) cannot be boundary-scanned.
8. The operating mode input pin (MDX) cannot be boundary-scanned.
9. USB dedicated pins (USB_QDP, USB_QDM, USB_VUBUSIN, USB_OTG_ID) cannot be boundary-scanned.
10. PCIE dedicated pins (PCIE_REFCLK_P0, PCIE_REFCLK_N0, PCIE_REFCLK_P1, PCIE_REFCLK_N1PCIE_RXDP_L0, PCIE_RXDN_L0, PCIE_RXDP_L1, PCIE_RXDN_L1, PCIE_TXDP_L0, PCIE_TXDN_L0, PCIE_TXDP_L1, PCIE_TXDN_L1) cannot be boundary-scanned.
11. DDR dedicated pins (DDR_ZN, DDR_DTEST, DDR_ATEST, DDR_RESET_N, DDR_CKA_T, DDR_CKA_C, DDR_CKB_T, DDR_CKB_C, DDR_CKEA[1:0], DDR_CKEB[1:0], DDR_CSA[1:0], DDR_CSB[1:0], DDR_CAA[5:0], DDR_CAB[5:0], DDR_DQA[15:0], DDR_DQB[15:0], DDR_DMIA[1:0], DDR_DMIB[1:0], DDR_DQSA_T[1:0], DDR_DQSB_T[1:0], DDR_DQSA_C[1:0], DDR_DQSB_C[1:0]) cannot be boundary-scanned.
12. The boundary-scan pin (BSCANP) cannot be boundary-scanned.
13. The boundary-scan pins (TCK, TMS, TRST#, TDI, and TDO) cannot be boundary-scanned.
14. The boundary scan function is not available when the chip is in the reset state.
15. For a pin that incorporates open-drain functionality and for which the open-drain function is enabled, if the boundary-scan function sets the corresponding bit in the output scan register and output enable register to 1, executing an EXTEST, CLAMP, or SAMPLE/PRELOAD instruction makes the pin output the high level rather than placing it in the high-impedance state.*1

Note 1. For details on boundary-scan target pins, refer to the BSDL file. Boundary-scan is not applicable to some pins and power pins.

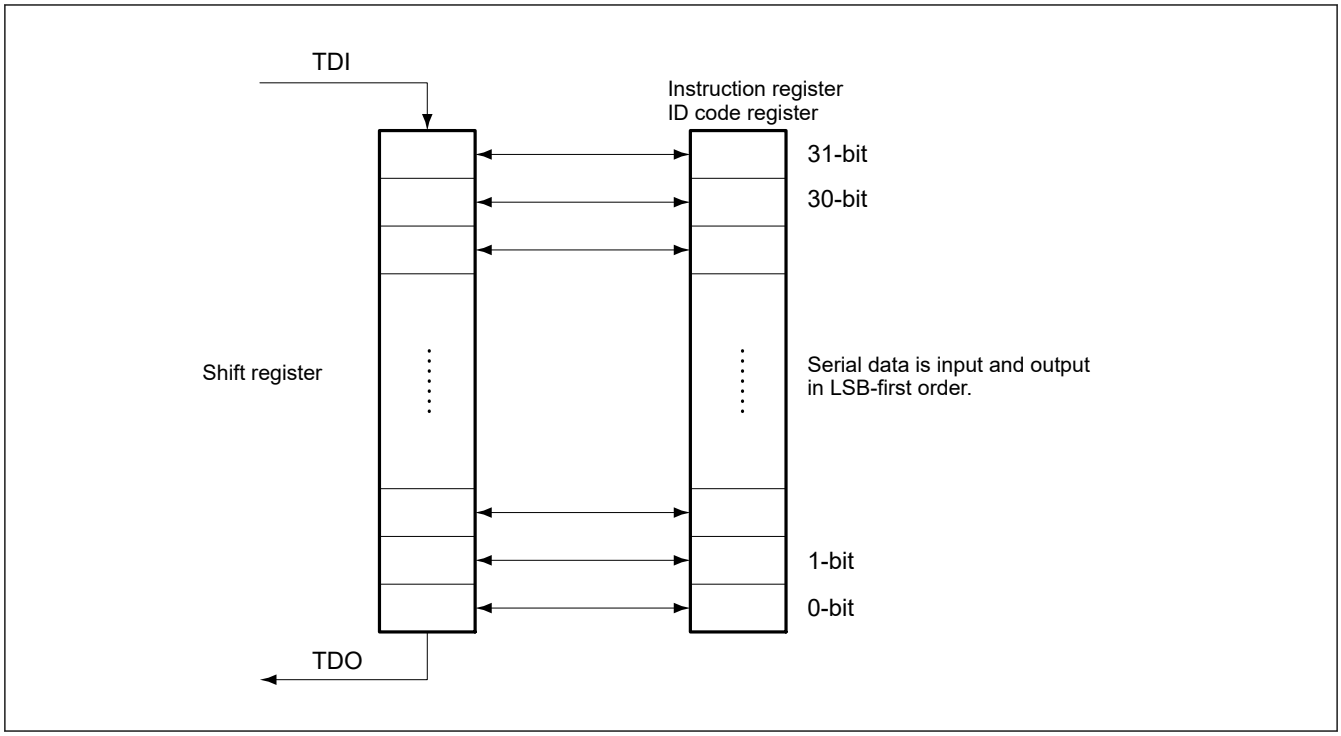

Figure 39.3 Serial data Input/Output

40. ΔΣ Interface (DSMIF)

40.1 Overview

The ΔΣ interfaces (DSMIF) can be connected with up to three external ΔΣ modulators. It is capable of filtering delta-sigma modulated 1-bit digital input data and converting it into 16-bit digital data.

Table 40.1 lists the specifications of DSMIF and Table 40.2 lists the functions of DSMIF. Figure 40.1 shows a block diagram of DSMIF.

Table 40.1 DSMIF specifications

Parameter	Description
Number of units	10 units (6 in LLPP0 and 4 in LLPP1)
Number of channels	3 channels per unit for a total of 30 channels
Decimation filter characteristics	Filter are selectable as Sinc 1st order, Sinc 2nd order, Sinc 3rd order Can select each channel.
Over-sampling rate (decimation rate)	Selectable from 4 to 256 Can select each channel.
Interface clock	Support Master mode (MCLK is used as output)/Slave mode (MCLK is used as input) by channel Master mode supports the following output clock: ● 25/20/12.5/10/6.25/5 MHz (Core Clock: 400 MHz, Bus Clock: 250 MHz) ● 25/20.8/12.5/10.4/6.25/5 MHz (Core Clock: 250 MHz, Bus Clock: 250 MHz) Filter received clock inversion function.
Data capture	Crests and troughs can trigger capture, allowing capture of values for current with the same timing. Can select one capture trigger from six triggers for each trigger input by channel. The PWM synchronization function is realized by initializing the decimation counter for the differential stage of the SINC filter with the trigger output from GPT.
Unit synchronization	Not supported
Reset function of differential filter clock divider	Support channel by channel. Can select one from three triggers.
Error source output (interrupt)	12 kinds of interrupt sources in 1 unit: ● Current data register update interrupt ● Current capture data register A update interrupt ● Current capture data register B update interrupt ● Short-circuit detection error interrupt ● Lower threshold overcurrent detection 0 error interrupt ● Upper threshold overcurrent detection 0 error interrupt ● Lower threshold overcurrent detection 1 error interrupt ● Upper threshold overcurrent detection 1 error interrupt ● Lower threshold overcurrent detection 2 error interrupt ● Upper threshold overcurrent detection 2 error interrupt ● Lower threshold current detection interrupt ● Upper threshold detection interrupt
Low-power consumption function	The module-stop state can be set (clock gating function is implemented)

Table 40.2 DSMIF functions

Parameter			Name
	Clock	I/O	MCLKmn

Note 1. Access from Cortex-R52 CPU0 and CPU1 is not protected by TrustZone. This slave access control is applied to access from other masters.

40.3 Register Descriptions

40.3.1 DSMIF Common Control Registers

40.3.1.1 DSCCSCR : Core Clock Selection Control Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLKSEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CLKSEL	Core Clock Selection 0: 250 MHz 1: 400 MHz	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

40.3.1.2 DSSEICR : Overcurrent Sum Error Detect Interrupt Control Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x080

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ISEH	ISEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ISEL	Overcurrent sum error lower limit detection interrupt enable bit 0: Do not output overcurrent sum error lower limit detection interrupt 1: Overcurrent sum error lower limit detection interrupt can be output	R/W
1	ISEH	Overcurrent sum error upper limit detection interrupt enable bit 0: Do not output overcurrent sum error upper limit detection interrupt 1: Overcurrent sum error lower upper detection interrupt can be output	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

40.3.1.3 DSSECSR : Overcurrent Sum Error Detect Channel Setting Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x084

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	SEDM[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SEDM[2:0]	Overcurrent sum error detect mode setting bit 0 0 0: Detects error of sum value of overcurrent data of CH0, CH1, CH2 0 0 1: Detects error of sum value of overcurrent data of CH0, CH1 0 1 0: Detects error of overcurrent data of CH0 0 1 1: Detects error of overcurrent data of CH1 1 0 0: Detects error of overcurrent data of CH2 Others: Setting prohibited (detects error of sum value of overcurrent data of CH0, CH1, CH2)	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

40.3.1.4 DSSELTR : Overcurrent Sum Error Detect Low Threshold Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x088

Bit position:	31														17																0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SCMPTBL[17:0]																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
17:0	SCMPTBL[17:0]	Overcurrent sum error detect lower limit These bits set the lower limit of the active current value for overcurrent sum error detection. Set these bits to the lower limit of the sum value of the overcurrent data for each channel.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

40.3.1.5 DSSEHTR : Overcurrent Sum Error Detect High Threshold Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x08C

Bit position:	31														17																0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SCMPTBH[17:0]																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
17:0	SCMPTBH[17:0]	Overcurrent sum error detect upper limit These bits set the upper limit of the active current value for overcurrent sum error detection. Set these bits to the upper limit of the sum value of the overcurrent data for each channel.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

40.3.1.6 DSSECR : Overcurrent Sum Error Detect Control Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x090

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SEEH	SEEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SEEL	Overcurrent sum error lower limit detection enable bit 0: The lower limit exceeded detection function of overcurrent sum error detection is invalid 1: The lower limit exceeded detection function of overcurrent sum error detection is valid	R/W
1	SEEH	Overcurrent sum error upper limit detection enable bit 0: The upper limit exceeded detection function of overcurrent sum error detection is invalid 1: The upper limit exceeded detection function of overcurrent sum error detection is valid	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

40.3.1.7 DSSECDRn : Overcurrent Sum Error Detect Capture Data Register n (n = 0 to 2)

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x0A0 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SECDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SECDR[15:0]	Overcurrent sum error detect capture data n Captures the overcurrent data of the target channel when the upper limit error or the lower limit error of the over sum current error detection occurs. See Table 40.11 for details of the data to be captured.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

40.3.1.8 DSCMSR : Common Mode Setting Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x0C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	CISM[1:0]		DFS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DFS	Data Format Select 0: Left justified 1: Right justified	R/W
2:1	CISM[1:0]	Common Interrupt Synchronous channel Mode 0 0: Common interrupts are not used 0 1: Common interrupts for ch0, ch1, and ch2 can be used 1 0: Common interrupts for ch0 and ch1 can be used 1 1: Setting prohibited	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

40.3.1.9 DSCICR : Common Interrupt Control Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x0C4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	IBUCE	IAUCE	IUCE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IUCE	Current data register update channel common interrupt enable 0: Do not output capture current data register update channel common interrupt 1: Capture current data register update channel common interrupt can be output	R/W
1	IAUCE	Capture current data register A update channel common interrupt enable 0: Do not output capture current data register A update channel common interrupt 1: Capture current data register A update channel common interrupt can be output	R/W
2	IBUCE	Capture current data register B update channel common interrupt enable 0: Do not output capture current data register B update channel common interrupt 1: Capture current data register B update channel common interrupt can be output	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

40.3.1.10 DSCSTRTR : Channel Software Start Trigger Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x200

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	STRTRG2	STRTRG1	STRTRG0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STRTRG0	Channel 0 start trigger 0: Do nothing 1: Start channel	R/W
1	STRTRG1	Channel 1 start trigger 0: Do nothing 1: Start channel	R/W
2	STRTRG2	Channel 2 start trigger 0: Do nothing 1: Start channel	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

40.3.1.11 DSCSTPTR : Channel Software Stop Trigger Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x204

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	STPTRG2	STPTRG1	STPTRG0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STPTRG0	Channel 0 stop trigger 0: Do nothing 1: Stop channel	R/W
1	STPTRG1	Channel 1 stop trigger 0: Do nothing 1: Stop channel	R/W
2	STPTRG2	Channel 2 stop trigger 0: Do nothing 1: Stop channel	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

40.3.1.12 DSCESR : Channel Error Status Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x220

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SUMERRH	SUMERRL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	SCF2	SCF1	SCF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SCF0	Channel 0 short circuit detection flag This bit becomes 1 when 1 is continuously input to the MDATm0 pin, exceeding the number of times set in DSSCTSRCH0.SCNTH, or when 0 is continuously input to the MDATm0 pin, exceeding the number of times set in DSSCTSRCH0.SCNTH. This bit becomes 0 when SCF0 = 1 and writing 1 to the channel 0 short circuit detection flag clear (DSCESCR.CLRSCF0 / DSCSCRCH0.CLRSCF). 0: Indicates that the MDATm0 pin short circuit is not detected 1: Indicates that a short circuit on the MDATm0 pin has been detected	R
1	SCF1	Channel 1 short circuit detection flag This bit becomes 1 when 1 is continuously input to the MDATm1 pin, exceeding the number of times set in DSSCTSRCH1.SCNTH, or when 0 is continuously input to the MDATm1 pin, exceeding the number of times set in DSSCTSRCH1.SCNTH. This bit becomes 0 when SCF1 = 1 and writing 1 to the channel 1 short circuit detection flag clear (DSCESCR.CLRSCF1 / DSCSCRCH1.CLRSCF). 0: Indicates that the MDATm1 pin short circuit is not detected 1: Indicates that a short circuit on the MDATm1 pin has been detected	R
2	SCF2	Channel 2 short circuit detection flag This bit becomes 1 when 1 is continuously input to the MDATm2 pin, exceeding the number of times set in DSSCTSRCH2.SCNTH, or when 0 is continuously input to the MDATm2 pin, exceeding the number of times set in DSSCTSRCH2.SCNTH. This bit becomes 0 when SCF2 = 1 and writing 1 to the channel 2 short circuit detection flag clear (DSCESCR.CLRSCF2 / DSCSCRCH2.CLRSCF). 0: Indicates that the MDATm2 pin short circuit is not detected 1: Indicates that a short circuit on the MDATm2 pin has been detected	R
15:3	—	These bits are read as 0.	R
16	SUMERRL	Overcurrent sum error lower limit detection flag This bit becomes 1 when the sum value of the overcurrent data is updated and this sum value is smaller than the lower limit (DSSELTR.SCMPTBL). This bit becomes 0 when SUMERRL = 1 and writing 1 to the overcurrent sum error lower limit detection flag clear (DSCESCR.CLRSUMERRL). 0: Indicates that the sum value of overcurrent data is not less than the lower limit 1: Indicates that the sum value of overcurrent data is less than the lower limit	R
17	SUMERRH	Overcurrent sum error upper limit detection flag This bit becomes 1 when the sum value of the overcurrent data is updated and this sum value is larger than the upper limit (DSSEHTR.SCMPTBH). This bit becomes 0 when SUMERRH = 1 and writing 1 to the overcurrent sum error upper limit detection flag clear (DSCESCR.CLRSUMERRH). 0: Indicates that the sum value of overcurrent data is not more than the upper limit 1: Indicates that the sum value of overcurrent data is more than the upper limit	R
31:18	—	These bits are read as 0.	R

40.3.1.13 DSCOCESR : Channel Overcurrent Error Status Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x224

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	OC1FH2	OC1FH1	OC1FH0	—	OC1FL2	OC1FL1	OC1FL0	—	OC0FH2	OC0FH1	OC0FH0	—	OC0FL2	OC0FL1	OC0FL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OC0FL0	Channel 0 overcurrent lower limit detection 0 flag This bit becomes 1 when the overcurrent data is updated and this data is smaller than the lower limit 0. This bit becomes 0 when OC0FL0 = 1 and writing 1 to the channel 0 overcurrent lower limit detection flag 0 clear (DSCOCESCR.CLROC0FL0 / DSCSCRCH0.CLROC0FL). 0: Indicates that the overcurrent data is not less than the lower limit 0 1: Indicates that the overcurrent data has been less than the lower limit 0	R
1	OC0FL1	Channel 1 overcurrent lower limit detection 0 flag This bit becomes 1 when the overcurrent data is updated and this data is smaller than the lower limit 0. This bit becomes 0 when OC0FL1 = 1 and writing 1 to the channel 1 overcurrent lower limit detection flag 0 clear (DSCOCESCR.CLROC0FL1 / DSCSCRCH1.CLROC0FL). 0: Indicates that the overcurrent data is not less than the lower limit 0 1: Indicates that the overcurrent data has been less than the lower limit 0	R
2	OC0FL2	Channel 2 overcurrent lower limit detection 0 flag This bit becomes 1 when the overcurrent data is updated and this data is smaller than the lower limit 0. This bit becomes 0 when OC0FL2 = 1 and writing 1 to the channel 2 overcurrent lower limit detection flag 0 clear (DSCOCESCR.CLROC0FL2 / DSCSCRCH2.CLROC0FL). 0: Indicates that the overcurrent data is not less than the lower limit 0 1: Indicates that the overcurrent data has been less than the lower limit 0	R
3	—	This bit is read as 0.	R
4	OC0FH0	Channel 0 overcurrent upper limit exceeded 0 flag This bit becomes 1 when the overcurrent data is updated and this data is larger than the upper limit 0. This bit becomes 0 when OC0FH0 = 1 and writing 1 to the channel 0 overcurrent upper limit exceeded flag 0 clear (DSCOCESCR.CLROC0FH0 / DSCSCRCH0.CLROC0FH). 0: Indicates that the overcurrent data doesn't exceed the upper limit 0 1: Indicates that the overcurrent data has exceeded the upper limit 0	R
5	OC0FH1	Channel 1 overcurrent upper limit exceeded 0 flag This bit becomes 1 when the overcurrent data is updated and this data is larger than the upper limit 0. This bit becomes 0 when OC0FH1 = 1 and writing 1 to the channel 1 overcurrent upper limit exceeded flag 0 clear (DSCOCESCR.CLROC0FH1 / DSCSCRCH1.CLROC0FH). 0: Indicates that the overcurrent data doesn't exceed the upper limit 0 1: Indicates that the overcurrent data has exceeded the upper limit 0	R
6	OC0FH2	Channel 2 overcurrent upper limit exceeded 0 flag This bit becomes 1 when the overcurrent data is updated and this data is larger than the upper limit 0. This bit becomes 0 when OC0FH2 = 1 and writing 1 to the channel 2 overcurrent upper limit exceeded flag 0 clear (DSCOCESCR.CLROC0FH2 / DSCSCRCH2.CLROC0FH). 0: Indicates that the overcurrent data doesn't exceed the upper limit 0 1: Indicates that the overcurrent data has exceeded the upper limit 0	R
7	—	This bit is read as 0.	R

Bit	Symbol	Function	R/W
8	OC1FL0	Channel 0 overcurrent lower limit detection 1 flag This bit becomes 1 when the overcurrent data is updated and this data is smaller than the lower limit 1. This bit becomes 0 when OC1FL0 = 1 and writing 1 to the channel 0 overcurrent lower limit detection flag 1 clear (DSCOCESCR.CLROC1FL0 / DSCSCRCH0.CLROC1FL). 0: Indicates that the overcurrent data is not less than the lower limit 1 1: Indicates that the overcurrent data has been less than the lower limit 1	R
9	OC1FL1	Channel 1 overcurrent lower limit detection 1 flag This bit becomes 1 when the overcurrent data is updated and this data is smaller than the lower limit 1. This bit becomes 0 when OC1FL1 = 1 and writing 1 to the channel 1 overcurrent lower limit detection flag 1 clear (DSCOCESCR.CLROC1FL1 / DSCSCRCH1.CLROC1FL). 0: Indicates that the overcurrent data is not less than the lower limit 1 1: Indicates that the overcurrent data has been less than the lower limit 1	R
10	OC1FL2	Channel 2 overcurrent lower limit detection 1 flag This bit becomes 1 when the overcurrent data is updated and this data is smaller than the lower limit 1. This bit becomes 0 when OC1FL2 = 1 and writing 1 to the channel 2 overcurrent lower limit detection flag 1 clear (DSCOCESCR.CLROC1FL2 / DSCSCRCH2.CLROC1FL). 0: Indicates that the overcurrent data is not less than the lower limit 1 1: Indicates that the overcurrent data has been less than the lower limit 1	R
11	—	This bit is read as 0.	R
12	OC1FH0	Channel 0 overcurrent upper limit exceeded 1 flag This bit becomes 1 when the overcurrent data is updated and this data is larger than the upper limit 1. This bit becomes 0 when OC1FH0 = 1 and writing 1 to the channel 0 overcurrent upper limit exceeded flag 1 clear (DSCOCESCR.CLROC1FH0 / DSCSCRCH0.CLROC1FH). 0: Indicates that the overcurrent data doesn't exceed the upper limit 1 1: Indicates that the overcurrent data has exceeded the upper limit 1	R
13	OC1FH1	Channel 1 overcurrent upper limit exceeded 1 flag This bit becomes 1 when the overcurrent data is updated and this data is larger than the upper limit 1. This bit becomes 0 when OC1FH1 = 1 and writing 1 to the channel 1 overcurrent upper limit exceeded flag 1 clear (DSCOCESCR.CLROC1FH1 / DSCSCRCH1.CLROC1FH). 0: Indicates that the overcurrent data doesn't exceed the upper limit 1 1: Indicates that the overcurrent data has exceeded the upper limit 1	R
14	OC1FH2	Channel 2 overcurrent upper limit exceeded 1 flag This bit becomes 1 when the overcurrent data is updated and this data is larger than the upper limit 1. This bit becomes 0 when OC1FH2 = 1 and writing 1 to the channel 2 overcurrent upper limit exceeded flag 1 clear (DSCOCESCR.CLROC1FH2 / DSCSCRCH2.CLROC1FH). 0: Indicates that the overcurrent data doesn't exceed the upper limit 1 1: Indicates that the overcurrent data has exceeded the upper limit 1	R
15	—	This bit is read as 0.	R
16	OC2FL0	Channel 0 overcurrent lower limit detection 2 flag This bit becomes 1 when the overcurrent data is updated and this data is smaller than the lower limit 2. This bit becomes 0 when OC2FL0 = 1 and writing 1 to the channel 0 overcurrent lower limit detection flag 2 clear (DSCOCESCR.CLROC2FL0 / DSCSCRCH0.CLROC2FL). 0: Indicates that the overcurrent data is not less than the lower limit 2 1: Indicates that the overcurrent data has been less than the lower limit 2	R
17	OC2FL1	Channel 1 overcurrent lower limit detection 2 flag This bit becomes 1 when the overcurrent data is updated and this data is smaller than the lower limit 2. This bit becomes 0 when OC2FL1 = 1 and writing 1 to the channel 1 overcurrent lower limit detection flag 2 clear (DSCOCESCR.CLROC2FL1 / DSCSCRCH1.CLROC2FL). 0: Indicates that the overcurrent data is not less than the lower limit 2 1: Indicates that the overcurrent data has been less than the lower limit 2	R

Bit	Symbol	Function	R/W
18	OC2FL2	Channel 2 overcurrent lower limit detection 2 flag This bit becomes 1 when the overcurrent data is updated and this data is smaller than the lower limit 2. This bit becomes 0 when OC2FL2 = 1 and writing 1 to the channel 2 overcurrent lower limit detection flag 2 clear (DSCOCESCR.CLROC2FL2 / DSCSCRCH2.CLROC2FL). 0: Indicates that the overcurrent data is not less than the lower limit 2 1: Indicates that the overcurrent data has been less than the lower limit 2	R
19	—	This bit is read as 0.	R
20	OC2FH0	Channel 0 overcurrent upper limit exceeded 2 flag This bit becomes 1 when the overcurrent data is updated and this data is larger than the upper limit 2. This bit becomes 0 when OC2FH0 = 1 and writing 1 to the channel 0 overcurrent upper limit exceeded flag 0 clear (DSCOCESCR.CLROC2FH0 / DSCSCRCH0.CLROC2FH). 0: Indicates that the overcurrent data doesn't exceed the upper limit 2 1: Indicates that the overcurrent data has exceeded the upper limit 2	R
21	OC2FH1	Channel 1 overcurrent upper limit exceeded 2 flag This bit becomes 1 when the overcurrent data is updated and this data is larger than the upper limit 2. This bit becomes 0 when OC2FH1 = 1 and writing 1 to the channel 1 overcurrent upper limit exceeded flag 2 clear (DSCOCESCR.CLROC2FH1 / DSCSCRCH1.CLROC2FH). 0: Indicates that the overcurrent data doesn't exceed the upper limit 2 1: Indicates that the overcurrent data has exceeded the upper limit 2	R
22	OC2FH2	Channel 2 overcurrent upper limit exceeded 2 flag This bit becomes 1 when the overcurrent data is updated and this data is larger than the upper limit 2. This bit becomes 0 when OC2FH2 = 1 and writing 1 to the channel 2 overcurrent upper limit exceeded flag 2 clear (DSCOCESCR.CLROC2FH2 / DSCSCRCH2.CLROC2FH). 0: Indicates that the overcurrent data doesn't exceed the upper limit 2 1: Indicates that the overcurrent data has exceeded the upper limit 2	R
31:23	—	These bits are read as 0.	R

40.3.1.14 DSCOCNSR : Channel Overcurrent Notification Status Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x228

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OWD0N0	Channel 0 overcurrent detection window notification 0 flag This bit becomes 1 when the condition of overcurrent detection window notification 0 is satisfied. See section 40.4.13.2. Overcurrent Detection Window Notification for detail. This bit becomes 0 when OWD0N0 = 1 and writing 1 to the channel 0 overcurrent detection window notification flag 0 clear (DSCOCNSCR.CLROWD0N0 / DSCSCRCH0.CLROWD0). 0: Indicates that the condition of overcurrent detection window notification 0 is not satisfied 1: Indicates that the condition of overcurrent detection window notification 0 was satisfied	R

Bit	Symbol	Function	R/W
1	OWD0N1	Channel 1 overcurrent detection window notification 0 flag This bit becomes 1 when the condition of overcurrent detection window notification 0 is satisfied. See section 40.4.13.2. Overcurrent Detection Window Notification for detail. This bit becomes 0 when OWD0N1 = 1 and writing 1 to the channel 1 overcurrent detection window notification flag 0 clear (DSCOCNSCR.CLROWD0N1 / DSCSCRCH1.CLROWD0). 0: Indicates that the condition of overcurrent detection window notification 0 is not satisfied 1: Indicates that the condition of overcurrent detection window notification 0 was satisfied	R
2	OWD0N2	Channel 2 overcurrent detection window notification 0 flag This bit becomes 1 when the condition of overcurrent detection window notification 0 is satisfied. See section 40.4.13.2. Overcurrent Detection Window Notification for detail. This bit becomes 0 when OWD0N2 = 1 and writing 1 to the channel 2 overcurrent detection window notification flag 0 clear (DSCOCNSCR.CLROWD0N2 / DSCSCRCH2.CLROWD0). 0: Indicates that the condition of overcurrent detection window notification 0 is not satisfied 1: Indicates that the condition of overcurrent detection window notification 0 was satisfied	R
3	—	This bit is read as 0.	R
4	OWD1N0	Channel 0 overcurrent detection window notification 1 flag This bit becomes 1 when the condition of overcurrent detection window notification 1 is satisfied. See section 40.4.13.2. Overcurrent Detection Window Notification for detail. This bit becomes 0 when OWD1N0 = 1 and writing 1 to the channel 0 overcurrent detection window notification flag 1 clear (DSCOCNSCR.CLROWD1N0 / DSCSCRCH0.CLROWD1). 0: Indicates that the condition of overcurrent detection window notification 1 is not satisfied 1: Indicates that the condition of overcurrent detection window notification 1 was satisfied	R
5	OWD1N1	Channel 1 overcurrent detection window notification 1 flag This bit becomes 1 when the condition of overcurrent detection window notification 1 is satisfied. See section 40.4.13.2. Overcurrent Detection Window Notification for detail. This bit becomes 0 when OWD1N1 = 1 and writing 1 to the channel 1 overcurrent detection window notification flag 1 clear (DSCOCNSCR.CLROWD1N1 / DSCSCRCH1.CLROWD1). 0: Indicates that the condition of overcurrent detection window notification 1 is not satisfied 1: Indicates that the condition of overcurrent detection window notification 1 was satisfied	R
6	OWD1N2	Channel 2 overcurrent detection window notification 1 flag This bit becomes 1 when the condition of overcurrent detection window notification 1 is satisfied. See section 40.4.13.2. Overcurrent Detection Window Notification for detail. This bit becomes 0 when OWD1N2 = 1 and writing 1 to the channel 2 overcurrent detection window notification flag 1 clear (DSCOCNSCR.CLROWD1N2 / DSCSCRCH2.CLROWD1). 0: Indicates that the condition of overcurrent detection window notification 1 is not satisfied 1: Indicates that the condition of overcurrent detection window notification 1 was satisfied	R
7	—	This bit is read as 0.	R
8	OWD2N0	Channel 0 overcurrent detection window notification 2 flag This bit becomes 1 when the condition of overcurrent detection window notification 2 is satisfied. See section 40.4.13.2. Overcurrent Detection Window Notification for detail. This bit becomes 0 when OWD2N0 = 1 and writing 1 to the channel 0 overcurrent detection window notification flag 2 clear (DSCOCNSCR.CLROWD2N0 / DSCSCRCH0.CLROWD2). 0: Indicates that the condition of overcurrent detection window notification 2 is not satisfied 1: Indicates that the condition of overcurrent detection window notification 2 was satisfied	R

Bit	Symbol	Function	R/W
9	OWD2N1	Channel 1 overcurrent detection window notification 2 flag This bit becomes 1 when the condition of overcurrent detection window notification 2 is satisfied. See section 40.4.13.2. Overcurrent Detection Window Notification for detail. This bit becomes 0 when OWD2N1 = 1 and writing 1 to the channel 1 overcurrent detection window notification flag 2 clear (DSCOCNSCR.CLROWD2N1 / DSCSCRCH1.CLROWD2). 0: Indicates that the condition of overcurrent detection window notification 2 is not satisfied 1: Indicates that the condition of overcurrent detection window notification 2 was satisfied	R
10	OWD2N2	Channel 2 overcurrent detection window notification 2 flag This bit becomes 1 when the condition of overcurrent detection window notification 2 is satisfied. See section 40.4.13.2. Overcurrent Detection Window Notification for detail. This bit becomes 0 when OWD2N2 = 1 and writing 1 to the channel 2 overcurrent detection window notification flag 2 clear (DSCOCNSCR.CLROWD2N2 / DSCSCRCH2.CLROWD2). 0: Indicates that the condition of overcurrent detection window notification 2 is not satisfied 1: Indicates that the condition of overcurrent detection window notification 2 was satisfied	R
11	—	This bit is read as 0.	R
12	OWD3N0	Channel 0 overcurrent detection window notification 3 flag This bit becomes 1 when the condition of overcurrent detection window notification 3 is satisfied. See section 40.4.13.2. Overcurrent Detection Window Notification for detail. This bit becomes 0 when OWD3N0 = 1 and writing 1 to the channel 0 overcurrent detection window notification flag 3 clear (DSCOCNSCR.CLROWD3N0 / DSCSCRCH0.CLROWD3). 0: Indicates that the condition of overcurrent detection window notification 3 is not satisfied 1: Indicates that the condition of overcurrent detection window notification 3 was satisfied	R
13	OWD3N1	Channel 1 overcurrent detection window notification 3 flag This bit becomes 1 when the condition of overcurrent detection window notification 3 is satisfied. See section 40.4.13.2. Overcurrent Detection Window Notification for detail. This bit becomes 0 when OWD3N1 = 1 and writing 1 to the channel 1 overcurrent detection window notification flag 3 clear (DSCOCNSCR.CLROWD3N1 / DSCSCRCH1.CLROWD3). 0: Indicates that the condition of overcurrent detection window notification 3 is not satisfied 1: Indicates that the condition of overcurrent detection window notification 3 was satisfied	R
14	OWD3N2	Channel 2 overcurrent detection window notification 3 flag This bit becomes 1 when the condition of overcurrent detection window notification 3 is satisfied. See section 40.4.13.2. Overcurrent Detection Window Notification for detail. This bit becomes 0 when OWD3N2 = 1 and writing 1 to the channel 2 overcurrent detection window notification flag 3 clear (DSCOCNSCR.CLROWD3N2 / DSCSCRCH2.CLROWD3). 0: Indicates that the condition of overcurrent detection window notification 3 is not satisfied 1: Indicates that the condition of overcurrent detection window notification 3 was satisfied	R
31:15	—	These bits are read as 0.	R

40.3.1.15 DSCOCRMR : Channel Overcurrent Comparator Result Monitor Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)

7	—	This bit is read as 0.	R
8	OC1CMPL0	Channel 0 overcurrent detect 1 lower limit compare result 0: Indicates that the overcurrent data is not less than the lower limit 1 1: Indicates that the overcurrent data has been less than the lower limit 1	R
9	OC1CMPL1	Channel 1 overcurrent detect 1 lower limit compare result 0: Indicates that the overcurrent data is not less than the lower limit 1 1: Indicates that the overcurrent data has been less than the lower limit 1	R
10	OC1CMPL2	Channel 2 overcurrent detect 1 lower limit compare result 0: Indicates that the overcurrent data is not less than the lower limit 1 1: Indicates that the overcurrent data has been less than the lower limit 1	R
11	—	This bit is read as 0.	R
12	OC1CMPH0	Channel 0 overcurrent detect 1 upper limit compare result 0: Indicates that the overcurrent data does not exceed the upper limit 1 1: Indicates that the overcurrent data has exceeded the upper limit 1	R
13	OC1CMPH1	Channel 1 overcurrent detect 1 upper limit compare result 0: Indicates that the overcurrent data does not exceed the upper limit 1 1: Indicates that the overcurrent data has exceeded the upper limit 1	R
14	OC1CMPH2	Channel 2 overcurrent detect 1 upper limit compare result 0: Indicates that the overcurrent data does not exceed the upper limit 1 1: Indicates that the overcurrent data has exceeded the upper limit 1	R

Bit	Symbol	Function	R/W
15	—	This bit is read as 0.	R
16	OC2CMPL0	Channel 0 overcurrent detect 2 lower limit compare result 0: Indicates that the overcurrent data is not less than the lower limit 2 1: Indicates that the overcurrent data has been less than the lower limit 2	R
17	OC2CMPL1	Channel 1 overcurrent detect 2 lower limit compare result 0: Indicates that the overcurrent data is not less than the lower limit 2 1: Indicates that the overcurrent data has been less than the lower limit 2	R
18	OC2CMPL2	Channel 2 overcurrent detect 2 lower limit compare result 0: Indicates that the overcurrent data is not less than the lower limit 2 1: Indicates that the overcurrent data has been less than the lower limit 2	R
19	—	This bit is read as 0.	R
20	OC2CMPH0	Channel 0 overcurrent detect 2 upper limit compare result 0: Indicates that the overcurrent data does not exceed the upper limit 2 1: Indicates that the overcurrent data has exceeded the upper limit 2	R
21	OC2CMPH1	Channel 1 overcurrent detect 2 upper limit compare result 0: Indicates that the overcurrent data does not exceed the upper limit 2 1: Indicates that the overcurrent data has exceeded the upper limit 2	R
22	OC2CMPH2	Channel 2 overcurrent detect 2 upper limit compare result 0: Indicates that the overcurrent data does not exceed the upper limit 2 1: Indicates that the overcurrent data has exceeded the upper limit 2	R
31:23	—	These bits are read as 0.	R

The DSCOCRMR register has monitor bits that return the comparison result with the upper/lower limit table for each overcurrent detection every time the overcurrent data is updated. There is no status clear bit of this register because the result updates when the overcurrent data is updated.

40.3.1.16 DSCSR : Channel Status Register

Base address: DSMIFm = 0x9002_0000 + 0x1000 × m (m = 0 to 5)
DSMIFi = 0x9012_0000 + 0x1000 × (i - 6) (i = 6 to 9)

Offset address: 0x240

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	CBUF2	CBUF1	CBUF0	—	CAUF2	CAUF1	CAUF0	—	DUF2	DUF1	DUF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DUF0	Channel 0 Data Update flag This bit is the Current Data Register Update Interrupt Status bit. This bit becomes 0 when DUF0 = 1 and 1 to the Channel n Data Update Clear flag (DSCSCR.CLRDUF0/ DSCSCRCH0.CLRDUF) or when the Current Data Register Channel 0 (DSCDRCH0) is read. 0: Indicates that the Current Data register has not been updated 1: Indicates that the Current Data register has been updated	R
1	DUF1	Channel 1 Data Update flag This bit is the Current Data Register Update Interrupt Status bit. This bit becomes 0 when DUF1 = 1 and 1 to the Channel n Data Update Clear flag (DSCSCR.CLRDUF1/ DSCSCRCH1.CLRDUF) or when the Current Data Register Channel 1 (DSCDRCH1) is read. 0: Indicates that the Current Data register has not been updated 1: Indicates that the Current Data register has been updated	R

Bit	Symbol	Function	R/W
2	DUF2	Channel 2 Data Update flag This bit is the Current Data Register Update Interrupt Status bit. This bit becomes 0 when DUF2 = 1 and 1 to the Channel n Data Update Clear flag (DSCSCR.CLRDUF2/ DSCSCRCH2.CLRDUF) or when the Current Data Register Channel 2 (DSCDRCH2) is read. 0: Indicates that the Current Data register has not been updated 1: Indicates that the Current Data register has been updated	R
3	—	This bit is read as 0.	R
4	CAUF0	Channel 0 capture data A update flag This bit becomes 0 when CAUF0 = 1 and 1 to the capture data update flag A clear (DSCSCR.CLRCAUF00 / DSCESCRCH0.CLRCAUF) or when the capture current data register A channel 0 (DSCCDRACH0) is read. 0: Indicates that the capture register A has not been updated 1: Indicates that the capture register A has been updated	R
5	CAUF1	Channel 1 capture data A update flag This bit becomes 0 when CAUF1 = 1 and 1 to the capture data update flag A clear (DSCSCR.CLRCAUF01 / DSCESCRCH1.CLRCAUF) or when the capture current data register A channel 1 (DSCCDRACH1) is read. 0: Indicates that the capture register A has not been updated 1: Indicates that the capture register A has been updated	R
6	CAUF2	Channel 2 capture data A update flag This bit becomes 0 when CAUF2 = 1 and 1 to the capture data update flag A clear (DSCSCR.CLRCAUF02 / DSCESCRCH2.CLRCAUF) or when the capture current data register A channel 2 (DSCCDRACH2) is read. 0: Indicates that the capture register A has not been updated 1: Indicates that the capture register A has been updated	R
7	—	This bit is read as 0.	R
8	CBUF0	Channel 0 capture data B update flag This bit becomes 0 when CBUF0 = 1 and 1 to the capture data update flag B clear (DSCSCR.CLRCBUF00 / DSCESCRCH0.CLRCBUF) or when the capture current data register B channel 0 (DSCCDRBCH0) is read. 0: Indicates that the capture register B has not been updated 1: Indicates that the capture register B has been updated	R
9	CBUF1	Channel 1 capture data B update flag This bit becomes 0 when CBUF1 = 1 and 1 to the capture data update flag B clear (DSCSCR.CLRCBUF01 / DSCESCRCH1.CLRCBUF) or when the capture current data register B channel 1 (DSCCDRBCH1) is read. 0: Indicates that the capture register B has not been updated 1: Indicates that the capture register B has been updated	R
10	CBUF2	Channel 2 capture data B update flag This bit becomes 0 when CBUF2 = 1 and 1 to the capture data update flag B clear (DSCSCR.CLRCBUF02 / DSCESCRCH2.CLRCBUF) or when the capture current data register B channel 2 (DSCCDRBCH2) is read. 0: Indicates that the capture register B has not been updated 1: Indicates that the capture register B has been updated	R
31:11	—	These bits are read as 0.	R

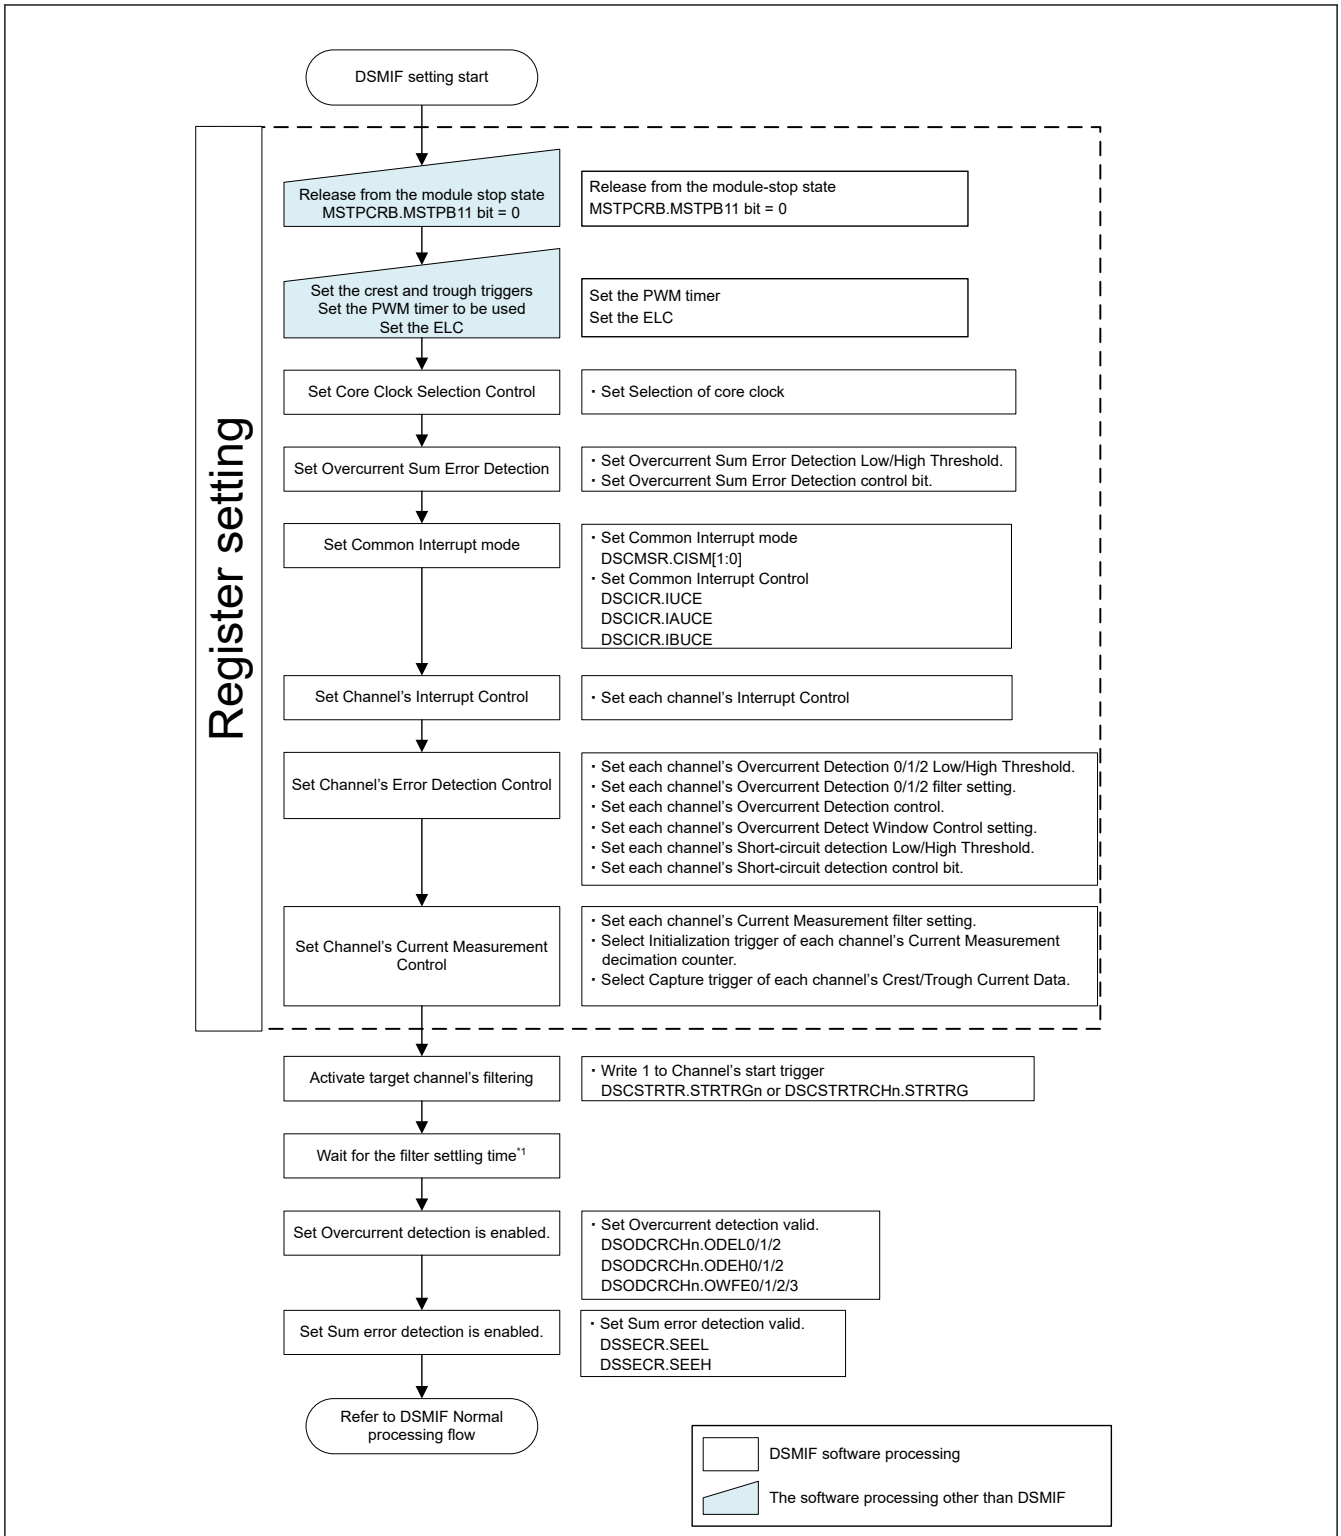
18	CLROWD2N	Channel n overcurrent detection window notification 2 flag clear Mirror register of DSCOCNSCR.CLROWD2n 0: Do nothing 1: Clear DSCOCNSR.OWD2Nn / DSCSRCHn.OWD2N	W
19	CLROWD3N	Channel n overcurrent detection window notification 3 flag clear Mirror register of DSCOCNSCR.CLROWD3n 0: Do nothing 1: Clear DSCOCNSR.OWD3Nn / DSCSRCHn.OWD3N	W
31:20	—	The write value should be 0.	W

The DSCSCRCHn register is a mirror register of various registers in section 40.3.1. DSMIF Common Control Registers.

40.4 Operation

40.4.1 Start Flow

Figure 40.2 shows an example of a start procedure for DSMIF.

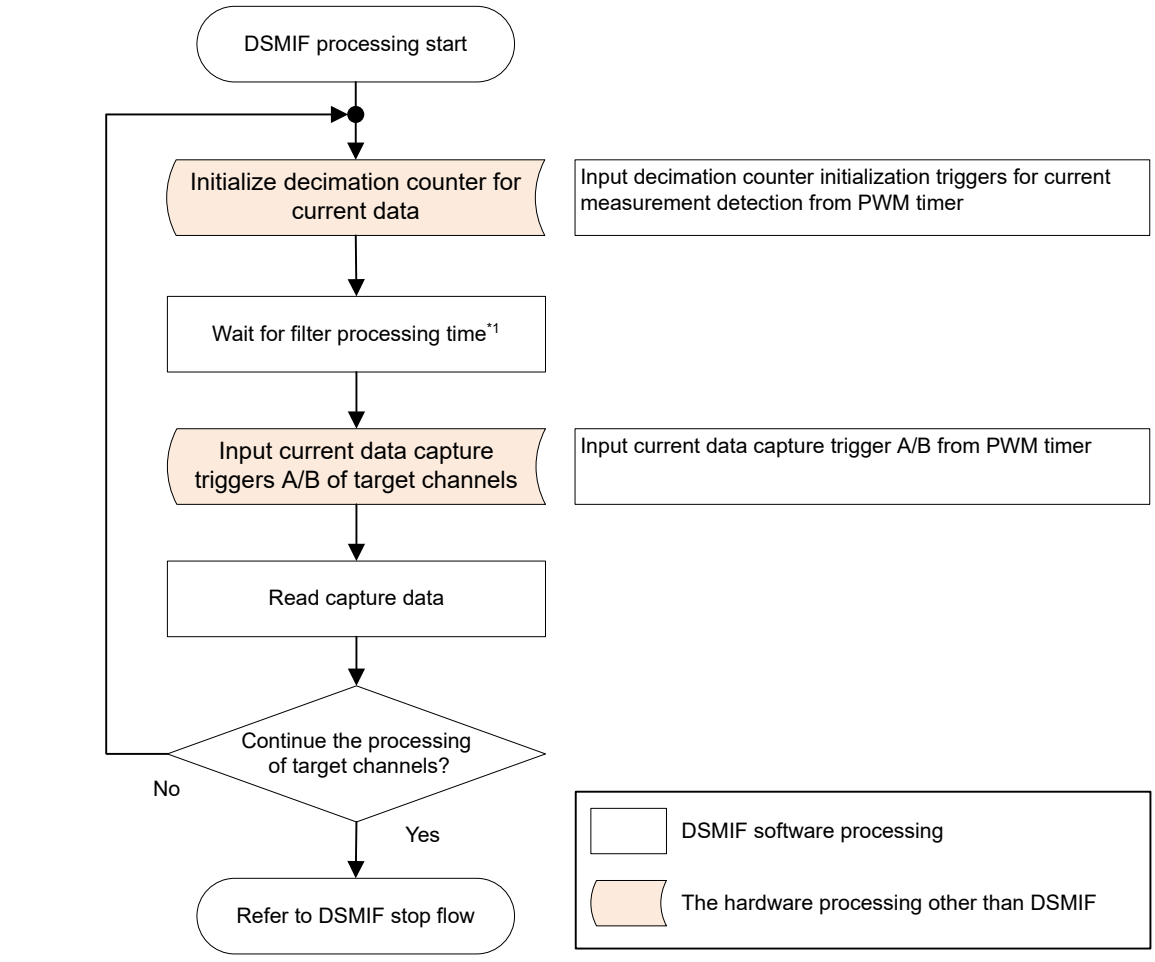


Note 1. See section 40.4.15.1. Settling Time of Channel Activation.

Figure 40.2 Start flow of DSMIF

40.4.2 Normal Processing Flow

Figure 40.3 shows an example of a normal processing procedure for DSMIF.



Note: The filter result during settling time is invalid. It is prohibited to use this data for capture data.
Note 1. See section 40.4.15.2. Settling Time after PWM Synchronization.

Figure 40.3 Normal processing flow for DSMIF

40.4.3 Stop Flow

Figure 40.4 shows an example of a stop procedure in channel synchronization control mode for DSMIF. Figure 40.5 shows the example of the stop procedure in channel individual control mode of DSMIF.

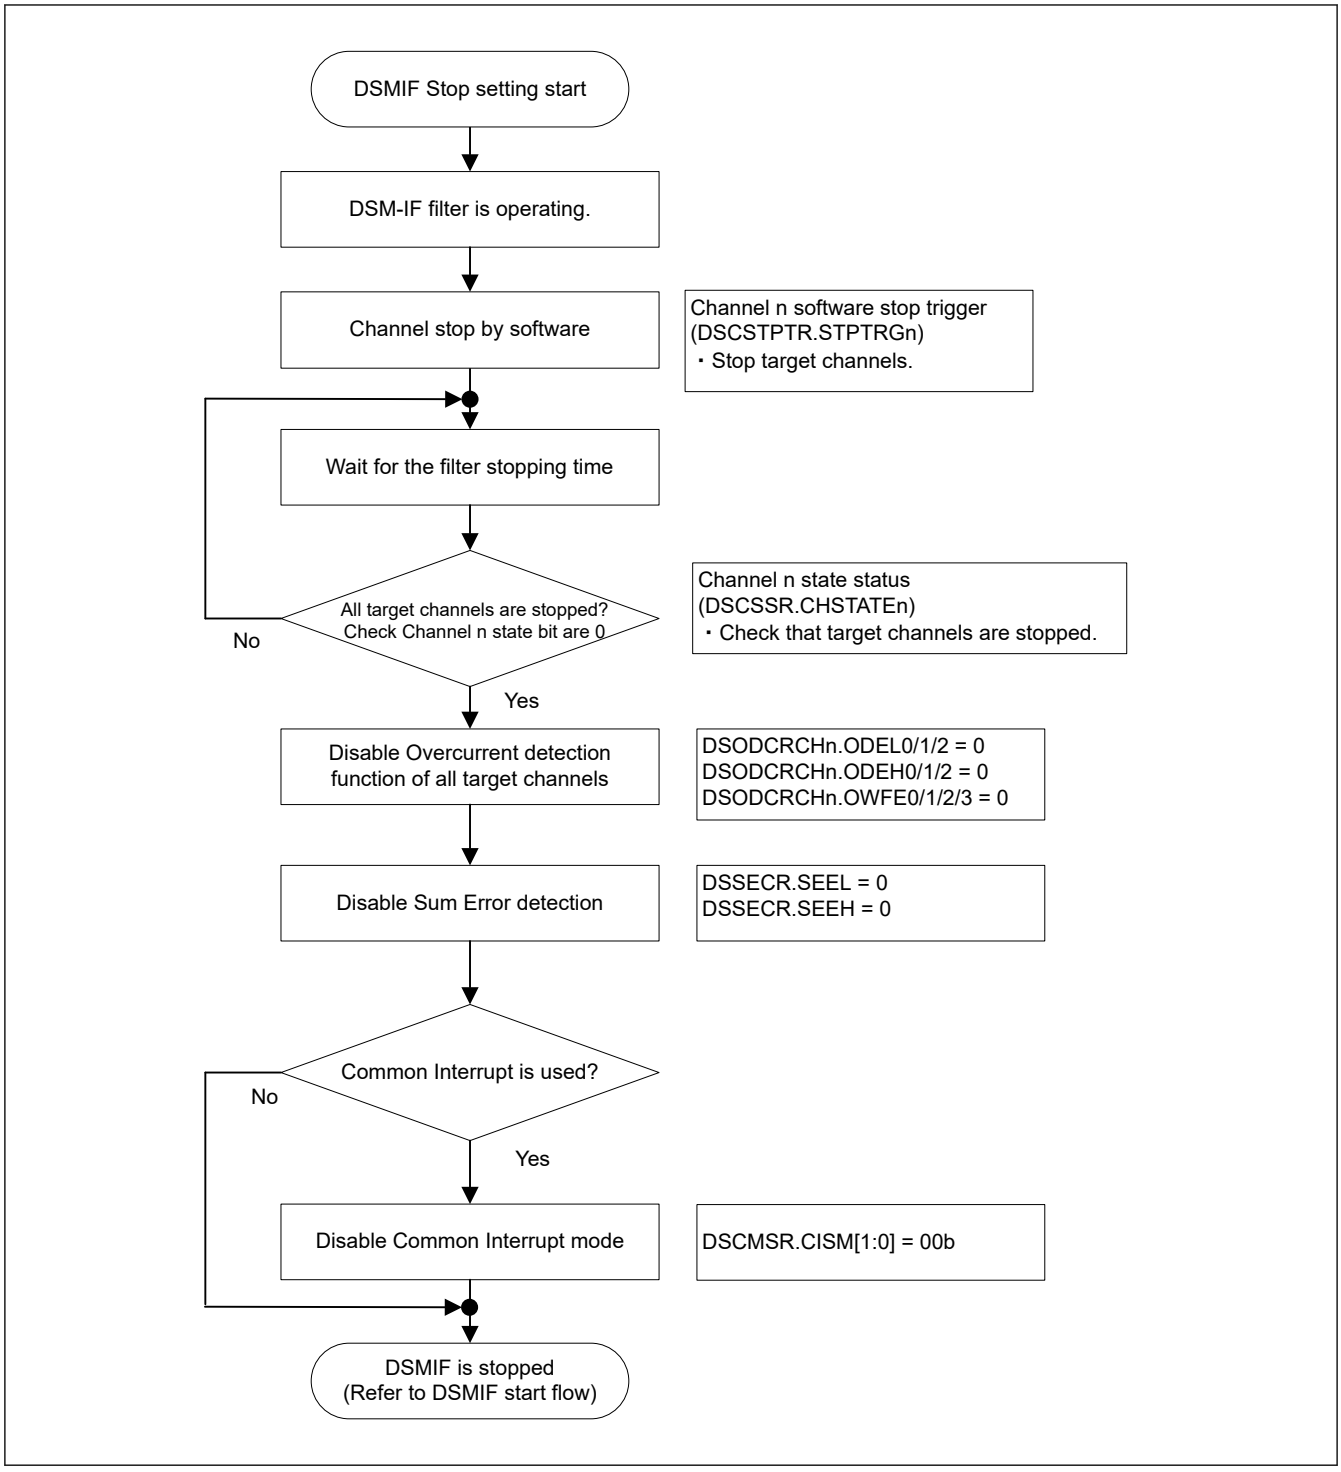


Figure 40.4 Stop flow for DSMIF (Channel synchronization control mode)

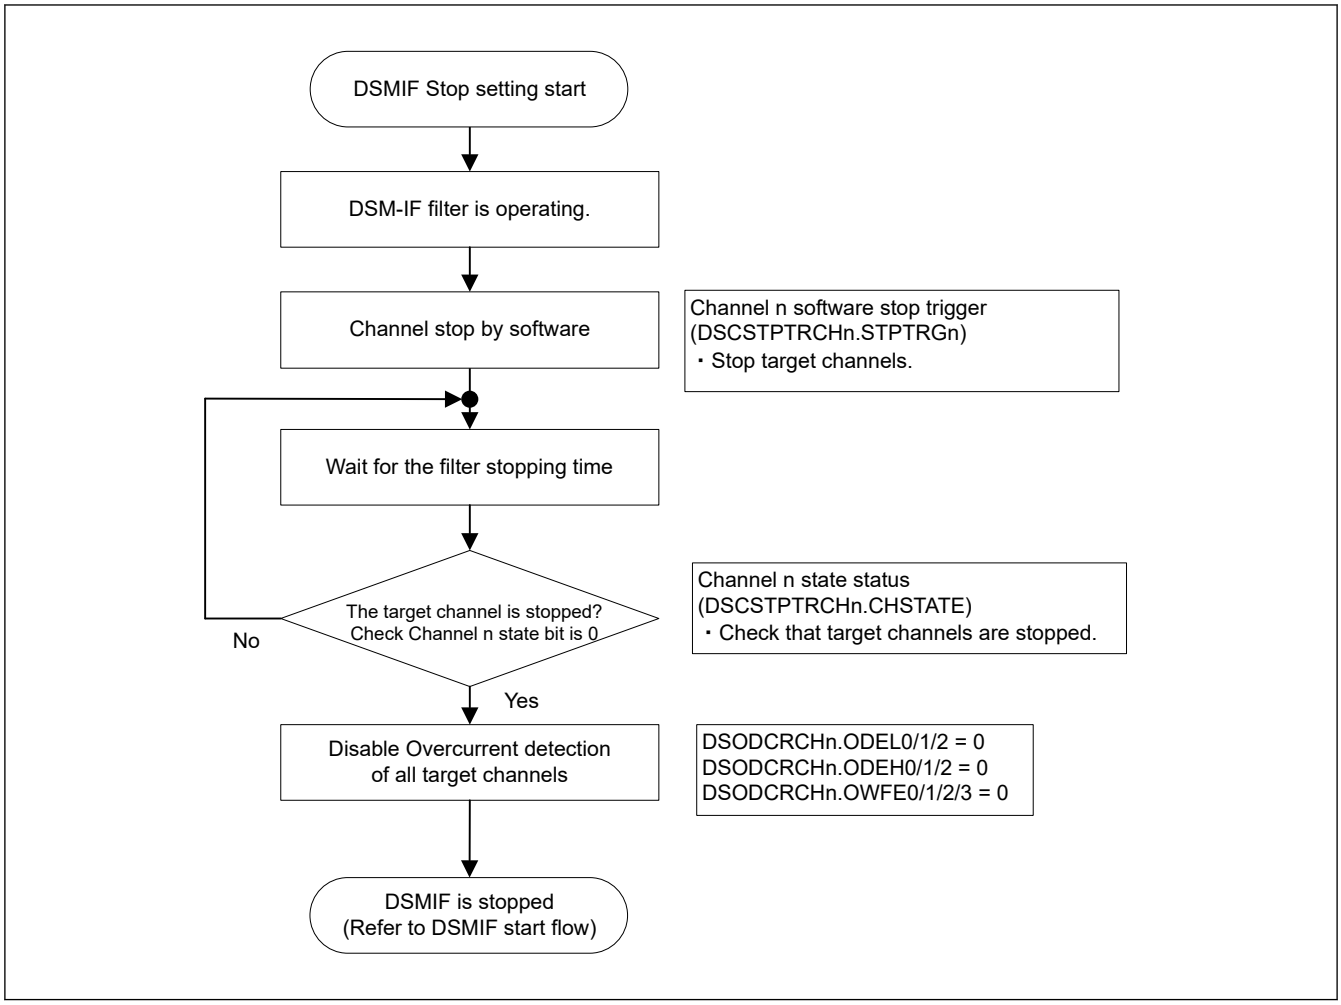

Figure 40.5 Stop flow for DSMIF (Channel individual control mode)

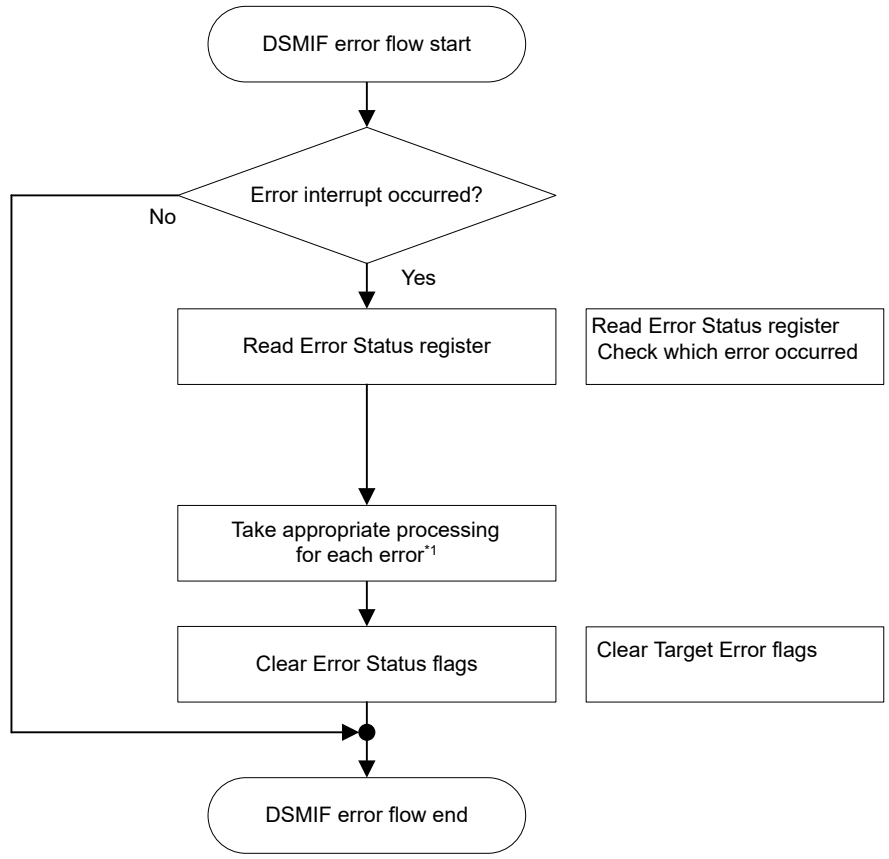
40.4.4 Error Flow

Figure 40.6 shows an example of an error procedure for DSMIF.



Note 1. The processing after each error detection depends on the user's system. Therefore, execute the error processing after the error detection according to each system.

Figure 40.6 Error flow for DSMIF

40.4.5 Clock Specification

When DSCMCCRCHn.CKDIR is set to 0 (clock slave mode), an external delta-sigma modulator clock is input to MCLKmn. When DSCMCCRCHn.CKDIR is set to 1 (clock master mode), the frequency-divided core clock is output to MCLKmn.

The frequency of the MCLKmn can be selected by the DSCCSCR.CLKSEL bit and the DSCMCCRCHn.CKDIV[5:0] bits.

Table 40.5 shows the clock division ratio of master mode in DSMIF.

Table 40.5 Clock division ratio of Master mode in DSMIF (1 of 2)

No.	Core clock (MHz)	MCLKmn (MHz)	Supported core clock division ratio	Setting value (DSCMCCRCHn.CKDIV[5:0])
1	250 (DSCCSCR.CLKSEL = 0b)	25	10	00_0100b
2		20.8	12	00_0101b
3		12.5	20	00_1001b
4		10.4	24	00_1011b
5		6.25	40	01_0011b
6		5	50	01_1000b

Table 40.5 Clock division ratio of Master mode in DSMIF (2 of 2)

No.	Core clock (MHz)	MCLKmn (MHz)	Supported core clock division ratio	Setting value (DSCMCCRCHn.CKDIV[5:0])
7	400 (DSCCSCR.CLKSEL = 1b)	25	16	00_0111b
8		20	20	00_1001b
9		12.5	32	00_1111b
10		10	40	01_0011b
11		6.25	64	01_1111b
12		5	80	10_0111b

40.4.6 Channel Start and Channel Stop

The channel start and channel stop are controlled by the register in Table 40.6. Set the channels to be synchronized to 1 simultaneously. Set the channel start according to section 40.4.1. Start Flow. Set the channel stop according to section 40.4.3. Stop Flow.

Table 40.6 Channel start trigger and channel stop trigger

Channel mode	Category	Register bit name
Channel synchronization control mode	Channel start	DSCSTRTR.STRTRG0
		DSCSTRTR.STRTRG1
		DSCSTRTR.STRTRG2
	Channel stop	DSCSTPTR.STPTRG0
		DSCSTPTR.STPTRG1
		DSCSTPTR.STPTRG2
Channel individual control mode	Channel start	DSCSTRTRCHn.STRTRG
	Channel stop	DSCSTPTRCHn.STPTRG

40.4.7 Channel Synchronization

To synchronize the Sinc filters of multiple channels, use the following procedure. To allow for multiple channels to be synchronized, follow the procedure in section 40.4.1. Start Flow.

1. Set the same clock settings.
2. Select the same trigger for division counter initialization trigger.
   Set the same value to Division counter initialization trigger select bits (DSCMCTCRCHn.DITSEL[1:0]).
3. Select the same trigger for capture trigger A and B.
   (a) Set the same value to the Current Capture Trigger A Select bits (DSCMCTCRCHn.CTSELA[2:0]).
   (b) Set the same value to the Current Capture Trigger B Select bits (DSCMCTCRCHn.CTSELB[2:0]).
4. Activate the channels simultaneously
   Write 1 to Channel n start trigger (DSCSTRTR.STRTRGn) at the same time.

40.4.8 Data Input Control

By using the DSCMCCRCHn.SEDGE bit, data receive can be selected to receive on the falling edge of MCLKmn or the rising edge of MCLKmn. Data input control receives clock and data from DSM. Synchronized data and clock are output to the sinc filter and short-circuit detection.

40.4.9 Sinc Filter

The differentiation stage is operated by decimation clock (the frequency is 1/M of MCLKmn). M is the decimation ratio and is set in the DSCMFCRCHn.CMDEC[7:0] bits for current measurement or in the DSOCFCRCHn.OCDEC[7:0] bits for overcurrent detection. The filter result is stored in register every decimation clock. In the case of current data, an interrupt is output at the same time when the filter result is stored.

Figure 40.7 shows a block diagram for the Sinc Filter.

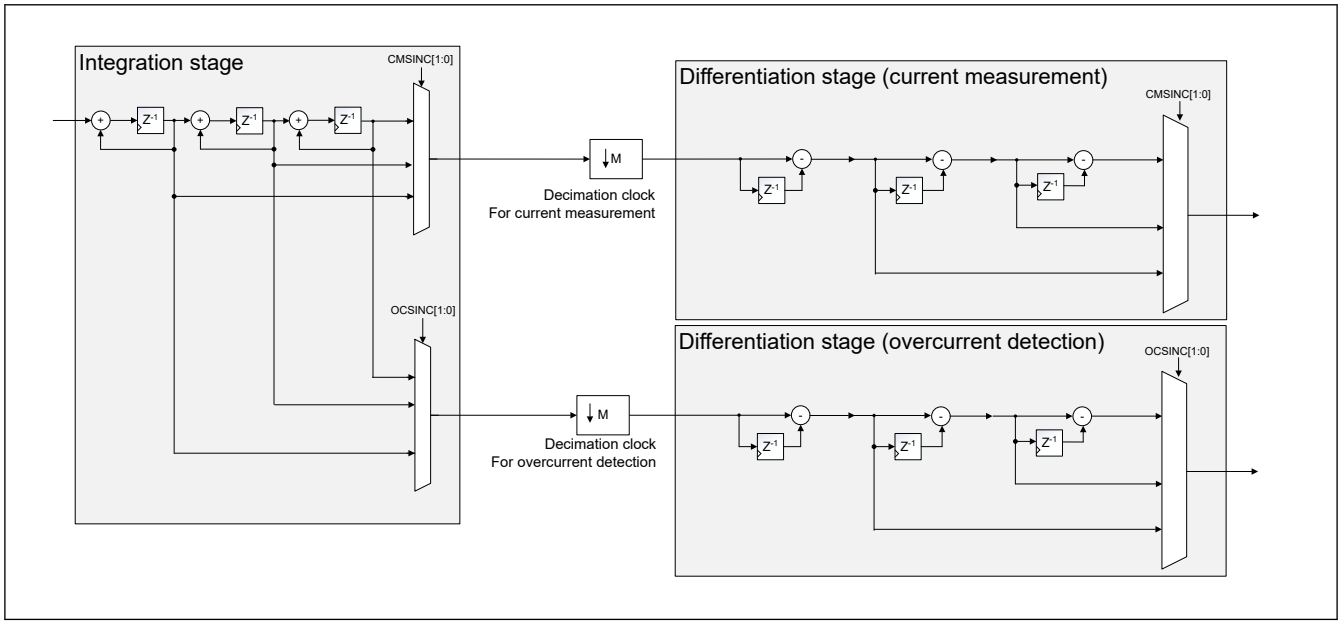


Figure 40.7 Block diagram of Sinc filter

40.4.10 Available Settings of Sinc Filter

Table 40.7 lists the available settings of the sinc filter and data shifting.

Table 40.7 Available settings of Sinc filter (1 of 2)

Sinc filter order	Decimation rate	Effective bits	Peak value (Decimal)	Peak value (Hexadecimal)	Stored data		CMSH[4:0] OCSH[4:0]	Resolution
					DFS = 0	DFS = 1		
3 (Sinc3)	4	[6:0]	63*1	000003F	[5:0], 00_0000_0000	00_0000_0000, [5:0]	0x12	6 bits

Note 1. When the filter result is the maximum value, it is rounded to the maximum value of -1.

Figure 40.8 shows the relationship between the filter settings and the stored values.

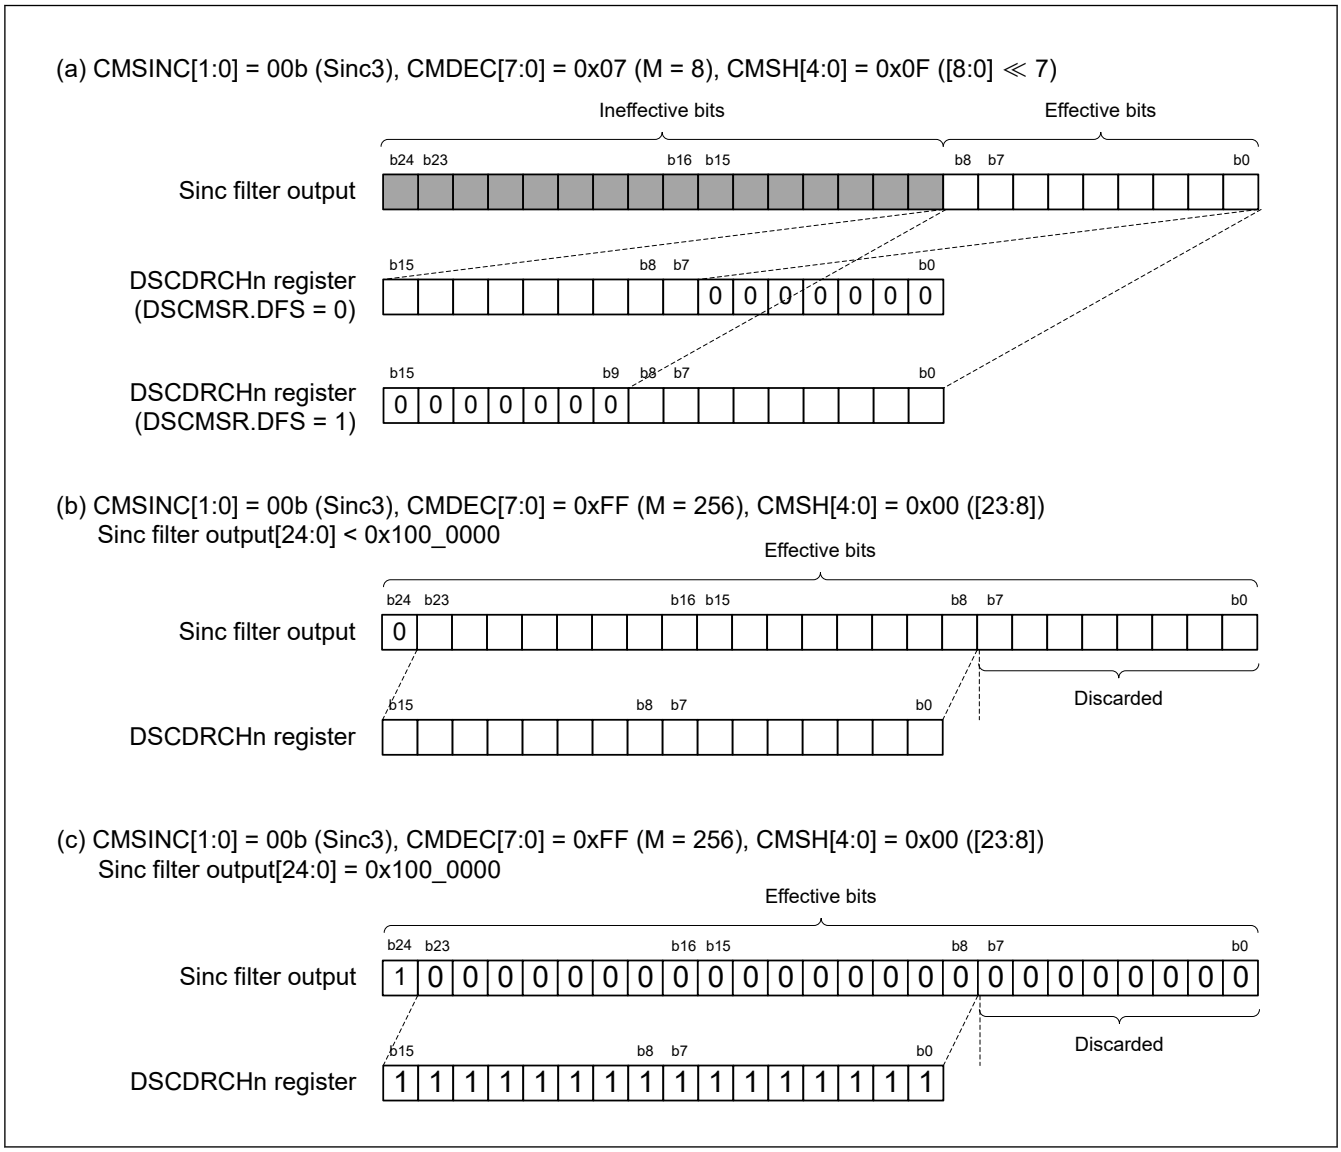

Figure 40.8 Relationship between the filter settings and the stored values

40.4.11 Current Measurement Data Processing

Each channel of DSMIF has the data registers specified in Table 40.8. Capture trigger A is selected by DSCMCTCRCHn.CTSELA[2:0] and capture trigger B is selected by DSCMCTCRCHn.CTSELB[2:0].

The trigger capturing function allows the capture of the values for current at the time of capture trigger A and capture trigger B using the event link controller (ELC) to set the capture trigger A or capture trigger B.

Table 40.8 Current measurement data list

No.	Register name	Symbol	Stored data
1	Current Data register	DSCDRCHn	The measured values for current
2	Capture Current Data Register A	DSCCDRACHn	The captured value of Current Data register by capture trigger A from the internal timer module
3	Capture Current Data Register B	DSCCDRBCHn	The captured value of Current Data register by capture trigger B from the internal timer module

40.4.12 Short-circuit Detection

When the short-circuit detection enable (DSEDCRCHn.SDE) is valid, the short-circuit detection can operate. A dedicated 13-bit counter counts consecutive 0's or 1's input from dsmdata n (n = 0 to 2). When the number of consecutive 0's exceeds the value set in the DSSCTSRCHn.SCNTL[12:0] register or the number of consecutive 1's exceeds the value set in the DSSCTSRCHn.SCNTH[12:0] register, a short-circuit detection interrupt request is generated.

40.4.13 Overcurrent Detection

The overcurrent detection function is used for abnormally detection. Overcurrent data is generated by the sinc filter result that is setting in section 40.4.9. Sinc Filter. The overcurrent data is compared with the value of the upper limit value or the lower limit value. The interrupt of overcurrent detection is output by these results.

It has 3 sets of upper limit value and lower limit value for each channel. And the interrupts can be output from each comparison results.

In addition, the overcurrent detection function also has overcurrent detection window notification function that notifies within range or out of range from the comparison result of the upper limit and the lower limit.

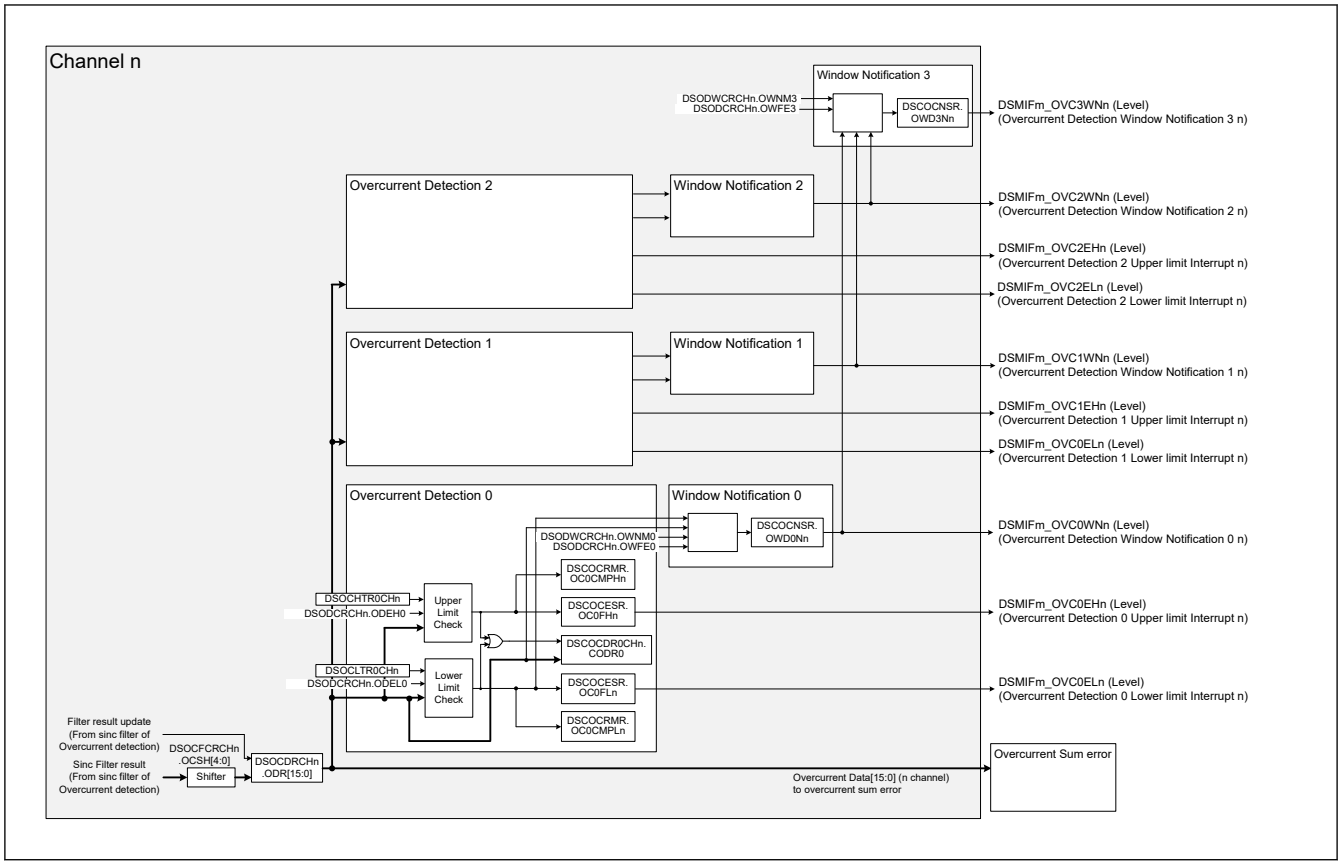

Figure 40.9 Configuration of overcurrent data registers

The measure values from current are stored as 16-bit values obtained by shifting the 25-bit data output from the sinc-filter in accordance with the setting of the DSOCFCRCHn.OCSH[4:0] bits.

The format of stored data can be selected by the DSCMSR.DFS bit. Either left-justified or right-justified can be selected.

40.4.13.1 Overcurrent Detection 0 to 2

Overcurrent detection has three upper limit excess judgments and three lower limit judgments for each channel. Table 40.9 shows the list of overcurrent detection.

Table 40.9 List of overcurrent detection

Function	Upper Lower	Enable	Comparator table	Error flag	Comparator result	Interrupt	Error capture data
Overcurrent Detection 0	Upper	DSODCRCHn.ODEH0	DSOCHTR0CHn.OCMPTBH0	DSCOCESR.OC0FHn	DSCOCRMR.OC0CMPHn	OVC0EHn	DSCOCDR0CHn.CODR0
	Lower	DSODCRCHn.ODEL0	DSOCHTR0CHn.OCMPTBL0	DSCOCESR.OC0FLn	DSCOCRMR.OC0CMPLn	OVC0ELn	
Overcurrent Detection 1	Upper	DSODCRCHn.ODEH1	DSOCHTR1CHn.OCMPTBH1	DSCOCESR.OC1FHn	DSCOCRMR.OC1CMPHn	OVC1EHn	DSCOCDR1CHn.CODR1
	Lower	DSODCRCHn.ODEL1	DSOCHTR1CHn.OCMPTBL1	DSCOCESR.OC1FLn	DSCOCRMR.OC1CMPLn	OVC1ELn	
Overcurrent Detection 2	Upper	DSODCRCHn.ODEH2	DSOCHTR2CHn.OCMPTBH2	DSCOCESR.OC2FHn	DSCOCRMR.OC2CMPHn	OVC2EHn	DSCOCDR2CHn.CODR2
	Lower	DSODCRCHn.ODEL2	DSOCHTR2CHn.OCMPTBL2	DSCOCESR.OC2FLn	DSCOCRMR.OC2CMPLn	OVC2ELn	

The overcurrent detection function is explained using overcurrent detection 0 as an example.

When the overcurrent upper limit detection 0 enable (DSODCRCHn.ODEH0) is valid, the overcurrent upper limit detection can operate. And when the overcurrent lower limit detection 0 enable (DSODCRCHn.ODEL0) is valid, the overcurrent lower limit detection can operate.

The current data is stored in the DSOCDRCHn as a 16-bit data shifted from 25-bit data output from sinc filter for overcurrent detection in accordance with the setting of the DSOCFCRCHn.OCSH[4:0] bits.

An overcurrent upper limit detection interrupt is requested when the value in the DSOCDRCHn register is upper than the value of OCMPTBH0.

An overcurrent lower limit detection interrupt is requested when the value in the DSOCDRCHn register is lower than the value of OCMPTBL0.

Overcurrent detection has the following two statuses.

1. Error flags that are set when the upper limit is exceeded / less than the lower limit is detected and cleared with the clear bit.
2. Monitor bits that return the comparison result for each decimation cycle.

40.4.13.2 Overcurrent Detection Window Notification

Overcurrent detection window notification is event notification function to notify within a range or out of range by comparison with upper limit and lower limit of overcurrent detection. There are four kinds of notification for each channel. Table 40.10 shows a list of overcurrent detection notification.

Table 40.10 List of overcurrent detection notification

Function	Enable	Mode bit	Flag	Notification
Overcurrent detection Window notification 0	DSODCRCHn.OWFE0	DSODWCRCHn.OWNM0	DSCOCNSR.OWD0Nn	OVC0WNn
Overcurrent detection Window notification 1	DSODCRCHn.OWFE1	DSODWCRCHn.OWNM1	DSCOCNSR.OWD1Nn	OVC1WNn
Overcurrent detection Window notification 2	DSODCRCHn.OWFE2	DSODWCRCHn.OWNM2	DSCOCNSR.OWD2Nn	OVC2WNn
Overcurrent detection Window notification 3	DSODCRCHn.OWFE3	DSODWCRCHn.OWNM3	DSCOCNSR.OWD3Nn	OVC3WNn

Overcurrent detection window notification 0 to 2 will be generated by comparison with upper limit and lower limit for overcurrent detection 0 to 2. The notification can be set for within a range or out of range as Figure 40.10.

1. OWNMm = 0: (overcurrent data channel n < lower limit m) or (overcurrent data channel n > upper limit m)
2. OWNMm = 1: lower limit m ≤ overcurrent data channel n ≤ upper limit m

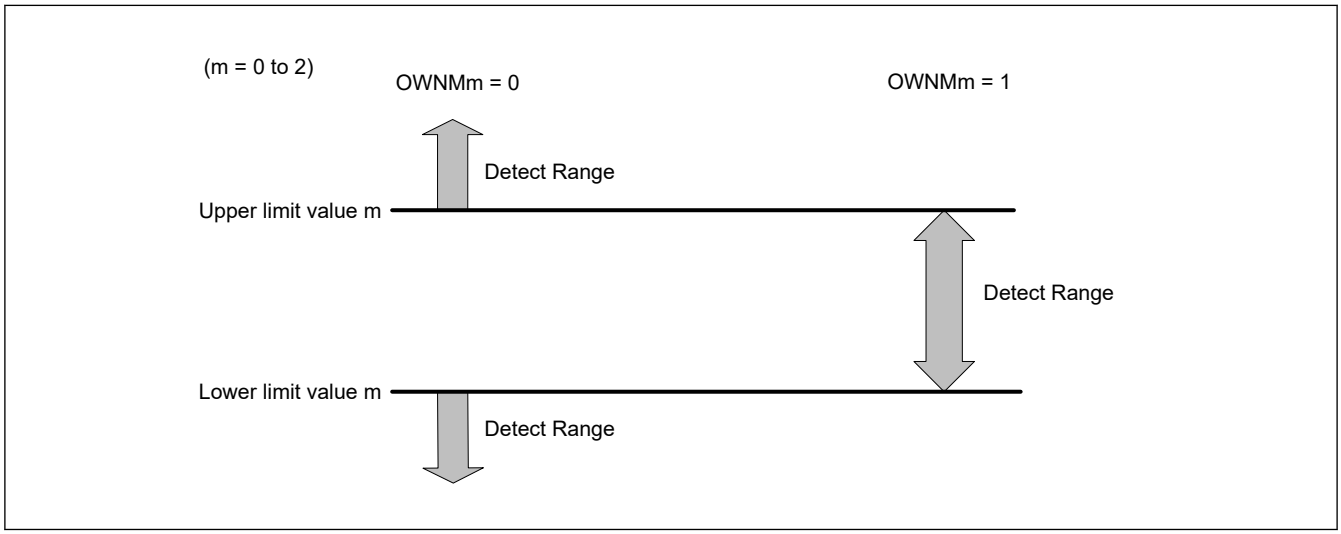

Figure 40.10 Detect range of overcurrent detection window notification

40.4.14 Overcurrent Sum Error Detection

When the overcurrent sum error upper limit detection enable (DSSECR.SEEH) is valid, the overcurrent sum error upper limit detection can operate. When the overcurrent sum error lower limit detection enable (DSSECR.SEEL) is valid, the

overcurrent sum error lower limit detection can operate. An overcurrent upper limit sum error detection interrupt is requested when the sum of the values for each mode (see Table 40.11) is higher than the value of SCMPTBH.

An overcurrent lower limit sum error detection interrupt is requested when the sum of the values for each mode is lower than the value of SCMPTBL.

Table 40.11 List of sum error mode detect mode and capture data

SEDM[2:0]	Sum error detect mode	CH0	CH1	CH2	DSSECDR0	DSSECDR1	DSSECDR2
000b	Three value sum error detect	✓	✓	✓	DSOCDRCH0	DSOCDRCH1	DSOCDRCH2
001b	Two value sum error detect	✓	✓	—	DSOCDRCH0	DSOCDRCH1	—*1
010b	One channel error detect	✓	—	—	DSOCDRCH0	—	—
011b		—	✓	—	DSOCDRCH1	—	—
100b		—	—	✓	DSOCDRCH2	—	—

Note 1. Do not store data, hold previous value.

40.4.15 Settling Time

40.4.15.1 Settling Time of Channel Activation

Settling time of channel activation is the time from when the channel is activated until the filter result is stable and output.

The settling time is calculated as follows.

Table 40.12 Settling time of channel activation

Core clock (MHz)	Sinc order	Processing time of settling time of channel activation
250 (DSCCSCR.CLKSEL = 0)	$Sinc^1$	(MCLK period × Decimation ratio) × sinc order + MCLK period × 1 cycle + PCLKH period × 18 cycles
	$Sinc^3$ $Sinc^2$	(MCLK period × Decimation ratio) × (sinc order + 1) + MCLK period × 1 cycle + PCLKH period × 18 cycles
400 (DSCCSCR.CLKSEL = 1)	$Sinc^1$	(MCLK period × Decimation ratio) × sinc order + MCLK period × 1 cycle + PCLKH period × 11 cycles + Core Clock period × 21 cycles
	$Sinc^3$ $Sinc^2$	(MCLK period × Decimation ratio) × (sinc order + 1) + MCLK period × 1 cycle + PCLKH period × 11 cycles + Core Clock period × 21 cycles

40.4.15.2 Settling Time after PWM Synchronization

Settling time after PWM synchronization is the time from the input of the decimation dividing counter initialization trigger to the stable output of the filter result.

Table 40.13 Settling time after PWM synchronization

Core clock (MHz)	Processing time of settling time of PWM synchronization
250 (DSCCSCR.CLKSEL = 0)	(MCLK period × Decimation ratio) × sinc order + PCLKH period × 13 cycles
400 (DSCCSCR.CLKSEL = 1)	(MCLK period × Decimation ratio) × sinc order + PCLKH period × 7 cycles + Core Clock period × 15 cycles

40.4.16 Common Interrupt

The common interrupt is a function that outputs a single common interrupt that is output for each channel. Common interrupts are provided for the following data update interrupts.

When using common interrupts, it is recommended that channel-specific data update interrupts are disabled.

Table 40.14 Data update common interrupt (1 of 2)

Function	Interrupt	Pulse or Level	Enable
Current data	Current data register update common interrupt	Pulse	DSCICR.IUCE

Table 40.14 Data update common interrupt (2 of 2)

Function	Interrupt	Pulse or Level	Enable
Capture data A	Current capture data register A update common interrupt	Pulse	DSCICR.IAUCE
Capture data B	Current capture data register B update common interrupt	Pulse	DSCICR.IBUCE

Common interrupts have two modes, 3ch synchronization mode and 2ch synchronization mode.

As shown in Table 40.15, common interrupts can be output when synchronization mode is enabled and all data on the target channel has been updated.

Table 40.15 Mode of common interrupt

CISM[1:0]	Function	Target channel			Target function		
		CH0	CH1	CH2	Current data	Capture data A	Capture data B
00b	Common interrupts can not be used	—	—	—	—	—	—
01b	Three channel synchronous mode	✓	✓	✓	✓	✓	✓
10b	Two channel synchronous mode	✓	✓	—	✓	✓	✓
11b	Setting prohibited	—	—	—	—	—	—

The operation timing of the common interrupt in the three channel synchronization mode is explained using the current data update common interrupt as an example. When the current data is updated for each of the three channels, the current data common interrupt is output at the same timing as the latest channel current data update interrupt.

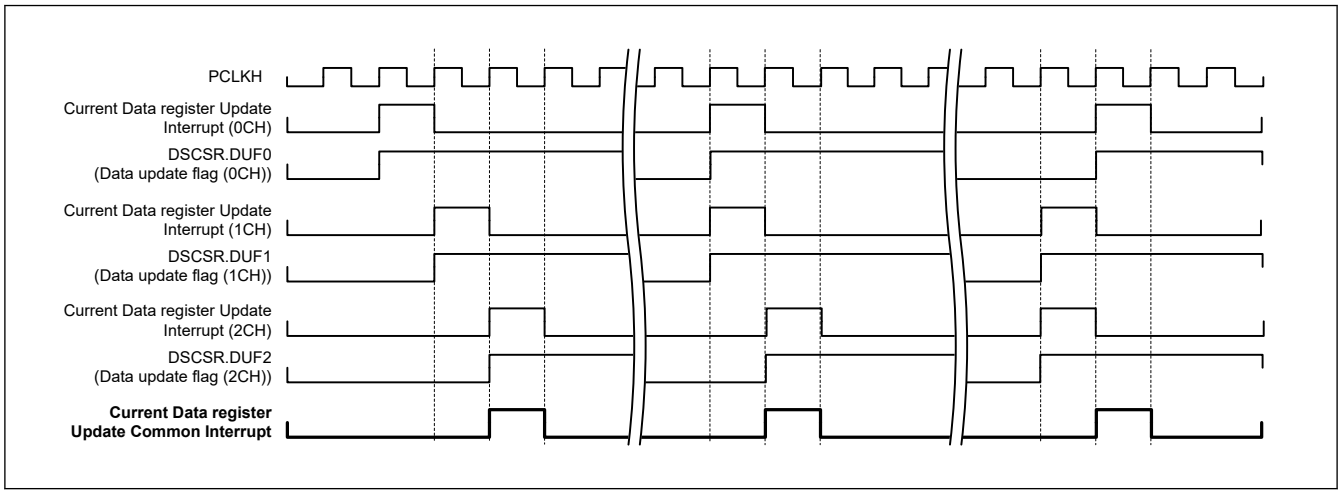

Figure 40.11 Common interrupt output timing (Three channel synchronous mode)

Similarly, in the two channel synchronous mode, the current data common interrupt is output at the same timing as the latest channel current data update interrupt.

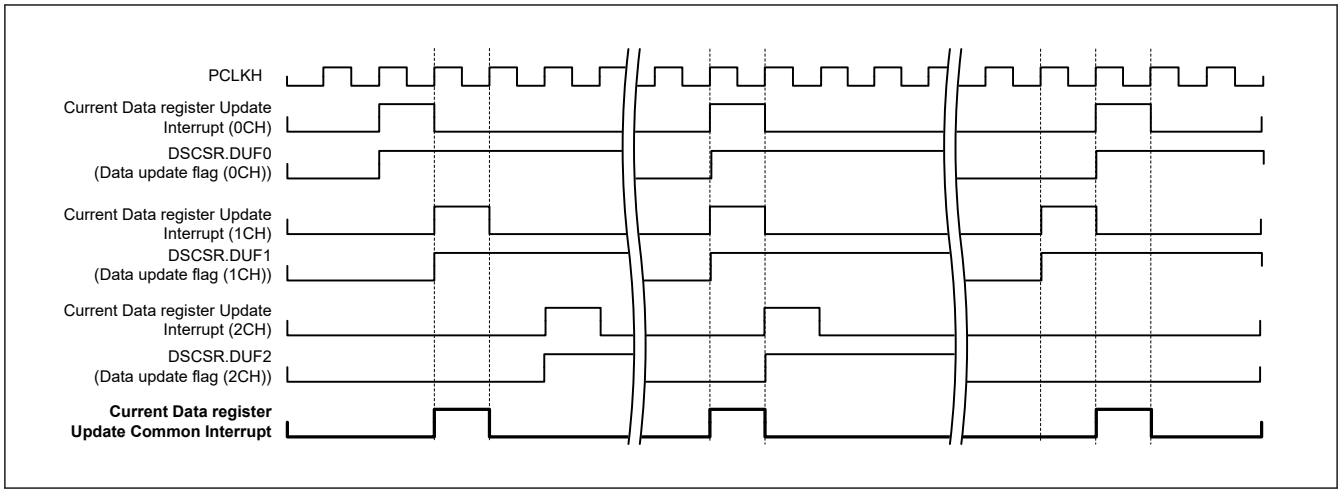

Figure 40.12 Common interrupt output timing (Two channel synchronous mode)

41. 12-Bit A/D converter (ADC12)

41.1 Overview

This LSI incorporates three unit of a 12-bit successive approximation A/D converter. Analog inputs of up to 4 channels are selectable for unit 0 and unit 1 (LLPP of Cortex-R52), analog inputs of up to 15 channels are selectable for unit 2 (NONSAFETY).

The 12-bit A/D converter converts analog inputs of up to 4/15 selected channels to a 12-bit digital value through successive approximation.

The 12-bit A/D converter has three operating modes: single scan mode in which analog inputs selected arbitrarily are converted only once in ascending order of channel number; continuous scan mode in which analog inputs selected arbitrarily are continuously converted in ascending order of channel number; and group scan mode in which analog inputs are arbitrarily selected and divided into two groups (group A and group B) or three groups (group A, group B and group C), and then analog inputs of channels selected for each group are converted in ascending order of channel number.

In group scan mode, the conditions for scanning start of each groups (A, B or A, B, C) (synchronous trigger) can be independently selected, thus allowing A/D conversion of each groups to be started independently. In addition to the above actions, the group priority operation in group scan mode accepts the start of scanning the priority group during the scan of the low priority group, interrupts the scan of the low priority group, and starts the scan of the priority group. The priority of group priority operations is group A > group B > group C. In group priority operation, if the scan start of group B is accepted during the scan of group C, the scan of group C is interrupted and the scan of group B is started. If the scan start of group A is accepted during the scan of group C, the scan of group A is started. The scan of Group C is interrupted and the scan of Group A is started. Similarly, if the scan start of Group A is accepted during the scan of Group B, the scan of Group B is interrupted and the scan of Group A is started. The interrupted group scan is able to resume after the priority group scan is complete also.

In double trigger mode, one analog input channel arbitrarily selected is converted in single scan mode or group scan mode (group A), and the resulting data of A/D conversion started by the first and second synchronous triggers are stored into different registers (duplication of A/D conversion data).

The compare function is a function that outputs an interrupt (ADCn_CMPAI/ADCn_CMPBI) when the A/D conversion value of the selected channel by specifying the upper and lower reference values for each window A/B matches the comparison conditions. The event (ADCn_WCMPM/ADCn_WCMPUM) is output according to the event conditions (A or B, A and B, A exor B). In addition, a comparator operation that compares the A/D conversion value with the lower reference value is also possible.

Table 41.1 lists the specifications of the 12-bit A/D converter and Table 41.2 indicates the functions of the 12-bit A/D converter. Figure 41.1 shows a block diagram of the 12-bit A/D converter.

Table 41.1 ADC12 specifications (1 of 2)

Item	Description
Number of units	Three units, 0, 1, and 2
Input channels	• Unit 0, 1: Up to 4 channels in LLPP of Cortex-R52 • Unit 2: Up to 15 channels in NONSAFETY
A/D conversion method	Successive approximation method
Resolution	12 bits
Conversion time	0.32 µs: Channel-dedicated sample-and-hold circuits not in use 0.64 µs: Channel-dedicated sample-and-hold circuits in use At PCLKADC in the 12-bit A/D converter: 62.5 MHz
A/D conversion clock	PCLKADC (62.5 MHz)

Table 41.1 ADC12 specifications (2 of 2)

Item	Description
Operating modes	• Single scan mode: A/D conversion is performed only once on the analog inputs of arbitrarily selected channels • Continuous scan mode: A/D conversion is performed repeatedly on the analog inputs of arbitrarily selected channels • Group scan mode: Two (groups A and B) or three (groups A, B, and C) can be selected as the number of the groups to be used. Only the combination of groups A and B can be selected when the number of the groups is two. Analog inputs that are arbitrarily selected are divided into two groups (group A and B) or three groups (group A, B, and C), and A/D conversion of the analog input selected on a group basis is performed only once. The conditions for scanning start of groups A, B, and C (synchronous trigger) can be independently selected, thus allowing A/D conversion of each group to be started independently. • Group scan mode (when Group A is given priority): If a priority-group trigger is input during scanning of the low-priority group, scan of the low-priority group is stopped and scan of the priority group is started. The priority order is group A (highest) > group B > group C (lowest). Whether or not to restart scanning of the low-priority group after processing for the high-priority group completes, is selectable. Rescan can also be set to start either from the beginning of the selected channel or the channel on which A/D conversion is not completed.
Conditions for A/D conversion start	• Software trigger • Synchronous triggers Trigger by the multi-function timer pulse unit (MTU3) and event link controller (ELC) • Asynchronous trigger A/D conversion can be triggered by the external trigger ADTRGn#.
Functions	• Dedicated sample-and-hold function with optional constant sampling and 3 channels in each unit • Variable sampling state count • Selectable A/D-converted value addition mode or average mode • Double-trigger mode (duplication of A/D conversion data) • Automatic clear function for A/D data registers • Digital comparison of values in the comparison and data registers, and between values in the data registers • Overwrite checking function of the A/D data register
Interrupt sources and ELC events	• ADCn_ADI (for ELC, trigger of interrupt is slightly different for CPU SPI) • ADCn_GBADI: A/D scan end interrupt for Group B • ADCn_GCADI: A/D scan end interrupt for Group C • ADCn_CMPAI: Window A compare match • ADCn_CMPBI: Window B compare match • ADCn_WCMPM: compare match • ADCn_WCMPUM: compare mismatch
ELC interface	• An ELC event is generated upon completion of all scans • Able to start scanning by a trigger from the ELC
Module-stop function	Module-stop state can be set to reduce power consumption

41.2 Register Map

Table 41.4 ADC12 register map (1 of 2)

Address	Register symbol	Register name	Write protection
0x9001_4000 + 0x400 x m (m = 0, 1) 0x8000_8000 (m = 2)	ADCSR	A/D Control Register	—
0x9001_4004 + 0x400 x m (m = 0, 1) 0x8000_8004 (m = 2)	ADANSA0	A/D Channel Select Register A0	—
0x9001_4008 + 0x400 x m (m = 0, 1) 0x8000_8008 (m = 2)	ADADS0	A/D-Converted Value Addition/Average Function Channel Select Register 0	—
0x9001_400C + 0x400 x m (m = 0, 1) 0x8000_800C (m = 2)	ADADC	A/D-Converted Value Addition/Average Count Select Register	—
0x9001_400E + 0x400 x m (m = 0, 1) 0x8000_800E (m = 2)	ADCER	A/D Control Extended Register	—
0x9001_4010 + 0x400 x m (m = 0, 1) 0x8000_8010 (m = 2)	ADSTRGR	A/D Conversion Start Trigger Select Register	—
0x9001_4014 + 0x400 x m (m = 0, 1) 0x8000_8014 (m = 2)	ADANSB0	A/D Channel Select Register B0	—
0x9001_4018 + 0x400 x m (m = 0, 1) 0x8000_8018 (m = 2)	ADDBLDR	A/D Data Duplication Register	—
0x9001_4020 + 0x400 x m + 0x02 × n (m = 0, 1) 0x8000_8020 + 0x02 × n (m = 2)	ADDRn	A/D Data Register n (n = 0 to 3 for unit 0, 1, n = 0 to 15 for unit 2)	—
0x9001_4066 + 0x400 x m (m = 0, 1) 0x8000_8066 (m = 2)	ADSHCR	A/D Sample and Hold Control Register	—

Table 41.4 ADC12 register map (2 of 2)

Address	Register symbol	Register name	Write protection
0x9001_407D + 0x400 x m (m = 0, 1) 0x8000_807D (m = 2)	ADELCCR	A/D Event Link Control Register	—
0x9001_4080 + 0x400 x m (m = 0, 1) 0x8000_8080 (m = 2)	ADGSPCR	A/D Group Scan Priority Control Register	—
0x9001_4084 + 0x400 x m (m = 0, 1) 0x8000_8084 (m = 2)	ADDBLDRA	A/D Data Duplication Register A	—
0x9001_4086 + 0x400 x m (m = 0, 1) 0x8000_8086 (m = 2)	ADDBLDRB	A/D Data Duplication Register B	—
0x9001_408C + 0x400 x m (m = 0, 1) 0x8000_808C (m = 2)	ADWINMON	A/D Compare Function Window A/B Status Monitoring Register	—
0x9001_4090 + 0x400 x m (m = 0, 1) 0x8000_8090 (m = 2)	ADCMPCR	A/D Compare Function Control Register	—
0x9001_4094 + 0x400 x m (m = 0, 1) 0x8000_8094 (m = 2)	ADCMPANSR0	A/D Compare Function Window A Channel Select Register 0	—
0x9001_4098 + 0x400 x m (m = 0, 1) 0x8000_8098 (m = 2)	ADCMPLR0	A/D Compare Function Window A Comparison Condition Setting Register 0	—
0x9001_409C + 0x400 x m (m = 0, 1) 0x8000_809C (m = 2)	ADCMPDR0	A/D Comparison Function Window A Lower Level Setting Register	—
0x9001_409E + 0x400 x m (m = 0, 1) 0x8000_809E (m = 2)	ADCMPDR1	AD Comparison Function Window A Upper Level Setting Register	—
0x9001_40A0 + 0x400 x m (m = 0, 1) 0x8000_80A0 (m = 2)	ADCMPSR0	A/D Comparison Function Window A Channel Status Register 0	—
0x9001_40A6 + 0x400 x m (m = 0, 1) 0x8000_80A6 (m = 2)	ADCMPBNSR	A/D Compare Function Window B Channel Select Register	—
0x9001_40A8 + 0x400 x m (m = 0, 1) 0x8000_80A8 (m = 2)	ADWINLLB	A/D Compare Function Window B Lower-Side Level Setting Register	—
0x9001_40AA + 0x400 x m (m = 0, 1) 0x8000_80AA (m = 2)	ADWINULB	A/D Compare Function Window B Upper-Side Level Setting Register	—
0x9001_40AC + 0x400 x m (m = 0, 1) 0x8000_80AC (m = 2)	ADCMPBSR	A/D Compare Function Window B Status Register	—
0x9001_40D4 + 0x400 x m (m = 0, 1) 0x8000_80D4 (m = 2)	ADANSC0	A/D Channel Select Register C0	—
0x9001_40D9 + 0x400 x m (m = 0, 1) 0x8000_80D9 (m = 2)	ADGCTRGR	A/D Group C Trigger Select Register	—
0x9001_40E0 + 0x400 x m + 0x01 × n (m = 0, 1) 0x8000_80E0 + 0x01 × n (m = 2)	ADSSTRn	A/D Sampling State Register n (n = 0 to 3 for unit 0, 1, n = 0 to 15 for unit 2)	—
0x9001_41F0 + 0x400 x m (m = 0, 1) 0x8000_81F0 (m = 2)	ADCALCTL	A/D Calibration Control Register	—

Table 41.5

Unit	Module reset- control register	Module stop control register	Slave access control register
Unit 0	—	MSTPCRC.MSTPCRC06	SLVACCCTL7.LLPP_SL*1
Unit 1	—	MSTPCRC.MSTPCRC07	SLVACCCTL7.LLPP_SL*1
Unit 2	—	MSTPCRC.MSTPCRC25	SLVACCCTL04.ADC2_SL

Note 1. Access from Cortex-R52 CPU0 and CPU1 is not protected by TrustZone. This slave access control is applied to access from other masters.

41.3 Register Descriptions

41.3.1 ADCSR : A/D Control Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADST	ADCS[1:0]		ADIE	—	—	TRGE	EXTRG	DBLE	GBADIE	—	DBLANS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	DBLANS[4:0]	Double Trigger Channel Select These bits select one analog input channel for double triggered operation. The setting is only valid while double trigger mode is selected.	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
6	GBADIE	Group B Scan End Interrupt Enable 0: Disables ADCn_GBADI interrupt generation upon group B scan completion 1: Enables ADCn_GBADI interrupt generation upon group B scan completion	R/W
7	DBLE	Double Trigger Mode Select 0: Deselects double trigger mode 1: Selects double trigger mode	R/W
8	EXTRG	Trigger Select 0: A/D conversion is started by a synchronous trigger (MTU3, ELC) 1: A/D conversion is started by the asynchronous trigger (ADTRGn#)	R/W
9	TRGE	Trigger Start Enable 0: Disables A/D conversion to be started by the synchronous or asynchronous trigger 1: Enables A/D conversion to be started by the synchronous or asynchronous trigger	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
12	ADIE	Scan End Interrupt Enable 0: Disables ADCn_ADI interrupt generation upon scan completion 1: Enables ADCn_ADI interrupt generation upon scan completion	R/W
14:13	ADCS[1:0]	Scan Mode Select 0 0: Single scan mode 0 1: Group scan mode 1 0: Continuous scan mode 1 1: Setting prohibited	R/W
15	ADST	A/D conversion Start 0: Stops A/D conversion process 1: Starts A/D conversion process	R/W

41.3.2 ADANSA0 : A/D Channel Select Register A0

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ANSA0[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ANSA0[15:0]	A/D conversion Analog input Channel Select ANSA0[0] bit corresponds to ch0 and ANSA0[15] corresponds ch15. 0: ch0-ch15 are not subjected to conversion. 1: ch0-ch15 are subjected to conversion.	R/W

41.3.3 ADADS0 : A/D-Converted Value Addition/Average Function Channel Select Register 0

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x08

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADS0[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADS0[15:0]	A/D-Converted Value Addition/Average Channel Select 0: A/D-converted value addition/average mode for ch0 to ch15 is not selected 1: A/D-converted value addition/average mode for ch0 to ch15 is selected	R/W

41.3.4 ADADC : A/D-Converted Value Addition/Average Count Select Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	AVEE	—	—	—	—	ADC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	ADC[2:0]	Addition Count Select 0 0 0: 1-time conversion (no addition; same as normal conversion) 0 0 1: 2-time conversion (addition once) 0 1 0: 3-time conversion (addition twice)*1 0 1 1: 4-time conversion (addition three times) 1 0 1: 16-time conversion (addition 15 times)*1 Others: Setting is prohibited	R/W
6:3	—	These bits are read as 0. The write value should be 0.	R/W
7	AVEE	Average Mode Enable 0: Addition mode is selected 1: Average mode is selected	R/W

Note 1. When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the Addition count to 3 times and 16times (ADADC.ADC[1:0] = 010b, 101b).

41.3.5 ADCER : A/D Control Extended Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x0E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADRFMT	—	—	—	—	—	—	—	—	—	ACE	—	—	ADPRC[1:0]		—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
2:1	ADPRC[1:0]	A/D Conversion Accuracy Specify 0 0: A/D conversion is performed with 12-bit accuracy Others: Setting prohibited	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	ACE	A/D Data Register Automatic Clearing Enable 0: Disables automatic clearing 1: Enables automatic clearing	R/W
14:6	—	These bits are read as 0. The write value should be 0.	R/W
15	ADRFMT	A/D Data Register Format Select 0: Right-alignment is selected for the A/D data register format 1: Left-alignment is selected for the A/D data register format	R/W

41.3.6 ADSTRGR : A/D Conversion Start Trigger Select Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x10

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	TRSA[5:0]						—	—	TRSB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	TRSB[5:0]	A/D Conversion Start Trigger Select for Group B Select the A/D conversion start trigger for group B in group scan mode. See Table 41.6 for details.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
13:8	TRSA[5:0]	A/D Conversion Start Trigger Select Select the A/D conversion start trigger in single scan mode and continuous mode. In group scan mode, the A/D conversion start trigger for group A is selected. See Table 41.7 for details.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Table 41.6 Selection of A/D activation sources by the TRSB[5:0] bits (for group B only) (1 of 2)

Module	Source	Remarks	TRSB[5]	TRSB[4]	TRSB[3]	TRSB[2]	TRSB[1]	TRSB[0]
Trigger source de-selection state			1	1	1	1	1	1
MTU3	TRGA0N	Compare match with or input capture to MTU0.TGRA	0	0	0	0	0	1
MTU3	TRGA1N	Compare match with or input capture to MTU1.TGRA	0	0	0	0	1	0

Table 41.6 Selection of A/D activation sources by the TRSB[5:0] bits (for group B only) (2 of 2)

Module	Source	Remarks	TRSB[5]	TRSB[4]	TRSB[3]	TRSB[2]	TRSB[1]	TRSB[0]
MTU3	TRGA2N	Compare match with or input capture to MTU2.TGRA	0	0	0	0	1	1
MTU3	TRGA3N	Compare match with or input capture to MTU3.TGRA	0	0	0	1	0	0
MTU3	TRGA4N	Compare match with or input capture to MTU4.TGRA, or an underflow of MTU4.TCNT (in the trough) in complementary PWM mode	0	0	0	1	0	1
MTU3	TRGA6N	Compare match with MTU6.TGRA	0	0	0	1	1	0
MTU3	TRGA7N	Compare match with MTU7.TGRA	0	0	0	1	1	1
MTU3	TRG0N	Compare match with MTU0.TGRE	0	0	1	0	0	0
MTU3	TRG4AN	Compare match between MTU4.TADCORA and MTU4.TCNT	0	0	1	0	0	1
MTU3	TRG4BN	Compare match between MTU4.TADCORB and MTU4.TCNT	0	0	1	0	1	0
MTU3	TRG4AN or TRG4BN	Compare match between MTU4.TADCORA and MTU4.TCNT, or between MTU4.TADCORB and MTU4.TCNT	0	0	1	0	1	1
MTU3	TRG4ABN	Compare match between MTU4.TADCORA and MTU4.TCNT, and between MTU4.TADCORB and MTU4.TCNT (when interrupt skipping function 2 is in use)	0	0	1	1	0	0
MTU3	TRG7AN	Compare match between MTU7.TADCORA and MTU7.TCNT	0	0	1	1	0	1
MTU3	TRG7BN	Compare match between MTU7.TADCORB and MTU7.TCNT	0	0	1	1	1	0
MTU3	TRG7AN or TRG7BN	Compare match between MTU7.TADCORA and MTU7.TCNT, or between MTU7.TADCORB and MTU7.TCNT	0	0	1	1	1	1
MTU3	TRG7ABN	Compare match between MTU7.TADCORA and MTU7.TCNT, and between MTU7.TADCORB and MTU7.TCNT (when interrupt skipping function 2 is in use)	0	1	0	0	0	0
ELC	ADCn A		0	1	0	0	0	1
ELC	ADCn B		0	1	0	0	1	0

Note: Trigger source from MTU3 is not available in ADC12 unit 2.

Table 41.7 Selection of A/D activation sources by the TRSA[5:0] bits (1 of 2)

Module	Source	Remarks	TRSA[5]	TRSA[4]	TRSA[3]	TRSA[2]	TRSA[1]	TRSA[0]

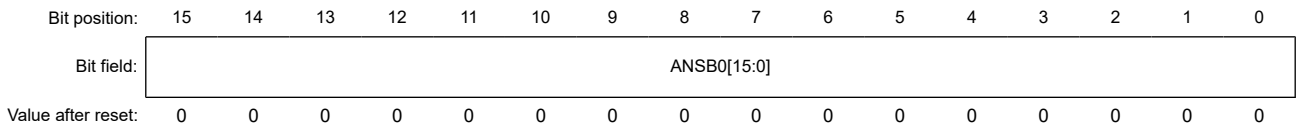
MTU3	TRG7ABN	Compare match between MTU7.TADCORA and MTU7.TCNT, and between MTU7.TADCORB and MTU7.TCNT (when interrupt skipping function 2 is in use)	0	1	0	0	0	0
ELC	ADCn A		0	1	0	0	0	1
ELC	ADCn B		0	1	0	0	1	0

Note: Trigger source from MTU3 is not available in ADC12 unit 2.

41.3.7 ADANSB0 : A/D Channel Select Register B0

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x14



Bit	Symbol	Function	R/W
15:0	ANSB0[15:0]	A/D Conversion Analog Input Channel Select ANSB0[0] bit corresponds to ch0 and ANSB0[15] corresponds ch15. 0: ch0-ch15 are not subjected to conversion 1: ch0-ch15 are subjected to conversion	R/W

41.3.8 ADDBLDR : A/D Data Duplication Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x18

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DBLDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DBLDR[15:0]	The result of A/D conversion in response to the second trigger in double trigger mode.	R

A/D-converted value is 12-bit accuracy. The formats for data in the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers vary according to the following conditions.

- The setting of the A/D data register format select bit (ADCER.ADRFMT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the Addition count select bits (ADADC.ADC[2:0]) (once, twice, three times, four times, or sixteen times is selectable.)
- The setting of the average mode enable bit (ADADC.AVEE) (Addition or average is selectable.)

When the number of the conversion count is set one to four in the addition mode, the A/D conversion addition result is expanded by 2 bits and stored in the A/D data register. When the number of the conversion count is sixteen in the addition mode, the A/D conversion addition result is expanded by 4 bits and stored in the A/D data register.

41.3.9 ADDRn : A/D Data Register n (n = 0 to 3 for unit 0, 1, n = 0 to 14 for unit 2)

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x020 + 0x002 × n (ADC120, ADC121: n = 0 to 3, ADC122: n = 0 to 14)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DR[15:0]	The result of A/D conversion (n: Number of channel)	R

A/D-converted value is 12-bit accuracy. The formats for data in the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers vary according to the following conditions.

- The setting of the A/D data register format select bit (ADCER.ADRFMT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the Addition count select bits (ADADC.ADC[2:0]) (once, twice, three times, four times, or sixteen times is selectable.)
- The setting of the average mode enable bit (ADADC.AVEE) (Addition or average is selectable.)

When the number of the conversion count is set one to four in the addition mode, the A/D conversion addition result is expanded by 2 bits and stored in the A/D data register. When the number of the conversion count is sixteen in the addition mode, the A/D conversion addition result is expanded by 4 bits and stored in the A/D data register.

41.3.10 ADSHCR : A/D Sample and Hold Control Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x66

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SHANS[2:0]			SSTSH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0

Bit	Symbol	Function	R/W
7:0	SSTSH[7:0]	Sample and hold period setting These bits set the sample and hold period in the range from 8 to 255 states. S/H period is set 12 + this register value.	R/W
10:8	SHANS[2:0]	Sample and hold use or bypass select for ch0-2 SHANS[2] corresponds to ch2, SHANS[0] corresponds to ch0. When sample and hold is used, In case of 1 channel: set 001b (use channel 0) In case of 2 channels: set 011b (use channel 0 and 1) In case of 3 channels: set 111b (use channel 0 to 2) Other settings are prohibited. 0: Bypass S/H 1: Use S/H	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

41.3.11 ADELCCR : A/D Event Link Control Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x7D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	GCELC	ELCC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	ELCC[1:0]	Event link control bits Control the end of scan event (ADCn_ADI). To enable the ELCC[1:0] setting, set GCELC to 0. 0 0: Output event signal at the end of scan except the end of group scan of group A, B 0 1: Output event signal at the end of group scan of group B 1 x: Output event signal at the end of scan	R/W
2	GCELC	Event control bit for Group C 0: Enable the setting of ELCC[1:0] 1: Disable the setting of ELCC[1:0] and output event signal at the end of group scan of group C	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

41.3.12 ADGSPCR : A/D Group Scan Priority Control Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x80

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GBRP	LGRRS	—	—	—	—	—	—	—	—	—	—	—	—	GBRSCN	PGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PGS	Group Priority Control Setting*1 0: Operation is without group priority control 1: Operation is with group priority control	R/W
1	GBRSCN	Group B Restart Setting (Enabled only when PGS = 1. Set 0 when PGS = 0.) 0: Scanning for group is not restarted when priority control is performed 1: Scanning for group is restarted when priority control is performed	R/W
13:2	—	These bits are read as 0. The write value should be 0.	R/W
14	LGRRS	Restart Channel Select (Enabled only when PGS = 1 and GBRSCN = 1, Set 0 when PGS = 0.) 0: Restart scan with first channel 1: Restart scan with suspended channel	R/W
15	GBRP	Group B Single Scan Continuous Start*2 (Enabled only when PGS = 1. Set 0 when PGS = 0.) 0: Single scan for group B is not continuously activated 1: Single scan for group B is continuously activated	R/W

Note 1. When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode). If the bits are set to any other values, proper operation cannot be guaranteed.
Note 2. When the GBRP bit has been set to 1, single scan is performed continuously for low priority group regardless of the setting of the GBRSCN bit.

41.3.13 ADDBLDRA : A/D Data Duplication Register A

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x84

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DBLDRA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DBLDRA[15:0]	The result of A/D conversion during extended operation in double trigger mode	R

A/D-converted value is 12-bit accuracy. The formats for data in the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers vary according to the following conditions.

- The setting of the A/D data register format select bit (ADCER.ADRFMT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the Addition count select bits (ADADC.ADC[2:0]) (once, twice, three times, four times, or sixteen times is selectable.)
- The setting of the average mode enable bit (ADADC.AVEE) (Addition or average is selectable.)

When the number of the conversion count is set one to four in the addition mode, the A/D conversion addition result is expanded by 2 bits and stored in the A/D data register. When the number of the conversion count is sixteen in the addition mode, the A/D conversion addition result is expanded by 4 bits and stored in the A/D data register.

41.3.14 ADDBLDRB : A/D Data Duplication Register B

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x86

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DBLDRB[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DBLDRB[15:0]	The result of A/D conversion during extended operation in double trigger mode	R

A/D-converted value is 12-bit accuracy. The formats for data in the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers vary according to the following conditions.

- The setting of the A/D data register format select bit (ADCER.ADRFMT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the Addition count select bits (ADADC.ADC[2:0]) (once, twice, three times, four times, or sixteen times is selectable.)
- The setting of the average mode enable bit (ADADC.AVEE) (Addition or average is selectable.)

When the number of the conversion count is set one to four in the addition mode, the A/D conversion addition result is expanded by 2 bits and stored in the A/D data register. When the number of the conversion count is sixteen in the addition mode, the A/D conversion addition result is expanded by 4 bits and stored in the A/D data register.

41.3.15 ADWINMON : A/D Compare Function Window A/B Status Monitoring Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x8C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MONCMPB	MONCMPA	—	—	—	MONCOMB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MONCOMB	Combination result monitor 0: Window A/B combination condition does not match. 1: Window A/B combination condition match.	R
3:1	—	These bits are read as 0.	R
4	MONCMPA	Comparing result monitor for window A 0: Window A comparing condition does not match. 1: Window A comparing condition match.	R
5	MONCMPB	Comparing result monitor for window B 0: Window B comparing condition does not match. 1: Window B comparing condition match.	R
7:6	—	These bits are read as 0.	R

41.3.16 ADCMPCR : A/D Compare Function Control Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x90

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPAIE	WCMPE	CMPBIE	—	CMPAE	—	CMPBE	—	—	—	—	—	—	—	CMPAB[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CMPAB[1:0]	Window A/B combination condition setting This bit is valid when both windows A/B are valid (CMPAE = 1 and CMPBE = 1). 0 0: Output ADCn_WCMPM when window A comparison condition match OR window B comparison condition match, otherwise output ADCn_WCMPUM 0 1: Output ADCn_WCMPM when window A comparison condition match EXOR window B comparison condition match, otherwise output ADCn_WCMPUM 1 0: Output ADCn_WCMPM when window A comparison condition match AND window B comparison condition match, otherwise output ADCn_WCMPUM 1 1: Setting prohibited.	R/W
8:2	—	These bits are read as 0. The write value should be 0.	R/W
9	CMPBE	Window B operation permission 0: Window B is not in operation. Output of ADCn_WCMPM/ADCn_WCMPUM is not permitted. 1: Window B is in operation.	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	CMPAE	Window A operation permission 0: Window A is not in operation. Output of ADCn_WCMPM/ADCn_WCMPUM is not permitted. 1: Window A is in operation.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	CMPBIE	Compare window B Interrupt Enable 0: Generation of an ADCn_CMPBI interrupt in response to matches with a condition for comparison is disabled. 1: Generation of an ADCn_CMPBI interrupt in response to matches with a condition for comparison is enabled.	R/W
14	WCMPE	Window Function enable 0: Window function disabled 1: Window function enabled	R/W
15	CMPAIE	Compare window A Interrupt Enable 0: Generation of an ADCn_CMPAI interrupt in response to matches with a condition for comparison is disabled. 1: Generation of an ADCn_CMPAI interrupt in response to matches with a condition for comparison is enabled.	R/W

41.3.17 ADCMPANSR0 : A/D Compare Function Window A Channel Select Register 0

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x94

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPCHA0[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPCHA0[15:0]	Window A Channel Select Set the CMPCHA0[15:0] bits when DCSR.ADST = 0. 0: Channel is not target 1: Channel is target	R/W

41.3.18 ADCMPLR0 : A/D Compare Function Window A Comparison Condition Setting Register 0

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x98

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPLCHA0[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPLCHA0[15:0]	Window A comparison condition for target channel (ch0-15) setting CMPLCHA0[15] corresponds channel 15 and CMPLCHA0[0] corresponds channel 0. When the comparison result of each channel input matches the set condition, the ADCMPSR0.CMPSTCHA0n bit is set to 1 and a compare interrupt (ADCn_CMPAI) is generated. 0: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 register value > A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): A/D-converted value < ADCMPDR0 register value or ADCMPDR1 register value < A/D-converted value 1: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 register value < A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value	R/W

41.3.19 ADCMPDR0 : A/D Comparison Function Window A Lower Level Setting Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x9C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPLLA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPLLA[15:0]	Reference data setting when using the compare function window A	R/W

41.3.20 ADCMPDR1 : AD Comparison Function Window A Upper Level Setting Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x9E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPULA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPULA[15:0]	Reference data setting when using the compare function window A	R/W

41.3.21 ADCMPSR0 : A/D Comparison Function Window A Channel Status Register 0

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0xA0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPSTCHA0[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPSTCHA0[15:0]	Window A Status Flag This flag shows the comparison result of each targeted channel, when window A is operating (ADCMPCR.CMPAE = 1b). If this flag is set while ADCMPCR.CMPAIE = 1, a compare interrupt (ADCn_CMPAI) request is generated. 0: Condition does not match 1: Condition matches	R/W

41.3.22 ADWINLLB : A/D Compare Function Window B Lower-Side Level Setting Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0xA8

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPLLB[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPLLB[15:0]	Reference lower data setting when using the compare function window B	R/W

41.3.23 ADWINULB : A/D Compare Function Window B Upper-Side Level Setting Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0xAA

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPULB[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPULB[15:0]	Reference upper data setting when using the compare function window B	R/W

41.3.24 ADCMPBSR : A/D Compare Function Window B Status Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0xAC

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CMPSTB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPSTB	Window B Flag When window B operation is enabled (ADCMPCR.CMPBE = 1b), this bit indicates the comparison result of channels to which window B comparison conditions are applied. 0: Comparison conditions are not met 1: Comparison conditions are met	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

41.3.25 ADCMPBNSR : A/D Compare Function Window B Channel Select Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0xA6

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CMPLB	—	CMPCHB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CMPCHB[5:0]	Window B Channel Select Select channels for comparing with window B condition. Set the CMPCHB[5:0] bits when the ADCSR.ADST bit is 0. 0x00: ch0 0x01: ch1 0x02: ch2 ⋮ 0x0F: ch15 0x3F: No channel is selected Others: Setting prohibited	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	CMPLB	Window B Comparison Condition Setting When the comparison result of target input matches the set condition, the ADCMPBSR.CMPSTB bit is set to 1 and a compare interrupt (ADCn_CMPBI) is generated. 0: When window function is disabled (ADCMPCR.WCMPE = 0): ADWINLLB register value > A/D-converted value. When window function is enabled (ADCMPCR.WCMPE = 1): A/D-converted value < ADWINLLB register value or ADWINULB register value < A/D-converted value. 1: When window function is disabled (ADCMPCR.WCMPE = 0): ADWINLLB register value < A/D-converted value. When window function is enabled (ADCMPCR.WCMPE = 1): ADWINLLB register value < A/D-converted value < ADWINULB register value.	R/W

41.3.26 ADANSC0 : A/D Channel Select Register C0

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0xD4

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ANSC0[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ANSC0[15:0]	A/D-Converted Channel Select for Group C in Group Scan Mode ANSC0[15] corresponds ch15, and ANSC0[0] corresponds ch0. 0: Channel is not target 1: Channel is target	R/W

41.3.27 ADGCTRGR : A/D Group C Trigger Select Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0xD9

Bit position:	7	6	5	4	3	2	1	0
Bit field:	GRCE	GCADIE	TRSC[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	TRSC[5:0]	Group C A/D Conversion Start Trigger Select Select starting trigger for A/D conversion of group C in group scan mode. See Table 41.8 for more details.	R/W
6	GCADIE	Group C Scan Completion Interrupt Enable 0: Group C scan completed interrupt (ADCn_GCADI) is disabled 1: Group C scan completed interrupt (ADCn_GCADI) is enabled	R/W
7	GRCE	Group C A/D Conversion Enable 0: Group C A/D conversion is disabled 1: Group C A/D conversion is enabled	R/W

Table 41.8 A/D conversion start trigger for Group C in group scan mode (1 of 2)

Module	Trigger	Description	TRSC					
			[5]	[4]	[3]	[2]	[1]	[0]
No Trigger is selected			1	1	1	1	1	1

MTU3	TRG7ABN	Compare match between MTU7.TADCORA and MTU7.TCNT, and Compare match between MTU7.TADCORB and MTU7.TCNT	0	1	0	0	0	0
ELC	ADCn A		0	1	0	0	0	1
ELC	ADCn B		0	1	0	0	1	0

Note: Trigger source from MTU3 is not available in ADC12 unit 2.

41.3.28 ADSSTRn : A/D Sampling State Register n (n = 0 to 3 for unit 0, 1, n = 0 to 14 for unit 2)

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0xE0 + 0x01 × n (ADC120, ADC121: n = 0 to 3, ADC122: n = 0 to 14)

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SST[7:0]							
Value after reset:	0	0	0	0	1	0	1	1

Bit	Symbol	Function	R/W
7:0	SST[7:0]	Sampling Time Setting These bits set the sampling time in the range from 7 to 255 states.	R/W

41.3.29 ADCALCTL : A/D Calibration Control Register

Base address: ADC12m = 0x9001_4000 + 0x0400 × m (m = 0, 1)
ADC122 = 0x8000_8000

Offset address: 0x1F0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	CAL_ERR	CAL_RDY	CAL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CAL	Calibration Start 0: No calibration. 1: Start calibration.	R/W
1	CAL_RDY	Calibration Status 0: Calibration is not started, or on progress. 1: Calibration is completed.	R

Bit	Symbol	Function	R/W
2	CAL_ERR	Calibration Result 0: Normal end. 1: Abnormal end.	R
15:3	—	These bits are read as 0. The write value should be 0.	R/W

The ADCALCTL register controls calibration of A/D Converter. After reset is released, make sure to calibrate A/D Converter before A/D conversion.

41.4 Operation

41.4.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

There are three operating modes: single scan mode, continuous scan mode, and group scan mode. In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until the ADCSR.ADST bit is cleared to 0 from 1. In group scan mode, the selected channels of group A and the selected channels of group B (and the selected channels of group C) are scanned once after starting to be scanned according to the respective synchronous triggers (MTU3, ELC).

In single scan mode and continuous scan mode, A/D conversion is performed for ANn pins selected by the ADANSA0 register, starting from the pin with the smallest number n. In group scan mode, A/D conversion is performed for ANn pins selected by the ADANSA0 register for group A, and performed for ANn pins selected by the ADANSB0 register for group B and performed for ANn pins selected by the ADANSC0 register for group C, respectively, starting from the pin with the smallest number n.

Double trigger mode is to be used with single scan mode or group scan mode. With double trigger mode being enabled, A/D conversion data of a channel selected by the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by any of the synchronous triggers (MTU3, ELC) selected by the ADSTRGR.TRSA[5:0] bits. In group scan mode, only group A can use the double trigger.

To enable double trigger extended mode, select double trigger mode, and then select the synchronous trigger by the ADSTRGR.TRSA[5:0].

- ADSTRGR.TRSA[5:0] = 001011b
  TRG4AN or TRG4BN
- ADSTRGR.TRSA[5:0] = 001111b
  TRG7AN or TRG7BN

In the double trigger extended mode, in addition to the normal double trigger mode operation, the A/D conversion data activated by the odd number trigger (TRG4AN, TRG7AN) is stored in the A/D data duplex register A (ADDBLDRA), and the A/D conversion data activated by the even number trigger (TRG4BN, TRG7BN) is stored in the A/D Data Duplication register B (ADDBLDRB).

If two types of trigger source occur at the same time, the data is not sorted by the trigger factor and the A/D conversion data is stored in the Data Duplication register B (ADDBLDRB). If one trigger is performing A/D conversion and the other trigger is input, the other trigger will be ignored.

Analog input AN000 to AN002 can use the S/H circuit by setting of ADSHCR.SHANS[2:0].

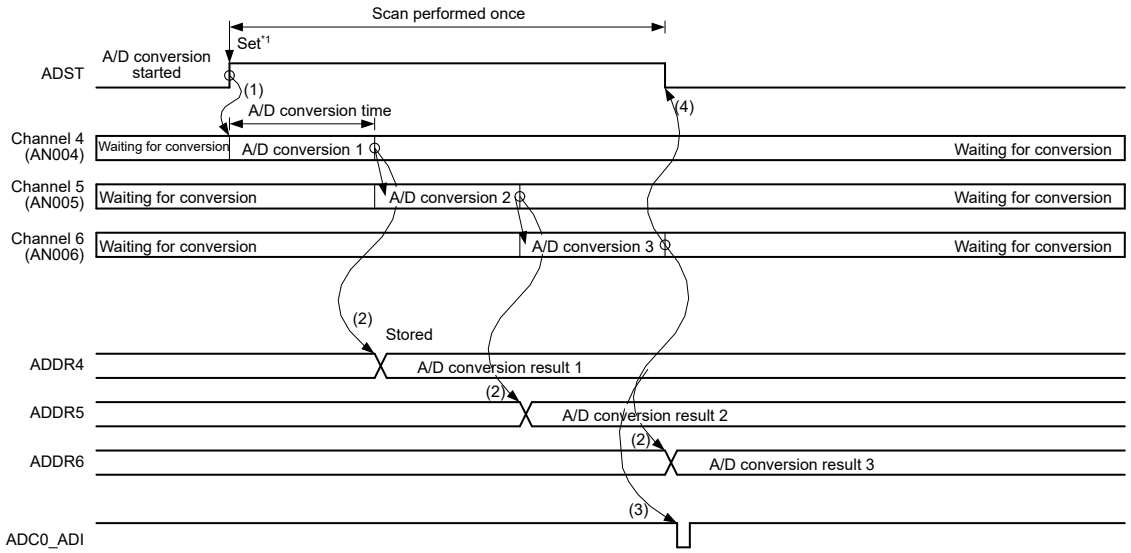
41.4.2 Single Scan Mode

41.4.2.1 Basic Operation (Not use S/H circuits)

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as below.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) due to software or synchronous trigger (MTU3, ELC) input, A/D conversion starts in ascending order of n of ANn selected in the ADANSA0 register.
2. When the A/D conversion of one channel is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).

3. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled at the end of scanning) after A/D conversion of all selected channels is completed, an ADC0_ADI interrupt request (pulse output) is generated.
4. ADCSR.ADST bit holds 1 (A/D conversion start) during A/D conversion and is automatically cleared when A/D conversion of all selected channels is completed, and the 12-bit A/D converter goes into a standby state.



Note 1. The arrows in this figure indicate instruction execution by software.

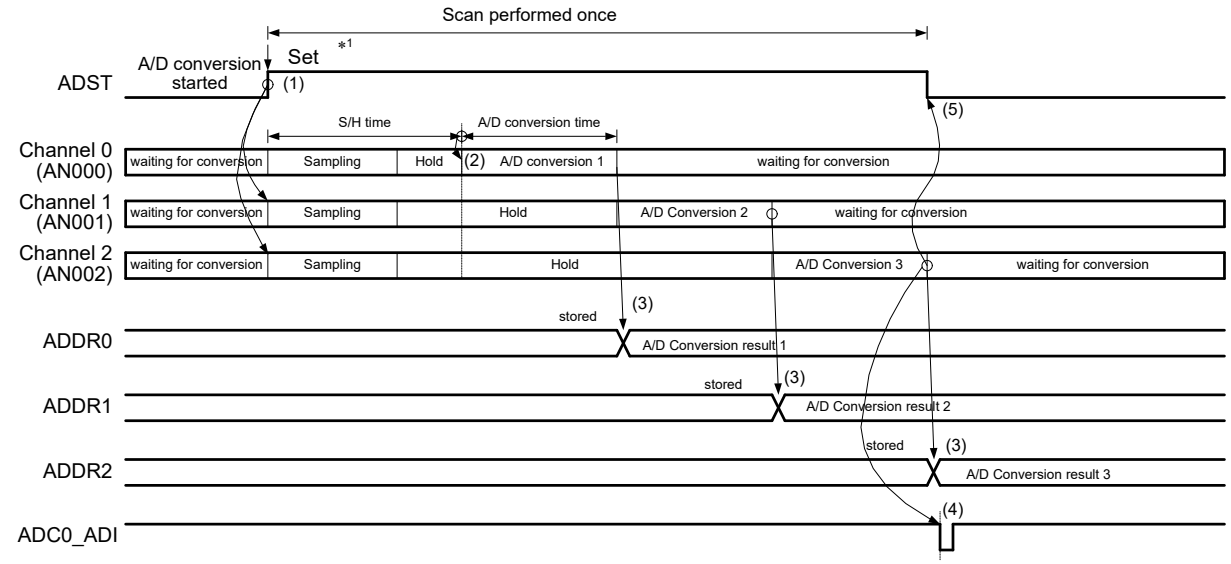
Figure 41.3 Example of operation in single scan mode (basic operation AN004 to AN006 selected)

41.4.2.2 Basic Operation (Use S/H circuits)

The S/H circuit is used to A/D Convert the analog inputs of all selected channels after S/H is performed only once.

The channel that uses the S/H circuit is selected with the ADSHCR.SHANS[2:0] bits.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by software or synchronization trigger (MTU3, ELC), all channels using the S/H circuit start sampling analog inputs.
2. After sampling and holding, A/D conversion is started in ascending order of n of the channel ANn selected in the ADANSA0 register.
3. When the A/D conversion of the channel is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).
4. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled at the end of scanning) after A/D conversion of all selected channels is completed, an ADC0_ADI interrupt request (pulse output) is generated.
5. The ADCSR.ADST bit holds 1 (A/D conversion start) during A/D conversion and is automatically cleared when A/D conversion of all selected channels is completed, and the 12-bit A/D converter goes into a standby state.



Note 1. The arrows in this figure indicate instruction execution by software.

Figure 41.4 Example of operation in single scan mode (basic operation with S/H, AN000 to AN002 selected)

41.4.2.3 A/D conversion in Double Trigger Mode

When double trigger mode is selected in single scan mode, A/D conversion is performed for two rounds of single scan operation started by a synchronous trigger (MTU3, ELC).

A/D conversion Data Duplication is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting ADCSR.DBLE to 1. When ADCSR.DBLE is set to 1, the channel selection of the ADANSA0 register is disabled.

To select the double trigger mode, use ADSTRGR.TRSA[5:0] to select the synchronous trigger (MTU3, ELC), set the ADCSR.EXTRG bit to 0, and set the ADCSR.TRGE bit to 1. Also, do not use software trigger.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) due to the synchronous trigger (MTU3, ELC) input, the A/D conversion of the 1 channel selected by the ADCSR.DBLANS[4:0] bits starts.
2. When the A/D conversion is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).
3. ADCSR.ADST is automatically cleared and the 12-bit A/D converter is in the standby state. At this time, the ADC0_ADI interrupt does not occur regardless of the setting of the ADCSR.ADIE bit (ADC0_ADI interrupt enabled by the end of scanning).
4. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by the second synchronous trigger input, A/D conversion of the 1 channel selected by the ADCSR.DBLANS[4:0] bits starts.
5. When the A/D conversion is completed, the A/D conversion result is stored in the A/D Data Duplication register (ADDBLDR) dedicated to the double trigger mode.
6. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled at the end of scanning), an ADC0_ADI interrupt request (pulse output) is generated.
7. The ADCSR.ADST bit holds 1 (A/D conversion start) during A/D conversion, is automatically cleared when A/D conversion is completed, and the 12-bit A/D converter is in the standby state.

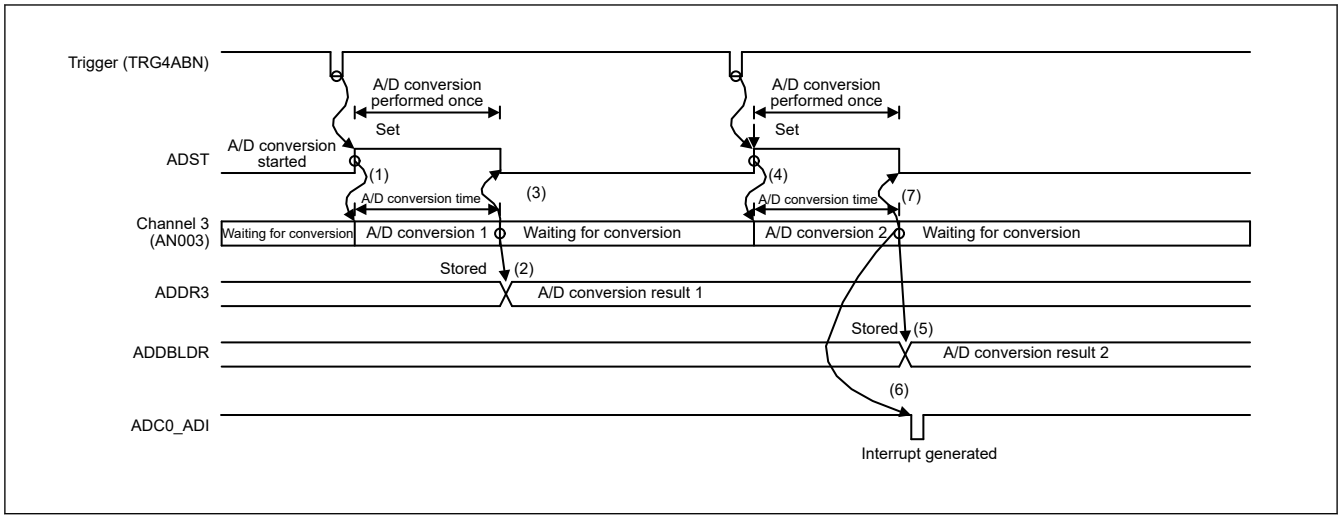


Figure 41.5 Example of operation in single scan mode (double trigger mode, AN003 duplicated, TRG4ABN is selected as the trigger)

41.4.2.4 Extended Operations When Double Trigger Mode is Selected

When double trigger mode is selected in single scan mode, single scan is performed twice.

To enable double trigger extended mode, and then select the following synchronous trigger by the ADSTRGR.TRSA[5:0].

- ADSTRGR.TRSA[5:0] = 001011b
  TRG4AN or TRG4BN
- ADSTRGR.TRSA[5:0] = 001111b
  TRG7AN or TRG7BN

And set the ADCSR.EXTRG bit to 0 and the ADCSR.TRGE bit to 1. Also, do not use software trigger.

A/D conversion Data Duplication is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting ADCSR.DBLE to 1. When ADCSR.DBLE is set to 1, the channel selection of the ADANSA0 register is disabled.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by TRG4AN, A/D conversion of 1 channel selected by the ADCSR.DBLANS[4:0] bits starts.
2. When the A/D conversion is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy) and A/D Data Duplication register A (ADDBLDRA).
3. ADCSR.ADST is automatically cleared and the 12-bit A/D converter is in the standby state. At this time, the ADC0_ADI interrupt does not occur regardless of the setting of the ADCSR.ADIE bit (ADC0_ADI interrupt enabled by the end of scanning).
4. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by TRG4BN input, A/D conversion of 1 channel selected by the ADCSR.DBLANS[4:0] bits starts.
5. When the A/D conversion is completed, the A/D conversion result is stored in the A/D Data Duplication register (ADDBLDR) and the A/D Data Duplication register B (ADDBLDRB).
6. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled at the end of scanning), an ADC0_ADI interrupt request (pulse output and level output) is generated.
7. The ADCSR.ADST bit holds 1 (A/D conversion start) during A/D conversion, is automatically cleared when A/D conversion is completed, and the 12-bit A/D converter is in the standby state.

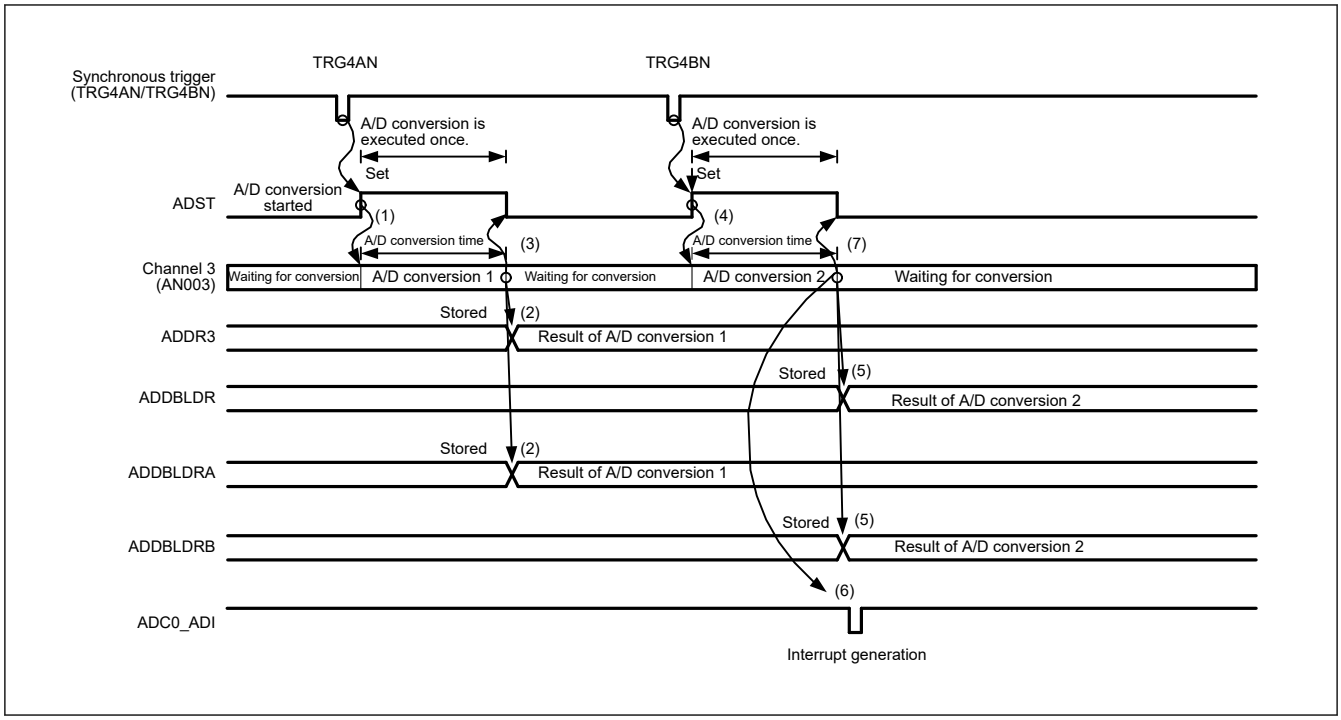

Figure 41.6 Example of extended operation in double trigger mode (duplication selected for AN003, TRG4AN, TRG4BN selected)

41.4.3 Continuous Scan Mode

41.4.3.1 Basic Operation (Not use S/H circuits)

In basic operation of continuous scan mode, A/D conversion is performed repeatedly on the analog input of the channels selected by the ADANSA0 register.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by software, synchronous trigger (MTU3, ELC), or asynchronous trigger, A/D conversion starts in ascending order of n of ANn selected in the ADANSA0 register.
2. When the A/D conversion of one channel is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).
3. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled at the end of scanning) after A/D conversion of all selected channels is completed, an ADC0_ADI interrupt request (pulse output) is generated. In addition, the 12-bit A/D converter continuously starts A/D conversion in ascending order of n of ANn selected in the ADANSA0 register.
4. The ADCSR.ADST bit is not cleared automatically, and (2) to (3) are repeated during 1 (A/D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stopped), A/D conversion is stopped and the 12-bit A/D converter is in the standby state.
5. After that, when the ADCSR.ADST bit becomes 1 (A/D conversion starts), A/D conversion starts again in ascending order of n of ANn selected in the ADANSA0 register.

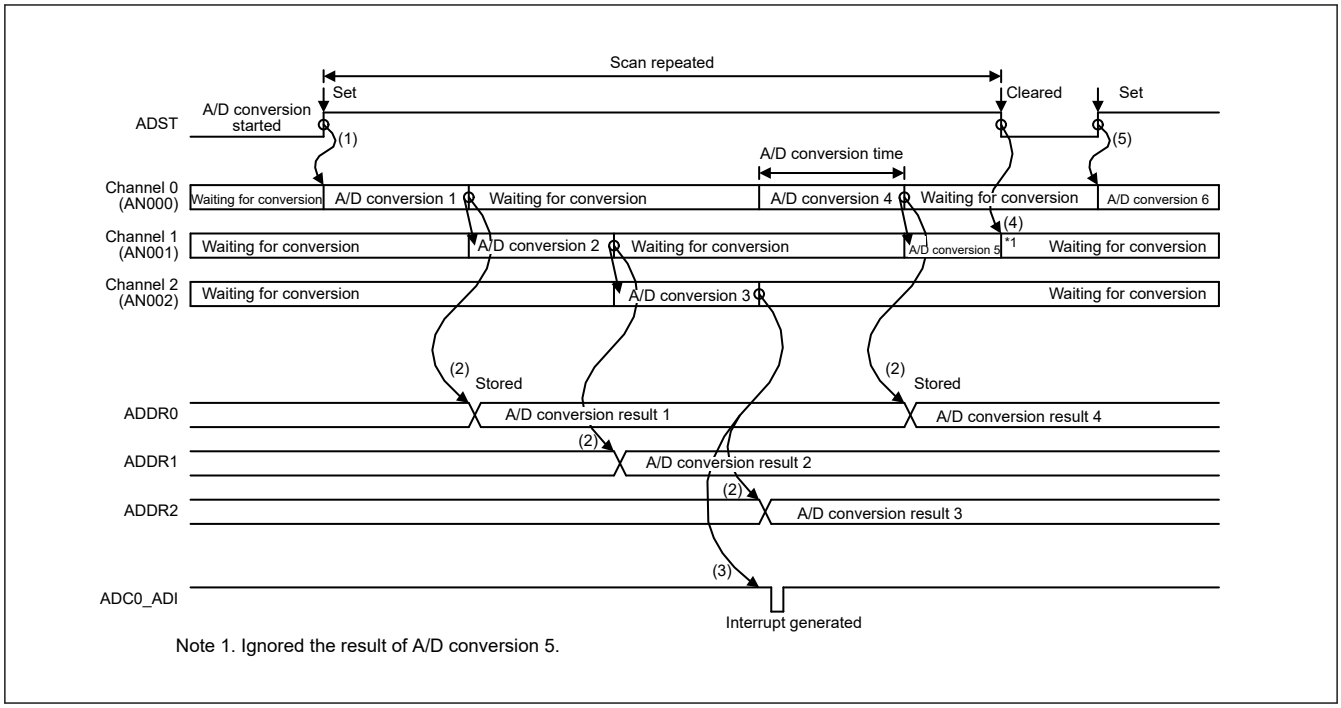

Figure 41.7 Example of operation in continuous scan mode (basic operation AN000 to AN002 selected)

41.4.3.2 Basic Operation (Use S/H circuits)

When the S/H circuit is used, the operation of A/D conversion of the analog inputs of all the selected channels is repeated after the sample and hold is performed. The channel that uses the S/H circuit is selected with the ADSHCR.SHANS[2:0] bits.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by software, synchronization trigger (MTU3, ELC), or asynchronization trigger, all channels using the S/H circuit start sampling analog inputs.
2. After sampling and holding, A/D conversion is started in ascending order of n of the channel ANn selected in the ADANSA0 register.
3. When the A/D conversion of the channel is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).
4. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled at the end of scanning) after A/D conversion of all selected channels is completed, ADC0_ADI interrupt request (pulse output) is generated. It also begins sampling the analog inputs of all channels that use the S/H circuitry.
5. The ADCSR.ADST bit is not cleared automatically, and (2) to (4) are repeated while it is set to 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stopped), A/D conversion is stopped and the 12-bit A/D converter is in the standby state.
6. After that, when the ADCSR.ADST bit becomes 1 (A/D conversion starts), sampling of analog inputs of all channels using the S/H circuit starts again.

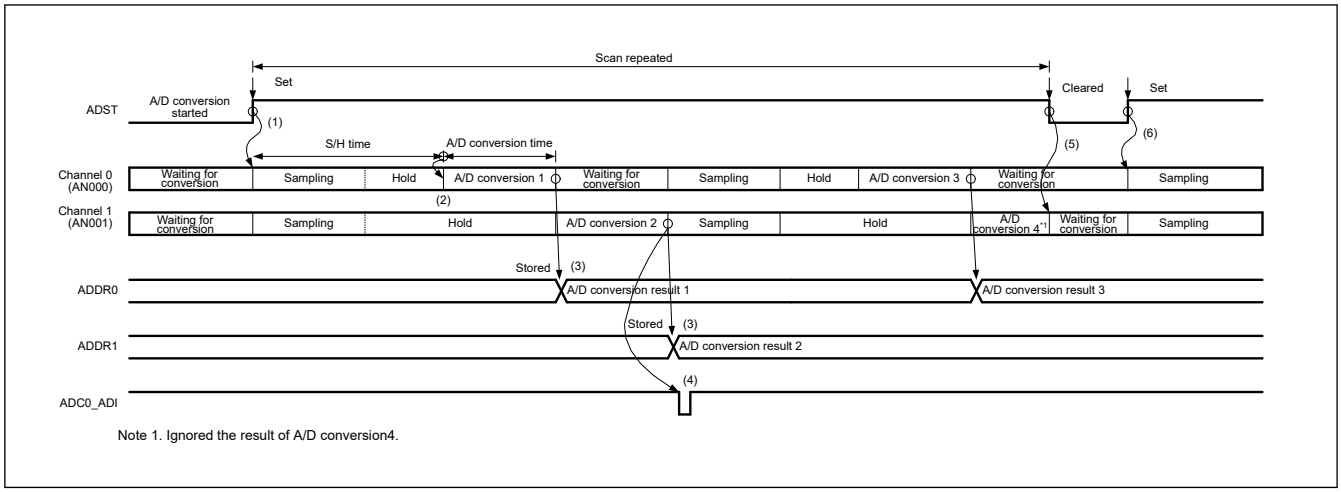

Figure 41.8 Example of operation in continuous scan mode (basic operation AN000 to AN001 selected, use S/H circuit)

41.4.4 Group Scan Mode

41.4.4.1 Basic Operation

In basic operation of group scan mode, A/D conversion is performed once on the analog inputs of all the specified channels in each group (A and B or A, B and C) after scanning is started by a synchronous trigger (MTU3, ELC). Scan operation of each group is similar to the scan operation in single scan mode.

To set the trigger for group scan mode, select the trigger for group A with the ADSTRGR.TRSA[5:0] bits, select the trigger for group B with the ADSTRGR.TRSB[5:0] bits, and select the trigger for group C with the ADGCTRGR.TRSC[5:0] bits. Triggers for groups A, B, and C should be separate triggers so that scans for groups A, B, and C do not occur at the same time. Also, do not use software triggers. For the channels to be scanned, select the group A channel in the ADANSA0 register, select the group B channel in the ADANSB0 register, and select the group C channel in the ADANSC0 register.

The following is an example of the operation of the group scan mode by the synchronous trigger from the MTU3. Group A is set to start conversion with a TRG4AN trigger from MTU3, Group B is set to start conversion with a TRG4BN trigger from MTU3, and Group C is set to start conversion with a TRG4ABN trigger from MTU3.

1. Start scanning of group A with TRG4AN trigger from MTU3.
2. If the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled) at the end of group A scanning, the ADC0_ADI interrupt is output.
3. Start scanning Group B with TRG4BN trigger from MTU3.
4. If the ADCSR.GBADIE bit is set to 1 (ADC0_GBADI interrupt enabled) at the end of Group B scanning, an ADC0_GBADI interrupt is output.
5. Trigger TRG4ABN from MTU3 to start scanning for Group C.
6. If the ADGCTRGR.GCADIE bit is set to 1 (ADC0_GCADI interrupt enabled) at the end of Group C scanning, an ADC0_GCADI interrupt is output.

In group scan mode, different channels and triggers should be selected for group A and group B.

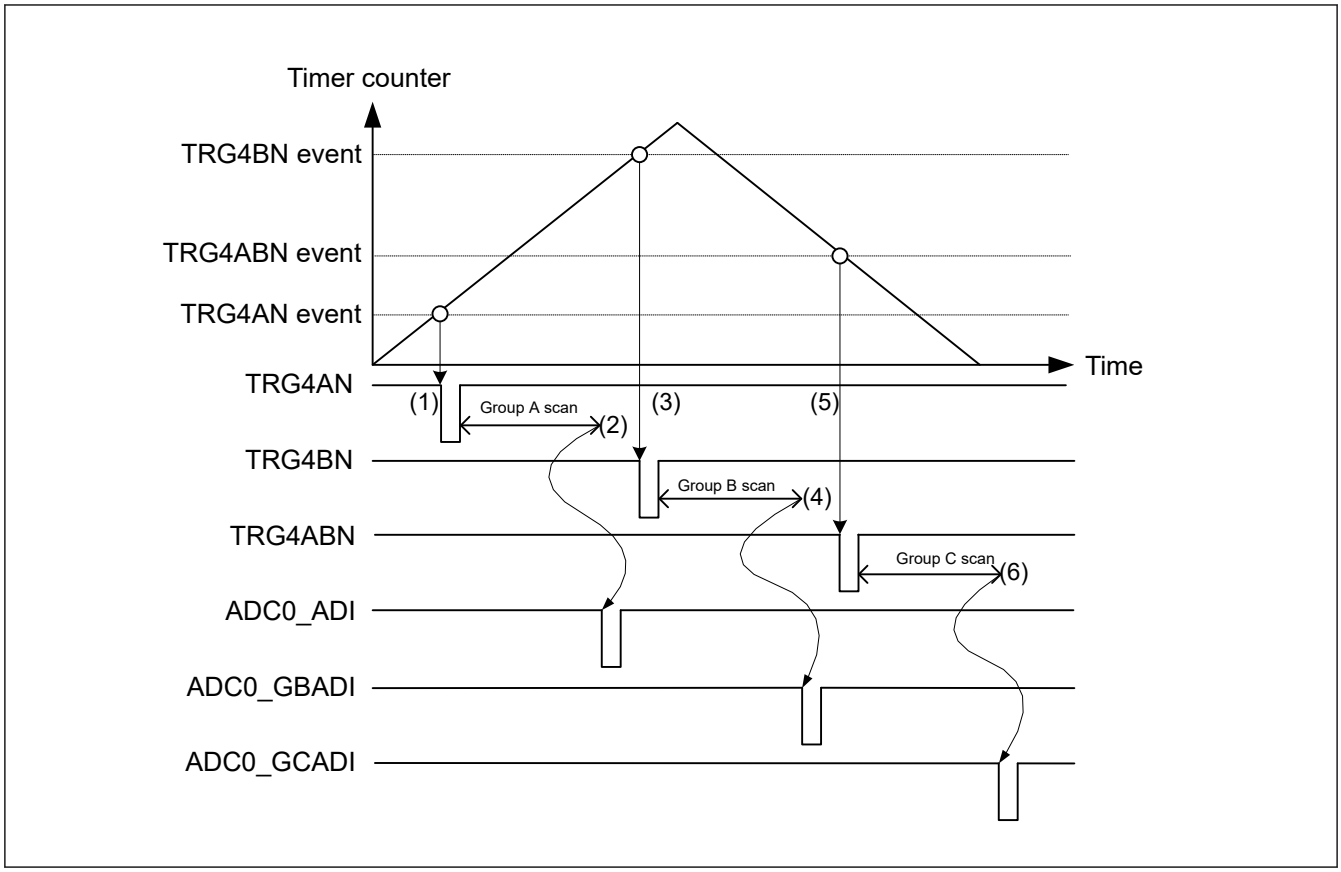

Figure 41.9 Example of operation in group scan mode (basic operation trigger from MTU3)

41.4.4.2 A/D conversion in Double Trigger Mode

When double trigger mode is selected in group scan mode, group A controls two single scan mode executions starting with a synchronous trigger (MTU3, ELC) as a series of operations. Group B and Group C behave in the same way as single scan mode started with a synchronous trigger (MTU3, ELC).For group scan mode trigger settings, the ADSTRGR.TRSA[5:0] bits select the trigger for group A, the ADSTRGR.TRSB[5:0] bits select the trigger for group B, and ADGCTRGR.TRSC[5:0] bits selects the trigger for Group C. Triggers for groups A, B, and C should be separate triggers so that scans for groups A, B, and C do not occur at the same time. Also, do not use software triggers.

If you select "TRG4AN" or "TRG4BN", "TRG7AN" or "TRG7BN" as the trigger for group A in the ADSTRGR.TRSA[5:0] bits, it operates in double trigger extended mode.

For the channels to be scanned, select the group A channel with the ADCSR.DBLANS[4:0] bits, select the group B channel with the ADANSB0 register, and select the group C channel with the ADANSC0 register.

A/D conversion Data Duplication is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following shows an operation example when the group scan mode and double trigger mode are set by the synchronous trigger from the MTU3. Group A is set to start conversion with a TRG4ABN trigger from MTU3, Group B is set to start conversion with a TRGA0N trigger from MTU3, and Group C is set to start conversion with a TRGA1N trigger from MTU3.

1. Start scanning Group C with the TRGA1N trigger from the MTU3.
2. If the ADGCTRGR.GCADIE bit is set to 1 (ADC0_GCADI interrupt enabled) at the end of Group C scanning, the ADC0_GCADI interrupt is output.
3. The TRGA0N trigger from the MTU3 starts scanning for group B.
4. If the ADCSR.GBADIE bit is set to 1 (ADC0_GBADI interrupt enabled) at the end of Group B scanning, an ADC0_GBADI interrupt is output.
5. The first TRG4ABN trigger from the MTU3 will start the first scan of Group A.

6. At the end of the first scan of Group A, the converted data is stored in ADDRy, and the ADC0_ADI interrupt request does not occur regardless of the setting of the ADCSR.ADIE bit.
7. The second TRG4ABN trigger from the MTU3 will start the second scan of Group A.
8. At the end of the second scan of group A, the conversion data is stored in ADDBLDR, and if the ADCSR.ADIE bit is set to 1 (ADC0_ADI interrupt enabled), the ADC0_ADI interrupt is output.
9. The second TRGA0N trigger from the MTU3 starts the second scan of group B.
10. At the end of the second scan of Group B, if the ADCSR.GBADIE bit is set to 1 (ADC0_GBADI interrupt enabled), an ADC0_GBADI interrupt is output.
11. The second TRGA1N trigger from the MTU3 starts the second scan of Group C.
12. At the end of the second scan of Group C, if the ADGCTRGR.GCADIE bit is set to 1 (ADC0_GCADI interrupt enabled), an ADC0_GCADI interrupt is output.

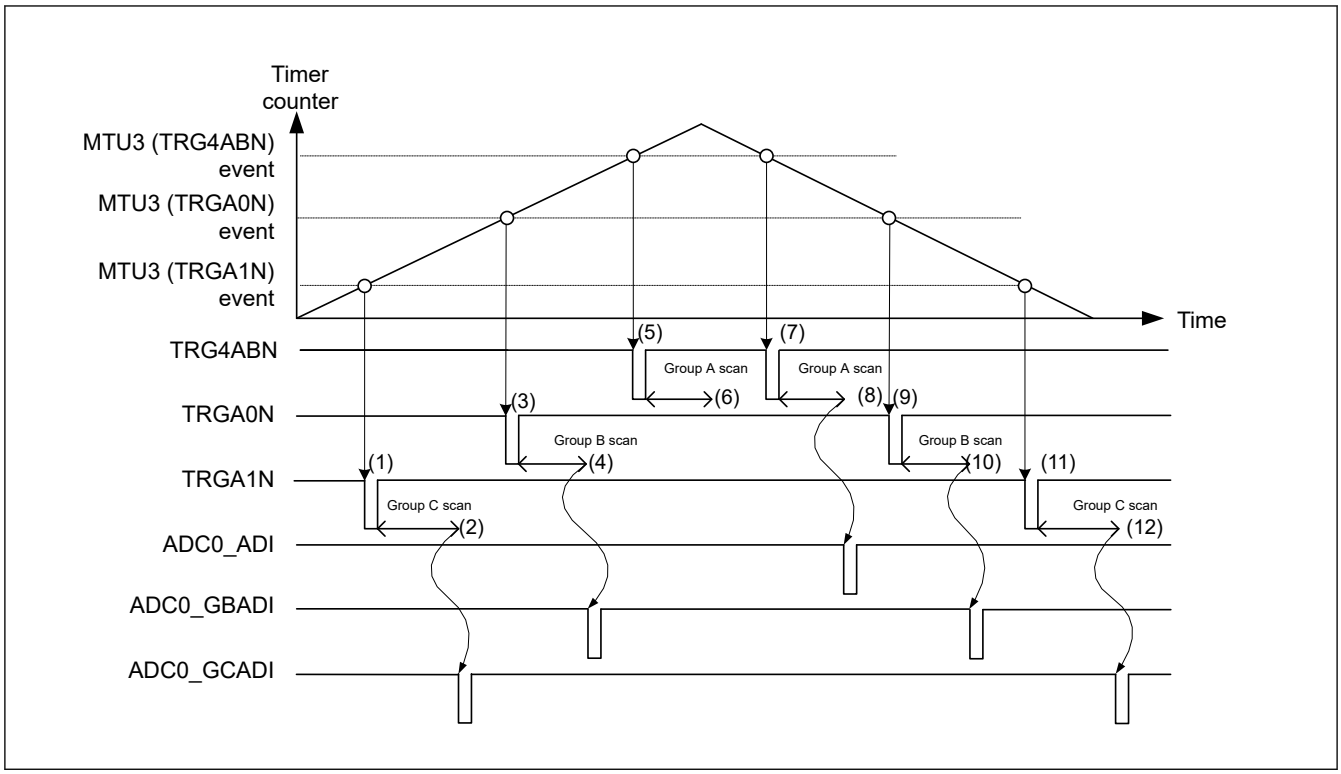

Figure 41.10 Example of operation in group scan mode with double trigger (trigger from MTU3)

41.4.4.3 Operation under Group Priority Control

When the ADGSPCR.PGS bit is set to 1 in group scan mode, group priority operation is performed. Group priority is in the order of group A > group B > group C. The number of groups used in group scan mode can be selected from either 2 (Groups A, B) or 3 (Groups A, B, C) depending on the setting of ADGCTRGR.GRCE. When setting the PGS bit in the ADPGSCR register to 1, follow the procedure in Figure 41.11 to set the relevant registers. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

In the basic operation of group scan mode, the trigger input generated during scanning of groups A, B, and C is ignored, and the scanning operation of groups A, B, and C is the same as that of single scan mode.

In the group priority operation, if there is a trigger input of the priority group during the scan of the low priority group, the scan of the low priority group is interrupted and the priority group is scanned.

When the ADGSPCR.GBRSCN bit is 0, the low priority group is in the standby state after the priority group scan is completed. Also, the low priority group trigger input that occurs during the scan is ignored.

When the ADGSPCR.GBRSCN bit is 1, the scan of the low priority group is automatically re-executed after the scan of the priority group is completed. In addition, the trigger input of the low priority group that occurred during the scan of the

priority group is valid, and the scan of the low priority group is automatically executed after the scan of the priority group is completed.

When the ADGSPCR.GBRSCN bit is 1 and the ADGSPCR.LGRRS is 0, the scan of the low priority group is restarted from the beginning. Also, when ADGSPCR.LGRRS is 1, the scan of the low priority group is re-executed from the interrupted channel.

Table 41.9 shows the setting of the ADGSPCR.GBRSCN bit and the operation when a trigger is input during scanning.

When the ADGSPCR.GBRP bit is set to 1, the scan operation of the lowest priority group is the operation of executing a single scan continuously.

For the trigger setting in group scan mode, select the group A synchronous trigger with the ADSTRGR.TRSA[5:0] bits, and set the group B synchronous trigger different from the group A trigger with the ADSTRGR.TRSB[5:0] bits. Select a Group C synchronous trigger that is different from the Group A and B triggers on the ADGCTRGR.TRSC[5:0] bits.

When the group scan mode is set to 2 groups (ADGCTRGR.GRCE bit is set to 0) and the ADGSPCR.GBRP bit is set to 1, the ADSTRGR.TRSB[5:0] bits is set to 0x3F.

If the group scan mode is set to 3 groups (ADGCTRGR.GRCE bit is set to 1) and the ADGSPCR.GBRP bit is set to 1, set the ADGCTRGR.TRSC[5:0] bits to 0x3F.

For the channels to be scanned, select the group A channel in the ADANSA0 register, select the group B channel in the ADANSB0 register, and select the group C channel in the ADANSC0 register.

Table 41.10 shows Group priority operation setting and operation mode of 2 groups, and Table 41.11 shows Group priority operation setting and operation mode of 3 groups.

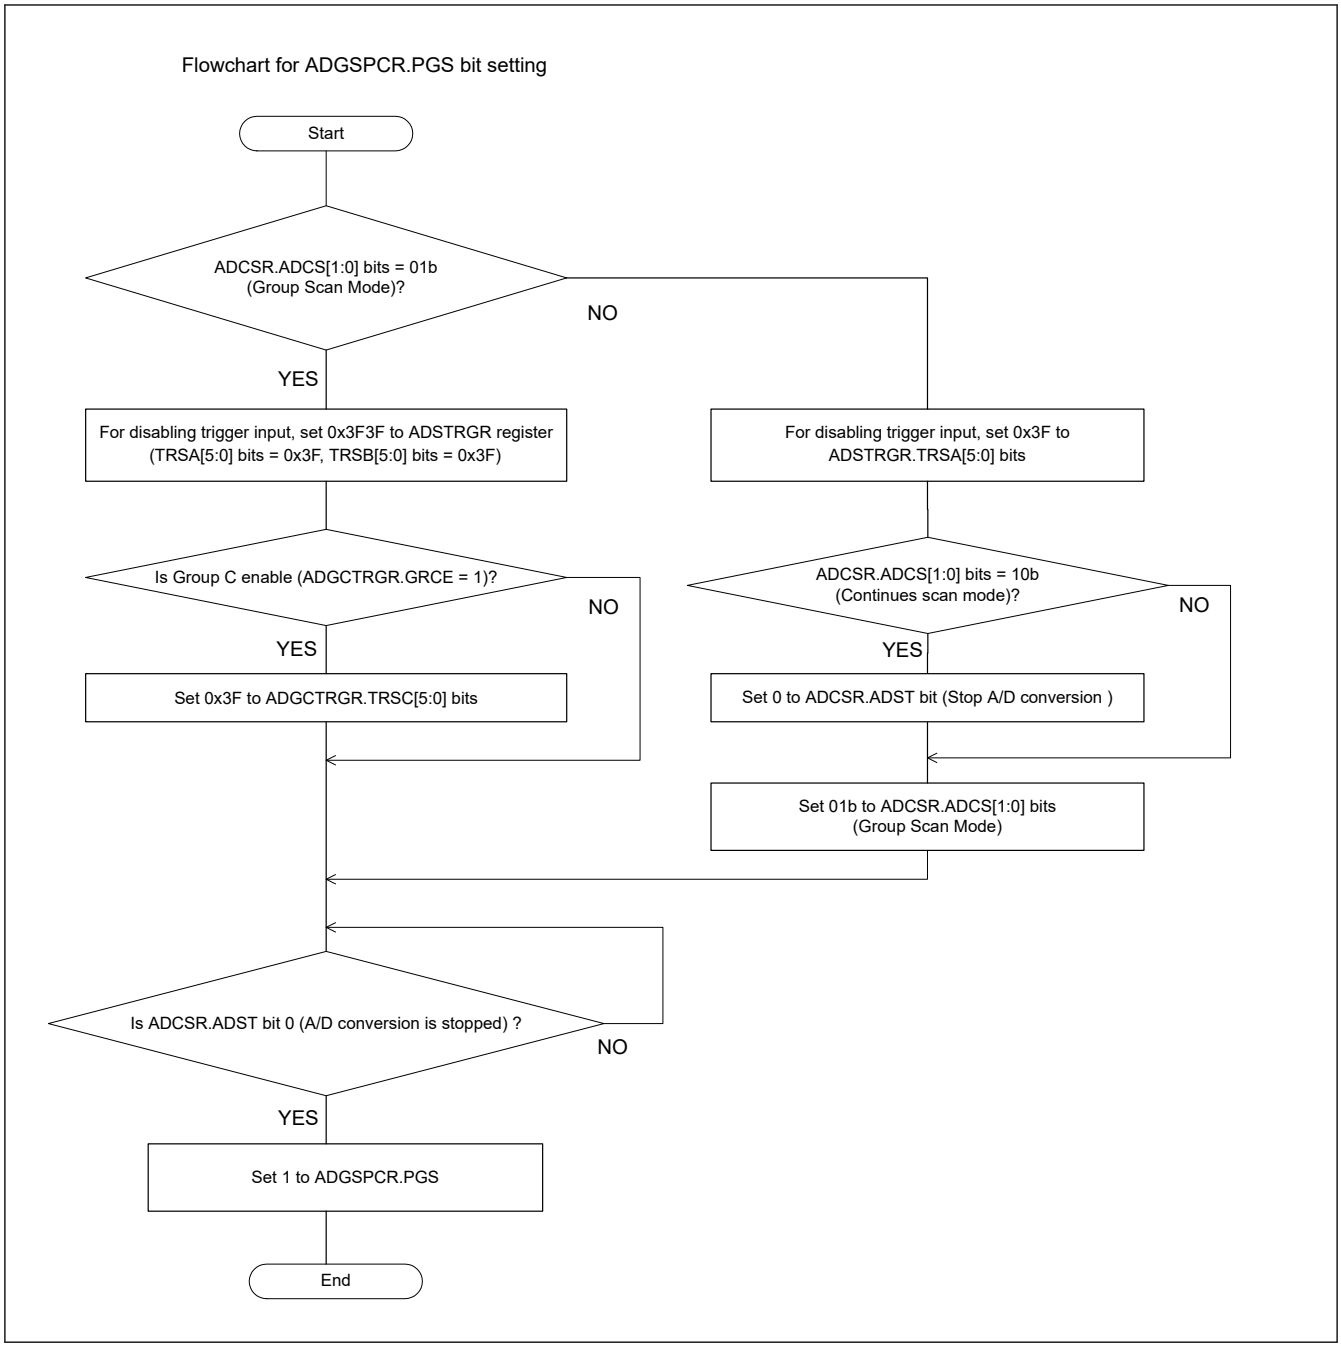

Figure 41.11 Flowchart for ADGSPCR.PGS bit setting
